The preparation of hydroxyapatite/hyaluronate composite gels has been achieved by three different methods. HA does not inhibit the nucleation and crystal growth of OHAp. The interaction of the oxidized hyaluronic acid with the ions of the hydroxyapatite is stronger than the interaction of the HA with the OHAp. The obtained gels are fully injectable materials.

[r.duan@utwente.nl](mailto:r.duan@utwente.nl)

### INTRODUCTION

Calcium phosphate (CaP) ceramics are used clinically as bone void fillers and their bone forming capacity depends on physicochemical properties<sup>1</sup>. Dissolution and reprecipitation of a surface apatite layer through epitaxial crystal growth is preceding bone bonding and a submicron surface structure has been reported to allow bone induction by these materials in ectopic sites<sup>2,3</sup>. Herein, we have used a hydrothermal treatment of an otherwise non-osteoinductive calcium phosphate to allow epitaxial crystal growth and investigated in osteogenic differentiation in vitro and in vivo.

### EXPERIMENTAL METHODS

Biphasic calcium phosphate (BCP, 10/90 HA/TCP ratio) was synthesized using a wet precipitation method and sintered at 1200°C for 8 hours. Granules (1-2mm) were prepared and a hydrothermal treatment was applied to obtain epitaxial crystal growth. After characterisation, the biological performance of the BCP granules before and after hydrothermal treatment was investigated in vitro with murine mesenchymal stromal cell (mMSC) at 14 days (basal medium), and in an intramuscular implantation model in dogs for 12 weeks (1cc; n=5).

### RESULTS

Fig 1. XRD of BCP before and after hydrothermal treatment (note the increase in HA after treatment).

Fig.2 Surface structure of BCP before and after hydrothermal treatment.

Hydrothermal treatment of the BCP resulted in an increase in HA content from 10% to 22% (Fig 1) and the formation of epitaxial polygons on the surface (Fig 2). As a result, the surface was modified from grains with a size of  $2.46 \pm 0.78 \mu\text{m}$  to epitaxial polygons measuring  $1.23 \pm 0.41 \mu\text{m}$ .

The surface modification of BCP did not affect the proliferation and osteogenic differentiation

of cultured mMSCs (Fig 3), while it did affect the bone forming ability in vivo. Bone induction occurred in 4 out of 5 hydrothermally treated BCP implants, while no bone was formed in any of the controls (0 out of 5) (Fig. 4).

Fig 3. Proliferation and osteogenic differentiation of mMSC grown on BCP before and after surface modification. Culture medium comprised of DMEM supplemented with 10%FBS, 1% sodium pyruvate and 1% Penicillin-Streptomycin.

Fig 4. Histology and incidence of bone formation in control and hydrothermally treated BCP implants after a 12-week intramuscular implantation in dogs (undecalcified sections; methylene blue and basic fuchsin staining; M: BCP; B: bone)

### DISCUSSION AND CONCLUSION

The hydrothermal treatment caused the formation of epitaxial polygons on the BCP surface. This resulted in a reduction of surface features from  $2.46 \pm 0.78 \mu\text{m}$  to  $1.23 \pm 0.41 \mu\text{m}$ . Although no in vitro effect was seen, the hydrothermal treatment led to *de novo* bone formation in 4 out of 5 implants. None of the control implants showed any bone formation.

The results present herein indicate that a hydrothermal treatment of BCP granules results in the formation of epitaxial polygons. The resulting material is osteoinductive in canine muscles after 12 weeks of implantation.

[\\*pauanton@pg.gda.pl](mailto:pauanton@pg.gda.pl)

### INTRODUCTION

The needs for dental treatment, including standard dental procedures and dental implantology, are very high and they are still growing. Only in Poland the approximately 70 thousands implants are implanted annually (in Germany more than 1 million). Moreover, Polish dental market is one of the fastest growing in the world. Implants have been 18% share in the global dental market calculated the Agency Markets and Markets. Such an advanced and complicated dental implantology procedures require precise, high resolution and reliable diagnosis tools [1]. One of the best and most commonly used methods are based on X-Ray computing tomography (CT). Despite of its awesome features the CT has some limitations in its imaging resolution (hundreds of microns) and exposure time on X-ray radiation. The number of CT measurements is limited in time period. Therefore, we propose to use the optical coherence tomography (OCT) as a complementary method in dental procedures. The OCT is a non-contact and non-invasive optical method, which delivers cross-sectional and 3D images with micrometer resolution. Since the optical radiation is used the OCT is safe for the patient and the diagnosis procedure can be repeated without any limitations [2][3]. Here these two methods, CT and OCT, have been compared.

### EXPERIMENTAL METHODS

For the experiment the IVS-2000 (Santec co., Japan) system has been used. This is the OCT system with polarization sensitive analysis (PS-OCT). Apart from the standard OCT the PS-OCT delivers also information about polarization state of backscattered light. It is useful in teeth diagnostics, since tooth tissue (enamel and dentine) is birefringent and thus changes polarization state of the light. The IVS-2000 PS-OCT system is capable to provide tomographic images with 12  $\mu\text{m}$  of axial resolution and 15  $\mu\text{m}$  in lateral resolution. The measurements have been taken for teeth with and without crowns prosthesis. All samples have been scanned in one hour from their extraction. The teeth without crowns prosthesis were tested from front and rear part of crown and root. The teeth with crowns prosthesis were investigated at the teeth and prosthesis junction. Obtained results have been confirmed with CT measurements.

### RESULTS AND DISCUSSION

In order to express the benefits of using OCT technique in dental procedures the OCT image of the tooth's crown has been compared with CT cross-sections. Obtained results have been presented in Figure 1.

**Figure 1. PS-OCT image of the crown part of tooth compared with CT tomography images.**

The OCT image has been taken by the use of PS-OCT system. This system is capable to evaluate the birefringence of the tooth tissue. The colour of the OCT picture determines polarization state of the backscattered light. However, the pixel intensity referees to the scattering coefficients for the particular points inside tested sample. The presented OCT image express the tooth's crown structure and its local optical anisotropy changes. Comparing the OCT results with CT images (also presented in the Figure 1) the OCT delivers the tomography images with better resolution. Moreover, the useful information on the tooth birefringence can be measured, which cannot be obtained by CT measurements. However, the OCT scanning depth range may reach a few millimetres, while the CT has no such a limitations.

### CONCLUSION

The OCT and its extensions (PS-OCT) can be used in dental diagnosis with success. However, it should be rather a complementary tool to CT than its replacement. The high application potential of this method including standard dental procedures and dental implantology is going to be confirmed fully during conference sessions.

### INTRODUCTION

Membrane fusion is the process whereby two separate lipid bilayers merge to become one. The energetic barrier for fusion is generally lowered by fusion proteins that, owing to conformational changes, bring membranes into close proximity and destabilize the lipid bilayers by inducing extreme membrane curvature.<sup>1</sup>

The peptide C8 (WEDWVGWI), which corresponds to the membrane proximal external region (MPER) of feline immune deficiency virus (FIV) coat glycoprotein (Gp36) is endowed with fusogenic activity destabilizing the lipid bilayer.<sup>2</sup>

In the present study we elucidate the structural basis of the molecular interaction of C8 with layers made of different composition of zwitterionic and negatively charged phospholipids. The ability of C8 to induce modifications of the membrane curvature and formation of membrane "nipples" is further evaluated by confocal microscopy.

### EXPERIMENTAL METHODS

Solution of lipids in the absence or presence of NBD labelled-C8 peptide was used for confocal microscope imaging. Confocal fluorescence microscopy was performed using an inverted microscope (IX 70, Olympus, Tokyo, Japan) equipped with a spinning disk confocal scanner (CSU10, Yokogawa, Tokyo, Japan) and a krypton argon ion laser (Melles Griot, Carlsbad, CA).

Funnel molecular dynamic simulations, were carried out using the NAMD 2.8 software<sup>3</sup>

<http://www.ks.uiuc.edu/Research/namd/>) and TIP3P as water solvation model. Each C8-bilayer system, was solvated using the vmd autoionize plugin.<sup>4</sup>

<http://www.ks.uiuc.edu/Research/vmd/>

### RESULTS AND DISCUSSION

Fluorescent C8 peptide synthesized by substituting Trp with nitrobenzoxadiazole (NBD) residue was studied on lipidic membranes by imaging 1,2-Dioleoyl-sn-glycero-3-phosphocholine (DOPC), 1,2-dioleoyl-sn-glycero-3-[phospho-*rac*-(1-glycerol)] (DOPG) and DOPC/DOPG (90/10), in absence and presence of C8 peptide. The imaging of DOPC and DOPG vesicles in the presence of NBD labeled C8 evidence the localization of the peptide on the membrane surface. DOPG/DOPG vesicles loaded with labeled C8 peptide show well-extended straight-chain tubular structures

**Figure 1** Selected binding mode for the C8 peptide (white cartoon and sticks) in DOPC-DOPG (90:10) membrane system (highlighted as yellow transparent surface), also, highlighted in yellow stick the DOPC polar heads interacting with C8.

Molecular interpretation of microscopy data using funnel molecular dynamics simulations (FMD) in explicit solvent describes a process where, the binding of C8 to the DOPC-DOPG membrane, induces an expansion of the membrane surface leading to a structural reorganization of the bilayer (Figure 1). Considering the timescale of our calculations it is attractive to suggest that our simulation describes the very early stages of the C8-membrane interaction, which leads in much longer timescale to the macroscopic effects observed by the confocal microscope imaging.

### CONCLUSION

Structural investigation of the fusogenic peptide C8 performed with confocal microscopy and molecular dynamic simulation, allows to elucidate the molecular mechanism that enable C8 to form "nipples" and have fusogenic activity. The comprehension of this mechanism is the basis to design molecular tools capable of modulating this process for therapeutic application.

### INTRODUCTION

Cells microencapsulation is a promising technology to treat a wide range of diseases through cells transplantation. This therapy is an alternative for tissue grafting and engineering and can overcome the problem of graft rejection. The scaffold materials for cells microencapsulation are biocompatible hydrogels which require specific physical properties<sup>1</sup>. The hydrogel network density, stiffness, and hydrophilicity can have a crucial impact on cell proliferation, differentiation, and function. These physical characteristics can be adjusted with covalent modification of the hydrogel materials. Here are investigated several chemical modifications of alginate(alg)-based hydrogels with poly(ethylene glycol) PEG 1000 and 2000 either on hydroxyl or carboxylic groups of the alg backbone (**Scheme 1**). Physical properties of the resulting microspheres (MS) will be reported and compared between the different systems.

**Scheme 1:** PEGylated Na-alg with two different systems.

### EXPERIMENTAL METHODS

#### Synthesis of $\alpha$ -amino- $\omega$ -mercapto PEG1000

-  $\alpha$ -Amino- $\omega$ -mercapto PEG was synthesized starting from commercially available PEG 1000. The unsymmetric alteration was performed through mono-Staudinger reduction as a key step<sup>2</sup>. Thiol functionality was then introduced by copper click reaction.

#### Modification of Na-alginate

- Na-alg was modified by grafting linear  $\alpha$ -amine- $\omega$ -thiol PEG 1000 and 2000 either to the carboxyl or hydroxyl groups up to 5 % of grafting.

#### Microsphere formation

- A BÜCHI Encapsulator B-395 Pro (BÜCHI Labortechnik AG, Switzerland) was used to extrude the polymer solutions into a gelation bath containing  $\text{CaCl}_2$ .

#### Characterization of the polymer solutions

- All polymer solutions were prepared at defined concentrations and characterized by their dynamic viscosity. The osmolality and the pH were adjusted to physiological conditions.

#### Physical characterization of microspheres

- The size of the MS, swelling in different media, and stability were observed by optical microscopy. Water uptake was gravimetrically determined. Mechanical stability, deformability and mechanical resistance to compression were analysed using a TA-XT2i (Stable

micro Systems, Godalming, UK). Ingress diffusion experiments using fluorescence labelled dextran standards (40, 70, 150 kg/mol) served to estimate the permeability.

### RESULTS AND DISCUSSION

The polymer grafting sites and the PEG chain length considerably changed the physical properties of the MS. On the first system, PEG 2000 was inserted on carboxyl functional groups decreasing the available sites needed for electrostatic crosslinking with calcium ions. The second system involving the modification on hydroxyl groups was thus investigated to preserve 100 % of the electrostatic crosslinking. In both systems were observed spontaneous covalent crosslinking through disulfide bond formations. As expected, PEGylation on hydroxyl groups offered a better mechanical resistance to compression and a better stability over time of the MS. A shorter PEG grafted on hydroxyl groups was suitable to modify the polymer network density and consequently the permeability and the mechanical resistance to compression of the MS. Many other parameters such as the degree of grafting can influence the physical properties of the MS.

### CONCLUSION

The combination of electrostatic and covalent crosslinking offers a variety of possibilities to adjust the physical properties of alginate-based MS and to adapt these characteristics to the microencapsulation of specific cell types. The fast electrostatic crosslinking of Na-alg with calcium ions was used to provide a spherical matrix for the simultaneously but slowly occurring covalent crosslinking. Grafting heterobifunctional PEG on Na-alg in such a way that sufficient carboxyl groups remain for fast electrostatic crosslinking also allows reinforcing the MS. The overall advantage of all modifications presented here is the applicability of a one-step MS formation process. Biocompatibility was confirmed for all MS types by *in vitro* and/or *in vivo* experiments including the microencapsulation of different cell types.

[arturp@fe.up.pt](mailto:arturp@fe.up.pt)

### ABSTRACT

Two types of graphene-nanoplatelets (GNPs) were incorporated in PLA (poly(lactic acid)) by melt blending. Materials were biodegraded during 6 months and characterized by XRD, tensile tests, DMA and biocompatibility assays. For both fillers, low loadings (0.25 wt.%) improved mechanical properties and decreased decay until 6 months biodegradation. PLA degradation decreased its toughness (AUC) by 10 fold, while for PLA/GNP-M and C, toughness was only reduced by 3.3 and 1.7 fold, respectively. Comparing with PLA, PLA/GNP-M and C composites presented similar (HFF-1) fibroblasts adhesion and proliferation at the surface and did not released toxic products (6 months).

### INTRODUCTION

A commercial available product, with reduced cost comparing with single layer graphene, GNPs, are constituted by few stacked graphene layers. These materials present high aspect ratio and possess oxygen-containing functional groups in the platelet edges, which may facilitate extensive interfacial interaction with polymer matrices. [1] Some typical composite production techniques like solvent mixing and electrostatic deposition lead to obtainment of toxic materials. [1,2] Thus, melt blending, which assures complete embedding of GNPs in polymer matrix preventing filler leaching, is studied in this work as a green method for production of PLA/GNPs composites.

### EXPERIMENTAL METHODS

PLA 2003D (Natureworks), GNPs (XG Sciences). Composites were prepared by melt blending and moulded in a hot press into thin sheets (0.3-0.5 mm). Samples were immersed in PBS and incubated for 6 months (37 °C, 100 rpm). Tensile properties were measured (Mecmesin Multitest-1d, Mecmesin BF 1000N) using a strain rate of 10 mm min<sup>-1</sup>. Creep/recovery assays were performed using a DMA 242 E Artemis (Netzsch). Biocompatibility of materials was evaluated using HFF-1 cells cultured at the surface of composite films and in direct contact with materials extracts obtained after 6 months degradation. Metabolic activity was determined using resazurin assay.

### RESULTS AND DISCUSSION

#### XRD

GNP-M and C powders present similar XRD spectra, typical of carbon materials. PLA, before (0M) and after 6 months (6M) biodegradation, presents similar spectra, also typical for this polymer. In composites PLA and GNPs peaks were observed. Degradation did not affected spectra.

### Tensile tests

Incorporation of GNP-C and M in PLA increased its Young's modulus by 14 %. Also, tensile strength is increased by 20% for GNP-C and by 6% for GNP-M. After 6 months biodegradation, decreases in tensile strength, elongation at break, and toughness are respectively, for PLA of 2.6, 2.5, and 10 fold, for PLA/GNP-M of 1.6, 1.8 and 3.3 fold, and for GNP-C of 1.4, 1.4 and 1.7 fold.

### Creep/recovery

Figure 1 shows that for undegraded PLA, dL<sub>f</sub> (final, at 6N) after 10 creep/recovery cycles was of 14.2 µm, being of 13.7 and 13.2 µm for PLA/GNP-M and C 0.25 wt.%, respectively. After 6 months degradation, PLA sample ruptured after 4 cycles (1.A) reaching a dL<sub>f</sub> of 56.3 µm. PLA/GNP-M and C 0.25 wt.% did not rupture (1.B,C) and presented only a slight increase in dL<sub>f</sub>, of 16.8 and 16.7 µm, respectively. Materials degradation was confirmed

Figure 1. Multi cycle DMA of PLA and composites before and after 6 months degradation.

in terms of molecular weight decrease and changes in surface morphology (results not shown).

### Biocompatibility evaluation

PLA/GNP-M and C 0.25 wt.%, metabolic activity never decreased below 90%, for both composites in comparison with PLA. Composites degradation products are not toxic (24, 48, 72h), comparing with PLA 6M (Figure 2). Also, cell morphology is normal and similar for all conditions tested (images not shown).

Figure 2. Cytotoxicity of PLA/GNP-M and C 0.25 wt.% 6 months degradation products, comparing with PLA in the same conditions. Assays were performed in triplicate, with 6 replicates for each condition tested. Error bars represent standard deviation. Red line represents cytotoxicity limit of 70%.

### CONCLUSION

GNP-M and GNP-C incorporation in PLA (0.25 wt.%) improved mechanical properties and decreased their decay after 6 months biodegradation. GNPs can be used to tune PLA mechanical performance during biodegradation in biomedical applications, since they did not decrease cell proliferation or cause toxicity.

<sup>2</sup>Industrial Systems Engineering and Design Department, Universitat Jaume I, Spain

<sup>3</sup>ICTP-CSIC, Spain

[beatriz.palla@ehu.es](mailto:beatriz.palla@ehu.es)

### INTRODUCTION

Dental implants in healthy patients have achieved excellent survival and success in the clinic for the recovery of tooth function and aesthetics. However, one of their major limitations is that there is, usually, strict patient selection criterion, because one of the most important requirements that they must achieve is a high capacity for osseointegration<sup>1</sup> in maxilar bone. It is also important, that this capacity of osseointegration include good osteoinduction and osteoconduction ability. The most common and significant problem associated with implantology are infections (peri-implantitis)<sup>2</sup> in association with medical implants and devices which can, in many cases, necessitate surgical removal or intervention and may lead to complications. Moreover, this is particularly the case for dental implants where the prevalence of bone loss induced by inflammation is of increasing importance. Thus, the main goal of this work is getting new active surfaces for dental implants, provided not only with osseointegration properties but also with a strong bactericidal effect through the gradual release of active agents over time.

### EXPERIMENTAL METHODS

Coatings were synthesized by the sol-gel method<sup>3</sup> from specific mixtures of an antimicrobial agent and alcoxysilanes: methyl-trimethoxysilane (MTMOS) and tetraethyl-orthosilicate (TEOS). Thus, the coatings would have a Si content that contributes to bone formation, as we have already demonstrated in previous works<sup>3</sup>, and a bactericidal capacity. Synthesis and characterization for each formulation were thoroughly carried out. After, many experiments were conducted in which both, the releasability of the active agent in time and the effective antibacterial action, were proved. Biocompatibility and antibacterial capabilities of the coatings were studied *in vitro*.

### RESULTS AND DISCUSSION

Figure 1 shows the release ability of the formulation with the bactericidal agent encapsulated over a period of 2 months.

The more antibacterial agent is encapsulated the more agent is released, so the release kinetics and the amount released are load dependent. In all the cases it can be observed that the release is fast at the beginning but followed by a slower, steady release over the time.

Figure 2 shows the strong bactericidal effect of the coatings charged with different amounts of active agent. As it can be seen, there is an increasing bactericidal effect related to the amount of antibacterial agent in the coating. It can be remarked that this strong bactericidal effect does not affect to the cellular viability.

### CONCLUSION

The excellent results obtained *in vitro* for the sol gel coated implants and the high release of bioactive agent obtained with small amounts containing coatings lead to expect an outstanding behaviour of the coated implants, offering accelerated osseointegration kinetics under infected conditions and as preventive coatings for risk patients. These new coatings present valuable characteristics for their application on orthopaedic and Ti dental implants.

# On-Demand Release of Dexamethasone from Conjugated Polymer Matrix

Katarzyna Krukiewicz<sup>1</sup>, Artur P. Herman<sup>2</sup>, Sławomir Boncel<sup>2</sup>, Jerzy K. Żak<sup>1</sup>

<sup>1</sup>Department of Physical Chemistry and Technology of Polymers, Silesian University of Technology, Poland

<sup>2</sup>Department of Organic Chemistry, Bioorganic Chemistry and Biotechnology, Silesian University of Technology, Poland  
[katarzyna.krukiewicz@polsl.pl](mailto:katarzyna.krukiewicz@polsl.pl)

## INTRODUCTION

Dexamethasone is a highly active glucocorticoid drug with anti-inflammatory and immunosuppressant effects. It is frequently used to treat numerous conditions including rheumatologic problems, skin diseases, severe allergies and chronic obstructive lung disease. Because of its efficiency against cerebral edema, it is used to minimize the negative effects of the implantation of neural probes into brain tissue<sup>1</sup>. To prevent the exposition of the whole body to high dosages of dexamethasone, local delivery of drug at the implant / tissue interface is a promising option.

Scheme 1. Chemical structure of dexamethasone

Due to their biocompatibility and ion-exchange properties, selected conjugated polymers can be applied as matrices for localized drug delivery systems<sup>2</sup>. Electrical stimulation is applied to change their reduction-oxidation state, which is followed by the release of a precise amount of drug<sup>3</sup>.

## EXPERIMENTAL METHODS

Poly(3,4-ethylenedioxythiophene), PEDOP, was chosen as a matrix for dexamethasone (Dex) immobilization. The process of Dex incorporation was performed simultaneously with the process of EDOP polymerization by means of cyclic voltammetry. Monomer concentration: 5 mM; Dex concentration: from 0 mM to 100 mM; environment: PBS aqueous solution; potential range: -0.3 V ÷ 0.8 V; number of CV cycles: 25; scan rate: 100 mV·s<sup>-1</sup>.

The process of Dex release was triggered by means of cyclic voltammetry (potential range: -0.5 V ÷ 0.3 V, number of CV cycles: 5, scan rate: 100 mV·s<sup>-1</sup>) and monitored by UV-Vis spectrophotometry.

## RESULTS AND DISCUSSION

Because of the fact that the processes of electrochemical polymerization and Dex immobilization were performed by means of cyclic voltammetry, it was possible to monitor their progress in-situ. CVs collected during electropolymerization of EDOP from solutions of varying Dex concentration (from 0 mM to 100 mM) showed that with the increase

in drug content lower oxidation currents are observed and the polymerization is suppressed.

In order to release Dex from PEDOP/Dex matrix, a cyclic voltammetry was applied in a potential range between -0.5 V and 0.3 V (vs. Ag/AgCl). Selected range of applied potentials is enough to reduce and oxidize PEDOP matrix and to provide the possibility of ion-exchange. To preserve the neutral character of the polymer matrix, together with Dex release, the incorporation of chlorides and phosphates takes place. The absorbance at  $\lambda = 268$  nm, which is characteristic for Dex, was recorded after the procedure of drug release and was the basis to calculate the concentration of released compound. Drug release experiments show that the drug capacity of PEDOP matrix increases with the increase in Dex concentration in the step of matrix synthesis. Because of the fact that higher Dex concentrations suppress the process of polymerization and thinner films are produced, one may conclude that under these conditions Dex is more available and easier to be released.

Fig.1. CVs of the process of EDOP (5 mM) polymerization in the presence of Dex (10 mM) in PBS aq solution (a). UV-Vis spectra of Dex released from matrices synthesized under different conditions (b).

## CONCLUSION

In this study, the electrically-triggered release system of dexamethasone from conjugated polymer, PEDOP, was described. It has been proven that by changing the conditions of polymerization, namely the amount of Dex, it is possible to tailor the drug capacity of matrix.

### INTRODUCTION

Intervertebral disc (IVD) degeneration is one of the major causes of low back pain<sup>1</sup>. Currently, low back pain is mainly managed by pharmacological treatments and, if unsuccessful, by surgical procedures. New regenerative medicine approaches are considered with great interest since they could offer less invasive and etiological alternatives to spinal reconstructive surgery<sup>2,3</sup>. Stem cells injection associated with a biomaterial to restore the hydration of the nucleus pulposus and provide a favorable 3D microenvironment constitutes an appealing strategy. Sustained release of bioactive growth factors added to the biomaterial could optimize stem cell differentiation and enhance synthesis of an appropriate *in situ* extracellular matrix.

In this context, we used recently designed mesoporous silica nanofibers (NFs)<sup>4</sup> as delivery systems. Lysozyme as a model protein was adsorbed onto the NFs and the protein-silica interactions were analyzed.

### EXPERIMENTAL METHODS

Lysozyme (Sigma-Aldrich) was incubated in presence of NFs under constant stirring in different conditions of (i) pH (4, 7, 10), (ii) time (from 1 to 48 hours) and (iii) concentrations (from 1 to 200 mg/mL) to determine the optimal conditions of adsorption. Analysis of protein-silica interactions were performed with transmission electron microscopy (TEM), attenuated total reflectance infrared (ATR/IR) and thermogravimetric analysis coupled with mass spectrometry (TGA/MS). Lysozyme release assays were then carried out in Phosphate Buffered Saline (PBS), pH 7.2 at 37°C for 20 days. Lysozyme concentration was assessed by a colorimetric method and biological activity was demonstrated by a micrococcus enzymatic assay.

### RESULTS AND DISCUSSION

In this study, we demonstrated that lysozyme could be efficiently adsorbed on NFs. On one hand, the highest amount of adsorbed lysozyme was obtained at pH 10, initial concentration medium of 200 mg/mL and 48h of incubation, corresponding to a 20% adsorption efficiency. On the other hand, we obtained a 100% adsorption efficiency in 1h for low initial concentrations (1 to 10 mg/mL). We thus hypothesized that when in contact with silica fibers, lysozyme would first adsorb very quickly, creating a protein monolayer. Then, additional layers would be stacked on the monolayer. Analysis performed with TEM, ATR/IR, TGA/MS confirmed this hypothesis. Single proteins or

multilayers of proteins onto the surface of NFs have been observed on TEM images. Very precise information was obtained from the IR study by comparison of amides, Si-O-Si, Si-OH and water bands between lysozyme or NFs alone and NFs/lysozyme.

Release experiments under physiological conditions show a burst after 1h of incubation leading to a slow kinetics release for up to 13 days. Although less than 20% of the initial adsorbed amount was released after 13 days from the NFs prepared at concentrations ranging from 1 and 5 mg/mL, up to 80% of lysozyme could be released from NFs prepared at higher concentrations. These kinetics results support the hypothesis that there is a two-step adsorption and thus, two different types of interactions between the protein and the NFs. At all time point, the released lysozyme was enzymatically active, showing that the adsorption phenomenon was not detrimental to the protein.

### CONCLUSION

We have demonstrated the protein adsorption/release capacity of the NFs and obtain precise clues on the protein-silica interactions. These data thus provide us with a better understanding of the adsorption phenomenon involved, as well as a way to control the amount of protein adsorbed and subsequently released. We also show the maintenance of the biological activity of the released protein from this novel biomaterial at any time point. Next steps will focus on Growth Differentiation Factor 5 (GDF5) adsorption and release studies, since GDF5 pivotal role in the differentiation of stem cells into IVD cells has been shown<sup>5</sup>. Its physicochemical properties, close to those of lysozyme, allow us to hypothesize a similar behavior in terms of adsorption/release from NFs.

[bernhard.neuhaus@uni-due.de](mailto:bernhard.neuhaus@uni-due.de)

### INTRODUCTION

Due to their size, nanoparticles are taken up by cells via endocytosis. Furthermore they can be functionalized with nucleic acids in order to serve as a transport vehicle over the cellular membrane.<sup>1</sup> Once endocytosed, the nanoparticles can release their cargo into the cytosol. Calcium phosphate nanoparticles are easily synthesized and functionalized with nucleic acids. Furthermore they are biocompatible and non-toxic. If they are functionalized either with pDNA or siRNA, they can be used to interfere with the protein biosynthesis of cells and either induce the expression of specific proteins (transfection by DNA) or induce their downregulation (gene silencing by siRNA).<sup>2, 3</sup>

During chronic inflammatory diseases like Crohn's disease or ulcerative colitis, pro-inflammatory proteins like TNF $\alpha$  are upregulated in the gut. Here we demonstrate how calcium phosphate nanoparticles can be utilized to regulate the expression of pro-inflammatory proteins in the gut.

Since calcium phosphate is dissolved in the acidic pH of the stomach and nucleic acids are degraded in the gastrointestinal tract, the second part of the study focused at delivery strategies of functionalized calcium phosphate nanoparticles to the gut.

### EXPERIMENTAL METHODS

Calcium phosphate nanoparticles were synthesized by rapid precipitation and instantly functionalized with different nucleic acids. Subsequently, the nanoparticles were stabilized by another layer of calcium phosphate and polyethyleneimine (PEI) to yield positively charged particles. The particles were tested *in vitro* on their ability to either silence specific genes or induce protein expression. The influence on protein expression was assessed by qPCR, FACS analysis and fluorescence microscopy.

To deliver the particles to the gut, two strategies were investigated. First, a gelatine capsule was filled with freeze-dried nanoparticles and coated with Eudragit L 100 to survive the acidic conditions in the stomach. Another approach was a suppository dosage form based on the incorporation of freeze-dried particles into a lipid base. The performance of these administration forms was investigated *in vitro*.

### RESULTS AND DISCUSSION

Calcium phosphate nanoparticles were used to influence the protein expression in different cell lines. The model protein eGFP was down-regulated in HeLa cells and the

pro-inflammatory protein TNF $\alpha$  was down-regulated in MODE-K cells.

Both cell lines were also transfected with pDNA by calcium phosphate nanoparticles. After transfection the expression of eGFP was detected in both cell lines. Appropriate delivery strategies of the particles to the gut were developed, i.e. an enteric coated gelatine capsule for oral administration and a nanoparticle-loaded suppository for rectal administration. The gene-delivery effect of the particles from these application forms was investigated *in vitro*.

Figure 1: Silencing of TNF $\alpha$  in MODE-K cells

### CONCLUSION

This study demonstrates the feasibility of nanoparticles to regulate the synthesis of inflammatory protein in cells. As it is necessary to transport the nanoparticles to the gut, an acid-resistant gelatine capsule and a suppository were developed as carriers of the nanoparticles.

## How the Interfacial Shear Strength in PLGA Fibre-Reinforced Brushite Cements Affects the Composites Mechanical Properties

### INTRODUCTION

Injectable calcium phosphate cements (CPCs) are promising materials for the minimal invasive treatment of bone defects. Unfortunately, currently available CPCs have a small mechanical strength and fracture toughness, respectively. One approach to overcome these limitations is the modification of the CPC with reinforcing fibres. The results of a previous study suggest that the interfacial shear strength between matrix and reinforcing poly(l-lactide-co-glycolide) (PLGA) fibres and, therefore, the critical fibre length is of importance for the reinforcing efficiency<sup>1</sup>.

Therefore, the aim of this current study is to control the interfacial strength by different modifications of the reinforcing fibres and to analyse the impact of the interfacial strength on the bulk mechanical properties of fibre-reinforced CPCs.

### EXPERIMENTAL METHODS

PLGA fibres with a diameter of 300 µm were either treated with oxygen plasma or coated with sol-gel layers of different compositions. The modified fibres were then embedded into cylinders of a brushite-forming CPC. The interfacial strength between PLGA and CPC matrix was tested in a single-fibre pull-out test. The fibre surfaces were characterized by SEM, XPS and EDX.

To analyse the impact of the interfacial strength on the bulk mechanical properties of fibre-reinforced CPCs, PLGA fibres with a diameter of 25 µm and a length of 1 mm were surface treated as described above and incorporated into a brushite-forming CPC with different fibre contents. The mechanical properties were determined in a 3-point flexural test.

### RESULTS AND DISCUSSION

The interfacial shear strength between the oxygen plasma treated PLGA fibres as well as the sol-gel coated PLGA fibres and the CPC matrix increased statistically significantly compared to untreated PLGA fibres by up to 100% (see Figure 1).

In the case of the sol-gel coated PLGA fibres we observed that the interfacial shear strength depends on the thickness of the sol-gel coating.

As a result of oxygen plasma treatment of the PLGA fibres their contact angle strongly decreases. Thus, the wettability of the PLGA fibres increases, and in consequence the interfacial shear strength between PLGA fibres and CPC increases.

Figure 1: Interfacial shear strength between PLGA-fibres and the brushite-forming CPC.

For the bulk mechanical properties of the fibre-reinforced CPC, we observed only a slightly increase in the flexural strength due to the increased interfacial strength. In contrast, the work of fracture increased strongly as a consequence of the fibre surface modification. The reason for this is a change in the fracture behaviour from a quasi-brittle failure to a more ductile failure.

### CONCLUSION

The present study demonstrates the possibility to improve the mechanical properties of fibre-reinforced CPCs by surface modifications of the reinforcing fibres. Oxygen plasma treatment as well as sol-gel coating resulted in increased interfacial shear strength between PLGA fibres and CPC and, thus, in improved mechanical properties of the composite.

### INTRODUCTION

Calcium phosphates (CaPs) are excellent materials for bone regeneration applications due to their close resemblance to natural bone. However, increasing efforts are being put towards further mimicking the biological environment loading organic moieties such as extracellular matrix components to activate/regulate specific signalling pathways. Collagen accounts for 90-95%wt. of the organic phase of bone, whilst the remaining 5%wt. contains non-collagenous proteins such as growth factors or proteoglycans. It has been demonstrated that proteoglycans are able to bind and regulate several signalling pathways. Specifically, several authors have pointed to the ability of sulphated polysaccharides to form complexes with bone morphogenetic proteins and hence, serve as ligands to their signalling receptors<sup>1</sup>. The present work focuses on the attachment of heparin onto various CaPs both covalent and electrostatically in views of providing materials with enhanced biological performance. Although the use of heparin is not new, little work has been done in the area of CaPs<sup>2</sup>.

### EXPERIMENTAL METHODS

The different CaPs investigated were produced with the same reactants. A solid phase containing 98%  $\alpha$ -TCP and 2% hydroxyapatite was mixed with a liquid phase consisting of water at two liquid to powder ratios, in order to obtain low and high porosities (L/P=0.35 and 0.55 mL/g, respectively). The paste was moulded in 15x2mm discs. Calcium deficient hydroxyapatite (CDHA,  $\text{Ca}_9(\text{PO}_4)_5(\text{HPO}_4)(\text{OH})$ ) was obtained by immersing the discs in water at 37°C for 10 days to complete setting. Stoichiometric hydroxyapatite (HA,  $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$ ) was obtained through hydrothermal treatment of the unset discs in presence of bicarbonate (2.5wt%  $\text{NaHCO}_3$ ) followed by sintering at 1100°C. Amino functionalization of CaPs was attained by silanisation in 95 v/v% absolute ethanol; 3 v/v% of water was added prior to the incorporation of 2 v/v% of (3-aminopropyl)triethoxysilane (APTES). Silanisation was investigated at different times: 1h, 4h and overnight (o.n.). After amino functionalisation, heparin was covalently immobilized onto CaP surfaces through EDC/Sulfo-NHS amidation. 1 mL of the heparin solution (24 $\mu\text{g/mL}$ ) was poured onto the CaPs discs. Heparinization was performed for 15min, 1h and 2h. Supernatants were collected to quantify the amount of unbound heparin. Heparin quantification was evaluated indirectly through a colorimetric method based in Toluidine Blue dye.

### RESULTS AND DISCUSSION

Silane coupling onto CaPs was performed to allow covalent binding of heparin to CaPs. Fig.1 shows that heparinisation is dependent on the silanisation time for HA discs (L/P=0.55). The efficiency of silanisation was indirectly measured through the amount of heparin remaining in solution. Overnight silanisation led to a lower heparin concentration which translated into a more efficient uptake by the material.

Figure 1. Heparin remaining in the supernatants after soaking samples silanised at different times (1h,4h and overnight). Heparin stock solution (dashed line) was 24 $\mu\text{g/mL}$ .

The effect of material composition, porosity and specific surface area on the immobilization of heparin is depicted in Fig2. Control samples (material without silane) were included. As the porosity (L/P 0.35 vs 0.55 mL/g) and the specific surface area (HA vs. CDHA) increases, higher amount of heparin was bound either electrostatically (control) and covalently (silanised) to the material. Nevertheless, the efficiency of heparin bonding significantly increased with silanisation.

Figure 2. Heparin amount collected from the supernatants after 2h for different L/Ps and different composition of CaPs. Heparin stock solution (dashed line) was 24 $\mu\text{g/mL}$ .

### CONCLUSION

This work proves that silanisation of CaP surfaces is a good method for heparin immobilisation. Porosity, specific surface area and composition of CaPs played an important role on the total heparin immobilised.

### INTRODUCTION

A major challenge in the repair of joint injuries lies in the reattachment of the soft tissue to the bone<sup>1</sup>. As such much investigation has taken place into the development of a viable method to promote bone and soft tissue regeneration. For example, Li *et al* developed a graded calcium phosphate coating on the surface of electro-spun nanofibres<sup>2</sup>. However, these studies have resulted in limited success<sup>3</sup>.

In this study we propose the use of novel nanoparticles (NPs) comprised of an amphipathic peptide (RALA) and osteogenic hydroxyapatite (HA). The RALA/HA NPs are designed to spontaneously self-assemble via electrostatic interaction, and aim to promote the bioavailability of HA and elicit a potent osteogenic response. Discriminating between HA-NPs and intrinsic cellular granulation is difficult and so the intercellular fate of HA-NPs is not well understood. Therefore, the use of a thiol-reactive fluorophore is proposed for NP intracellular tracking.

### EXPERIMENTAL METHODS

**Formulation of RALA/HA NPs:** NPs were prepared at a range of mass ratios. Particle size and zeta potential (ZP) were measured using a Malvern Zetasizer Nano ZS to determine the optimal formulation. The NPs were tested for stability up to 28 d in addition to the temperature range 4–40°C.

**Cell viability and immunocytochemistry for osteogenic markers:** MG63 osteoblast-like cells were treated with pure HA or transfected with RALA/HA NPs at corresponding doses for 4 h prior to replacement with complete medium. Cell viability was determined by LDH assay. Collagen type I (col-I) expression was determined visually using standard immunocytochemistry method up to 28 d using the MG63 cell line.

**MPTS-functionalized silica-substituted-HA (SiHA-MPTS) fluorophore conjugation:** SiHA-MPTS was prepared as described by Grover *et al*<sup>4</sup>. SiHA-MPTS (6mg) was suspended in phosphate-buffered saline and 7.14 mM stock solution of thiol-reactive Texas Red maleimide (TRM) (Life Technologies Ltd, UK) was added and mixed 2 h at 37°C. The SiHA-MPTS-TRM particles were washed twice with absolute ethanol and five times with double distilled water.

### RESULTS AND DISCUSSION

NPs prepared with a mass ratio of 5:1 exhibited a size of  $57 \pm 9$  nm and a zeta potential of  $17.8 \pm 6.2$  mV. The

size and shape of the NPs was confirmed by TEM (Fig. 1C). The NP particle size and ZP remained consistent up to 28 d (Fig. 1B) at room temperature. Cell viability (Fig. 1A) was seen to decrease 24 h post-transfection with the RALA/HA NP treatment. However by 7 d cytotoxicity decreased to a level similar to that seen in an untreated control group. SiHA-MPTS-TRM NPs were successfully formulated and exhibited fluorescence under excitation at 585 nm.

Figure 1. A) MG63 cytotoxicity as measured by LDH assay to evaluate the toxicity of 4 hour transfection with RALA/HA-NPs B) Long term stability (28 d) of RALA/HA-NPs C) TEM image of RALA/HA NPs. Results are displayed as mean  $\pm$  SEM,  $n=3$ , where  $n$  represents the number of independent batches prepared for measurement.

### CONCLUSION

We have successfully demonstrated that RALA peptide is capable of forming biocompatible NPs with HA, which are stable across a range of temperatures and over an extended duration. Transfection of MG63 cells with NPs resulted in increased collagen expression by 21 d indicating the osteogenic properties of the NPs. The formulation of fluorescent SiHA-MPTS-TRM NPs facilitates further analysis of the intracellular trafficking and localisation of internalised SiHA-NPs, by means of particle tracking.

## INTRODUCTION

Particle-based systems have great potential as scaffolds for tissue engineering, since they are injectable, avoiding the need for open surgery [1, 2]. In this study we are investigating the ingrowth of cells into highly porous particles. Specifically how human embryonic stem cell derived mesenchymal progenitor cells (hES-MP) respond to monodisperse porous microparticles. Cells were found to bind the particles together after just a few days into large agglomerations. Differentiated cells were also found to penetrate deep within the porous structure of the particles.

## EXPERIMENTAL METHODS

Porous Poly-High Internal Phase Emulsion (polyHIPE) particles were created by a T-junction set-up in which a small internal diameter (100  $\mu\text{m}$ ) syringe needle injects the photocurable PolyHIPE into a 6 mm diameter silicone tube containing a continuous stream of  $\text{H}_2\text{O}$  (sustained *via* a peristaltic pump) and subsequently curing the spheroidal particles with a UV lamp [3]. Particles were formed with 80% interconnected porosity with a median pore size of 18  $\mu\text{m}$ . Particles were then coated with acrylic acid by plasma treatment. Particles were grown with cells in static culture for 30 days with particles removed at certain time points for analysis. Cells were grown with osteogenic supplements and dexamethasone was added for the positive control to induce osteogenesis. Samples were analysed via histology and confocal microscopy.

## RESULTS AND DISCUSSION

Within the T-flasks, multiple small particle aggregates were formed after a few days, which then increased in size as single particles and other small aggregates combined with each other. After 30 days, only a few very large aggregates remained. Zhang et al. [4] found a similar result using PLGA microspheres and an ovarian cancer cell line (HO8910) cells over 7 days. By the 30 day time point, cells were present within the internal pores of the samples grown in both the positive control (DEX) and within the osteogenic media. There was significantly less cell penetration into particles in the negative control. The scaffold directed the hES-MP's towards an osteoblast lineage without the requirement of DEX. Equally important is that this differentiation allowed cells to penetrate throughout the porous particle. The morphology of the cells within the pores appeared to resemble that of osteocytes (see figure 1) which would be consistent with the expected hypoxic environment within the centre of the cell-particle agglomeration, away from a nutrient supply. There is evidence that the cells within the agglomeration

remained viable as we have seen growth over extended periods of time deep within the particle, indicating the cells could have adapted to the hypoxic environment.

Figure 1: An optical micrograph of 15 $\mu\text{m}$  thick D30 particle slice stained with H&E. It is possible to see cells within the particle's internal porosity linked by cell protrusions. Large quantities of ECM and cells can be seen encircling the microparticles, forming a large cell driven particle agglomeration.

## CONCLUSION

Porous microparticles have been produced in monodisperse populations from 80  $\mu\text{m}$  to 600  $\mu\text{m}$  in size. Particle size was controllable through the production setup. The hES-MP cells grew into the porosity of the particles and also formed anchor points between particles. Evidence currently suggests that the progenitor cells terminally differentiated into osteocyte-like cells. The binding of the particles by cells shows that it will be possible to create a continuous scaffold, with tissue-like properties, from individual particles over a period of time.

## INTRODUCTION

Bone defects raise many challenges in reconstructive surgery. Bone substitute materials made using polymers and composites are preferred over the use of traditional bone grafting methods. Polyhydroxyalkanoates (PHAs) are bacterial derived biopolymers having wide ranging mechanical properties, biocompatibility, surface degradation, as well as biodegradability and hence have more potential than synthetic biopolymers<sup>2</sup>. SCL-PHAs, like P(3HB) have been combined with fillers such as Bioglass<sup>®</sup> and clay to form composites with enhanced mechanical strength, bioactivity and tailored degradability. *Bacillus* spp. fed with different carbon sources and precursors can be used to produce both the homopolymer P(3HB) and the copolymer P(3HB-3HV). Appropriate cell seeding onto the bioactive scaffold can promote the restoration of functional bone. In this study, P(3HB) and P(3HB-3HV) based Cu doped Bioglass<sup>®</sup> composites were fabricated for bone tissue engineering study.

## EXPERIMENTAL METHODS

**Production of P(3HB):** *Bacillus cereus* SPV was grown in Kannan and Rehacek medium with glucose as main carbon source. The cells were harvested after 48 hours.

**Extraction of P(3HB):** P(3HB) was extracted using Soxhlet extraction technique and was precipitated out with chilled methanol and purified.

**Solvent casting technique:** 2D composite films were fabricated, characterised and cut to produce 1cm diameter films for cell culture studies with human bone marrow stromal cells (hMSC).

**Statistical analysis:** A Statistic analytical approach was carried out using a one way ANOVA test in Graph Pad Prism 6 software.

## RESULTS AND DISCUSSION

The homopolymer, P(3HB) was successfully produced using *Bacillus cereus* SPV by utilizing glucose as the main carbon source. Various concentrations in weight percentage of 45S5 and Cu doped Bioglass<sup>®</sup> composites were fabricated using the solvent casting method and characterised. XRD results confirmed the presence Bioglass<sup>®</sup> does not have any impact on the crystalline structure of the polymer (Figure 1). DSC analysis of the neat and composite films showed that the incorporation of Bioglass<sup>®</sup> reduced the crystallization onset temperature of the composites when compared to the neat films. Whereas a decrease in melting onset temperature and a lower glass transition temperature was observed in the Cu<sup>2+</sup>-incorporated 45S5 Bioglass<sup>®</sup>. The surface roughness also increased with the addition of Bioglass<sup>®</sup> which is known to enhance cell adherence.

Fig 1: XRD plot showing the crystalline structure of (a) PHB-N, neat P(3HB) with different wt % BG (b) PHBV-N, neat P(3HB-3HV) with different wt % BG.

SEM images of the P(3HB)/Bioglass<sup>®</sup> composites after incubation in simulated body fluid (SBF) are shown in Figure 2. These revealed an increased formation of hydroxyapatite in the case of Cu doped Bioglass<sup>®</sup> composites.

Fig 2: P(3HB)45s-1D P(3HB)Cu-1D P(3HB)45s-7D P(3HB)Cu-7D

Cell culture study on the composites using human bone marrow stromal cells, hMSC, showed the presence of live cells and the expression of osteogenic markers after a 14 day period of study.

## CONCLUSION

P(3HB) was successfully produced and characterised. This was then used to produce 45S5 and Cu doped Bioglass<sup>®</sup> composites. The hydroxyapatite formed after incubation in SBF is known to provide a strong bond to the tissues inside the body. In addition, the release of Cu<sup>2+</sup> from composite scaffolds made of P(3HB) and P(3HB-co-3HV) could enhance vascularization, thereby promoting angiogenesis, without compromising the mechanical stability of the scaffold<sup>1</sup>. Hence, this study provides a potential step forward in bone tissue engineering.

### INTRODUCTION

Layer-by-layer self-assembly of polymers show great potential in building multi-layered films on materials due to their flexibility, facile production, ability to respond to multiple stimuli, and incorporate several agents for controlled-release purposes<sup>1</sup>.

Most pathogenic bacteria colonize on surfaces and form biofilms, preventing the penetration of antibiotics. Biofilm-associated bacteria are 100 – 1000 times less susceptible to antibiotics than planktonic bacteria<sup>2</sup>, so alternative methods to controlled-release of antibiotics from surfaces have been designed. One of them is using anti-adhesive surfaces to prevent bacterial adherence and so biofilm formation on surfaces.

Previous studies showed that zwitterionic polymers, including block copolymer-micelles with zwitterionic coronae, showed anti-adhesive property against bacteria<sup>3</sup>.

As much as we know, this is the first study presenting how anti-adhesive property of micelles with zwitterionic coronae gets enhanced when they are in polyelectrolyte multilayered form. Prepared multilayered film is also pH-responsive and was used to release bactericidal agent triclosan; so, it is dual-functional in being anti-adhesive and pH-responsive.

### EXPERIMENTAL METHODS

βPDMA-*b*-PDPA block copolymer, which has zwitterionic and pH-responsive blocks, was previously synthesized and has been used to form polyelectrolyte films with anionic polymers DNA and poly (styrene sulfonate) (PSS). Triclosan was loaded into micelles by self-diffusion at pH 7.5. Glass wafers were base-treated to form negatively-charged SiO<sub>2</sub> layer, so micelle monolayers could be deposited. Other layers are deposited by dip-coating method. Physicochemical properties of micelles and films are determined by electrophoretic light scattering (for zeta potential and nanoparticle size), Ellipsometry, and AFM.

Agar-plating method, Live/Dead Cell Vitality Assay, and light microscopy experiments are carried out to determine bacteria adherence and viability. BSA adherence on wafers is determined by microBCA assay. All of the above bacterial experiments are carried out after incubating wafers in Müller-Hinton Broth containing *Staphylococcus aureus* for 1 h. each.

Statistically, bacteria numbers on coated wafers are compared by the numbers on control samples by Sidak's multiple comparisons test and ANOVA.

### RESULTS AND DISCUSSION

AFM images showed that the fluctuation in the anti-adhesive properties of 1 layered, 3 layered, and 5 layered-films are not significantly dependent on the roughness of film surfaces. The bacteria number is expected to increase with increasing roughness of surfaces, because of the difference in surface area, however 3-layered film of the micelle and PSS showed a lower amount of bacteria adherence, compared to the micelle-covered single-layered surface, and 5-layered surface showed adherence amount as high as the control sample showed. When it came to multilayered-film composed of the micelle and DNA, 5-layered films had lower bacteria adherence than 3-layered films and the degree of adherence was very close to the adherence on single-layered film.

At pH 5.5, triclosan release from surfaces were higher compared to the release at pH 7.5; but there was still diffusion of the bactericidal drug throughout the film at physiological pH.

### CONCLUSION

The main purpose of this investigation was to see if the anti-adhesive property of films incorporating zwitterionic micelles increases as layer number increases. Secondly, to design a multi-layered film which incorporates high amount of hydrophobic drug to be released in mildly acidic conditions, without major loss in the anti-adhesive property. Such pH-responsive systems are highly useful at infection sites around bio-implants, where *in situ* pH is mildly acidic.

We observed the lowest amount of adherence on 3-layered films of micelle and PSS. The drug release was also higher at mildly acidic conditions, but anti-adhesive property decreases at this pH (pH 5.5).

## Production of Spray Dried Calcium Phosphate-Gelatin Composite and The Impact of Cross-linking Agent on Composite Structure and Bioactivity in Simulated Body Fluid

Tugba Basargan Ozsagioglu<sup>1</sup>, Gulhayat Nasun Saygili<sup>1</sup>

<sup>1</sup> Chemical Engineering Department, Istanbul Technical University, Turkey  
[basargant@itu.edu.tr](mailto:basargant@itu.edu.tr)

### INTRODUCTION

Calcium phosphates (CaPs) are key factors of biological calcification. Hydroxyapatite ((Ca<sub>5</sub>(PO<sub>4</sub>)<sub>3</sub>(OH)), HAP), has been drawn attraction due to its similarity to the mineral phase of bones and teeth. Among the other crystalline calcium phosphate, phases dicalcium phosphate dihydrate (CaHPO<sub>4</sub>·2H<sub>2</sub>O) is significant to be used in the fabrication of biomaterials and be co-precipitated with other CaPs and/or a product resulted in their transformation. Some researchs showed that they could act as precursors for the calcinification of bone<sup>1</sup>. Hydroxyapatite-Gelatin (HAp-GEL) composites are among the most suitable materials for hard tissue applications due to their similarity to tissues and high osteo-conductivity properties<sup>2</sup>. On the other hand, the usage of gelatin is limited as a result of its rapid degradation in aqua medium. To solve this issue, cross-linking may be applied to GEL. Cross linking of gelatin is not only increasing the mechanical and thermal strength of gelatin, but also, degradation of gelatin gets slower in aqua medium<sup>3</sup>.

The aim of this study is to prepare Ca<sub>2</sub>P<sub>2</sub>O<sub>7</sub>·2H<sub>2</sub>O-Ca<sub>5</sub>(PO<sub>4</sub>)<sub>3</sub>(OH)-GEL (CaPs-GEL) microspheres via spray drying after in one simple step precipitation in the presence of Simulated Body Fluid (SBF) and investigate samples bioactivity in Simulated Body Fluid (SBF). In this content, glutaraldehyde (GA) was used as cross-linking agent.

### EXPERIMENTAL METHODS

CaPs-GEL (weight ratio of 50-50) composites were synthesized in the presence of Simulated Body Fluid. Ca(OH)<sub>2</sub>-SBF solution were added H<sub>3</sub>PO<sub>4</sub>-SBF-GEL solution and mixed at 40 °C. During mixing, pH was maintained around 9 by adding NaOH. The suspension was aged for a night. Next day, it was filtered and washed with distilled water with several times. After distilled water addition, the solution was fed to the spray dryer. The produced microspheres, then, were treated with various ratios of GA (8% and 2%,v/v) after turning into pellets. To dispose of excess GA, the pellets were waited in dilute sodium bisulfate solution for a while. On spray dried composites, XRD, FTIR and SEM analyses were conducted. Lastly, SBF studies were run to evaluate the bioactivity of the selected samples. The samples were soaked in SBF. After immersion in SBF up to 14 days, dried samples were conducted to XRD, FTIR, SEM and SBF absorption measurements. pH measurement was done, as well.

### RESULTS AND DISCUSSION

FTIR analysis of spray dried samples showed a chemical interaction between carboxyl group from GEL and Ca<sup>2+</sup> ion from CaPs. Also, XRD analysis confirmed that composites included Ca<sub>2</sub>P<sub>2</sub>O<sub>7</sub>·2H<sub>2</sub>O-Ca<sub>5</sub>(PO<sub>4</sub>)<sub>3</sub>(OH) structure. After GA addition, it was observed in FTIR analysis C-H stretch bond became sharper in the sample with 8% GA.

In SBF analysis, after 14 days, a pH change of SBF was observed, which might be related with Ca release (pH increase) subsequently followed by apatite formation (pH decrease) on composites. According to pH difference, it was assumed that degradation of sample with 2% was higher than the one with 8%. Also, SBF absorption was calculated based on the Eq. 1.

$$\text{SBF Absorption (\%)} = [(W_s - W_i)/W_i] * 100 \quad (\text{Eq.1})$$

W<sub>i</sub> = Weight os sample before taking in SBF

W<sub>s</sub> = Wet weight of sample after taking of SBF

SBF absorption increased due to GEL presence in the structure and reached around 20%.

SEM analysis (Fig. 1) indicated the production of apatite layer on composites.

Fig. 1. a) SEM graphs of CaPs-GEL treated with 2% GA, b) 8% GA (14th days)

### CONCLUSION

Analysis conducted confirmed the occurrence of desired CaPs-GEL structure and chemical bonding between CaP and GEL. It was concluded that CaPs-GEL composites may be biocompatible and usable as biomaterials.

### INTRODUCTION

Spray drying is the process of contacting an atomized stream to be dried with a gas stream that is at a higher temperature than the liquid stream. The higher temperature of the gas stream causes evaporation of the liquid from the droplets, forming particles. Recently, the use of this process to manufacture hollow, micron and sub-micron particles has also been demonstrated [1]. Furthermore, amorphous solid dispersions, soluble complexes, encapsulated systems, solid self-emulsifying systems and nano-dispersions of poorly soluble drugs prepared by spray drying are primary solubilization strategies [2].

Microspheres based on polycaprolactone (PCL), polyethylene glycol (PEG), and casein (CS) is prepared by spray drying technique. Microparticles are in vitro characterized in terms of yield of production, particle size, morphology, and thermal characterization. The importance of the study is producing of a stable and effective bioblends using ternary polymer mixture by spray dryer. First step of the study is preparation of low particle size, high surface area and homogeneous blend material using spray dryer. Second part is to characterize bioblends using Metasizer, SEM, and TGA. At the end of studies, we achieved minimum  $27.540 \pm 0.656 \mu\text{m}$  particle size with  $0.512 \text{ m}^2/\text{g}$  surface area. In particular, PCL-PEG-CS microspheres can be used for so many areas such as drug delivery systems and tissue engineering applications.

### EXPERIMENTAL METHODS

Polycaprolactone with  $M_n = 10,000 \text{ g/mol}$ ,  $M_w = 14,000 \text{ g/mol}$  and casein from bovine milk are purchased from Sigma-Aldrich. Polyethylene glycol (PEG-6000) is a gift from Ashland Inc. Acetic acid (Merck) and formic acid (Merck) are used as solvent agents for polymer mixtures and used without any further purification.

PCL+PEG+CS polymer mixture solutions are prepared by acetic acid-formic acid solutions with 3:7 (v/v) ratios. The value of 3:7 (v/v) acetic acid:formic acid is determined by previous studies [2]. Polymer contents in all solutions are 10 wt% and all ternary polymer mixtures are prepared by 1:1:1 (wt/wt) ratio.

### RESULTS AND DISCUSSION

Yield and particle size distribution with standard deviation are shown for all studies in Figure 1 and Figure 2, respectively. Due to the Figure 2, Metasizer analyses are done 3 times and particle diameter distribution is determined by standard deviation of the results. Final values demonstrate particle size ( $\mu\text{m}$ ) with standard mean of PCL-PEG-CS microspheres. Figure 1 determines that drying efficiency increase by decreasing of flow rates at  $120^\circ\text{C}$ ,  $135^\circ\text{C}$  and  $150^\circ\text{C}$ . The reason of these results are that increasing drying

temperature resulted in agglomeration of polymer mixture, so contact time with polymer mixture and drying temperature had adversely effect on diameter distribution [20]. Due to these results,  $135^\circ\text{C}$  and  $3 \text{ ml/min}$  are the best drying conditions because the lowest particle diameter and highest surface area are also obtained with  $27.540 \pm 0.656 \mu\text{m}$  particle size with  $0.512 \text{ m}^2/\text{g}$  surface area in this study. Yields are same, compared to the results reported for optimized runs using other laboratory scale spray dryers (Lab Scale Spray Dryer) [21].

**Figure 1.** Yield (wt%) at different drying temperature ( $^\circ\text{C}$ ) and flow rates (ml/min).

**Figure 2.** Particle diameter ( $\mu\text{m}$ ) with standard deviations at different drying temperature ( $^\circ\text{C}$ ) and flow rates (ml/min).

Furthermore, higher spray rates have been reported to have a negative influence on the yield. Figure 1 shows the tendency of the yield to be higher when the spray rate was low. Additionally, particle size diameters are increased at higher spray rates as seen in Figure 2. It is revealed that we have to avoid higher spray rates because of its reverse effect on encapsulation material.

### CONCLUSION

In comparison the spray dryer method to others, we obtained much more uniform microspheres and lower particle diameters. Significantly, the experimental results indicate that to obtain particle diameter  $27.540 \pm 0.656 \mu\text{m}$  with  $0.512 \text{ m}^2/\text{g}$  surface area does not need to any additive effects during drying process.

### 3D-Powder-Printing of Strontium Modified Magnesium Phosphate Cements for Bone Augmentation

Emilie März, Claus Moseke, Uwe Gbureck, Jürgen Groll, Elke Vorndran

Department for Functional Materials in Medicine and Dentistry, University of Würzburg, Germany  
[elke.vorndran@fmz.uni-wuerzburg.de](mailto:elke.vorndran@fmz.uni-wuerzburg.de)

Magnesium phosphate cement (MgPC) for bone augmentation was processed by 3D-Powder-Printing (3DP) as well as by cement paste formulation. Since strontium (Sr) is known to positively influence the bone metabolism, a modification of the cement with Sr was performed. In this study chemical and physical properties and Sr release kinetic of printed and paste-derived MgPC specimens were investigated.

#### INTRODUCTION

3D-Powder-Printing is an excellent method for the fabrication of bone substitutes for non-load-bearing defects especially in the case of complex defect geometry. The applicability of calcium phosphate cement (CPC) scaffolds produced by 3DP in maxillofacial surgery was recently shown [1]. A new approach is given by the 3DP of struvite forming MgPC, which is biocompatible and shows a faster biodegradation and higher osteoconductive potential compared to CPC [2]. The modification of MgPC with Sr is intended to enhance bone formation and radiopacity and to inhibit bone degradation of peripheral diseased bone tissue by Sr ion release.

#### EXPERIMENTAL METHODS

Raw materials consisted of cement powders with the general composition  $\text{Mg}_{3-x}\text{Sr}_x(\text{PO}_4)_2$  ( $x = 0, 0.33, 0.67, 1.00$ ) and an ammonium phosphate based binder solution. Solidification of the cements was performed by printing the cement materials with a 3DP system (Z510, Z-Corporation) or by manual mixing of the cement powder with the binder in a powder-to-liquid ratio of 5:2. The compressive strength, porosity (Archimedes principle), microstructure (scanning electron microscopy, SEM), chemical composition (X-ray diffraction), radiopacity and Sr release (inductively coupled plasma mass spectrometry, ICP-MS), were analyzed after several time points of elution in a phosphate buffered solution (PBS).

#### RESULTS AND DISCUSSION

Cement raw powders consisted of pure farringtonite ( $\text{Mg}_3(\text{PO}_4)_2$ ) or in the case of Sr modification of a mixture of farringtonite and two unreactive Sr containing MgPC phases ( $\text{Mg}_2\text{Sr}(\text{PO}_4)_2$ ,  $\text{Mg}_3\text{Sr}_2(\text{P}_4\text{O}_{15})$ ). After solidification of the cements, farringtonite was partially converted to struvite ( $\text{MgNH}_4\text{PO}_4 \cdot 6\text{H}_2\text{O}$ ) or in the case of paste formulations to struvite and newberyite ( $\text{MgHPO}_4 \cdot 3\text{H}_2\text{O}$ ). Printed MgPC showed a characteristic high porosity of  $(21 \pm 1) \%$ , which was increased by Sr modification to a maximum of  $(29 \pm 1) \%$ . In contrast, a significant lower porosity of  $(5 \pm 2) \%$  for cement paste formulations was shown, which was increased by Sr addition by a factor of 1.2 –

1.8. In comparison to printed MgPC a significant higher compressive strength, varying between 72 MPa and 47 MPa, was determined for the MgPC paste formulation, which decreased with increasing Sr content (Figure 1). Furthermore the radiopacity could be enhanced by the addition of Sr for both application forms.

Figure 1: Compressive strength of pure and strontium modified MgPC for printed specimen and paste formulations.

The Sr release was investigated over a period of 14 days. While cement pastes released Sr ions continuously with a rate of approximately 30 – 40  $\mu\text{g}/\text{day}$ , printed specimens showed a first order release kinetic with an accumulated maximal ion release of 45  $\mu\text{g}$  after 14 days.

#### CONCLUSION

MgPC processed by 3DP as well as by cement paste formulations seems to be a promising bone replacement material, since compressive strengths are comparable to proven CPC systems but shows improved osteoconductivity [2]. The Sr content can be adjusted with regard to biological effectiveness and suitable radiopacity without changing the physical or chemical properties of the MgPC system.

### INTRODUCTION

The improvement of 3D-printing processes (3DPP) technology in biomedical and tissue engineering has dramatically affected the potential ability of making biomedical implants and scaffolds by applying data of clinical imaging and computer aided designs. Among different types of 3D printing techniques, Selective laser sintering / Melting (SLS/M) and Stereolithography (SLA) are very appropriate for manufacturing highly precise structures which can be used for different biomedical applications such as aids for surgery, scaffolds and body implants. [1] The aim of this work is to select and optimize appropriate hydroxyapatite (HA) or chlorapatite (CIA) powder applied in 3DPP. Different Powders were characterised in order to see the effect of particle size (P.S), flowability and thermal stability for various 3DPP. Synthesis of CIA from HA was described. Also some comparison analysis between CIA and HA were conducted.

### EXPERIMENTAL METHODS

Hydroxyapatite [three different size distributions (0-30µm), (30-50µm) and (50-80µm)] was supplied by TEKNIMED S.A. (France). Expected chlorapatite feedstock was prepared from previous powder HA (50-80µm) using thermal exchange method at 950°C between sublimated NH<sub>4</sub>Cl and commercial HA involving the following chemical reaction [2]:

X-ray diffraction patterns were obtained on Seifert (Cu K $\alpha$  radiation). Fourier-transformed infrared spectroscopy (FTIR) analyses on powders were carried on for complementary phase identification (Nicolet 5700). Raman spectra were recorded, on a Horiba Jobin Yvon HR 800 spectrometer ( $\lambda=632.8$  nm). Thermal stability of starting powder was evaluated by thermogravimetric analyses (TGA) from 30°C to 1400°C under Argon. The flowability was determined as recommended by the European Pharmacopeia. Some Selected powders were applied for fabrication of 3D samples with complexes shape (figure 1) via SLA ( $\lambda=405$  nm using clear resin for making solution) or SLM (Yb-fiber continuous wave  $\lambda=1060$  nm) to see the effect of properties of the powder on the process.

Figure 1: SLA 3D-printed HA

**RESULTS AND DISCUSSION** Figure 2 shows XRD diffraction on raw powder (HA 50-80µm) and obtained powders after chlorination previously described. All peaks in raw powder diffractogram, were indexed using JCPDS 9-432 which prove HA was the only crystalline phase without impurity. For the second diffractogram, all peaks could be attributed to CIA using JCPDS 1-70-1454. This result highlights the full transformation from HA to CIA. These results were confirmed by FTIR and Raman (not show here). The thermal stability of CLA was higher than HA, according to weight loss shown in figure 3, only for HA at  $T > 800^\circ\text{C}$ .

Figure 2: XRD patterns of raw and obtained powders

Figure 3: TGA on CIA, HA powders

Flowability and morphology measurement allow selecting appropriate powders for each process. For example, Hausner ratio (HR) measurement allow to reject the use of HA 0-30 ( $1.47 \pm 0.17$ ) because the HR was higher than  $\text{HR}_{\text{limit}} = 1.25$  for SLS/M[3].

### CONCLUSION

According to TGA and XRD characterization CIA has a higher thermal stability than HA which shows that by using CIA we expect better results in both SLS/M and SLA techniques. Also, particles size plays an important role for SLS/M due to the limitation of flowability for this process.

## INTRODUCTION

Zirconium Oxide ( $\text{ZrO}_2$ ), because of its promising structural, chemical and thermal properties is used in widespread applications such as manufacturing of gas sensors<sup>1</sup>, corrosion-resistant and thermal barrier's coatings<sup>2</sup> and biomaterials<sup>3</sup>. Pure  $\text{ZrO}_2$  exists in three polymorphic phases namely monoclinic (m), tetragonal (t) and cubic (c). Among these monoclinic phase is stable but tetragonal and cubic phases are metastable. Application of  $\text{ZrO}_2$  as a structural material for biomedical applications and in many other areas depends mostly from synthesis methods and post-synthesis thermal treatment<sup>4</sup>.

The sol-gel method has become a popular method for fabricating wide range of ceramic products including powders and coatings. The main advantage of the sol-gel method is the ability to form inorganic structures at relatively low temperature and to produce with simply process route ceramic powders on large scale.

The goal of the present study was to prepare zirconia-ceria solid solutions ( $0.9\text{ZrO}_2\cdot 0.1\text{CeO}_2$ ) by sol-gel method. The influence of reagents molar ratios and hydrolysis ratio for the macroscopic morphology and the nature of thermal decay of the prepared gels were discussed<sup>5</sup>.

## EXPERIMENTAL METHODS

**Sample preparation:** As a reagents for synthesis were used zirconium *n*-propoxide (ZNP) (Acros) as a zirconia oxide precursor, 2-propanol (PrOH) (analytical grade, Avantor) as organic solvent, acetylacetone (AcAc) as a chelating agent, cerium nitrate hexahydrate (CNH) (Sigma Aldrich) as a ceria oxide precursor, and ultrapure water. Whole sol-gel synthesis and reagent dosing were carried out in nitrogen atmosphere in sealed glass apparatus. Stabilization of the zirconia precursor was achieved by the carefully addition of acetylacetone. Obtained hydroxide gels were dried ( $t = 80^\circ\text{C}$ ,  $\tau = 2,5\text{h}$ ) and calcined. Resultant powders were grinded in hand mortar with pestle. Based on macroscopic observations, the effect of the molar ratios of the ZNP:AcAc and ZNP:H<sub>2</sub>O on homogeneity of gels and powders an morphology. The molar ratios are shown in the table (Table 1).

**Characterization:** The TGA/DTA studies were carried out using a Q 1500D (MOM) in static air with a heating rate of  $10^\circ\text{min}^{-1}$  in the temperature range from 24 to  $1000^\circ\text{C}$ .

## RESULTS AND DISCUSSION

According to our observations, the molar ratios of ZNP: AcAc:H<sub>2</sub>O play an important role in the powders synthesis because they affect on the rate of hydrolysis ratio and same powders macroscopic morphology. Use of lower concentrations of water (in the range of 2÷5) and AcAc (in the range of 0.750÷0.6) resulted in a slow hydrolysis rate and completely foreseeable water addition. Resulting gels were characterized by a very high homogeneity. Obtained powders consisted a large number of big homogeneous agglomerates. Use of water in concentration in the range of 5÷10 and AcAc in the range of 0.4÷0.194 led to inhomogeneous gels, for which water was dosed in extremely gentle drop-by-drop manner. The resulting powders were characterized by considerable heterogeneity and small size of the agglomerates. b

ZNP	AcAc	H <sub>2</sub> O
1	0.750÷0.194	2÷10

Table 1 Used reagents molar ratio range

Noticeable differences was also observed in the TG/DTA spectra under which could be seen an approximate thermal stability of ZNP-AcAc complex. With the increase of complex was observed increase in the obtained powders particle size.

## CONCLUSION

The most satisfying result of applied sol-gel process treatment was observed for high molar ratios of water and low acetyl-acetone concentration which led to small fine grained powders.

### INTRODUCTION

Yttrium oxide doped zirconia is an advanced ceramic used in wide applications in the dental restorations using CAD/CAM techniques and dental implants<sup>1</sup>. Unfortunately use of zirconia in prosthetic dentistry has raised many problems associated with reports of uncontrolled martensitic type phase transformation from the tetragonal ( $\beta$ ) to monoclinic ( $\alpha$ ) in the oral environment and human biomechanics conditions<sup>2,3</sup>. Occurred changes led to increase of zirconia volume and unpredictable prosthetic restorations cracking and irreversible damage<sup>4</sup>. To fully prevent zirconia from unfavorable transformation is doping the zirconia with metal oxides with bigger atomic radius than  $Zr^{4+}$ <sup>5,6</sup>. On the basis of many studies it can be assumed that  $CeO_2$  as a dopant provides complete stability of the  $\beta$  phase and nanoscale grain size<sup>7,8</sup>. Very important for the stabilization of tetragonal zirconia is the method used to prepare the ceramic powders. One of the best preparation process is the sol-gel method because it allows strict control of the chemical composition and the achieving of a homogeneous grain size<sup>8</sup>.

The main objective of this study was to prepare with sol-gel method  $0.9ZrO_2-0.1CeO_2$  (mol%) ceramic powders in different pH conditions to determine that variable for the phase composition and morphology of obtained powders affecting to the final values of zirconia dental ceramics.

### EXPERIMENTAL METHODS

**Sample preparation:** As a starting materials were used zirconium *n*-propoxide (ZNP) (Acros), 2-propanol (PrOH) (analytical grade, Avantor), acetylacetone (AcAc), cerium nitrate hexahydrate (CNH) (Sigma Aldrich), ammonia water (Avantor) and acetic and hydrochloric acids (Sigma Aldrich) as pH agents and ultrapure water. Whole sol-gel synthesis and reagent dosing were carried out in nitrogen. Stabilization of the zirconia precursor was achieved by the addition of acetylacetone as the chelating agent. Obtained hydroxide gels were dried, calcined. Resultant powders were grinded in hand mortar with pestle.

**Characterization:** X-ray diffraction was performed using a Seifert XRD7 diffractometer and  $Co\ K\alpha$  radiation ( $\lambda = 0.179021\text{ nm}$ ). Powders morphology were performed with SEM pictures taken with an FEI INSPECT S50 microscope. The TGA/DTA studies were carried out using a Q 1500D (MOM) in static air with a

heating rate of  $10^\circ\text{ min}^{-1}$  in the temperature range from 24 to  $1000^\circ\text{C}$ .

### RESULTS AND DISCUSSION

Solution of ZNP with PrOH has a pH in the range  $6.5\div 7$ . Therefore it was decided to select four different values of pH: 2, 4, 8 and 10. For the acidic range at 2 resulted powders have a relatively wide range of inhomogeneities and considerable size of the agglomerates. It is noted that, with rise of pH are obtained more dispersed fine-crystal powders. The most homogeneous powders were obtained for pH of 8. It should be stated that the analysis of TG/DTA curves and XRD help confirmed in the range of  $2\div 4$  occurrence of undesirable phase  $\alpha\text{-}ZrO_2$  (the most characteristic peaks of  $2\theta = 28.48, 36.97$ ). In contrast, at pH 8 were found only full tetragonal phase peaks (most characteristic at  $2\theta = 34.99, 40.27$ ). On the basis of the thermograms for obtained powders, samples prepared at pH 8 show only characteristic peaks for crystallization of  $\beta$  phase (sharp peak at  $t = 400\div 420^\circ\text{C}$ ).

### CONCLUSION

In the summary it should be noted that the pH has a significant influence for the phase composition and morphology of the obtained zirconia-ceria powders. The most satisfying result of the applied pH values were obtained for pH = 8.

## INTRODUCTION

The mineral trioxide aggregate (MTA) is a mixture of a refined Portland cement, which is mainly consisted of tricalcium silicate, dicalcium silicate, tricalcium aluminate, gypsum, and bismuth oxide as a radiopacifier.<sup>1</sup>

The MTA has been used for pulp capping, pulpotomy, apexogenesis, apical barrier formation in teeth with open apexes, repair of root perforations, and as a root canal filling material because it is known to be nontoxic, noncarcinogenic, nongenotoxic, biocompatible with the host tissues, insoluble in tissue fluids, and dimensionally stable.<sup>2</sup>

The setting of MTA begins from the hydration of tricalcium silicate, dicalcium silicate, and tricalcium aluminate. Thus, the reaction rate and resultant microstructure are dependent on the size of initial powder. However, the size of powder produced by current method is about tens of micrometers.

The purpose of this experiment is to synthesize sub-micron meter sized MTA powder by spray-pyrolysis method.

## EXPERIMENTAL METHODS

The MTA powder was synthesized by spray pyrolysis. A CaO-SiO<sub>2</sub>-Al<sub>2</sub>O<sub>3</sub> gel solution for spray pyrolysis was prepared by gelation for 1 hour at room temperature after dissolving calcium nitrate tetrahydrate (Aldrich), tetraethyl orthosilicate (Aldrich), and aluminium nitrate nonahydrate (Aldrich) in deionized water followed by adding nitric acid (60%; Aldrich). The CaO-SiO<sub>2</sub>-Al<sub>2</sub>O<sub>3</sub> gel solution was then made into small droplets using an ultrasonic spray generator (1.7 MHz, 17 vibrators) fed into an alumina reaction tube (120 cm in length and 7 cm in diameter) at 1500°C with carrier gas (air) flow rates of 10 L/min, made by a compressor. The droplets were collected in a Teflon<sup>®</sup> filter placed in the exhaust line of the reactor, which was kept at around 100°C to avoid water condensation.

The phase of the powder was evaluated by XRD and microstructure was observed by FE-SEM. The elemental analysis on the sprayed powder was carried out using EPMA.

## RESULTS AND DISCUSSION

The phase analysis using XRD on the powder obtained through spray-pyrolysis was displayed in Fig. 1. It was composed of dicalcium silicate, tricalcium silicate, tricalcium aluminate, and some glass phases. The EPMA analyses showed that the Ca, Si, and Al distributed evenly in a particle. This means that the three major elements of MTA were successfully synthesized through spray-pyrolysis.

Figure 1. XRD pattern of the MTA powder obtained through spray-pyrolysis at 1500°C at carrier gas flow rate of 10 L/min.

The shape and size of the MTA powder was observed using FE-SEM (Fig. 2). They showed almost spherical shape and the particle size distribution was ranged from about 0.02 to 2.5 μm.

Fig. 2. FE-SEM micrograph of MTA powder obtained through spray-pyrolysis at 1500°C at carrier gas flow rate of 10 L/min.

The results demonstrated that the MTA powder could be synthesized by spray-pyrolysis based on sol-gel method. The final setting of this MTA powder was occurred within 10 min.

## CONCLUSION

The MTA powder was successfully synthesized by spray-pyrolysis based on sol-gel method. Its size and setting time were smaller and faster than those of white Portland cement. This means that it has a potential to be used as a MTA powder.

### INTRODUCTION

There are several techniques for fabrication of porous metallic scaffold like fugitive based technique<sup>1</sup>, direct foaming and casting<sup>2</sup>, freeze drying<sup>3</sup>, extrusion, and rapid prototyping. Amongst all the techniques, additive rapid prototyping technique<sup>4</sup> is an advanced technique to develop 3D physical model by computer controlled sequential transfer of energy and/or material to identified points in space. This technique has been extensively studied to develop customized implants through manipulation of geometrical distribution, modification of mechanical properties and creating porous structures for tissue in-grow as well as better fixation. Amongst all other biomaterial, metals have great potential for long-term load-bearing applications due to its excellent resilience and mechanical strength. Titanium and its alloys exhibit better performance in this aspect.

### EXPERIMENTAL METHODS

For development of titanium lattice, CAD file of 3D model was designed using SolidWorks and the file was saved in 'stl' format and further converted into \*BFB format prior to 3D writing. Using a customized 3D printing machine, titanium slurry was poured into a dispenser and extruded using a compressed air driven extruder through a microtip based nozzle. After each layer of extrusion, the lattice structure was crosslinked to avoid spreading of the filaments and subsequently up to 22 layers were printed. The vacuum dried samples were sintered at 1450 °C under inert atmosphere.

### RESULTS AND DISCUSSION

The titanium lattice structure was successfully sintered under controlled atmosphere and the lattice structure was maintained after sintering. The porosity of the lattice structure, lattice parameters such as diameter of the strand, spacing between strands, number of layers and geometry can be varied based on the design of the CAD model, slurry properties, nozzle diameter etc. The

resultant lattice structure had highly open porous structure and the strands were laminated during printing as well as sintering. This highly open porous structure is most suitable for tissue integration at the interface via tissue in-growth.

### CONCLUSION

The scaffolds showed good compressive strength which is close to natural bone. It also showed promising results in *in vitro* study for 3 days, 5 days and 7 days and bio-compatibility *in vivo*.

## Preparation of Electroconductive Titania Scaffolds for Bone Tissue Regeneration

Inga Narkevica<sup>1</sup>, Jurijs Ozolins<sup>1</sup>

<sup>1</sup> Institute of General Chemical Engineering, Riga Technical University, Latvia  
[inga.narkevica@rtu.lv](mailto:inga.narkevica@rtu.lv)

### INTRODUCTION

Use of scaffolds as sacrificial templates for bone ingrowth is the basis of bone tissue regeneration. The main reasons for using bone scaffolds are to provide an environment for bone formation, maintain the space and at the same time supply mechanical support to the skeleton during healing process<sup>1</sup>. Bone healing can be significantly improved by applying electrical stimuli in the injured region. Thus, electrically active ceramics with three-dimensional porous structure are of interest as bone graft substitute materials<sup>2</sup>. Highly porous TiO<sub>2</sub> ceramic scaffolds has attracted particular attention as a bone substitute material due to its excellent mechanical properties compared to other ceramic materials, biocompatibility and good osteoconductivity<sup>3</sup>. Thus, our research goal was to obtain electroconductive and 3D porous TiO<sub>2</sub> ceramic scaffolds. Such materials could enhance bone healing process by providing electrical stimuli in the regeneration site of bone defects.

### EXPERIMENTAL METHODS

Ceramic scaffolds were produced via polymer foam replica method. Commercially available anatase powder, 5% polyvinyl alcohol solution, ethylene glycol, ammonia solution and deionised water were used as raw materials for ceramic slurry preparation. Homogenisation of the slurry was conducted by stirring for 3 hours at 1000 rpm. Cylindrical polyurethane (PU) foams with fully interconnected pore structure (Fig. 1 (a)) serves as a sacrificial template. PU foam templates were dipped into the ceramic slurry and excess slurry was squeezed out of the foam to ensure that only a thin layer of slurry covered uniformly the entire surface of foam. After drying for 24 h, the polymer was slowly burned out and scaffolds were sintered in air for 30 h at 1500°C temperature. In order to obtain electroconductive TiO<sub>2</sub> ceramic scaffolds, they were additionally thermally treated under high vacuum conditions at 1200°C for 5 h.

Macrostructure and surface morphology was characterized by field emission scanning electron microscopy. Total porosity of the scaffolds was measured by gravimetry. Mechanical strength of the scaffolds was determined by compression test. Electrical resistance was measured using DC Wheatstone bridge.

### RESULTS AND DISCUSSION

Highly porous TiO<sub>2</sub> ceramic scaffolds with fully interconnected and open pore structure were obtained (Fig. 1 (b) and Table 1). Pore size was in the range from 100 to 600 µm that is wide enough to ensure cell migration and vascularisation throughout all scaffold structure.

Fig.1. PU foam template (a) and TiO<sub>2</sub> scaffold after thermal treatment in air (b).

Table 1 summarises the main characteristics of obtained scaffolds after thermal treatment in different environments. No significant changes were observed in porosity and mechanical properties of the scaffolds. Electrical conductivity of the scaffolds after sintering in air was very low ( $\sim 3 \cdot 10^{-7}$  µS/m). Thermal treatment under high vacuum conditions caused dramatic increase in electrical conductivity ( $\sim 40$  µS/m). Increased electrical conductivity can be explained by reduction of TiO<sub>2</sub> that results in formation of different crystal lattice defects (oxygen vacancies, Ti<sup>3+</sup> or Ti<sup>4+</sup> interstitials). The reduction changes titanium-oxygen ratio in titanium dioxide. Even a small deviation from stoichiometry results in a significant decrease in electrical resistivity.

Table 1

Thermal treatment environment	Porosity, %	Compressive strength, MPa	Electrical conductivity, µS/m
Air	94±0.5	0.41±0.15	$\sim 3 \cdot 10^{-7}$
Air-Vacuum	93±1.4	0.31±0.05	$\sim 40$

### CONCLUSIONS

Using replica method porous TiO<sub>2</sub> ceramic scaffolds with porosity >90% and pore size >100 µm were obtained. Scaffolds showed fully open and interconnected pore structure. Thermal treatment under high vacuum conditions greatly increased electrical conductivity of the scaffolds. Due to obtained porous structure and electrical conductivity they can be potentially used in bone tissue regeneration to supply electrical stimuli and enhance bone healing process.

## A Novel Model of Nonalcoholic Fatty Liver Disease in a 3D Liver-on-Chip Device

Manuele Gori<sup>1</sup>, Maria Chiara Simonelli<sup>1</sup>, Luca Businaro<sup>2</sup>, Marcella Trombetta<sup>1</sup>, Alberto Rainer<sup>1,2</sup>

<sup>1</sup>Tissue Engineering Lab, University Campus Bio-Medico of Rome, Rome, Italy; <sup>2</sup>Institute for Photonics and Nanotechnologies, National Research Council (CNR), Rome, Italy

[m.gori@unicampus.it](mailto:m.gori@unicampus.it)

### INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is a chronic liver disease, ranging from simple steatosis to nonalcoholic steatohepatitis, which may progress to cirrhosis, leading eventually to hepatocellular carcinoma (HCC). HCC ranks as the third highest cause of cancer-related death globally, requiring an early diagnosis of NAFLD as a potential risk factor<sup>1,2</sup>. However, the molecular mechanisms underlying NAFLD are still under investigation. So far, many *in vitro* studies on NAFLD have been hampered by the limitations of 2D culture systems, in which cells rapidly lose tissue-specific functions. The present liver-on-chip approach aims at filling the gap between conventional *in vitro* models, often scarcely predictive of an *in vivo* condition, and animal models that are potentially biased by their xenogeneic nature.

### EXPERIMENTAL METHODS

Microfluidic devices were fabricated by soft-lithography, starting from a photolithographically-obtained SU-8 master that was used as a mold for replicas in polydimethylsiloxane (PDMS), and seeded with HepG2 cells, a human hepatoblastoma cell line that retains many characteristics of normal differentiated hepatocytes<sup>3</sup>. Cells were cultured in 3D under microfluidic perfusion, through a set of microchannels that mimic the endothelial-parenchymal interface of a liver sinusoid, allowing the necessary diffusion of nutrients<sup>4</sup>. A continuous flow of medium (flow rate: 18  $\mu$ L/day), supplemented with a mixture of Free Fatty Acids (FFAs), namely palmitic and oleic acid at a final concentration of 1mM, was provided. Controls were represented by on-chip and 2D adherent cultures in plain medium. Intracellular lipid accumulation was measured using AdipoRed assay (Lonza). Cell viability was evaluated using LIVE/DEAD assay (Life Technologies), and oxidative stress by analyzing intracellular ROS levels through 2',7'-dichlorodihydrofluorescein diacetate (H<sub>2</sub>DCFDA, Life Technologies).

### RESULTS AND DISCUSSION

Our preliminary data show that on-chip FFA treatment produced a marked intracellular lipid accumulation, with different cytotoxic effects and ROS levels *vs.* 2D controls. Overall, the liver-on-chip system provides a more suitable culture microenvironment, representing a better and more reliable model, close to the *in vivo* liver pathophysiology, for investigating NAFLD pathogenesis.

**Figure 1.** Left: Microfluidic liver-on-chip device (scale bar 200  $\mu$ m). Right: The different intracellular lipid accumulation (green fluorescence), evaluated through AdipoRed assay, between control (left panel) and FFA-treated (right panel) HepG2 cells cultured within the microfluidic device (scale bar 50  $\mu$ m).

### CONCLUSION

The liver-on-chip approach constitutes a paradigm shift for developing robust 3D *in vitro* models, representative of *in vivo* liver metabolic disorders, to unveil the molecular basis of NAFLD. In a long-term perspective, liver-on-chip implementation may boost the evaluation of therapeutic effects, selection of tailored treatments and novel therapeutic targets in both NAFLD and other metabolic disorders. This work will be extremely relevant to build a bridge between liver studies and micro-technologies, providing a starting point in genome- or proteome-scale analysis in the framework of metabolic diseases.

## Stainless Steels Alloyed with Molybden for Medical Applications

Victor Geanta, Ionelia Voiculescu

University Politehnica of Bucharest, Romania  
[victorgeanta@yahoo.com](mailto:victorgeanta@yahoo.com)

### INTRODUCTION

The paper analyses the effect of Mo on microstructure and microhardness of some austenitic stainless steels for medical applications. The addition of one or two percent molybdenum into stainless steels significantly increases the corrosion resistance and the elevated temperature strength. Due to their large atom, molybdenum increases the elevated temperature strength of stainless steels through solid solution hardening<sup>1, 2, 3</sup>.

### EXPERIMENTAL METHODS

The experimental alloys were produced by melting in an argon inert atmosphere of the VAR (vacuum arc remelting) unit, using high purity metallic materials. The alloys composition was conducted from a base of commercial alloy (316L stainless steel), and subsequently 5 experimental stainless steels were obtained, by keeping constant the content of main elements, like Cr and Ni, and changing the content of molybdenum.

### RESULTS AND DISCUSSION

Metallographic analysis revealed microstructure morphology, constituents and different phases, depending on the content of molybdenum. Has been

examined the effects of heat treatment at 1100 °C for 2 hours followed by water quenching, on the evolution of microhardness.

### CONCLUSION

Evolution of microhardness express the hardening effects promoted by increasing molybdenum content in austenitic stainless steel metal matrix.

## INTRODUCTION

Materials such as pure titanium and its alloys, or those containing Nb and Ta, have high polarization resistance and exhibit an inert behavior in relation to biological fluids. Metallic materials with polarization resistance similar to these, such as 316L and Co-Cr alloys, are covered by a tissue membrane and their long-term behavior is not considered inert<sup>1, 2, 3, 4</sup>.

## EXPERIMENTAL METHODS

In the paper are presented results on obtaining new titanium alloys, like Ti Mn, TiFe and TiAl. Ti, Ta and Nb are reported to be biocompatible due to their capacity to form a protective layer of oxide, which is a semi-conductive or non-conductive oxide. The experimental alloys were produced by melting in an argon inert atmosphere of the RAV unit, using high purity metallic materials and the commercial alloy Ti8Al4V. Were developed, under the same conditions, some binary alloys (Ti9Al, Ti5Fe, Ti3Mn) for highlighting the effects of the singular elements Al, Fe and Mn on the characteristics of titanium alloys.

## RESULTS AND DISCUSSION

Microstructural aspects and micro-hardness values are analyzed in order to estimate the effects promoted by each element separately. Experimental alloys are compared with a commercial technical alloy, Ti6Al4V respectively, against which performance is evaluated in

terms of microstructural features and microhardness values.

## CONCLUSION

Analyzing the microhardness values has been revealed that items that cause hardening of titanium metal matrix are, in order of decreasing effectiveness, iron, manganese and aluminum. It was found that by combining of certain chemicals we can get an increase in the hardness of titanium metal matrix, such as the simultaneous use of iron and aluminum.

## INTRODUCTION

One of the major obstacles to the diffusion of additive manufacturing (AM) in tissue engineering has long been represented by the limited set of available biomaterials that could be directly processed. In this regard, processing of hydrogels represents a main challenge in view of soft tissue engineering applications. Furthermore, direct manufacturing of tissue precursors with a cell density similar to native tissue has the potential to overcome the extensive *in vitro* culture required for conventional cell-seeded scaffolds. Aim of this study was the investigation of hepatic metabolism in a novel composite 3D scaffold, which better approximates the *in vivo* liver conditions compared to a conventional cell culture system. HepG2 cells, a human hepatoblastoma cell line that retains many characteristics of normal differentiated hepatocytes<sup>1</sup>, have been used as a model cell system.

## EXPERIMENTAL METHODS

Pluronic/Alginate scaffolds were fabricated by pressure-assisted deposition using a custom designed AM equipment<sup>2</sup>. A Pluronic/Alginate solution (20 wt% PF127, 2 wt% sodium alginate in diluted DMEM) was loaded into a gel dispensing syringe at 4 °C. The syringe was then heated to 37 °C, leading to gelation, and gel was extruded through a 250 µm nozzle at a pressure of 1.2 bar. Squared scaffolds were obtained by depositing layers of fibers laminated in a 0°/90° pattern. Scaffolds were briefly exposed to a sterile 25 mM CaCl<sub>2</sub> aq. solution to induce alginate crosslinking. Mechanical properties were assessed by unconfined compression tests. Scaffold degradation was measured in terms of weight loss following incubation in PBS. Similarly, cell-laden constructs were prepared by suspending HepG2 cells at a concentration of 2x10<sup>6</sup> cells/mL into ice-cold polymer solution. Afterwards, the gel was extruded at 37 °C using the previously described equipment.

Cell morphology and distribution within the scaffold were assessed by immunofluorescence staining. After 24h, cell viability was determined by Trypan Blue and Vybrant cytotoxicity assay. Proliferation of HepG2 cells on the AM-scaffold, in comparison with a 2D culture plate, was investigated by MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide) assay at selected time points (i.e., 1, 4, 7 days). To study the liver-specific functions of the HepG2 cells embedded into the scaffold, secreted albumin and urea levels were determined through specific ELISA assays.

## RESULTS AND DISCUSSION

3D structures with controlled architectures were successfully manufactured starting from a Pluronic/Alginate system, in which Pluronic F127 conferred thermo-sensitive properties, while alginate endowed the formation of a strong gel upon exposure to bivalent cations in aqueous solution. This positive combination led to constructs with precisely defined microarchitectures and enhanced stability.

Embedded HepG2 cells survived the deposition process, homogeneously spread inside the gel phase, and showed albumin and urea production during the culture period.

Figure 1: A) Macroscopic image of a four-layered hydrogel scaffold: top view. B) Optical micrograph of scaffold microarchitecture, scale bar: 250 µm. C) Confocal fluorescence microscopy showing distribution of HepG2 cells within the scaffold (magnification 10x). D) Enlarged view of the HepG2 cell morphology (magnification 40x), green (phalloidin) and blue (DAPI) stainings.

## CONCLUSION

Our cell-laden scaffold provides optimal conditions for hepatic cell proliferation as well as a suitable microenvironment for liver-specific metabolic functions. In light of the obtained results, the proposed 3D culture system may represent a novel human hepatic model for drug screening and toxicological studies.

**As-cast Biodegradable MgCa alloys –Structure, Mechanical and Corrosion Properties**

Sonia Boczekal<sup>1</sup>, Michał Karaś, Anna Kozik<sup>1</sup>, Dawid Kapinos<sup>1</sup>, Marzena Lech–Grega<sup>1</sup>

<sup>1</sup>Institute of Non-Ferrous Metals, Light Metals Division, Skawina, Poland  
[sboczekal@imn.skawina.pl](mailto:sboczekal@imn.skawina.pl)

Magnesium plays the fundamental role in the biological system as a component of bone tissue. The yield module and the compressive strength of magnesium with calcium is the closest to the properties of natural bone as compared to other commonly used implants. These alloys are biodegradable in aqueous solutions containing in particular chloride ions. The properties of magnesium alloys predispose them to the study of biocompatibility and biodegradability .

The structure of magnesium alloys containing 1%wt., 2.5%wt. and 5%wt. Ca was examined in as-cast condition. After the casting process, the presence of Mg<sub>2</sub>Ca as eutectic phase at grain boundaries was observed under the scanning electron microscope (SEM) and examined by the X-ray Diffraction (XRD). The quantitative share of the eutectic increased with the

increase of the additive Ca in alloys. Mechanical properties were determined in the compression test at temperatures in the range of 37° C to 420°C. It was found the highest properties were achieved for an alloy containing 5% wt. Ca. The analysis of strength-hardening coefficient in the compressed tests showed that with increasing temperature followed by a rapid decrease in the strengthening value. The strength-hardening coefficient stabilized for the tested alloys at 380°C. This material was subjected to the corrosion test in Ringer solution in order to determine the dissolution kinetics of the alloys at 37°C. The progress of corrosion in MgCa alloys was investigated in the structure observations.

## INTRODUCTION

X-ray microtomography ( $\mu$ CT) is commonly known as a gold standard for evaluation of bone morphology and microarchitecture in both animal and human models *ex vivo*<sup>1</sup>. It is also being used to study the porous artificial bone replacement structures. Both measured and generated structures can be manufactured in meso- and macro-scale using Additive Manufacturing (AM)<sup>2</sup>. It is an automated technique for direct conversion of 3D data into physical objects using a variety of approaches. Materials for bone-like structures should have properties similar to the bone tissue, while manufactured structures must have certain mechanical properties - both geometry and material is important herein. In the presented study assumptions stated above were the basis for the methodology of AM and  $\mu$ CT for 3D porous structures. Also preliminary validation of the properties using mechanical tests in Finite Element Method (FEM)<sup>3</sup> before and micro-loading with FEM verification after manufacturing was also performed.

## EXPERIMENTAL METHODS

To produce biocompatible porous structures of bones and artificially generated bone-like models in meso- and macro-scale several AM methods were chosen. For each standardized input data in the form of STL files with 3D geometry of the structure were used. Fused Filament Fabrication (FFF) is AM method that uses a plastic filament unwound from a coil to lay down material in layers and produce a part in analogous way to Fused Deposition modeling (FDM). Digital Light Processing (DLP) is AM method that uses a similar process to Stereolithography (SLA) with selective polymerization of model layers in liquid resins with the usage of light source. Selective Laser Sintering (SLS) is AM method that uses a laser as the power source to sinter powdered material to create a solid structure. Selective laser melting (SLM) uses a comparable concept, but in SLM the material is fully melted rather than sintered. 3D structure of porcine cancellous bone from  $\mu$ CT with 10  $\mu$ m voxel was manufactured in ten times enlarged macro-scale resulting in size of 5 cm using FDM (PLA filament), SLS (polyamide powder) and DLP (proprietary resin) methods. Artificially generated 3D heterogeneous porous structures were manufactured in meso-scale resulting in cubic size of 5 mm using SLM (titanium alloy powder) and DLP (proprietary resin). High-resolution  $\mu$ CT measurements of the structures were performed after manufacturing.

## RESULTS AND DISCUSSION

The use of  $\mu$ CT measurements allowed for the acquisition of the 3D structure and inspection of the surface roughness. It also provided the opportunity to use direct three-dimensional methods for the calculation of the morphometrical parameters such as porosity, diameters for the rods and pores, and the degree of anisotropy. Meso-scale artificially generated structures were measured in  $\mu$ CT with voxel size of 3.5  $\mu$ m and also tested in miniature loading machine in linear range. FEM mechanical tests before and after manufacturing were also performed, allowing for the comparative analyses and positive verification of the whole process. The methodology can be illustrated based on the comparison of the input and prepared for AM methods geometries with the reconstructions from  $\mu$ CT scans. These results imply that DLP is currently the most suitable AM method in presented methodology, allowing for the exact reproduction of the geometry and properties of structure both for meso- and macro-scale. Further research may lead to strengthen the mechanical properties, which are actually too small in compare to bone tissue. Designing of the biomaterials paying special attention to fabrication of the geometry of porous structures shall be currently prioritized.

## CONCLUSION

The Advanced techniques for the preparation of porous structures based on AM are becoming increasingly important with the development of new experimental methods. Application of such strategy in conjunction with  $\mu$ CT and FEM opens up new opportunities in designing and study the mechanical properties of more complex materials with well-defined geometrical and precisely measured morphometrical parameters of structures that are impossible to achieve using existing methods and models.

## INTRODUCTION

One of the main challenges currently faced by tissue engineers is the loss of tissues post implantation due to delayed neovascularization upon implantation<sup>1</sup>. Several strategies are under investigation to create vascularized tissue but none have yet overcome this problem. As blood vessel formation is a complex process that is controlled by a large number of interrelated factors it is not surprising that this remains a challenge. To induce vascularization within TE substitutes these same processes will need to occur and therefore an understanding of the basic principles and factors affecting angiogenesis is needed. Many angiogenesis models fail to combine the ability to combine supporting cells, the extracellular matrix and perfusion<sup>2</sup>. In this study we use a detergent treatment to create a natural vascular scaffold from rat intestine that can be used as a platform for angiogenesis studies.

## EXPERIMENTAL METHODS

To produce the natural vascular nets intestine was harvested from fresh rat cadavers. The main vessel of the mesentery was cannulated and flushed with heparin solution before treatment with 1% Triton-X 100 and 0.1% ammonium hydroxide. Distilled water was then circulated to remove residual detergent and the resultant matrix was sterilized using 0.1% peracetic acid. Residual peracetic acid was removed with sterile PBS. Blue dye was injected into the matrix to assess vascular patency. The presence of DNA, GAG, elastin and collagen before and after decellularization were identified through histochemical staining and then quantified. The inherent angiogenic properties of the matrix was analysed using the chick chorioallantoic membrane (CAM) assay cultured for 8 days, with a collagen gel negative control. To recellularize, a co-culture of dermal fibroblasts and human dermal microvascular endothelial cells (HDMECs) were injected through the mesenteric artery of the decellularized intestine and subsequently perfused continuously with cell culture medium for 5 days at 37°C. Samples were taken at days 1 and 5 for histological analysis and fluorescence microscopy.

## RESULTS AND DISCUSSION

A well-defined vascular tree with multiple branching was visible from blue dye injection. Quantitative analyses showed a 97% reduction of DNA upon decellularization. ECM components such as collagen and GAGs were found to be retained whilst almost all elastin was removed by the process. The CAM assay showed good integration of the matrix with the host whilst indicating increased angiogenic properties of the decellularized matrix when compared to the collagen gel control. Upon recellularization, histochemical

analysis showed that the cells attached to the matrix and occupied the blood vessels. Confocal microscopy showed a re-organisation of the HDMECs after 5 days in culture with the cells lining the vessel architecture and showing evidence of sprouting (Fig 1).

Figure 1 - Representative confocal microscopy images of sections of recellularized jejunum infused with HDMECs (red) and HDFs (green) under static culture with no sign of either cell type occupying the vascular architecture (A) and culture under constant perfusion of media with evidence of cellular adhesion within the vascular structures and vascular sprouting (arrow) (B) after 5 days. After 1 day under perfusion conditions HDMECs and HDFs show the distinct occupation of areas within the native vascular architecture (arrows) (C) reorganizing after 5 days with HDMECs lining the vessels (arrow) (D) and showing evidence of vascular sprouting (arrow) (E).

## CONCLUSION

Histological and quantitative analyses show the almost complete removal of cellular material and the preservation of the native architecture and connective tissue components, whilst recellularization via perfusion through the vascular network shows good cellular adhesion and redistribution and further demonstrates that the inclusion of a stromal cell and of flow lead to new blood vessel formation-not evident in their absence.

### INTRODUCTION

The success of islet transplantation as a treatment for type 1 diabetes mellitus is restricted by various problems such as angiogenesis. Rapid reestablishment of a functional vasculature in transplanted islets is crucial for their survival and function. Functionally, blood vessel endothelium provides a niche essential for the maintenance of  $\beta$ -cell fate. By using vascular endothelial growth factor (VEGF),  $\beta$ -cells attract endothelial cells, which form capillaries with a vascular basement membrane next to them<sup>1</sup>. The proposed mechanism has recently been recapitulated by the development of several synthetic matrices. These matrices have been used to improve current islet culture techniques for islet isolation as well as the design of an artificial immunoprotective islet carrier for transplantation<sup>2</sup>. For example, islets cultured on collagen type I-coated surfaces and those treated with soluble fibronectin exhibited a greater  $\beta$ -cell survival and insulin secretion *in vitro*<sup>3</sup>. However, the control of the cross-talk between  $\beta$ -cells and endothelium vessels is still a significant challenge. The present work aims to investigate the effects of ECM-based substrates on the pancreatic  $\beta$ -cell line Min6 when in co-culture with umbilical vein endothelial cells, HUVECs.

### EXPERIMENTAL METHODS

MIN6  $\beta$ -cells (ATCC, UK) were seeded in a 24 well plate previously coated with 100  $\mu$ l of Matrigel (BD biosciences, UK), in DMEM (Gibco, UK) containing 10%  $\nu$ /<sub>v</sub> FBS (Sigma, UK) in a humidified atmosphere at 37°C and 5% CO<sub>2</sub>. After 24 hour incubation, Min6  $\beta$ -cells were co-cultured with HUVECs (ATCC, UK) at a density of  $3 \times 10^4$  per well with F12-K medium (LGC Ltd., UK) supplemented with 0.1 mg/ml sodium heparin (Fisher Scientific, UK), 0.05 mg/ml ECGS (Sigma, UK) and 10%  $\nu$ /<sub>v</sub> FBS and left for 24 hour under standard culture conditions. MIN6  $\beta$ -cells and HUVECs were also seeded on polystyrene tissue culture plate (TCP) used as a control.

Cells were assessed for their viability and adhesion by Hoescht Propidium Iodide staining (HPI; Sigma, UK). Cytoskeletal actin formation was investigated by staining cells with AlexaFluor 488®-Phalloidin (Invitrogen, UK), after washing with PBS and fixing with 3.7% formaldehyde (Fisher Scientific, UK) for 10 minutes at room temperature. Cellular nuclei were stained with 4',6-diamidino-2-phenylindole (DAPI; Vectashield, UK) and cells were then analysed with a laser scanning confocal microscopy (Leica TCS SP5, UK). Data were expressed as mean cell number/field (standard deviation) from n=6.

### RESULTS AND DISCUSSION

HPI staining revealed that MIN6  $\beta$ -cells were able to attach onto both TCP and Matrigel substrates and to be viable after 24 hour incubation. However, cell adhesion was more pronounced onto Matrigel surfaces ( $72.6 \pm 8.06$  cells/field) compared to the TCP,  $45.7 \pm 7.4$  cells/field suggesting a strong effect of both laminin and collagen IV, the major protein components of Matrigel, on promoting  $\beta$ -cell survival and function. The importance of these ECM proteins was also found to influence cell morphology and indeed cell-cell interaction (Figure 1). On TCP, HUVECs showed a relatively irregular shape with the formation of pointed protrusions indicative of the formation of F-actin extensions likely to facilitate cellular interaction with the MIN6  $\beta$ -cells. On the Matrigel substrate, alongside the expected endothelial sprouting, tight interactions between the two cell populations were observed with pseudo-islets forming in close proximity of the endothelial tubular structures.

**Figure 1.** Phase contrast images showing a) cell monolayer on TCP; b) Co-culture on Matrigel. Scale bar=50  $\mu$ m.

### CONCLUSION

ECM-based substrates facilitate the *in vitro* organisation of  $\beta$ -cell pseudo-islets and endothelial sprouting into tissue lattices. Such bioengineered tissue units could have a potential in both the treatment and research of Type 1 diabetes through tissue engineering applications and clinically reflective tests.

### INTRODUCTION

A major drawback of vascular implants is the thromogenicity of polymer-based prosthesis surfaces. We aim to biofunctionalize the prosthesis biomaterial by capturing blood-born endothelial progenitor cells (EPCs) in situ. Towards this goal monoclonal antibodies were generated against the EPC specific receptor VEGFR-2.

### MATERIALS AND METHODS

Trapping antibodies were generated by genetic immunization and screened by cell-based flow cytometry (FACS). Antigen phosphorylation was monitored by Western blot analysis. Tube formation was microscopically analyzed with human umbilical vein endothelial cells (HUVECs) on matrigel. Cytotoxicity was qualified by fluorescence microcopy. Cell proliferation was determined by metabolic labelling with bromo-deoxy-uridine (BrdU). Uptake of acetylated low-density lipoprotein (ac-LDL-DiI) into HUVECs was investigated by FACS and fluorescence microscopy. Trapping experiments were performed with protein G and the different trapping antibodies. HUVECs were employed under static conditions and in a flow chamber to qualify antibody trapping characteristics.

### RESULTS

Out of 10,200 hybridoma clones eight antibodies specific for all seven VEGFR-2 extracellular domains were selected and affinity purified. All antibodies left cell viability (calcein staining), proliferation (BrdU labelling) and the angiogenic potential of HUVECs unaffected. No side effects were evident with regard to cell differentiation (tube formation capability) and cell functioning (LDL uptake). Antibodies did not significantly modify receptor phosphorylation. The antibodies did neither interfere with growth factor binding nor did they directly activate receptors in a ligand-independent manner indicating that they do not imitate growth factors. Coating of antibodies to microscopic flow chamber surfaces was used to demonstrate the trapping capacity for cells.

We produced antibodies against all seven extracellular domains of the vascular endothelial growth factor receptor 2, which left biological functions of the endothelium essentially unaffected. Different antibodies are specific for pig or human, others crossreact with both species, which aims at combinatorial implantation experiments and finally human applications. One selected rat antibody has already been humanized. Current experiments focus on biofunctionalization of biomaterials and polymer vessels.

### INTRODUCTION

Poly( $\alpha$ -hydroxy esters) are one of the most commonly tested materials for tissue engineering applications thanks to their well-characterized biodegradability and Food and Drug Administration (FDA) approval. This polymer family includes e.g. poly(glycolic acid) (PGA), poly(lactic acid) (PLA), their copolymer (PLGA) and polycaprolactone (PCL)<sup>1</sup>. All of those polymers can be easily processed and copolymerized or blended in order to widen spectrum of their application within the field of tissue engineering.

Developing a biocompatible and nontoxic substrate for cells proliferation and differentiation is one of the contemporary challenges of tissue engineering. Mesenchymal stem cells (MSC) are promising cell type which could be utilized in biomedical applications. MSC are multipotent stem cells, which can give rise to different cell lineages. They are characterized e.g. high differentiation potential and low immunogenicity.

The aim of the study was to analyze the potential of polymer surfaces (polycaprolactone and polylactide) for biology and angiogenic differentiation of MSC derived from human umbilical cord Wharton's jelly (hUC-MSC).

### EXPERIMENTAL METHODS

In current study we examined an influence of bioresorbable polymer-based substrate on hUC-MSC phenotype and functions.

5% polymer solutions were prepared by dissolution of PCL (Sigma-Aldrich,  $M_n = 80\ 000$ ) and PLA (Ingeo<sup>TM</sup> 3051D) in glacial acetic acid and dioxane, respectively. Thin layer of the polymer solutions were poured into 24-well plate and left for 96h to evaporate the solvents. The PCL and PLA films were rinsed with alcohol and sterilized under UV radiation, prior to cell culture.

Cells were cultured in standard conditions, in DMEM/F12 medium supplemented with 10% FBS, at 37°C with 5% CO<sub>2</sub>. The analysis of morphology and migratory activity of cells cultured on polymer films were performed by microscopy techniques (conventional light microscopy, fluorescence microscopy and scanning electron microscopy (SEM)). Proliferation rate was assessed for every 24 hrs. To evaluate cells viability and apoptosis flow cytometry analysis was performed. Cell migration and motility was quantitatively examined via on-live movie recording during cell culture. Furthermore, the influence of polymers on hUC-MSC angiogenic differentiation potential was evaluated on gene expression level by real-time PCR.

### RESULTS AND DISCUSSION

The results demonstrated that both analyzed polymers (PCL and PLA) constitute non-toxic culture substrate for hUC-MSC and do not affect cell viability. However, data revealed that proliferation rate was partially reduced. Microscopic analysis of hUC-MSC indicated their slight morphology changes depending on the different type of culture substrate. Figure 1 shows SEM images of hUC-MSC spreading on PCL (A) and PLA (B) substrates. Also, different microstructure of the polymers is visible.

Interestingly, analysis of cells trajectories revealed, that polymers stimulate migratory activity and speed of cells movement. Moreover, we observed, that hUC-MSC, which are cultured on polymers-based substrate are able to spontaneous differentiation into angiogenic cells. We observed expression of genes related to angiogenic differentiation after 8 days of cell culture. This data suggests, that evaluated polymers constitute promising surfaces in stem cell research and regenerative medicine.

### CONCLUSION

Our preliminary data suggested that biodegradable polymers may enhance regenerative properties of selected stem cell populations. However, further studies are necessary to analyze the impact of utilization of stem cells and 3D-composites structures in biomedical applications.

## INTRODUCTION

Modern medicine has been built upon the power of antibiotics to deal with infections. However, antibiotics can no longer be relied upon at a time when the World Health Organisation classifies antibiotic resistance as one of the three greatest threats to human health. Strategies to minimise the risk of infection are of greater importance than ever, yet healthcare associated infections (HAI) have become one of the most serious issues in our health systems today. Annually within Europe 1 million infections are associated with the presence of invasive medical devices. It is clear that better materials must make a contribution to tackling this major problem. In this study high throughput materials discovery using polymer microarrays<sup>1</sup> has been applied to discover new materials resistant to *Staphylococcus epidermidis*. High throughput screening methodologies are relevant when the underlying biological-material interactions are poorly understood. Of particular interest is the production of a coating on metallic substrates such as those employed in fracture victims utilising external fixation devices where a nosocomial infection rate of 20% in the general population increases to 100% for diabetics.<sup>2,3</sup>

## EXPERIMENTAL METHODS

Polymer microarrays were formed using a XYZ3200 pin printing workstation (Biodot) onto poly(hydroxyethyl methacrylate) coated slides. Printing was carried out using slotted metal pins. Polymerisation solution was composed of 75% (v/v) monomer, 24% (v/v) DMF and 1% (w/v) photoinitiator 2,2-dimethoxy-2-phenylacetophenone. After printing polymers were UV cured and vacuum extracted.<sup>4</sup> A bacterial attachment assay was developed using *S. epidermidis* RP62A. After attachment of bacteria to each material bacterial coverage was measured by staining the bacteria with the DNA binding dye DAPI and imaging by confocal microscopy. Protein adsorption to each material was also assessed by incubating the polymer microarray with tetramethyl-rhodamine isothiocyanate labelled albumin and imaging using a fluorescence scanner.

## RESULTS AND DISCUSSION

In order to identify a novel material resistant to bacterial attachment that can function in high protein environments an array of 36 polyacrylates was incubated with protein. Albumin adsorption was quantified by measuring the fluorescence from a rhodamine fluorescence tag (Figure 1A).

Polymer microarrays were also incubated with *S. epidermidis* and the bacterial coverage was measured on each spot (Figure 1B). This enabled the identification of materials that were resistant to both bacterial attachment and protein adsorption (Figure 2).

Figure 1 – Quantification of (A) fluorescence of rhodamine labelled albumin or (B) *S. epidermidis* coverage on polymer spots. Within each square the middle region is the average of 6 replicate measurements, whilst the small left and right regions represent  $\pm$  standard deviation unit.

Figure 2 – Fluorescence intensity due to protein adsorption against the bacterial coverage measured for each polymer spot.

## CONCLUSION

A polymer microarray was used to successfully screen for materials that were resistant to both *S. epidermidis* attachment and protein adsorption. The hit materials will be suitable for application to *in vivo* use, particularly for external fixation devices used for fracture victims.

## INTRODUCTION

Titanium and titanium alloys are frequently used in orthopaedic implants because of their good biocompatibility and reliable mechanical properties. After implantation the formation of a bacterial surface biofilm and compromised immunity at the implant/tissue interface may lead to persistent infections on and around titanium implants. Despite this and the contaminated oral surgical field through which they are placed, success rates are reported as being as high as 90-95%. Bacterial infection, extensive inflammation and poor osseointegration have been identified as the major reasons for early orthopaedic implant failures based on titanium (Ti). Some literatures point out that creating implants with drug-eluting properties to locally deliver drugs is an appealing way to address some problems like systemic toxicity of the drugs, reaching deliver drugs locally and continuously.<sup>1</sup>

## EXPERIMENTAL METHODS

In this study, we focuses on the development of a polymer-coated ceramic composite for antimicrobial drug delivery. A micro-arc oxidation (MAO) was used to produce a porous structure comprising calcium acetate hydrate ( $\text{Ca}(\text{CH}_3\text{COO})_2 \cdot \text{H}_2\text{O}$ ) and sodium phosphate monobasic monohydrate ( $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ ) for improving the biocompatibility of titanium. Using a spray coating method, aqueous drug was loaded into the porous surface. Finally, gamma polyglutamic acid ( $\gamma$ -PGA), a well-known natural hydrophilic biodegradable polymer,<sup>2</sup> Dependent on two types of  $\gamma$ -PGA mixing ratio, water soluble Na<sup>+</sup> type and water insoluble H<sup>+</sup> type, was coated layer-by-layer through spin coating as a barrier to control drug release.<sup>3</sup> The bactericidal effect of antibiotic on the porous surface was evaluated by using *Escherichia coli* (*E. coli*) bacteria(ATCC®PTA-10989™). Additionally, the results obtained from UV-Vis suggested that the drug was successfully filled into coatings and released over time with antibiotic/ $\gamma$ -PGA solution could provide a high bactericidal effect against *E.coli* by the bactericidal effect of antibiotic.

## RESULTS AND DISCUSSION

The morphology of the prepared MAO/Ti substrates was characterized by SEM and is summarized in Fig. 1. These pores are well separated and distributed homogeneously over the surface. The anti-inflammatory, antibiotic was chosen as a test drug to be loaded inside the MAO porous. The deposition of  $\gamma$ -PGA Na<sup>+</sup> type and H<sup>+</sup> type polymers onto drug loaded MAO/Ti by a spin-coating process was evaluated by ESCA characterization. Fig2. Significant changes in the drug release profile were observed as a result of coating

a polymer film on the top of the MAO surface. As expected, the drug release characteristics showed a strong dependence on the mixing ratio of polymer layer. Significantly fewer bacterial colony forming units (CFUs) appeared in samples containing antibiotic modified MAO/Ti prepared with deposition times than were detected in the cp Ti control sample (Figure 3).

Figure 1. Series of SEM images of MAO fabricated by micro arc oxidation of Ti in Ca/P electrolyte

Figure 2. Comparative drug release graphs of anti-inflammatory drug (antibiotic) from polymer coated MAO/Ti.

Figure 3. Evaluation of the antimicrobial effects by the antimicrobial susceptibility test against confluent lawns of *Escherichia coli* bacteria. Pure Ti was used as a control compared to duplicate  $\gamma$ -PGA disks treated with antibiotic.

## CONCLUSION

Together, these findings demonstrate that using porous structure with  $\gamma$ -PGA is promising as cost-effective drug delivery formulation for delivering drugs locally and continuously. Further antimicrobial activity demonstrate that the antimicrobial activity of antibiotic toward the growth inhibition of a model bacterium of *E. coli* is not compromised after being loaded into the porous structure. With the reserved drug activity, the porous structure based drug delivery system may find various applications in tissue engineering and pharmaceutical science.

## INTRODUCTION

Silver-containing hydroxyapatite ceramic is of great medical interest, primarily in terms of its antimicrobial properties. Silver is the bactericidal agent and can be introduced into the ceramic as a dispersed metal phase or as ions replacing calcium ions in the apatite lattice and forming silver-substituted hydroxyapatite. Such ceramics will exhibit different antibacterial properties depending on the localization of silver. In the study, phase composition, microstructure, the effect of silver additives on sintering and physical properties of Ag-containing ceramics were examined.

## EXPERIMENTAL METHODS

An initial powder of hydroxyapatite HA was prepared through the reaction of calcium carbonate,  $\text{CaCO}_3$ , and a solution of the orthophosphoric acid,  $\text{H}_3\text{PO}_4$ . Silver dopants were introduced into the HA powder by soaking the powder in a solution of argentic nitrate,  $\text{AgNO}_3$ , at  $60^\circ\text{C}$  until the solvent was completely evaporated. The concentration of solution was varied so that the amount of silver in the soaked powders was from 0.25–1.5 wt% with a step of 0.25 wt%. Powder compacts as pellets (3 mm height and 8 mm diameter)

Figure 1. XRD patterns of silver-containing composite ceramics

were prepared in a mold by uniaxial pressing under 120 MPa. The compacts were fired in a muffle in a wet atmosphere at  $1200^\circ\text{C}$  for 2h. The phase composition and microstructure of ceramics were studied by XRD, SEM and IR spectrometry. The density, compressive strength and microhardness of the samples were measured depending on silver concentration by conventional methods.

## RESULTS AND DISCUSSION

XRD analysis (Figure 1) detected that the ceramics are biphasic. One phase is HA, and the other – silver, which results from the decomposition of  $\text{AgNO}_3$ . Silver maxima are reliably identified since an Ag concentration of 0.25 wt%. The lattice constants of HA matrix are faintly dependent on the silver concentration. IR spectra over the entire range of silver additives are consistent with the spectrum of HA. Spectra show the absorptions of  $\text{PO}_4^{3-}$  ions at 566, 602, 962, 1042,  $1090\text{ cm}^{-1}$ . Bands at  $3570$  and  $630\text{ cm}^{-1}$  indicate the presence of  $\text{OH}^-$  groups in the lattice.

SEM examination showed that the ceramics were consisted of HA grains and inclusions of silver nanoparticles on (in) grain boundaries (Figure 2). The density of ceramics slightly increased, the microhardness slightly decreased but the compressive strength slightly increased with increasing silver concentration. Throughout the silver concentrations, the ceramics tended to brittle fracture.

Figure 2. SEM picture of ceramics with 1.5 wt% silver. The inset is an enlarged fragment of the surface

## CONCLUSION

Ceramics based on HA and silver dopants are two-phase composites. One of the phases is (possibly, Ag-substituted) HA, and the other – silver nano-particles. Examined concentrations of the silver additives have no adverse effect on the physical and mechanical properties of the composites.

## INTRODUCTION

With the increasing prevalence of antibiotic-resistant bacteria, there has been a considerable drive to design and fabricate new antimicrobial surfaces to overcome implant-related infections.<sup>1</sup> Here we propose novel chlorhexidine-hexametaphosphate nanoparticles (CHX-NPs)<sup>2,3</sup> as a novel method for coating polyurethane (PU) central venous catheters to reduce bacterial adhesion and biofilm formation.

CHX-NPs act as a slow-release device for the broad-spectrum antimicrobial agent CHX. CHX reacts with negatively charged groups on a bacterial cell wall which causes cytoplasmic membrane disruption and intracellular leakage. This study investigates the antimicrobial efficacy of CHX-NPs against methicillin-resistant *Staphylococcus aureus* (MRSA), *Pseudomonas aeruginosa*, *Escherichia coli* and *Klebsiella pneumoniae*, in addition to preliminary *in vitro* nanoparticle toxicity studies with placental BeWo b30 cells<sup>4</sup> selected as a model to evaluate potential for fetal exposure and damage in women of child-bearing age who may be exposed to CHX-NPs.

## EXPERIMENTAL METHODS

**Nanoparticle synthesis:** 5 mM CHX-NP suspensions were prepared by mixing a 1:1 ratio of aqueous CHX: aqueous hexametaphosphate<sup>2</sup>.

**PU Sample functionalisation:** PU specimens (12 x 15 mm) were immersed in rapidly stirred CHX-NP for 30 s then in deionised water for 10 s before drying in air.

**Total Viable Counts (TVCs):** CHX-NP-functionalised PU specimens, in addition to untreated controls, were inoculated with  $1.5 \times 10^8$  CFU/mL pre-culture of bacteria and incubated at 37 °C for 20 h to allow growth of biofilms. Subsequent TVCs were performed as described by Miles *et al.*,<sup>5</sup> and repeated in triplicate. Results were analysed by 1-way ANOVA with Tukey *post-hoc* test.

**BeWo b30 cell culture:** BeWo b30 cells were cultured in complete medium supplemented with 10% fetal bovine serum<sup>4</sup>, seeded at  $1.75 \times 10^5$  cells/mL and grown until approximately 70 % confluent.

**Cytotoxicity assays:** Cells were treated for 2 and 24 h with 1/100 and 1/1000 dilutions of 5 mM CHX-NPs suspensions, in addition to the same dilutions of 5 mM CHX and 25  $\mu$ M CHX (residual concentration of aqueous CHX in CHX-NPs) controls. Lactate dehydrogenase (LDH) release was measured in culture medium to determine cytotoxicity. Cellular metabolism after NP exposure was assessed using the WST-1 assay. Bicinchoninic acid (BCA) was determined after exposure, to deduce the total cellular protein present. Assays were repeated in triplicate. Results were analysed by 2-way ANOVA with Tukey *post-hoc* test.

## RESULTS AND DISCUSSION

CHX-NP functionalised specimens prevented biofilm

formation of MRSA and *P. aeruginosa*. Growth was observed with *E. coli* and *K. pneumoniae* specimens, however this was significantly less than the untreated controls.

Figure 1. TVCs. \* $p < 0.05$  vs. respective control.

No significant LDH release was observed for 1/1000 CHX-NPs, and cell viability and protein concentration were unaffected. An increase in CHX-NP dose significantly reduced viability over 24 h. Toxicity of CHX-NPs was lower than that of aqueous CHX.

Figure 2. LDH release from BeWo b30 cells exposed to CHX-NPs. \* $p < 0.05$  vs. respective negative control.

## CONCLUSION

CHX-NP functionalised PU fully inhibited MRSA and *P. aeruginosa* under biofilm conditions and significantly reduced growth of *E. coli* and *K. pneumoniae*. CHX-NP toxicity is both concentration and time dependent. At lower CHX-NP levels, cells appear undamaged even after longer exposure times. The nanoparticles, at both dilutions, are significantly less toxic than the equivalent concentrations of aqueous CHX. Further studies are necessary in order to determine the CHX-NP concentration required to dope the PU surfaces, in order to optimise antimicrobial efficacy with the minimum cytotoxicity.

## INTRODUCTION

The increase in the number of multi-drug resistant microorganisms is a critical global problem<sup>1</sup>. Hence, it has become relevant to develop novel antibiotic drugs. Small peptides such as dendrimers are proposed as alternatives to antibiotics, with reports of antimicrobial activity. However, most studies have focused on the efficacy of high generation dendrimers but the smaller units: dendrons have received lesser attention.

This study aimed to clarify if dendrons of similar generations could be used as novel antibacterial agents, also minimising the high immunogenicity associated with dendrimers<sup>2</sup>. The antimicrobial potential of the dendron against *Proteus mirabilis* a significant pathogen and biofilm former in wound infections was performed *in vitro*. The mode of action of these poly-ε-lysine dendrons is currently unknown, hence the interaction between the cationic dendrons and bacterial cell membranes was also investigated.

## EXPERIMENTAL METHODS

### Synthesis/Characterisation of Dendron

An Fmoc-based solid phase peptide synthesis approach was applied to synthesise generation-3 poly (ε-lysine) dendrons (G<sub>3</sub>K)<sup>3</sup>. The dendrons were characterised by Fourier transform infra-red spectroscopy (FTIR), mass spectrometry and analytical high performance liquid chromatography.

### Antimicrobial assay

A microtitre plate assay was used to assess the antimicrobial potential of G<sub>3</sub>K. Different doses of the dendron were administered (0.25 – 2 mg/ml) to clinically significant concentrations of bacteria (10<sup>7</sup> CFU/ml). The effect on biofilm and bacterial cytotoxicity were assessed *via* crystal violet staining and turbidity measurements, at different time points. Anti-biofilm effects were confirmed by light microscopy study. Three replicates per test over 2 different days were performed, and results were analysed with analysis of variance statistical tests.

### Interaction between G<sub>3</sub>K and bacterial cells

Fluorescein-isothiocyanate (FITC) (0.025mmol), was conjugated by solid-phase synthesis to the peripheral amino groups of G<sub>3</sub>K (0.05mmol), and incubated in the dark for 18h. The conjugate (G<sub>3</sub>K-FITC) was characterised by FTIR, UV-Vis and trinitrobenzene sulfonate assay to quantify attached FITC. For cellular interaction studies, G<sub>3</sub>K-FITC and *P. mirabilis* bacterial cells were incubated over 24h. Cells were visualised by confocal microscopy.

## RESULTS AND DISCUSSION

G<sub>3</sub>K showed significant bactericidal effect during the first incubation hours (8 and 16 hours), and reduced the

quantity of adherent bacteria and biofilm extracellular matrix (Fig. 1) by 87% after 48h treatment, whereas the quantity of bacteria in suspension was only reduced by a maximum of 23% up to 16 hours. G<sub>3</sub>K biofilm prevention was time/dose dependent, with dispersal of the biofilm's extracellular matrix at higher doses, which may be due to electrostatic interactions between the negatively charged bacterial cell wall and cationic G<sub>3</sub>K which was also able to target the bacterial cell wall (Fig. 2).

**Figure 1:** Time-Dose Effect of G<sub>3</sub>K on *P. mirabilis* biofilm. The green linear trend-line ( $R^2=0.86$ ) of 1mg/ml G<sub>3</sub>K, showed that G<sub>3</sub>K has time-dose effect on biofilm formation up to 48h

**Figure 2:** Localisation of G<sub>3</sub>K in *P. mirabilis* bacterial cells.

## CONCLUSION

Generation-3 poly (ε-lysine) dendrons were bactericidal at concentrations as low as 0.25 mg/ml and prevented *P. mirabilis* biofilm formation, with preferential localisation at bacterial cell poles, which may impact bacterial cell division/adherence. The cationic/multivalent nature of the dendron could be harnessed for improvement of the anti-biofilm effect. The dendron therefore has potential as an anti-biofilm agent in biofilm related infections such as wounds and nosocomial infections.

## INTRODUCTION

Calcium phosphates (CaPs) are used in many medical applications especially in regeneration and reconstruction of bone tissue. The most common calcium phosphate is hydroxyapatite (HA). The modification of HA structure with Ag ions may influence its physicochemical and biological properties. Incorporation of silver leads to development of the implant materials with antibacterial properties<sup>1</sup>. Calcium sulphate (CS) is well known for its fast resorption after implantation. The combination of hydroxyapatite with CS may provide materials with high surgical handiness and controlled resorption rate in a living organism<sup>2</sup>. The purpose of the study was to evaluate the influence of silver additive (amount and source of Ag ions) on the physicochemical properties of the new cement type bone substitutes.

## EXPERIMENTAL METHODS

Hydroxyapatite doped with silver (1 and 2 wt.%) was synthesized by the wet chemical method. Silver acetate or nitrate served as sources of Ag ions. In order to assess thermal stability of Ag-HA the synthesized powders were heat treated above 1000°C. Non-calcined Ag-HA powders were mixed with calcium sulphate hemihydrate (CSH, Acros Organics). Material based on undoped hydroxyapatite and CSH served as reference. As the liquid phase distilled water was applied. The phase composition (XRD) of modified hydroxyapatite powders as well as final composites after setting and hardening were determined. The setting times (Gillmore Needles), compressive strength (Instron 3345) and open porosity (Auto Pore IV) were checked. The chemical stability of obtained materials were assessed *in vitro*.

## RESULTS AND DISCUSSION

Non-calcined Ag-HA powders showed only hydroxyapatite as a crystalline phase. Heat treatment above 1000°C resulted in the appearance of small amount of  $\beta$ -tricalcium phosphate. Calcined powders demonstrated also a characteristic XRD peak at 38.18° corresponding to the metallic silver (Fig. 1). Developed cements after setting and hardening composed of two phases: hydroxyapatite and calcium sulphate dihydrate (CSD). They set from 6 to 12 minutes. Compressive strength of studied materials was from 5 to 7 MPa. Incorporation of Ag via silver nitrate during the

synthesis of hydroxyapatite slightly decreased compressive strength of the final bodies.

Fig. 1 XRD pattern of heat treated Ag-HA (2 wt.% Ag, source of Ag ions: silver nitrate).

Obtained cements exhibited comparable open porosity (~ 50 vol.%) and pores below 1.5µm with a bimodal pore size distribution. The results of chemical stability of developed materials confirmed gradual release of silver ions during incubation in simulated body fluid. Due to the content of calcium sulphate dihydrate and silver modified hydroxyapatite, they will probably reveal complex (two steps) resorption *in vivo*.

## CONCLUSION

New resorbable cement-type materials based on Ag-HA and CSH were developed and assessed. The results of conducted studies indicated that the obtained cements may not only effectively fill bone defects but also will ensure the local antibacterial treatment. Influence of 1 and 2 wt.% silver additive on the physicochemical properties of the new biomaterials was confirmed. Further studies *in vitro* and *in vivo* are necessary.

### INTRODUCTION

The aim of the study was to determine *in vitro* antimicrobial activity of bioglasses doped with Mg, Sr and Au.

The presence of magnesium in the composition of the biomaterial enhances its bioactivity<sup>1</sup>. Strontium improves the proliferation of bone cells<sup>1</sup>. Gold belongs to the group of “ultra elements” which show antibacterial activity and activate metabolism by acting on enzymes<sup>2</sup>. The silane used for the synthesis of sol-gel bioglasses may also increase bioactivity<sup>3</sup>.

Physical and chemical properties of bioglasses containing Mg, Sr and Au produced by sol-gel method as well as its grain morphology and bioactivity in simulated body fluid and the results of *in vitro* cytotoxicity were presented in previous publication<sup>4</sup>.

This paper presents the results of *in vitro* antibacterial activity of these bioglasses.

### EXPERIMENTAL METHODS

Four bioglasses doped with Mg, Sr and Au and undoped bioglass as a reference material were used for the research. Bioglass P5-VS containing 70 wt.% of SiO<sub>2</sub> and 25 wt.% of CaO and 5 wt.% of P<sub>2</sub>O<sub>5</sub> being a reference material was produced using tetraethoxysilane, vinyltriethoxysilane (VS), calcium nitrate tetrahydrate and triethyl phosphate as basic substrates. Bioglasses P5-VS-1\_Mg and P5-VS-1\_Sr with the same composition as P5-VS were obtained by substituting 1 wt.% of CaO by MgO or SrO respectively. In the case of bioglasses P5-VS-Au\_r-r and P5-VS-Au\_nzk nanoparticles of Au in the form of 0,00065 wt.% colloidal solution and 0,002 wt.% nonionic colloidal gold respectively were added.

The process of preparing bioglasses by sol-gel method was carried out according to procedures described in earlier reports<sup>4</sup>.

Studies of antibacterial activity were performed by a dilution method, using precultures of test bacterial strains of *Pseudomonas aeruginosa* and *Staphylococcus aureus* which were deposited on substrates at concentrations of 1,0 mg/ml, 5,0 mg/ml, 10 mg/ml, 20 mg/ml and 50 mg/ml. The 24-wells plates with the bacterial strains were incubated at the temperature (37±1)°C. Antibacterial activity of bioglasses was identified by counting live bacteria population after 24, 48 and 148 h of incubation. The controls consisted of broth cultures of microorganisms without bioglasses.

### RESULTS AND DISCUSSION

Results of *in vitro* antibacterial activity tests carried out with different concentration of bioglasses indicate that all of them lead to reduction of the number of bacteria. The best results were obtained using the highest concentration of bioglass samples. Figure 1 shows the result of antibacterial activity of bioglasses at concentration of 20 mg/ml on selected strains.

Fig. 1: Survival of strains determined after 148 h at a concentration of 20 mg/ml of bioglasses P5-VS, P5-VS-1\_Mg, P5-VS-1\_Sr, P5-VS-Au\_r-r and P5-VS-Au\_nzk.

### CONCLUSION

*In vitro* studies of antibacterial activity of bioglasses in selected strains of bacteria showed higher activity against strain of *Staphylococcus aureus* than *Pseudomonas aeruginosa*.

Bioglass P5-VS-1\_Sr is the one that inhibits growth of micro-organisms during the tested period most effectively.

## INTRODUCTION

Use of local antibiotics in connection with bone substitutes has 3 indications: prevention of primary infection, implantation into a contaminated area or the prevention of recurrent infection. These cases all have their requirements in terms of choice of antibiotics and length of release time, so there is no universal coating technique for all cases. We aimed to develop a sustained-release coating for bone allografts, which can achieve long-term characteristics for several antibiotics.

## MATERIALS AND METHODS

Human bone allografts (50±5 mg each) were coated with water-soluble antibiotics amoxicillin, ciprofloxacin or vancomycin. The simple coating methods were soaking (method **A**) or freeze drying (method **B**) using concentrations from 0,1 mg/ml up to 10 mg/ml. The controlled release film coating was prepared in single or double layers. When using one layer, the antibiotics were mixed with 2% chitosan and the coating was freeze dried (method **C**). The preparation of the two layer controlled release coating involved a freeze drying step with the antibiotic followed by a water insoluble film preparation step by using 4% Na-alginate, which was converted with 10% CaCl<sub>2</sub> solution to Ca-alginate (method **D**). Preparations were incubated in 2 ml H<sub>2</sub>O and antibiotic release was measured in the supernatant by spectrophotometry in the specific concentration interval of each antibiotic where the absorbance – concentration ratio was linear. For the antibiotic that we found best, the MIC (minimal inhibitory concentration) was also assessed.

## RESULTS

The antibiotic coating experiments showed that the best concentration was 10 mg/ml using all the antibacterial agents and with method **B**, we were able to enhance the coating compared to the conventional soaking method with every antibiotic. All the antibiotic content was released within 48 hours, so method **A**, **B** and **C** were only suitable for short-term antibiotic release. With method **D** we were able to prepare a coating that released amoxicillin over a 7 day period; ciprofloxacin was released over a 28 day period and vancomycin release exceeded 50 days well over the MIC concentration (0,2 µg/ml).

Fig. 1. Antibiotic release into 2 ml volumes.

## DISCUSSION AND CONCLUSIONS

Simply adding antibiotics or freeze-drying them onto the allograft only reaches a 2-day release profile, which is even shorter than the closure time of the surgical wound. Insoluble alginate coating achieved a sustained release of each selected antibiotic to various lengths, depending on the physico-chemical characteristics of the drugs. Amoxicillin may be applicable for primary prevention while ciprofloxacin or vancomycin is suitable for more challenging cases.

### INTRODUCTION

Maintaining human health is a matter of major concern at any time. Under particular conditions, for example in hospitals or during long-term missions in closed habitats such as the ISS (International Space Station), emergence of aggressive multi virulent species is high<sup>1,2</sup>. To address the issue of microbial contamination, several different methods are already in place. However, conventional decontamination methods are too cumbersome for astronauts' to perform on regular basis. The use of antimicrobial surfaces is a promising tool to reduce microbial contaminations in space and even on the Earth. Copper as an antimicrobial metal is also an essential metal and has been used for medical issues and the storage of drinking water for thousands of years<sup>3</sup>. While the toxicity of copper is well known, the exact mechanism is still unclear. In this study the antimicrobial effects of copper ions were tested.

### EXPERIMENTAL METHODS

Type strains of two human-associated microorganisms *Escherichia coli* (DSM 498) and *Staphylococcus cohnii* (DSM 20260) were cultured in LB (Luria-Bertani, *E. coli*) and in TSY medium (Trypticase Soy Broth with Yeast extract, *S. cohnii*) at optimal growth conditions.

Stainless steel (AISI 304: X5CrNi18-10) and copper samples from 99.99% pure rolled copper sheet were cut into 2.25 cm<sup>2</sup> coupons, grounded, polished and sterilized by ethanol.

Wet contact killing experiments have been conducted. Therefore cells in 0.1 PBS (0.7% Na<sub>2</sub>HPO<sub>4</sub> x 2 H<sub>2</sub>O, 0.3% KH<sub>2</sub>PO<sub>4</sub>, 0.4% NaCl, pH 7.5) were exposed on the surfaces for 0, 2 and 4 hours.

For the detection of membrane integrity the Live/Dead staining assay was applied to stainless steel and copper exposed cells. The different fluorescence colours were visualized by the Zeiss AxioImager M2 microscope.

Ex vivo and in vivo DNA and RNA damages were visualized with agarose gel electrophoresis.

The release rate of copper ions was detected by using the ICP-MS 7500 Series, Agilent Technologies. Four hundred µl PBS and cell suspension was exposed for 4 hours. Thereafter, the copper concentration of the whole suspension, in the cells and the supernatant was measured.

### RESULTS AND DISCUSSION

When exposed to metallic copper surfaces high cell inactivation rates have been determined in a concentration depending manner.

A loss in membrane integrity was detectable with the Live/Dead staining. When 10<sup>6</sup> cells/ml were applied for 4 hours on copper surfaces 50% of *S. cohnii* and 75% of *E. coli* cells exhibited a degradation of the cell membrane.

Measurements of the release rate showed that cells indirectly dissolve copper from surfaces and import it.

Despite a relatively high copper concentration inside the cells, the *ex* and *in vivo* studies of the DNA and RNA analysis pointed out that the degradation is much higher under *ex vivo* conditions.

Reasons for the differences in cell survival and membrane integrity can be caused by differences in the cell wall, the uptake and export of copper ions or detoxification effects.

### CONCLUSION

Copper ions are indirectly dissolved from copper surfaces and can be actively taken up by cells. Since in vivo DNA and RNA seem to be protected by cellular components, the damage of the cell membrane appears to be the main target of copper ion toxicity.

For further analysis mechanistic studies on the im- and export are useful targets.

## Antibacterial Sol-Gel Coating of Ceramic TiO<sub>2</sub> Scaffolds for Bone Regeneration

David Wiedmer<sup>1</sup>, Cédric Bossard<sup>1,2</sup>, Hanna Tiainen<sup>1</sup>, Håvard Haugen<sup>1</sup>

Department of Biomaterials, University of Oslo, Norway  
 ENSIACET, National Polytechnic Institute of Toulouse, France  
[d.j.wiedmer@odont.uio.no](mailto:d.j.wiedmer@odont.uio.no)

### INTRODUCTION

Highly porous TiO<sub>2</sub> scaffolds may be used to augment and promote bone regeneration for large bone defects caused by periodontitis or peri-implantitis<sup>1</sup>. However, accumulation of pathogenic bacteria and biofilm deposition can endanger the success of bone regeneration and result in loss of the affected tooth or implant. A crystalline sol-gel coating may add bactericidal properties to the substitute material based on the photocatalytic generation of antimicrobial radicals on the catalyst surface.

### EXPERIMENTAL METHODS

Highly porous TiO<sub>2</sub> scaffolds are produced as previously described elsewhere<sup>1</sup>. The sol-gel coating process steps are illustrated in Figure 1.

Fig.1: (a) TiO<sub>2</sub> scaffolds were fabricated by polymer sponge method and dipped (b) into a TTIP-HCl-H<sub>2</sub>O-iPrOH system. After a two-step heating treatment (c) a crystalline, thin coating (d) remains on the substrate.

The scaffolds were withdrawn from the solution at a low vertical speed ( $v_{\text{pull}} = 6 \text{ cm} \cdot \text{min}^{-1}$ ). A two-step heating treatment was applied to evaporate the solvent ( $T_{\text{evap}} = 120^\circ\text{C}$ ) and to crystallise the nanoparticle coating ( $T_c = 450^\circ\text{C}$ ). A holding time of 1 h at  $T_c$  was chosen to ensure complete crystallisation. The homogeneity of the coatings was examined by scanning electron microscopy (SEM). UV-vis spectroscopy was used to measure the degradation of the organic dye methylene blue (MB) under UV-irradiation due to the photocatalytic capacity of coated and uncoated TiO<sub>2</sub> scaffolds.

### RESULTS AND DISCUSSION

TiO<sub>2</sub> scaffolds were covered by a thin, homogenous film after sol-gel coating and heat treatment. Only minor flakes or ruptures of the coating were detected for  $v_{\text{pull}} = 6 \text{ cm} \cdot \text{min}^{-1}$ . Higher withdrawal speeds resulted in the agglomeration of microparticles on the 3D structure, incomplete coating of the struts and partly blocked pore windows. Figure 2 shows a randomly picked section of a coated scaffold for  $v_{\text{pull}} = 6 \text{ cm} \cdot \text{min}^{-1}$ .

Fig.2: Highly porous and interconnective scaffold (A1) and detailed view (A2) of the applied sol-gel coating.

The dip-coated, amorphous TiO<sub>2</sub> film is crystallised to anatase during the heat treatment at  $T_c = 450^\circ\text{C}$  overlaying the rutile substrate and thereby changing the crystal structure of the scaffold surface. The crystal phase of the substrate is determined by high sintering temperatures ( $\sim 1500^\circ\text{C}$ ) during the fabrication process to obtain appropriate mechanical strength. However, anatase is known to show superior photocatalytic activity compared to rutile when irradiated with UV-light<sup>2</sup>. One explanation for this may be the increased generation of radical oxygen species (ROS), e.g. OH<sup>•</sup> and O<sub>2</sub><sup>•-</sup>, on the catalyst surface. Sol-gel coated scaffolds were found to degrade MB stronger compared to uncoated substrates which also indicates an enhanced generation of ROS. It is the idea to take advantage of this effect and develop a nanoparticle coating with improved bactericidal properties for TiO<sub>2</sub> scaffolds to encounter bacteria-induced inflammation in bone regeneration.

### CONCLUSION

A homogenous, thin sol-gel coating was successfully applied to ceramic TiO<sub>2</sub> scaffolds. A nanoparticle surface with different crystal structure was induced to the substrate while retaining its favourable morphology for osteogenesis. An *in vitro* bacteria study is planned to evaluate the potential antibacterial effect of the coating due to increased generation of oxidising radicals on the TiO<sub>2</sub> surface.

### INTRODUCTION

Copper-based, antimicrobial materials are extensively discussed as an alternative strategy to antibiotics in order to combat dangerous germs in the healthcare environment. Applications range from bulk copper alloys used as self-decontaminating door knobs to highly functionalized, metallic surfaces employing copper as an additional, antimicrobial agent (e.g. for implants).

It seems to be clear that copper ions act via multiple toxicity mechanisms, which renders them also effective against otherwise multi-resistant microbes and the so called “superbugs” (e.g. methicillin resistant *Staphylococcus aureus*, MRSA).<sup>[1]</sup> Although worldwide field studies already account for the potential to reduce infection risks in hospitals, the actual killing mechanism as well as the linked material and surface properties of copper-based antimicrobial materials are not yet fully understood.

The presentation will give an overview of the ongoing interdisciplinary research project “Antimicrobial copper - Functional surfaces and toxicity mechanisms” (German Research Foundation, MU 959/26-1&2) and include the latest findings of the project.

### EXPERIMENTAL METHODS

An important aspect of the presented project is the generation of model surfaces with tailored properties. As a unique tool for this purpose, Laser Interference Surface Patterning (LISP) by a nanosecond pulsed laser was used to create periodical microstructural, topographical and chemical patterns on the micro- and sub-micrometer scale.<sup>[2]</sup> These patterns were tailored larger, smaller and of the same size as bacteria in order to study possible size effects (see Figure.1).

Figure 1: a) and b) intensity distribution (top) of LISP and structured metal surfaces (bottom). c) *E. hirae* bacteria on LISP-surface with periodicity of the same scale.

The nature of the LISP-generated pattern was thoroughly characterized by SEM- and White Light Interferometric (WLI-) techniques and evaluated for their antimicrobial impact and specific interactions with bacteria. Further on, general questions like the impact of surface oxidation on copper or the influence of alloying elements on the antimicrobial behavior were studied.

### RESULTS AND DISCUSSION

Three mayor findings of the project are: By creating inert LISP-arrays on copper surfaces, it was shown that the direct contact between bacteria and metallic copper is a beneficial factor for the killing behavior.<sup>[3]</sup> LISP-generated topographical surface patterns can be used to influence the adhesion of bacteria on metall surfaces. Copper surface oxidation induces different antimicrobial effects depending on the oxide type ( $\text{Cu}_2\text{O}$  or  $\text{CuO}$ ).  $\text{Cu}_2\text{O}$  tends to be more antimicrobially active than  $\text{CuO}$ .<sup>[4]</sup> These findings as well as results of ongoing experiments will be presented in the talk and discussed in the context of biomaterials applications..

### CONCLUSION

The influence of specific materials and surface properties on the killing behavior of metallic copper was studied. The adhesion of bacteria, as one example, can be controlled by LISP surface topography design. Regarding the composition of antimicrobial copper alloys, the formation of  $\text{Cu}_2\text{O}$  should be favored.

## INTRODUCTION

The use of biopolymers for biomedical applications makes smart therapies feasible<sup>1</sup>. In fact, a polymer-drug miscible system is able to release the drug in a controlled way. The purpose of this work is to find out a miscible system based on a biodegradable polymer and a biologically active molecule.

## EXPERIMENTAL METHODS

**Materials.** Poly(DL-lactide) (PDLLA) and poly( $\epsilon$ -caprolactone) (PCL), both biodegradable polymers, were supplied by Purac Biochem. Biologically active molecules, i.e., molecules that kill or inhibit the growth of microbes, erythromycin, thiamphenicol, tetracycline, sulphanilamide, sulfacetamide, sulfachloropyridazine, sulfamethazine trimethoprim, levofloxacin, bronidox and thymol were supplied by Sigma-Aldrich.

**Blend Preparation.** Blends were prepared by two methods: solvent casting and melting the components together for the system PCL/Thymol.

**Differential Scanning Calorimetry (DSC).** Approximately 5-10 mg of each equimolar blend was weighted and sealed in an aluminium pan. Glass transition temperatures ( $T_g$ ) were studied for systems with PDLLA (amorphous) and melting points ( $T_m$ ) for those with PCL (semicrystalline).

**Melting Point Depression.** Specific annealing treatments were conducted under isothermal conditions to obtain the melting point depression values ( $T_m^{mix}$ ).

**Infrared Fourier Spectroscopy (FTIR).** Spectra were taken with a resolution of 2  $cm^{-1}$  and were averaged over 64 scans. Chloroform solutions containing 0.7 % of solute were cast on KBr pellets and evaporated.

## RESULTS AND DISCUSSION

**DSC analysis.** It was studied the miscibility for systems with PDLLA analyzing if the  $T_g$  of the equimolar blend was intermediate between those of the pure components<sup>2</sup>. For blends with PCL, the miscibility was evaluated studying the depression of  $T_m$ .

**Melting point depression.** From the DSC analysis, it was found that PCL/Thymol was susceptible to be a miscible polymer-drug system. Thus, the Flory-Huggins interaction parameter ( $\chi$ ) was estimated adjusting the equation for a polymer-drug system<sup>3</sup> and representing  $(-\Delta H_{thymol}/R)[(1/T_m^{mix}) - (1/T_m^{thymol})] - \ln \phi_{thymol} - \phi_{PCL}$  vs.  $\chi \phi_{PCL}$ , where  $T_m^{mix}$  is the melting temperature of the blend in which the major component is thymol (83-96 %),  $T_m^{thymol}$  is the melting temperature of thymol,  $\Delta H_{thymol}$  is the heat of fusion of thymol,  $\phi_{thymol}$  is the volume fraction of thymol,  $\phi_{PCL}$  is the volume fraction of PCL, and  $R$  is the gas constant. The blends were prepared melting the components together into a closed

bottle inside a heated paraffin bath, in order to avoid thymol volatilization.

Fig. 1. Flory-Huggins equation plot for PCL/Thymol blends.

The slope of the plot in Figure 1 gives the interaction parameter  $\chi = -2.69$  that confirms that PCL/Thymol is a thermodynamically miscible blend.

## FTIR analysis.

Fig. 2. Carbonyl stretching region for PCL/Thymol blends.

	1735 $cm^{-1}$ Amorphous PCL	1724 $cm^{-1}$ Crystalline PCL	1710 $cm^{-1}$ -C=O...H-O-
PCL	Shoulder	Peak	-
80/20	Shoulder	Peak	-
60/40	Peak	-	Peak
40/60	Peak	-	Peak
20/80	Shoulder	-	Peak

Table 1. Assignment of bands in the spectra for PCL/Thymol blends<sup>4</sup>. Table 1 shows that from a 40 % of thymol in the blend, PCL loses its crystallinity and a new band appears at 1710  $cm^{-1}$ , which can be attributed to hydrogen bonded carbonyl groups (-C=O...H-O-).

## CONCLUSION

A negative interaction parameter ( $\chi = -2.69$ ) indicates miscibility between PCL and thymol. FTIR results show that specific hydrogen bonding interactions are established between PCL and Thymol.

### INTRODUCTION

Constrain of current bioresorbable polymers for osteosynthesis are mainly related to their lack of bioactivity and low mechanical properties, which is behind the increasing demand of new bioresorbable materials. Mg and its alloys are among the most interesting options because their suitable mechanical strength and stiffness. However, their use as implants has been limited by their fast degradation rate under physiological conditions. The development of polymer/magnesium composites as new biodegradable and bioresorbable materials for osteosynthesis implants may overcome these problems. The polymeric matrix will benefit from the higher strength and modulus of the Mg particles, whereas Mg will benefit from the surrounded protective polymeric matrix that will control its degradation rate. In this sense, it has been recently reported that incorporation of biodegradable metals such as Mg in a matrix of poly-L-lactic acid improves the hardness of the polymer and its Young's modulus [1].

One of the most important concerns with implants, particularly in elderly people, is related with microbial infections. Most of the infections related to prosthesis are originated during their implantation from the cutaneous flora of the patient, the personnel in charge of performing the implantation and/or the environment of the operating theatre, mainly in the case of *S. epidermidis*.

### EXPERIMENTAL METHODS

#### SUBSTRATES

Two polymeric matrix materials PLDA (acid poly-D-lactide) with different concentrations of Mg (1 wt.% and 10 wt.%) were tested. The polymer PLDA without Mg was used as control.

#### BACTERIA

*Staphylococcus epidermidis* ATCC35983 a gram-positive strain with extracellular polysaccharide substance production were used.

#### BACTERIAL ADHESION TESTS

Samples were located on an orbital shaker with slightly agitation and bacteria were left to deposit mainly by sedimentation for 240 min at 37°C. Quantification of the surface density of bacteria on the surface samples were carried out with an epifluorescence microscope (Leitz DIAPLAN, Leitz Wetzlar, Germany) by staining the adhered microorganisms with the kit Live/Dead BacLight L-7012 (Invitrogen SA, Spain). Bacteria were counted with the software NIS-Elements BR 4.10 (Nikon Instruments INC., Melville, USA).

### RESULTS AND DISCUSSION

The results obtained of the surface density of adhered bacteria on: PLDA, PLDA+1 wt.% and PLDA+10 wt.% surface are shown in Figure 1 for *S. epidermidis*. These results indicate that the adhesion of *S. epidermidis* on the PLDA+1 wt.% and PLDA+10 wt.% surface is similar. However, the adhesion on PLDA+10 wt.% surface decreases in respect to the PLDA surface.

Figure 1. Surface density of *S. epidermidis* bacteria adhered on the samples: PLDA, PLDA+1 wt.% and PLDA+10 wt.%. Asterisks indicate statistical differences ( $p < 0.05$ ) when comparing the specified data using a ANOVA test.

Focusing on the viability of adhered bacteria, all bacteria deposited on the PLDA surface are 100% viable, while bacteria attached to the PLDA+1 wt.% and PLDA+10 wt.% surface show a loss in viability.

### CONCLUSION

The surface of the new biomaterial PLDA+Mg shows bactericidal effect for *S. epidermidis* after 240 min of contact and the adhesion on PLDA+10 wt.% decreases in respect to the PLDA surface without Mg.

### INTRODUCTION

Burns can be considered as a major global health problem. It has been estimated that annually 265,000 people die from the consequences of burn wounds. Moreover, the majority of non-fatal burn wounds results in long hospitalizations, disfigurement and disability.<sup>1</sup> Novel wound dressings accelerating the healing process can tackle these issues.<sup>2</sup> Therefore, the present work is focusing on the development of biopolymer-based wound dressings providing an ideal moist wound environment and antimicrobial activity for the prevention of infections.

### EXPERIMENTAL METHODS

#### Synthesis of photo-crosslinkable gelatin derivatives

Varying photo-crosslinkable functionalities including (meth)acrylamides and vinyl groups were introduced onto the gelatin backbone. The resulting derivatives were characterized via <sup>1</sup>H NMR spectroscopy. Rheology and texturometry were applied to study the cross-linking potential and the final strength of the resulting hydrogel films.

#### Quantification of the incorporated antimicrobial agent and *in vitro* study of the antibacterial activity

In a second part, poly(vinylpyrrolidone)-iodine (PVP-I), one of the most effective and widely used anti-infective agents, was incorporated into the hydrogel films by incubation. The amount of introduced (PVP-)iodine was determined via XRF spectroscopy and electrochemistry. In addition, *in vitro* bacterial tests using *Staphylococcus aureus* were performed to examine the antibacterial effect of the developed hydrogel films.

### RESULTS AND DISCUSSION

In a first step, the cross-linking kinetics and final hydrogel properties of the various gelatin derivatives were compared in order to select the most appropriate strategy for future work. As illustrated by the rheology results in figure 1 (a), gelatin-methacrylamide (gel-MA) with a DS 65% showed the best mechanical properties and was selected for incorporation of PVP-I.

PVP-I was introduced via incubation after UV treatment of the photo-crosslinkable gelatins since chemical cross-linking was shown to be inhibited by the incorporated iodine. PVP-I incorporation was studied via XRF and electrochemistry.

Figure 1 (a) Storage moduli of gelatin-methacrylamide (gel-MA), gelatin-acrylamide (gel-AA) and gelatin-pentenoate (gel-PE) hydrogel films. (b) Amount of bacteria able to form a biofilm (colony-forming unit, CFU) after 24h of incubation with various hydrogels.

Bacterial tests (figure 1b) indicate higher reductions in bacterial count when a larger amount of PVP-I is incorporated. The introduced amount of PVP-I was characterized via XRF and electrochemistry. Interestingly, the cross-linking degree of the hydrogel films appears to have no influence on PVP-I uptake.

### CONCLUSIONS

Gelatin-methacrylamide hydrogels showed the best mechanical properties of all developed derivatives and were selected for incorporation of the antimicrobial agent PVP-I. In addition, microbicidal effectiveness was studied via antibacterial tests indicating increased bacterial count reduction with increasing PVP-I concentration.

### INTRODUCTION

The actual challenge in the dental and orthopedic surgery is to obtain implants with good mechanical, physical, chemical and surface compatibility with the bone and with superior antibacterial properties<sup>1-3</sup>. The main goal of the paper is to obtain osteoconductive and antibacterial coatings in order to enhance the osteoconductive capability and the resistance to the bacteria of the Ti-based alloy. For the present study, hydroxyapatite (HAP) coatings enriched with SiC and Ag were prepared and investigated. SiC was added to enhance film hardness and corrosion resistance, while Ag addition was foreseen to improve the antibacterial properties.

### EXPERIMENTAL METHODS

The reactive magnetron sputtering technique was used to prepare the coatings, by using three cathodes made of HAP, SiC and Ag (99.9% purity, 1 inch diameter, Kurt J. Lesker Company). The base pressure in the deposition chamber was  $1.3 \times 10^{-4}$  Pa. The coatings were deposited in Ar atmosphere at  $6.6 \times 10^{-1}$  Pa. The RF powers on HAP and SiC cathodes were kept constant at 50 W and 15 W, while that on the Ag cathode was varied as 0.6 W, 0.9 W and 1.2 W (SA-1, SA-2 and SA-3). The HAP coating was used as reference coating.

The elemental composition and the chemical binding state of the coatings, close to the film surface, was investigated by energy dispersive X-ray (EDS) and Fourier transform infrared spectroscopies (FTIR), respectively. The phase composition was determined by X-ray diffraction (XRD). Surface topography was examined by AFM, using an INNOVA atomic force microscope. The antimicrobial tests were carried out for antibacterial activity using *Staphylococcus aureus* MRSA. The corrosion resistance was investigated by electrochemical tests in simulated body fluid (SBF) solution, pH=7.2, at  $37 \pm 0.4$  °C, using a VersaSTAT 3 Potentiostat/Galvanostat.

### RESULTS AND DISCUSSION

The EDS results showed that the Ca/P ratios are close to 1.67, which corresponds to a stoichiometric HAP. For all the coatings, XRD diffraction revealed the presence of the HAP crystalline structure, without calcium oxide, calcium phosphate hydroxide or any other calcium phosphate phases such as tricalcium phosphate, tetracalcium phosphate. The FTIR analysis indicated that all bands can be attributed to HAP; the SiC or Ag additions did not have any effect on the chemical bonds in the coating (Fig.1). All coatings improved the corrosion resistance of the Ti-based alloy (Fig.2).

Compared with HAP, the coatings with SiC and Ag exhibited better corrosion behaviour and antibacterial properties. It was shown that the increase in RF power on the Ag target led to an improvement in the antibacterial properties.

Fig. 1. The FTIR spectra of the HAP coatings with SiC and Ag additions

Fig. 2. Potentiodynamic curves of the HAP coatings with SiC and Ag additions

### CONCLUSION

The main conclusion is that Ag addition improves the antibacterial properties without changing the other properties of HAP coatings. The HAP coatings were found to be stoichiometric and no change of stoichiometry by Ag addition was observed. Also, no significant change in phase composition and corrosion resistance with variation of the RF power on Ag cathode was observed. By increasing the Ag content, the antibacterial activity increased.

### INTRODUCTION

The increasing emergency to combat resistant bacterial strains has been promoting the development of new generations of antimicrobial agents, being the antimicrobial peptides (AMP) one of the most promising alternatives. However, AMP still present some drawbacks that prevent efficient therapeutic application such as low stability and high toxicity<sup>1</sup>. Therefore, AMP improvement towards high potency and selectivity to bacterial cells is needed. MSI-78 (commercially known as Pexiganan), a highly effective and broad spectrum AMP is one of the most promising AMP for clinical application<sup>2</sup>. In this study, we aimed at designing a shorter derivative of MSI-78 with the aim of improving selectivity, while maintaining antimicrobial activity. Shorter 17-mer derivatives were created by truncating MSI-78 (22-mer) at the N-and/or C-termini, while spanning MSI-78 sequence.

### EXPERIMENTAL METHODS

The 17-mer derivatives were evaluated regarding antimicrobial activity against selected gram-positive *Staphylococcus* strains and the gram-negative *Pseudomonas aeruginosa* (*P. aeruginosa*). Antimicrobial activity was assessed by Minimal Inhibitory Concentration (MIC). The method used to determine MIC was the broth microdilution assay in microtiter plates. Cytotoxicity was assessed by hemolysis assays using human Red Blood Cells (RBC). The mechanism of action, of the most efficient 17-mer was determined using several biophysical assays and simple membrane models that mimic the mammalian and bacterial lipid composition. Secondary structure of the peptides upon interaction with membrane mimetic systems was also determined.

### RESULTS AND DISCUSSION

Despite the truncations made, we found a 17-mer peptide, MSI-78(4-20) (KFLKKAKKFGKAFVKIL), which demonstrated to be as effective as MSI-78 against the gram positive *Staphylococcus* strains tested and against the gram negative *P. aeruginosa*. This shorter derivative was more selective towards bacterial cells as it was less toxic to RBC than MSI-78,

representing an improved version of the lead peptide. Biophysical studies support a mechanism of action for MSI-78(4-20) based on the disruption of the bacterial membrane permeability barrier, which in turn leads to loss of membrane integrity and ultimately to cell death. These features point to a mechanism of action similar to the one described for the lead peptide MSI-78.

### CONCLUSION

In this study, we found a very effective and broad-spectrum AMP, MSI-78(4-20). This MSI-78 derivative is as effective as the lead peptide, while having reduced hemolytic activity, therefore representing an improved version of MSI-78. We can envisage a wide application for this AMP in the field of antimicrobial research.

[djohns@its.jnj.com](mailto:djohns@its.jnj.com)

### INTRODUCTION

Topical absorbable hemostats (TAH) provide several benefits during a surgical procedure, including hemostasis and visualization of the operative field. Oxidized cellulose (OC), and oxidized regenerated cellulose-based (ORC) TAH products have bactericidal properties that occur when an acidic environment is created upon contact between the hemostat and blood or other fluid, a characteristic created through oxidation of the cellulose component. The bactericidal properties of SURGICEL® Original Absorbable Hemostat, an ORC, have been demonstrated in various *in vitro* and *in vivo* evaluations<sup>1</sup>. This study compared SURGICEL® with other ORC and oxidized cellulose products to evaluate the degree of oxidation (carboxyl content) and bactericidal activity against 5 challenge bacteria<sup>2</sup>.

### EXPERIMENTAL METHODS

The carboxyl content was determined by titration, using methodology as described in the United States Pharmacopeia (USP)<sup>3</sup>. Tryptic soy broth was used to measure pH over time. Test articles were challenged *in vitro* with 5 strains identified by the National Healthcare Safety Network as the most common pathogens accounting for health care-associated infections, and bactericidal activity was measured using standard plate count method.

### RESULTS AND DISCUSSION

The USP specification for ORC carboxyl content is 18 – 24 w/w percent. Only one product met the USP criteria (Table 1). It also exhibited the lowest pH at all-time intervals (Figure 1), and showed consistent efficacy against all 5 challenge bacteria evaluated (Table 2). The actual log reduction was 4 logs or more from the initial inoculum within 24 hours for all 5 bacteria tested. All other products exhibited lower levels of oxidation and varying antibacterial activity.

Sample	ORC or OC	pH @ 24 Hours in TSB	COOH (w/w %)
SURGICEL®	ORC	3.31	19.5
BLOODCARE	OC	3.70	15.5
CURACEL®	ORC	3.60	14.1
Equitamp®	ORC	4.68	1.4
GELITACEL®	OC	3.55	15.0
OKCEL®	OC	3.65	15.7
Oxycel	OC	3.53	15.0
Reoxcel®	OC	3.63	13.9
Traumastem	OC	3.38	16.5
RESO-CELL®	ORC	3.49	16.2

Table 1: The pH in TSB of 25 mg/mL at 24 hours with associated test article carboxyl content (COOH)

Fig. 1: The pH time-course for test articles in TSB at 25 mg/mL

Sample	MRSA	MRSE	VRE	<i>E. coli</i>	<i>P. aeruginosa</i>
SURGICEL®	>4	>4	>4	>4	>4
BLOODCARE	>4	4	1.0	<1	>4
CURACEL®	>4	3.8	<1	3.2	>4
Equitamp®	1.2	1.0	<1	-2.9	-0.1
GELITACEL®	>4	3.0	<1	<1	>4
OKCEL®	>4	2.8	<1	<1	>4
Oxycel	>4	3.9	>4	1.4	>4
Reoxcel®	>4	4	<1	2.8	>4
Traumastem	>4	>4	2.7	3.2	>4
RESO-CELL®	>4	>4	<1	1.3	>4

Table 2: Log reduction at 24 hours from the initial inoculum for each test article

### CONCLUSION

Only one ORC product met the USP specification for carboxyl content for ORC, and also exhibited the lowest pH at all-time points, and had consistent bactericidal efficacy against all 5 challenge bacteria evaluated. One ORC product within the group actually resulted in increased bacterial count for *E.coli* and *P.aeruginosa*. All other products tested exhibited varying but lesser antibacterial activity against 5 bacterial strains. These results suggest that different processes and oxidation levels may lead to different levels of bactericidal effectiveness.

### INTRODUCTION

Instead of the widely used titanium titanium-silver can be an alternative group of alloys for medical implants used in dentistry and orthopaedics. Mechanical properties of Ti-Ag produced by powder metallurgy enables obtaining of biocompatible materials with good mechanical properties and with bacteriostatic or bactericidal ability. The aim of this work was to study biological response to Ti-Ag alloys with the silver content lower than 20%at.

### EXPERIMENTAL METHODS

Titanium-silver alloys with nominal chemical composition of silver 3.5at%; 5at.%; 10at.% or 20at.% were manufactured by powder metallurgy. A titanium powder (Atlantic Equipment Engineers) was mixed with silver powder (Nanoamor) and compressed in a hydraulic press with pressure of 8MPa. Cylinder-shaped compacts (10 mm in diameter and 5 mm height) were sintered in vacuum furnace ( $5 \cdot 10^{-4}$  mbar) at 900°C for 10 hours.

*In vitro* tests allowed to evaluate biocompatibility and antimicrobial activity of Ti-Ag alloys. For tests samples with shape in disk were sterilized and placed into 48-well culture plates. Their biocompatibility was tested in fibroblasts cell culture. Murine fibroblasts L-929 (Sigma-Aldrich, Germany) were seeded on surface of samples at a density of  $1.5 \times 10^5$ /ml per well. The interaction of L-929 fibroblasts with Ti-Ag samples: cells adhesion, spreading, viability/proliferation and cytotoxicity were determined after 3 and 7 days from seeding. Adhesion, spreading and proliferation of cells on the surface of biomaterials were observed using a fluorescence microscope (Olympus, Japan). In order to determine cytotoxicity of biomaterials and cells viability/proliferation, a ToxiLight\_BioAssay Kit and ToxiLight™ 100% lysis reagent set (Lonza, USA) were applied.

Susceptibility of bacteria to Ti-Ag alloys were determined from Kirby-Bauer disk diffusion test, carried out according to SNV 195920 standards. The bactericidal effect of materials against *Staphylococcus aureus* and *Escherichia coli* was estimated based on the zone of inhibition around them. The presence of the inhibition zone is a result of diffusion of the antibacterial agent into the solid agar nutrient. An amount of dissolved agent must be therefore sufficient to reach MIC (minimal inhibitory

concentration) or MBC (minimum bactericidal concentration) values for each tested bacterial strain.

### RESULTS AND DISCUSSION

*In vitro* tests proved the good biocompatibility of all studied titanium-silver alloys. The cells on their surface adhered and spread well. The ratio of viability and proliferation was relatively high. Sample fluorescence microphotographs of L-929 cells cultured for 7 days on the surface of titanium-silver alloy (Ti-Ag3,5%) were shown in figure 1.

Fig.1 Morphology of L-929 cells seeded on the titanium-silver (3.5at% Ag) after 7 days in culture. Stained with Acridine Orange, Objective magnification: a)10x, b)20x

Antibacterial activity can be determined from the width of the inhibition zone. According to the SNV 195920 standard, the antibacterial behaviour can be defined as good when width of a zone is larger than 1 mm. For all studied alloys bacterial strains were comprised between 1 and 3 mm. Hence, it can be concluded that Ti-Ag surface exhibits significant antimicrobial properties.

### CONCLUSION

Biological response of the Ti-Ag alloys was studied by means of determination of their biocompatibility as well as antimicrobial properties. Obtained results have shown that titanium-silver sinters possess good properties for fibroblasts adhesion, migration and proliferation *in vitro* as well as cells were growing with correct morphology. Moreover, antibacterial test carried out with use of *Staphylococcus aureus* and *Escherichia coli* bacteria proved antibacterial properties of the Ti-Ag alloys.

### INTRODUCTION

Severe bacterial infections has become a major clinical and public health problem. The number of resistant bacterial strains is constantly and rapidly increasing<sup>1</sup>. Biofilm forming bacteria can easily adhere to different surfaces creating attached communities. The isolation from the unfavorable environmental conditions enables bacterial survival even under prolonged antibiotic treatment. Nowadays, additional efforts are needed to develop effective antibacterial materials. The preparation of polymer-metal nanoparticle-based composites is one of the most promising strategies<sup>2,3</sup>. Herein, we present chitosan (CS) based silver and gold nanoparticles (AgNPs, AuNPs) films and their biological activity evaluation.

### EXPERIMENTAL METHODS

The synthesis of chitosan based silver and gold nanoparticles was optimized by factorial design. In both cases CS, a biocompatible polymer, was used as a reducing and stabilizing agent. Three different polymer grades were used, varying in their average molecular weight and deacetylation degree value. The dependence between chitosans properties and obtained NPs features was determined. Several experimental techniques for nanoparticles and nanocomposites characterization were applied: UV-Vis and IR spectroscopy, TG, TEM, XPS, ICP-MS *etc.* Moreover, the biological activity of obtained materials was evaluated. The cytotoxicity was checked by the MTT and LDH assays on selected cell lines (human keratinocytes: HaCaT, mouse fibroblasts: NIH3T3, human lung adenocarcinoma epithelial cell line: A549 and mouse colon fibroblast carcinoma cells: CT26). The antibacterial activity was also examined on Gram-negative (*Pseudomonas aeruginosa*) and Gram-positive (*Staphylococcus aureus*) bacterial strains.

### RESULTS AND DISCUSSION

Chitosan with the medium molecular weight and the highest deacetylation degree appeared to be the most optimum for the silver and gold nanoparticle synthesis providing with an homogeneous particle size and inter-batches reproducibility. A fast reduction of metal ions was favored which consequently leads to smaller nanoparticle formation homogenously dispersed across the film. A complete bactericidal effect towards stationary phase cultures of *Pseudomonas aeruginosa*

and *Staphylococcus aureus* bacterial strains was proven for the most efficient materials. The resulting nanocomposites with AuNPs did not show any cytotoxicity against mammalian somatic (HaCaT, NIH3T3) and tumoral cells (A549, CT26). Films with AgNPs exhibited a negligible toxicity towards somatic cells and a distinct toxicity towards tumoral ones. Both types of materials induced a disruptive effect on the bacteria wall while their internalization was hindered on the eukaryotic cells. This selectivity against bacteria and safety towards eucariotic cells make them potentially applicable as antimicrobial coatings in the biomedical field.

### CONCLUSION

The optimization of silver and gold nanoparticle synthesis allowed obtaining materials with desired properties such as size and NPs distribution in the resulting polymeric film. Chitosan based gold nanocomposites exhibited a significant antibacterial activity and simultaneously low cytotoxicity. For silver containing materials, the bactericidal effect was confirmed. However, significantly higher cytotoxicity towards keratinocyte and fibroblast cell lines was also observed. Presented nanocomposites could be potentially applied in biomedical field as successful antimicrobial materials.

### INTRODUCTION

Silver nanoparticles (AgNPs) are widely used in pharmaceutical, industrial and medical applications. Using of plant extracts to avoid toxic by-products reveal is very common route to synthesis of AgNPs. It is known that green synthesized AgNPs are environmentally friendly, cheap and safe for medical applications [1, 2]. The size, amount and surface charge on AgNPs vary depending on several parameters such as plant species and volume of extract used. Nowadays, AgNPs are obtained using many different plants extract [3]. However, we could not find any study related to green synthesis of AgNP's using lime (*Tilia tomentosa*) leaf extract and its antimicrobial properties in literature survey. In this study, we aimed to conduct rapid biosynthesis, characterization and antimicrobial activity of AgNP's using a medicinal plant (*T. tomentosa*) extract as reducing and stabilizing agent.

**Keywords:** Biosynthesis; Silver nanoparticle; *Tilia tomentosa*; characterization; antimicrobial activity

### EXPERIMENTAL METHODS

#### Synthesis of AgNP

The leaves of lime were collected from local area of Erciyes University campus. Collected samples were washed thoroughly with distilled water several times to remove dust. The cleaned leaves were shade dried for 10 days. The dried leaves were pulverized in a blender to obtain a fine powder. 10 g of pulverized leaves were boiled in 100 ml of sterile distilled water for 5 min, cooled and filtered through Whatman No. 1 filter paper. This filtrate was used as a reducing and stabilising agent for  $10^{-3}$  M of silver nitrate ( $\text{AgNO}_3$ ). 10 ml of the above filtrate was added to 90 ml of  $10^{-3}$  M  $\text{AgNO}_3$  solution and stirred and incubated at room temperature for 20 min. After incubation the NPs were collected by repeated (3–4 times) centrifugation of the reaction mixture at 10.000g for 10 min.

#### Characterization

Characterization of obtained NP's were conducted by UV-visible spectroscopy, scanning electron microscopy (SEM), X-ray diffraction (XRD), dynamic light scattering (DLS) and Fourier Transform Infra-Red spectroscopy (FTIR).

#### Antimicrobial activity

The agar diffusion method was used for the determination of antimicrobial activities of the AgNP's. *Escherichia coli* O157 was selected as test organism. At the end of the exposure, petri dish was examined for zones of growth inhibition, and the diameters of these zones were measured in millimeters.

### RESULTS AND DISCUSSION

According to SEM image, Ag NPs are spherical with size of  $40 \pm 5$  nm. The weight and atomic percentages of Ag indicated by EDX analysis are about 8.01% and 1.07%, respectively. The FT-IR spectra of *T. tomentosa* extract directed Ag NPs revealed that the O-H bonds (phenolic compounds in plant extract) stretching was observed at  $3389.01 \text{ cm}^{-1}$ . The presence of C=O bonds peak from aldehydes or ketones or ester was found around at  $1620.82 \text{ cm}^{-1}$  with right shift. The vibration bands of aromatic C=O existed at  $1384.73 \text{ cm}^{-1}$ . The vibration band at  $1066.19 \text{ cm}^{-1}$  was attributed to C-O stretching in epoxy. The crystal structure containing peak position and relative intensity of Ag NPs was analyzed by X-ray diffraction technique. The XRD analysis showed the diffraction peaks at  $38.26^\circ$ ,  $46.19^\circ$ ,  $64.85^\circ$  and  $78.35^\circ$  which are relevant to (111), (200), (220) and (311) of the lattice planes of a faced center cubic, respectively. The UV-vis spectrum exhibited a peak at around 292 nm belonging to plant extract while the characteristic absorption peak of Ag NP aqueous solution were absorbed at range of 480–500 nm. The effective diameter of Ag NPs was  $45 \pm 5$  nm. We demonstrated that the Ag NPs was negatively charged with a  $-29.8 \text{ mV}$ . The synthesized AgNPs had significant antimicrobial activity against *E. coli*.

### CONCLUSION

We synthesized an eco-friendly and convenient approach for the synthesis of AgNPs using *T. tomentosa* leaf extract in which no harmful chemical reagent or surfactant template was required. Obtained AgNPs may probably be used as effective antimicrobial agent.

### INTRODUCTION

Current biodegradable polymers for osteosynthesis present low mechanical properties and lack of bioactivity<sup>[1]</sup>. Mg and its alloys are among the most interesting options because of their utmost mechanical strength and stiffness although they exhibit a high corrosion rate under physiological fluids. An interesting alternative to these materials is presented as a new approach by the incorporation of Mg and Mg alloys particles into a polymer matrix. The amount of the particles dispersed into the matrix should be high enough to improve the mechanical properties of the polymer, but low enough to avoid the hydrogen accumulation and the subsequent fast increase in pH (caused as a result of the above mentioned behaviour). The degradation process of Mg may damage adjacent tissues<sup>[2]</sup>, and also, metal ions will be released to the blood stream, regulated by the polymer degradation rate, and therefore will interact with the present macromolecules on the surroundings. After surgery, biofilm formation is one of the most important issues. On this work an interaction of the Mg ions with bacteria is proposed as a simulation of the expected release. The study also includes the influence over adhered bacteria onto Ti6Al4V, other well-know biomaterial which hydrophobicity could be modified by UV-light irradiation<sup>[3]</sup>.

### EXPERIMENTAL METHODS

Disks of Ti6Al4V of 25 mm in diameter were kindly supplied by SURGIVAL S.A., Spain. They were mechanically polished with diamond paste, and finished with colloidal silica. Prior to their use, the Ti6Al4V disks were carefully cleaned with DSF disinfectant (DERQUIM DSF 11; Panreac Quimica S.A., Spain), then rinsed and sonicated in deionized water (Milli-Q system), 70% acetone and finally ethanol for periods of 15 min each. Samples used as controls were not subjected to any further treatment. A second set of samples was exposed to an UV-C source for 120 min. This period was sufficient to guarantee the hydrophilization of the surface, as we have recently shown<sup>[3]</sup>.

Mg ions solutions were obtained from the dissolution of metallic Mg alloy particles in the PBS buffer. Final concentrations of ions were determined by mass spectrometry (ICP-MS) as 71 mg L<sup>-1</sup> (named as 1/1).

*S. epidermidis* ATCC35983, gram-positive strain, extracellular polysaccharide substance producer was used in this work.

Static adhesion experiments were carried out with the help of a sterile reusable silicone chamber (flexiPERM, Greiner bio-one, Germany), fixed to the Ti6Al4V surface for 60 min at 37 °C and 20 rpm. Mg ions was used at different concentrations (1/1, 1/2 and 1/4 from the saturated one) were incorporated for 60, 150 and 240 min after static adhesion experiment.

After the adhesion process, the Live/Dead kit BacLight L-7012 (Invitrogen SA, Spain) was used to show out the viability of adhered bacteria to the Ti6Al4V surface before and after being exposed to the UV irradiation.

Also, the pH of the suspensions after the exposure time was measured.

### RESULTS AND DISCUSSION

Slightly differences have been found on the number of adhered bacteria between hydrophobic and hydrophilic Ti6Al4V surfaces. Over the adhered ones, the bactericidal effect of Mg ions follows an increase with both concentration and exposure time but shows no relations with the hydrophobicity of the substrate neither with the pH.

### CONCLUSION

Mg ions have a remarkable antibacterial behaviour. Their controlled-release from the new proposed biomaterial would bring great benefits after implants.

## INTRODUCTION

Biofilm formation is the critical factor and ultimate cause of persistence in chronic bacterial infections such as implant-associated osteomyelitis<sup>1</sup>, heart valves endocarditis, catheters, among many others<sup>2, 3</sup>. Degradable polymer coatings were mostly considered as tools to improve biocompatibility of the matrixes which exhibited controlled release of therapeutic molecules. Poly (lactic-co-glycolic acid) (PLGA), a biodegradable and biocompatible synthetic polymer was explored in thin film formulation<sup>4</sup>. Alginate (ALG), a natural polymer, has attracted researchers owing to its ease of availability, compatibility with hydrophobic as well as hydrophilic molecules, biodegradability under physiological conditions and the ability to confer sustained release potential<sup>5</sup>. Immobilization of enzymes for antimicrobial strategy has been applied for the protection of biomaterial devices and implantation. Lysozyme (LYS) is the enzyme that has strong antibacterial potential against Gram-positive bacteria<sup>6</sup>. The aim of the present work was to develop and characterize a thin film as a coating system using degradable materials and evaluate the capacity of immobilization and release of LYS.

## EXPERIMENTAL METHODS

### Preparation of thin film by Dip coating

PLGA (50:50) solution (6.25%) (solution A) was prepared through the dissolution in dichloromethane. ALG sodium solution (3%) (solution B) and LYS (12 mg/ml) (solution C) were prepared through the dissolution in 0.1 M phosphate buffer solution pH 6.5. The 0.1 ml of solution B was added to solution C and mixed for 2 min in vortex to form mix D. The 0.8 mL of solution A was added to 0.2 mL of mix D and taken to homogenize using a homogenizer Silentcrusher S at a speed of 45000 rpm for 90 seconds. After the PE sheet substrates (5 cm<sup>2</sup>) were subjected to microwave plasma oxygen treatment on both sides and then was dipped into the mix D, before drying at ambient conditions. For crosslinking the films were immersed for 2 min into a bath consisting of 10 mL of a solution of CaCl<sub>2</sub> (5%) and glycerol (5%). Then, the films were removed from the bath, washed with water. The excess of water was removed with a filter paper and maintained on a support for 4h at room temperature for drying. PLGA/ALG coating was prepared without LYS as control. The thickness of the films was determined in dry state.

### Surface contact angle measurement

The wettability of the films was measured using the sessile drop method using an OCA 40 contact angle system. (n=5)

### Scanning electron microscopy (SEM)

Morphological characterization of the films was done using a field emission SEM.

## ATR-FTIR

FTIR spectra were collected and the LYS secondary structure was analysed during the *in vitro* release test. (n=6)

### *In vitro* release

Lysozyme release was evaluated by immersion of the film (5 cm<sup>2</sup>) into 1.5 ml of 0.1 M HEPES at pH of 7.3 in 2 ml Eppendorf tubes in a thermostatic shaking bath at 37 °C. The amount of LYS released was measured spectrophotometrically at ( $\lambda$ ) 281 nm in samples periodically taken up and placed again into the same tube. (n=6)

## RESULTS AND DISCUSSION

Thin film of PLGA-ALG polymers were successfully produced by dip coating. The SEM micrographs reveal an ordered array of approximately 2  $\mu$ m size pores on the surface<sup>4</sup>. An average thickness of the film is  $\sim$ 5  $\mu$ m. The obtained water contact angle of 80° indicated the relative hydrophobicity of the material. The incorporation of hydrophilic ALG does not affect the proprieties of PLGA structure and can promote modulation of the enzyme release. The results of an *in vitro* lysozyme release assay demonstrated a sustained and prolonged release time for up more to 1 month. The percentage of  $\alpha$ -helices and  $\beta$ -sheets was calculated using the FTIR spectra and confirmed the presence of the secondary structures of LYS.

## CONCLUSION

PLGA-ALG films were prepared using biodegradable polymers and were a suitable platform for incorporated and sustained LYS release. Biodegradable polymers can emerge as an appealing technology platform to functionalize biomaterial surfaces with antimicrobial activities.

## Bacteria, Biofilms and Mass Spectroscopy: Following the Bacteria's Footprints

E. Peter Magennis<sup>1</sup>, Andrew Hook<sup>1</sup>, David Barrett<sup>1</sup>, Paul Williams<sup>2</sup>, Morgan Alexander<sup>1</sup>

<sup>1</sup> Laboratory of Biophysics and Surface Analysis, University of Nottingham, UK

<sup>2</sup> School of Molecular Medical Sciences, University of Nottingham, UK

[peter.magennis@nottingham.ac.uk](mailto:peter.magennis@nottingham.ac.uk)

### INTRODUCTION

Bacteria are a cause of significant acute and chronic disease and their infections can have a serious and detrimental impact upon quality of life and mortality, whilst socio-economic factors associated with infectious diseases have larger impacts. Device related infections are common in modern healthcare and many types of devices are known to become colonized by bacterial biofilms.<sup>1</sup> Bacterial “footprints” including adhesins<sup>2</sup> deposited on surfaces can facilitate attachment but the full range and identity remain unknown. Surface analysis techniques, such as time of flight secondary ion mass spectroscopy (ToF-SIMS) have provided structural information of compounds deposited by microorganisms after culturing and biofilm formation.<sup>3</sup> However, ToF-SIMS analysis supported ambient mass-spectroscopy *before* biofilm development can illuminate a further range of the footprints from bacteria. The differences in these depositions between high-fouling and low-fouling biomaterials can further guide novel material development.

### EXPERIMENTAL METHODS

Known co-polymers resistant to bacterial attachment<sup>4</sup> were synthesised and deposited on glass slides. The coated surfaces were incubated with *Pseudomonas aeruginosa* over a period of 24 hours in RPMI-1640 media and the changes in surfaces were monitored as a function of time. Surfaces were analysed using ToF-SIMS and liquid extraction surface analysis mass spectrometry (LESA-MS).

### RESULTS AND DISCUSSION

Further to incubation with bacteria, principle component analysis of the TOF-SIMS spectra showed that after 24 hours with bacteria significant alteration had occurred to the surface. For example, there was deposition of proteins indicated by the dramatic increase in the  $\text{CN}^-$  and  $\text{CNO}^-$  peaks (figure 1). This change was readily apparent through mass spectroscopy imaging of  $\text{CNO}^-$  (figure 2). However these proteins were less pronounced on the resistant materials after 3 hours of incubation.

Figure 1. Negative ion ToF-SIMS spectra of polymers before incubation (top) after incubation with media (middle) and after incubation with bacteria (bottom). Highlighted ions  $\text{CN}^-$  [26]<sup>-</sup> and  $\text{CNO}^-$  [42]<sup>-</sup>.

Figure 2. Negative ion ToF-SIMS images of secondary ion  $\text{CNO}^-$  [42]<sup>-</sup> before incubation (left) after incubation with media (centre) and after incubation with bacteria (right). Image area is 500  $\mu\text{m}^2$ .

The use of LESA-MS also provided further information on how the surfaces were altered after exposure to bacterial cultures and facilitated identification of compounds.

### CONCLUSION

Further insight into the deposits of bacteria over time has been explored. Changes in biomaterial surfaces have been demonstrated using mass spectroscopy techniques. Changes include but are not limited to proteins.

## INTRODUCTION

The detection and control of microorganisms is important in a wide range of industries and settings. Traditional antimicrobial agents have been successful but resistance is spreading and alternatives to antibiotics are needed.<sup>1</sup> Non-lethal or cell binding systems include soft-lithography, molecular imprinting and carbohydrate processes.<sup>2-4</sup> However, these techniques have adaptive limitations. The use of hydrophilic co-polymers may be advantageous as they can act as a mimetic of the extracellular matrix (ECM). Such natural systems are operated by bacteria to adapt to their environment and also include redox cascades and metal binding systems. These suggest that, through control of redox processes a synthetic ECM could be produced, capable entombing bacteria in a material of their own design. Using copper mediated ATRP bacterial-instructed ligands could be constructed which are capable of rebinding bacteria targets. The same process could also be applied to a copper-catalysed Huisgen cycloaddition (click-chemistry) to fluorescently tag the bacteria *in situ*.

## EXPERIMENTAL METHODS

Bacterial strains of *E. coli* and *P. aeruginosa* were obtained from stocks held within the University of Nottingham. Bacteria were grown for 24 hours then washed and condensed. Polymers were synthesised by bacteria-activated (b-ATRP) or standard ATRP. For bacterial polymerisations: Monomers were charged into a reaction flask with initiator and bacteria before deoxygenating. The catalyst was degassed separately and added to initiate polymerisation. Polymers were retrieved from bacteria through washing steps. Bacteria-polymer interactions were assessed by cluster analysis. For chemo-labelling of bacteria, a cationic polymer displaying alkynes was incubated with bacteria then an azide-coumarin dye was added which fluoresces after successful "clicking".

## RESULTS AND DISCUSSION

Using novel b-ATRP, polymer constructs were formed which were selective for the microorganism from which they were formed and also compared to control polymers produced by standard ATRP (figure 1). Furthermore, using copper mediated click chemistry, direct fluorescent tagging of bacteria has been demonstrated using a cationic targeting polymer.

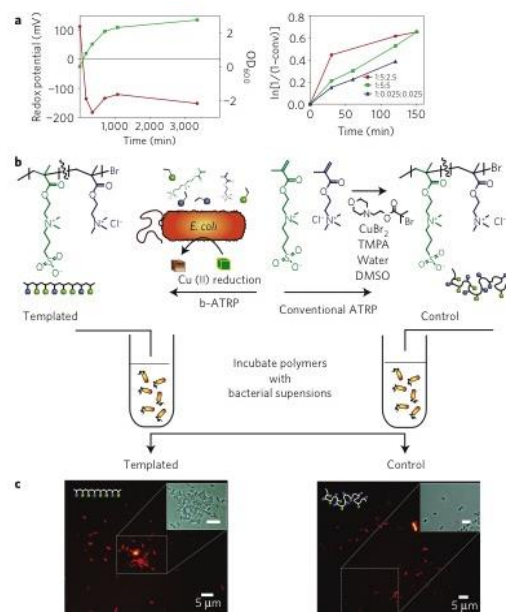

Figure 1. a) Left: Change in redox potential during bacteria growth, Right: Polymerisation kinetics of b-ATRP. b) Schematic of bacteria-instructed synthetic process. c) Fluorescent microscopy of *E. coli* mCherry with bacteria instructed and control polymers.

## CONCLUSION

This work shows that bacterial metabolic processes can be high-jacked for synthetic chemistry. The rebinding by the materials offers a novel approach to bacterial capture. The induction of fluorescence was detectable using a smart phone camera, as potentially simple diagnostic test.

### INTRODUCTION

An increased use of antibiotic drugs has led to the development of numerous multi-resistant microbes in the last years. Due to this medical situation the treatment of biomaterials-associated infections (BAI) with antibiotics is critically discussed. Therefore, a reduced adhesion of microorganisms on biomaterials surfaces is of high interest for preventing BAI<sup>1</sup>. The most frequently isolated fungus from BAI is *Candida albicans*, the pathogen of candidacies and the most frequently isolated bacteria is *Staphylococcus aureus*.

One strategy is the modification of the topographical characteristics of biomaterials surfaces. In a previous work we showed a decreased adhesion of Gram-positive and Gram-negative bacteria on nanorough biomaterials in the range between 2 nm and 6 nm<sup>2</sup>. The aims of this study are [i] to investigate the adhesion of *C. albicans* and *S. aureus* on biomaterials structured physically with nanoparticles and [ii] to identify and understand microbial adhesion mechanisms on these surfaces.

### EXPERIMENTAL METHODS

For reproducible fabrication of gold surfaces physical vapor deposition (PVD) was used. Gold nanoparticles with different size and concentration were used to get different distances between these nanoparticles immobilized on gold surfaces via a chemical reaction pathway. These surfaces were characterized by atomic force microscopy, scanning electron microscopy and contact angle measurements. For microbial adhesion a previously established *in-vitro* testing device was used<sup>3</sup>. For determining the microbial adhesion a confocal laser scanning microscope and focused ion beam scanning electron microscope for cross-sectioning of adhered microbial cells on the surface obtaining the nano-interface between the cells and the biomaterial were used.

### RESULTS AND DISCUSSION

Preliminary results showed an increased microbial adhesion with extending the adhesion time on both the nanostructured surfaces and the control sample without chemically bounded nanoparticles on the surface. On nanostructured biomaterials surfaces the microbial adhesion is reduced compared to the control for each adhesion time. In addition, it is demonstrated that the microbial adhesion on biomaterials surfaces is reduced by decreasing the amount of bounded nanoparticles on the surface. The nanoparticles may act as attachment points for the microbes. By reducing these attachment points the microorganisms need to spread between the

nanoparticles which results in a decreased adhesion on structured surfaces with the lower amount of nanoparticles.

### CONCLUSION

The microbial adhesion of different model organisms can be influenced by modifying the nanostructure of biomaterials surfaces. Therefore, the use of nanoparticles may be a promising antibiotic-free strategy to reduce microbial adhesion on biomaterials surfaces and decrease the risk of BAI.

## Design of Ag@SiO<sub>2</sub> Nanorattles for Antimicrobial Implant Coatings

Sarah-Luise Abram<sup>1</sup>, Katharina M. Fromm<sup>1</sup>

<sup>1</sup>Department of Chemistry, University of Fribourg, Switzerland  
[sarah-luise.abram@unifr.ch](mailto:sarah-luise.abram@unifr.ch)

### INTRODUCTION

Medical progress and an ageing world population have led to an increasing use of foreign materials inside the human body. Consequently also the number of infections related to these implants has grown significantly.<sup>1</sup> Antimicrobial coatings that prevent the formation of infectious biofilms on the surface of the implants could make an important contribution to overcome that issue. Silver is known for its good antimicrobial and biocompatible properties and could therefore play an important role in the fight against implant infections, especially if they are caused by antibiotic resistant bacteria.<sup>2</sup>

This project covers the synthesis of silver nanoparticles that are encapsulated inside a protective silica shell in order to prevent aggregation or a too fast release of the antimicrobially active Ag<sup>+</sup> ions. The silica shell provides reactive sites to covalently attach the antimicrobial nanocontainers to the implant surface. Furthermore it enables the functionalization with biosensor units to create a stimuli responsive release of the Ag<sup>+</sup> only in the presence of bacteria.

### EXPERIMENTAL METHODS

Ag colloid:

A variation of the polyol process<sup>3</sup> was used for the synthesis of silver nanoparticles with an average diameter of 24 nm.

Silica coating:

The silver nanoparticles were coated with a silica shell according to a modified Stöber method.<sup>4</sup>

Etching:

The inner part of the silica shell was removed by etching with hot water in presence of PVP<sup>5</sup>.

### RESULTS AND DISCUSSION

The combination of the polyol process for the preparation of a silver colloid with the Stöber method for the synthesis of a silica shell resulted in homogeneously coated Ag@SiO<sub>2</sub> core-shell particles with an average size of 75 nm. The presence of PVP on the particle surface during the following etching procedure allows the selective removal of the inner part of the silica. This creates a hollow container with a shell thickness of about 12 nm. The silver nanoparticles are believed to be freely moveable inside that sphere. Silver ions should be released through the pores of the shell to ensure the antimicrobial properties of the nanorattles. This possibility could be proven by first dissolving the silver cores in nitric acid and then imaging the empty silica containers with TEM.

Figure 1: TEM picture and synthesis route to Ag@SiO<sub>2</sub> nanorattles

### CONCLUSION

As a first step in the design of an antimicrobial implant coating we established a reliable synthesis of Ag@SiO<sub>2</sub> nanorattles where just one silver nanoparticle is encapsulated inside a larger hollow silica shell.

A functionalization with amino groups by co-condensation of (3-aminopropyl)trimethoxysilane offers possibilities to coat implant surfaces and for further functionalization in order to obtain an effective and biocompatible antimicrobial material to fight implant infections.

# Synthesis of Poly(N-Isopropylacrylamide)-Silver Nanocomposite for Biomedical Applications

Milène Tan, Katharina M. Fromm

Department of chemistry, University of Fribourg, Switzerland

[Milene.tan@unifr.ch](mailto:Milene.tan@unifr.ch)

## INTRODUCTION

In the last decades, polymeric materials have attracted a significant interest in the biomedical field especially in their use as implants. With the emergence of new multi-drug resistant bacteria and despite advances sterilization procedures, the contamination of implant surfaces by bacteria is a new challenge to overcome.<sup>1</sup> Then, the design of new surfaces in order to prevent bacterial adhesion and biofilm formation is a serious concern. Silver has already been proved to be effective against bacteria even at low concentrations.<sup>2</sup> Besides, silver in nano-size could present higher efficiency against bacteria over a longer time-activity.<sup>3</sup> For these reasons, silver nanoparticles (NPs) have been exploited in the framework of this project.

Poly(N-isopropylacrylamide) (PNiPAAm) is very suitable for biomedical applications owing to its good biocompatibility and thermosensitivity with a lower critical solution temperature (LCST) close to 32°C. Practically, the polymer is readily soluble under this temperature but above, it becomes insoluble and precipitates out. Furthermore, its synthesis by RAFT polymerization requires a sulfur compound as chain transfer agent, making the polymer very suitable for silver binding.

## EXPERIMENTAL METHODS

Polymer synthesis:

PNiPAAm was obtained by RAFT at 70°C in THF using 2-(Dodecylthiocarbonothioylthio)-2-methylpropionic acid (DMP) and AIBN as RAFT agent and initiator respectively, for a targeted DP of 50. The initial concentration in monomer was established at 3M and with molar ratio [NiPAAm]/[DMP]<sub>0</sub>/[AIBN]<sub>0</sub> 50/1/0.2.

Ag nanoparticles:

Silver NPs were synthesized by reducing silver nitrate in mild conditions in a solution containing the PNiPAAm.

## RESULTS AND DISCUSSION

As shown in the results presented in the table 1, it obviously appears that the RAFT polymerization leads to the controlled synthesis of the PNiPAAm. Indeed, a good correlation between the theoretical  $M_n$  and the experimental  $M_n$  (obtained by NMR) was observed, as well as a low polydispersity.

Conv (%)	$M_n$ theo (g.mol <sup>-1</sup> )	$M_n$ NMR (g.mol <sup>-1</sup> )	$M_{napp}$ SEC (g.mol <sup>-1</sup> )	PDI
85	4680	4890	4210	1.18

Table 1. Macromolecular parameters of PNiPAAm

Scheme 1 Synthetic route of the nanocomposite

The silver nanoparticles were obtained by reducing the silver ions in the presence of the PNiPAAm in order to prevent their aggregation believed to decrease the antimicrobial properties of the silver.<sup>4</sup> The reduction needs to be done in mild conditions to avoid the reduction of the RAFT end-group of the polymer.

## CONCLUSION

The PNiPAAm was synthesized in a first step by RAFT polymerization known to be an effective and controlled synthetic route to obtain polymers. Besides, the presence of sulphur RAFT end-group in the polymer makes it very suitable for possible silver binding. That kind of nanocomposite provides a biocompatible and effective antimicrobial material for further biomedical applications.

## INTRODUCTION

Wound healing represents a public health problem with an increase in susceptible populations like geriatric or diabetic patients<sup>1</sup>. The major complication is infection, associated to an increase of morbidity (amputation) or mortality (septicemia). In particular, the infection of the diabetic wounds delays the healing process and progresses to bone destruction<sup>2</sup>. We recently develop a wound dressing functionalized by layer-by-layer system based on chitosan (positive polyelectrolyte, PE+) and cyclodextrin polymer (negative polyelectrolyte, PE-) for synergic bi-therapy with silver or iodide associated to chlorhexidine.

## EXPERIMENTAL METHODS

In a first step, the non woven polyester (PET) is functionalized by chitosan (CHT) crosslinked by citric acid (CTR) to obtain a first charged layer (positive or negative in function of the CTR concentrations) or by genipin to obtain a first positively charged layer only. The textile is characterized by FTIR, SEM and the ionic charge density is evaluated by titration. Then the positively and negatively charged PET-CHT is impregnated in iodine or silver solutions to obtain the first bioactive coating. The drug loading is quantified by elementary analysis and titration. In a second step, the multilayer system is build up on the loaded PET-CHT according to the method develop in our lab<sup>3</sup> using alternatively cyclodextrin polymer (PCD, PE-) and CHT (PE+). In a last step, the multilayer system is impregnated in a chlorhexidine (CHX) solution. The CHX loading and CHX release is measured by HPLC method in function of the number of bilayers. Finally, the kinetic of release of the final wound dressing (PET-CHT-Ag/CHX and PET-CHT-I/CHX) is studied in physiological medium (PBS, pH7.4, 37°C, 80 rpm). The antibacterial activity is evaluated on different bacterial strains (*S. aureus* CIP224; *E. coli* K12; MRSA 07001 and *P. aeruginosa* ATCC 27583) by kill-time method. At each step of the functionalization process, the cytocompatibility is evaluated with epithelial cells (ATCC-CCL5, L132) according to ISO 10993-5 standard.

## RESULTS AND DISCUSSION

The evaluation of the charge density on the functionalized PET with CHT shows the ability of the system to be adapted with the CTR concentrations either with an anionic exchange functions ([CTR] >1%) either with a cationic exchange functions ([CTR] <1%). After impregnation of anionic and cationic PET-CHT in silver and iodine solution, the titration shows a silver loading of 3% and iodine loading of 1600 ppm. *In vitro*,

microbiology evaluation reports the efficiency of the loaded PET-CHT. Indeed, the silver loaded PET-CHT reduces significantly two bacterial population after 24 hours (*S. aureus* : 4 log; *E. coli* : 5 log reduction).

The multilayer system, applies on the loaded PET-CHT, has three functions thanks to the cyclodextrin polymer as previously described<sup>4</sup> i) barrier effect to reduce the release of the cytotoxic silver into the wound ii) gel formation to drain exudates iii) complex-inclusion formation to adsorb other drug. Systems with 5.5, 7.5 and 10.5 bilayers are performed on the PET-CHT-Ag. As show in figure 1a, the presence of silver has no influence on the build-up of the multilayer. Additionally, the figure 1b shows the CHX loading and CHX release depends on the number of bilayers.

**Fig 1. a. Evolution of weight gain of textiles during the construction of the system. b. Kinetic of release of CHX in function of the number of bilayer (PBS, 80rpm, 37°C) (b).**

The evaluation of cell vitality by the method of the Alamar blue shows an excellent cytocompatibility of the functionalization of the dressings at each stage of the process (vitality rate >70%). Finally, microbiological evaluation confirms the CHX release studies with a prolonged antibacterial effect (>30 days) of the Ag/CHX loaded on wound dressing against *S. aureus* and *E. coli*.

## CONCLUSION

We demonstrate the safety and the prolonged antibacterial effect of a multilayer wound dressing loaded with silver or iodide associated with CHX. The three main characteristics of multilayer system (drug sorption, gel formation, ionic exchange capacity) allow us to obtain a new generation of wound dressing for combined biotherapy.

## INTRODUCTION

In the past two decades, many chemically sophisticated drug delivery systems were developed however, with rather disappointing end results *in vivo*<sup>1</sup>. *N*-Vinylcaprolactam (VCL) based nanogels (NGs) belong to the top candidates to be utilized as drug delivery system due to sizes tunability, biocompatibility<sup>2</sup> and biodegradability. Moreover, they can be functionalized for multiple drug loading<sup>3</sup>. Hence, our scientific goal is to develop degradable, pH-sensitive NGs (< 150 nm) that can be post-modified with a fluorescent dye and covalently bind an antitumor drug. The tumor accumulation and organ biodistribution of these NGs can be monitored non-invasively using hybrid imaging, e.g. combining fluorescence molecular tomography (FMT) with micro computed tomography ( $\mu$ CT), *in vivo*.

## EXPERIMENTAL METHODS

### Nanogel Synthesis

The NGs were synthesized via precipitation copolymerization of VCL with the comonomers itaconic acid dimethyl ester (IADME) and the linear macromonomer (VBA-50)<sup>4</sup> in water. As acid-degradable crosslinker 3,9-divinyl-2,4,8,10-tetraoxa-spiro[5.5]undecane (DTOU) was inserted and for initiation 2,2'-azobis(2-methylpropionamidine)dihydrochloride (AMPA) was used.

### Post-Modification of Nanogels

Via Steglich Esterification thiols were incorporated into the NGs. By thiol-maleimide reaction the NGs were labelled with the fluorescent dye Cyanine7 maleimide (Cy 7) and Mal-DOX was bound covalently. Mal-DOX contains a pH-sensitive hydrazone bond between doxorubicin (DOX) and the maleimide group for pH-sensitive drug release.

### Nanogel Characterization

The NGs were characterized by Raman spectroscopy and H-NMR spectroscopy to confirm the integration of the comonomers and the thiol-functionalization. The size of the NGs was determined by DLS and also degradation of the nanogels was monitored by DLS and AFM.

### Organ Biodistribution Monitoring

Two A431 tumor-bearing mice were injected i.v. with 2 nmol NG-Cy7 in the tail vein. The mice were imaged at 0.25, 3, 6 and 24 h post-injection using a novel imaging protocol of hybrid  $\mu$ CT/FMT (Fig. 3a). NG-Cy7 tumor accumulation and organ biodistribution was quantified for each imaging point using  $\mu$ CT based organ segmentation (Fig. 3b).

## RESULTS AND DISCUSSION

Fig. 1: The desired size range (< 150 nm) of the PVCL-based NGs could be achieved.

Due to the incorporated acid-degradable crosslinker (DTOU) the NGs degrade slowly in acidic medium.

Fig. 2: The thiol-functionalization of the NGs (left) as well as the Cy7 (middle) and Mal-DOX (right) coupling were successful, respectively.

Fig. 3: a) Hybrid  $\mu$ CT/FMT images with organ segmentation: the highest NG-Cy7 accumulation can be seen in the liver (red) and the kidneys (yellow and blue). b) Analysis of organ biodistribution of NG-Cy7 *in vivo*: highest tumor accumulation after 6 h.

## CONCLUSION

The first pilot-study indicated that degradable NG-Cy7 are stable *in vivo* and they accumulate in tumors with minimal renal excretion.

## INTRODUCTION

Surface Plasmon Resonance (SPR) has been used already for a few decades for label-free detection and characterization of biochemical kinetics and affinities of many different types of analytes. The physical phenomenon is not limited to biochemistry, but is applicable to other nanoscale characterization of thin films<sup>1</sup>.

## EXPERIMENTAL METHODS

Aside of the traditional interactions, Multi Parametric Surface Plasmon Resonance (MP-SPR) can be utilized to determine unique refractive index (*RI*) and thickness (*d*) of ultrathin (*d* 0.5-100 nm) and slightly thicker films (*d* 300 nm- few  $\mu$ m) without prior assumptions of the *RI* of the material. These are important properties not only for thin film coating industries and applications, but also for gaining important knowledge in biomaterials. Two methods utilizing MP-SPR to thickness and *RI* calculations have been introduced, either measuring in two different media (2M) with high *RI* difference, such as air and water<sup>1-3</sup>, or at two or more different wavelengths (2W) of light<sup>2,3</sup> in order to characterize properties of the thin films.

The MP-SPR method also allows study of wide variety of different coatings including plastics, cellulose, lipid layers, minerals and hydrogels. The interactions of different biomolecules towards these coatings can also be characterized using the method.

## RESULTS AND DISCUSSION

MP-SPR is suitable for film deposition *in situ* or *ex situ*, which makes it compatible with several deposition methods and thereby makes it applicable to a wide range of polymers also. Polyelectrolyte multilayer deposition *in situ* was monitored in real-time with MP-SPR. Thickness of each deposited layers was determined utilizing two wavelength method.

Similarly layer thickness and *RI* was determined also for *ex situ* spin coated cellulose layer. MP-SPR was used not only to determine thickness and *RI* of the deposited layer but also for real time monitoring of

other molecules interaction to the cellulose model surface<sup>4,5</sup>.

Recently, MP-SPR was used also to monitor polymer layer structural changes in real time, such as polymer swelling due to pH or electric potential change<sup>6</sup>. At pH = 9 poly (acrylic acid) (PAA) brushes were extended but the brushes collapsed at acidic pH.

The MP-SPR method has also been used in characterizing different materials for their ability to support either lipid bilayer or liposome layer formation<sup>7</sup>. In addition interaction of antimicrobial peptide to lipid bilayers has been studied.

## CONCLUSION

With the ability to characterize both kinetics and nanoscale layer properties, MP-SPR proves to be a versatile tool for nanomaterial, biomaterial and biochemical interactions research, which makes MP-SPR invaluable for multidisciplinary research, where both physical and interaction properties of the materials need to be characterized.

## Quantitative Characterization of Adhesion and Mechanics of Single Cells and Their Interactions With Biomaterials by AFM

Torsten Müller, Dimitar Stamov, Jörg Barner, Anne Hermsdörfer, Carmen Pettersson, Torsten Jähnke

JPK Instruments AG, Germany

[mueller@jpk.com](mailto:mueller@jpk.com)

Topography, roughness and mechanical properties of biomaterials are crucial parameters influencing cell adhesion/motility, morphology and mechanics as well as the development of stem/progenitor cells [1,2,3,4,5]. Atomic force microscopy is a powerful tool not only to study the morphology in terms of high resolution imaging and roughness measurements, but also to map mechanical and adhesive properties of the sample/cells at high resolution. Combining these remarkable abilities with advanced optical microscopy allows for extensive characterization of biomaterials. The JPK NanoWizard® 3 AFM provides advanced imaging and mapping modes which can be combined with inverted as well as upright optical microscope techniques. Using single cell force spectroscopy (SCFC), cell adhesion can be quantified [6], and the contribution of different components e.g. from the extra cellular matrix, can be assessed [7]. Additionally, based on scanning force microscopy, the nano-indentation technique has emerged as a useful tool to determine elastic properties like the Young's modulus for biological samples. Nano-mechanical analysis of cells increasingly gains in importance in different fields in cell biology like cancer research [8] and developmental biology [9]. We present a strategy to comprehensively characterize biomaterials as well as their interaction with cells and influence on cell behaviour.

## INTRODUCTION

There exists a pressing need to develop diagnostic technologies, so-called biosensors, in order to leverage explosion of information provided by the “-omics,” (genomics, proteomics, etc.). Importantly, in addition to sensitivity and specificity, an ideal biosensor platform needs to be fast, affordable, and simple, thus reducing the barrier of entry, especially in the developing world. Graphene nanocomposite inks for ultrasonic, non-contact printing are particularly attractive for achieving these goals. However, successful and low cost application of this technology requires parallel development of suitable substrate platforms.

Here we present a modular polymeric platform, combining the design space flexibility provided by 3D printing with surface optimization enabled by spin coating.

## EXPERIMENTAL METHODS

Basic electrode design (0.63 mm thick) was 3D printed using Zortrax M200 printer and Z-ABS or Z-GLASS polymers.

Surface polymer selection was driven by wettability with ethylene glycol (EG), main component of our graphene nanocomposite ink, and thermal stability up to 170°C. Tested polymers included the family of copolyesters (PET-DLA)<sup>1</sup> consisting of polyethylene terephthalate (PET) hard segments and dilinoleic acid (DLA) soft segments, ranging from 50 to 70% hard segment ratio.

For spin coating, 1 to 15 wt.% of PET-DLA was first allowed to dissolve in hexafluoroisopropanol at room temperature for 24 hours. Next, 1 mL of PET-DLA solution was spread on the 3D printed substrate and spin coated in 4 steps, with a maximum speed of 3000 rpm for 30 sec using Spincoater Spin 3000 (Laurell Technologies).

Surface modification aimed at improving EG wettability and introducing additional functional groups was carried out using 6M NaOH (up to 2 hours) or hydrogen peroxide (30 minutes) at 60°C.

Surfaces wettability with water and EG was evaluated using contact angle goniometer (Krüss DSA100S). Surface printability was tested using graphene/chitosan/EG nanocomposite ink and non-contact ultrasonic microplotter (Sonoplot GIX Microplotter Desktop).

## RESULTS AND DISCUSSION

Basic electrode designs were successfully 3D printed, individually or in triplicate, using both Z-ABS and Z-GLASS. Z-GLASS surfaces tended to be smoother.

PET-DLA copolymers containing at least 50% hard segments possessed suitable thermal properties to resist thermal annealing of graphene nanocomposite ink at 170°C. Contact angle of materials ranging from 50 to 70% hard segments was tested with both water and EG.

Fig. 1: Contact angle of PET-DLA polymers.

In order to improve EG wettability, PET-DLA copolymers were treated with either NaOH or hydrogen peroxide, resulting in a further ~10° drop in contact angle.

Printing tests with graphene nanocomposite ink determined that 70PET-DLA surfaces were preferable for printing, primarily due to greater hardness.

Fig. 2: Printing graphene nanocomposite ink on 70PET-DLA (60 micron tip).

## CONCLUSION

The combination of 3D printing of supports and spin coating of surfaces allows for a modular design of appropriate polymeric electrodes for inkjet printing with graphene nanocomposite inks.

## INTRODUCTION

Some dental materials used by the dentist can cause a hypersensitivity reaction in certain individuals. Potential allergens include the metals, plastics or acrylics in denture, filling materials and different rubber products. According to international data nickel is the most common cause of contact allergy among dental metals<sup>1</sup>. Based on a study the presence of histatins in saliva is responsible for nickel allergy. The histatine-5 (Hst-5) is a histidine-rich (His) protein. N-terminal Asp-Ser-His of Hst-5 is coordinated to the nickel ions<sup>2</sup>. There are some possibilities to detect a wide diversity of biomolecular interactions that may have an important role in the multi-step process of hypersensitivity reaction. The surface plasmon resonance spectroscopy (SPR) is very sensitive technique to recognize label free biomolecular affinity<sup>3</sup>. The formation of self-assembled monolayer (SAM) can ensure the specific binding on sensor chip surface<sup>4</sup>. The main concern of the present study is to investigate the application possibilities of modified SPR sensor chip that can relate to the antigen presentation process. Our aim is to analyse binding affinity of histidine and histidine-nickel complex to different SAM by FT-SPR technique.

## EXPERIMENTAL METHODS

The applied materials are L-histidine (Sigma-Aldrich, Japan), and NiCl<sub>2</sub>·6H<sub>2</sub>O (Sigma-Aldrich, France) in His-Ni binding process. The histidine concentrations are 4, 6, 8, 10, 15 and 20 mM in distilled water (DW) and PBS buffer at three different pH values (pH=3, 7 and 10). The concentration of Ni is 4 mM in distilled water. FT-SPR measurements are carried out using a SPR-100 (GWC Instruments, WI, USA) module coupled with a Nicolet 6700 FT-IR spectrometer (Thermo-Electron, Madison, WI, USA) working in the near infrared (NIR) region which is equipped with a tungsten halogen near-infrared light source, a CaF<sub>2</sub> beam splitter and an InGaAs detector. Two types of SAM are created on SPR gold chip surface. One is amino functionalized by 8-amino-1-octanethiol (AOT; Dojindo, Japan), the other is carboxyl functionalized by 6-mercaptophexanoic acid (MHA; Sigma-Aldrich, USA).

## RESULTS AND DISCUSSION

Based on the measuring it has found the SPR sings shift to lower wavenumbers with increasing His concentration that indicates stronger affinity to sensor chip surface. On the amino functionalized surface (AOT) the histidine binds stronger at acidic pH in the order pH3>pH7>pH10 in distilled water and in PBS too. In the case of carboxyl functionalized surface (MHA) the binding of His is in the order

pH7>pH3>pH10 in distilled water and pH3>pH10>pH7 in PBS. It has showed that the protonated form of histidine binds stronger (at pH=3) in buffer. The shift of SPR sign are detected in real time during the kinetic measurements of the His-Ni binding process. It has found the histidine-nickel complex gives a characteristic sign during the measurement independently of the His concentration. The complex is washable off from the surface.

Figure 1 show the histidine bindings on carboxyl functionalized sensor chip surface at different concentration in distilled water (DW) and in PBS buffer at pH=3, pH=7 and pH=10

## CONCLUSION

According to the results it has established that histidine has higher affinity to carboxyl functionalized surface in acidic conditions. Based on this study the SPR is a suitable tool to investigate the binding affinity between amino acids and dental allergens on SAM. These findings can contribute to a better understanding of dental allergen mechanism.

### INTRODUCTION

It is known that several agents (e.g. drugs, nanoparticles, cytokines) may induce interesting and unexpected changes in cells phenotype – biological and physical parameters, e.g. morphology, cytoskeleton reorganization, intercellular communication or elasticity. Endothelial cells, similarly to muscle or red blood cells, due to their function and location undergo constant squeezing and stretching from the environment. As regards endothelium, elasticity plays a key role in the maintaining vascular pressure regulation. This parameter can be essential in case of evaluation of endothelial cell dysfunction [1] and effectiveness of prospective endothelial drugs [2]. Presented work comprises the study on the influence of three kinds of nanoparticles (NPs): polyamidoamine dendrimers (PAMAMs) of 4.0 generation, silver nanopowders (SNPs) and multi-walled carbon nanotubes (MWCNTs) on EAhy.926 endothelial cell line. Despite dendrimers are intensively studied, their metabolism by the cells, tissues and organs is not well recognized [3]. The comprehensive analysis of nanoparticles influence on cells morphology and elasticity can be useful for understanding of endothelium response during drug and other agent transport by nanoparticles application.

### EXPERIMENTAL METHODS

The endothelial cells were cultured for 24h, and stimulated with examined agents for next 24h. The influence of nanoparticles was investigated for selected concentrations: PAMAM (0.005, 0.012 and 0.024 μM); MWCNT (51.5, 74.1 and 166 μg/ml) and SNP (2.8, 74.8 and 139.6 μg/ml). Atomic force microscopy and nanoindentation with AFM tip were used to characterize the changes in the endothelial cell phenotype. Morphology and elasticity were measured using NTEGRA scanning probe microscope (NT-MDT, Russia) with soft cantilevers (CSG01, with nominal spring constant 0.003 N/m, NT-MDT Probes, Russia). Quantitative morphological cell parameters: volume, surface area and aspect ratio of the central part of the cell (defined as above half of the cells height) were examined for fixed cells in phosphate buffer (pH 7.4). Additionally, the roughness parameters: density of summits (Sds) and texture aspect ratio (Sdr) of the surface were calculated. In order to detect the cell stiffness, the elasticity parameter E (reduced Young's modulus) of the cell central part was measured for live cells in cultured medium in relation to the stimulation agent. The acquired data was compared with the results

obtained at control conditions.

### RESULTS AND DISCUSSION

Precise visualization of the cells morphology confirmed that MWCNTs and SNPs accumulation on the endothelium cell membrane is dose-dependent. Roughness evaluation showed significant increase of Sds value for cells treated with MWCNTs, what may indicate the distinct changes related to actin and myosin fibers reorganization and/or nanotubes accumulation under the cell membrane. Morphological parameters calculation revealed shape changes of the cell central part from longitudinal (control condition) to spherical (incubated with dendrimers). Elasticity results showed the differences for cells incubated with nanoparticles compared to reference sample. Obtained results for NPs indicated the cytotoxicity effects of selected agents, what was confirmed by fluorescent staining and cytometry measurements.

### CONCLUSION

Atomic force microscopy supported with nanoindentation method can be a useful tool for determination of endothelial cells morphology and elasticity changes induced by nanoparticles. Moreover, these methods may help in the evaluation of “endothelium-safe” nanoparticles.

### INTRODUCTION

The use of implants with magnetic properties in medicine has increased in recent years [1]. Diagnosing of patients treated with such implants requires an individual approach. The Magnetic Resonance Imaging (MRI) is one of the safeties and non-invasive imaging techniques used in medicine [2], however the presence of nanoparticles with magnetic properties incorporated in the implant may induce the deformation of the image [3]. Therefore, it is important to study the visualization process of such implants to obtain proper images and to examine the influence of the magnetic nanoparticle concentration on resulting images. Additionally relationship between the shape of an implant and the quality of the MRI image was investigated.

### EXPERIMENTAL METHODS

For this study composite samples with nanomagnetic particles were prepared. Polylactide (PLA) was a matrix and the nanomagnetite powder was used as the modifier. The samples with three different concentrations were prepared: 0,01wt%; 0,05wt%; 0,5wt%. As a reference PLA (pure polymer) samples were also prepared. Tested materials were shaped in the form of: a) rings of diameter 15 mm, height of 10 mm and the wall thickness 1 mm; b) rollers with a diameter of 9 mm and a height of 10 mm.

Obtained materials were investigated by the MRI technique. The different pulse sequences were tested with the aim to find the optimal sequence for imaging of such materials. In result the spin echo T<sub>1</sub> weighted sequence was chosen for further imaging.

### RESULTS AND DISCUSSION

MRI visualizations allowed to obtain images of the composite samples modified with nanomagnetite. For all three types of composites and for both shapes, the best images were obtained with the spin-echo T<sub>1</sub>-weighted sequence. Analysis of the images showed that increasing the concentration of magnetite in the samples causes more distorted images. Quantitative analysis of number and type of distortions connected with the amount of magnetic modifier were also performed. Images of the highest quality were obtained for the materials with the smallest amount of modifier (0.01wt%). Second type of analysis for this type of

composite was connected with the influence of the sample shape (the ring and the roll) on the quality of the images. It was observed that better results were obtained for the ring-shaped samples and the images were less distorted as compared with the images of roll-shaped samples which were not sharp enough showing less details.

### CONCLUSIONS

The performed analysis have shown that there is a direct connection between the amount of magnetic modifier in the composite and the quality of MRI images.

It was stated in this research that the critical amount of the modifier is 0,5wt%. Addition of such quantity of the modifier made the images very distorted and disqualified them from medical diagnosis. This means that, if a good quality of image is needed, the amount of nanomagnetite particles should be much smaller, the best ~0,01wt%. Another factor affecting the quality of the MRI images is the shape of the samples. For the ring-shaped composite better results were obtained than those for roll-shaped ones.

Based on the presented results it can be concluded, that the use of the spin-echo T<sub>1</sub>-weighted MRI sequence produces the best images of implants with magnetic modifier and can be used for medical diagnosis, but the investigated implants need to have a proper, much less than 0,5wt%, concentration of the nanomagnetite. Furthermore the implants hollow in shape are more preferable than bulk ones, because their images are less distorted.

## INTRODUCTION

The use of in vitro platforms presents obvious ethical and cost advantages over in vivo models. Moreover, important scientific benefits in the study of biological mechanisms of action focusing on isolated variables/effects can be obtained. Different 2D and 3D cell culturing systems, static and dynamic (e.g., bioreactors) have been proposed, along the years [1]. However, the lack of suitable physical structures capable of supporting the generation of multilayered tissues has been hampering the tissue engineering (TE) field developing improved models [2]. The existing cell culture technology is not adapted to this need, but new systems are now arising, as adapted bioreactors and 3D well culture plates [1]. With the development of TE tools and cell culture systems, interfaces could be recreated in a more realistic way. In this work a novel bioreactor adapted for multi-layered cell culture was developed [3]. The system can provide a mechanism to enhance cellular homogenization and stratification inside of the 3D construct. So far, the developed system is being tested to create an osteochondral (OC) 3D in vitro model.

## EXPERIMENTAL METHODS

A rotational dual chamber bioreactor capable of improving medium diffusion into 3D layered structures, providing different culture medium to each layer and an homogeneous cell distribution in the scaffolds, as well as of introducing mechanical stimuli by 180° stirring and compression, was fabricated in-house [3]. Two different bilayered sponge-like scaffolds were developed to act as a template for co-culturing rabbit adipose stem cells (rASCs)-derived osteoblasts and chondrocytes. Bilayered low acyl gellan gum (LAGG) 2%w/v-LAGG2%w/v/hydroxyapatite (HAp) 30%w/w structures with and without gelatin (1:1) were produced forming the cartilage- and bone-like layers. The developed cell-scaffolds constructs were cultured in static conditions as control of the dynamic cultures.

## RESULTS AND DISCUSSION

A bioreactor comprising a multiposition magnetic stirred plate on which are connected dual chambers by magnetic attraction has been developed. The dual chambers can have rotational movement, which is horizontal and/or vertical. The size of the scaffold is dependent on the ability of the medium to enter and exit the interior of the 3D structure. By introducing the stirring movement over the cell culture, the diffusion potential increased. This allows the use of bigger 3D scaffold consequently enhancing the ability to produce larger tissues in vitro. Moreover, the multi-chamber bioreactor is adapted for co-culturing different cells types allowing the generation of multi-cell type tissues.

A chamber cap allowing cyclic compression over the respective cell-scaffold construct, creating physical stimuli that intend to mimic the body weight was included. The compartments of the dual chamber allow flowing different culture medium per compartment or the creation of an air-liquid interface.

Figure1. A: Rotational Dual Chamber Bioreactor prototype [3]; B: Bilayered structures of LAGG-LAGG/HAp30% (left) and LAGG/Gelatin-LAGG/Gelatin/HAp30% (right).

The freeze-dried bilayered scaffolds composed of LAGG2%(w/v)-LAGG2%/HAp30% (w/w) and LAGG/Gelatin 1:1 2%(w/v)-LAGG/Gelatin 1:1 2%/HAp30% (w/w) have a gradient of HAp in the bone-like layer that, unlike cartilage-like layer, present a bioactive behavior. The bilayered structures possess about 90% porosity, 500 µm of pore size and 85% interconnectivity as determined by Micro-CT analysis. Swelling and degradation tests revealed that the structures can absorb about 120% of their weight and lost 10% of their mass after 30 days in phosphate buffered saline solution. In vitro studies with rASCs from fat pad are being performed to compare static and dynamic cultures.

## CONCLUSION

The described technology can be used in the development of an in vitro stratified OC tissue model and potentially for developing other interfaces (e.g. epithelia, skin, blood-brain barrier). These can allow decreasing the animal models for basic research and drug screening and efficacy studies.

### INTRODUCTION

The success or failure of a biomaterial depends ultimately on the immune response triggered after its implantation. Macrophages are the main components of innate immune system. This cell type presents a remarkable functional plasticity, existing a whole spectrum of populations between the proinflammatory (M1) and reparative (M2) extremes<sup>1</sup>. The M1/M2 balance has been recently related to the capacity of macrophages to play both positive and negative roles in disease processes and tissue remodelling after injury<sup>2</sup>. In the present study, the effects of nanocrystalline hydroxyapatite (nano-HA) and nanocrystalline silicon substituted hydroxyapatite (nano-SiHA) on murine macrophage populations have been evaluated in basal conditions and in the presence of either pro-inflammatory (LPS) or anti-inflammatory (IL-10) stimuli.

### EXPERIMENTAL METHODS

Either RAW 264.7 cells or mouse peritoneal macrophages were cultured for 24 and 72 hours in the presence of 1 mg/ml of nano-HA and nano-SiHA. Specific macrophage surface markers CD80 and CD163 were used to identify M1 and M2 macrophages respectively by flow cytometry and confocal microscopy after immunostaining with phycoerythrin-labelled antibodies. LPS and IL-10 were used as pro-inflammatory and anti-inflammatory stimuli, respectively. Cell viability, proliferation, intracellular reactive oxygen species, IL-6 and TNF- $\alpha$  were also evaluated after treatment with these hydroxyapatites.

### RESULTS AND DISCUSSION

**Figure 1** shows that the treatment of RAW 264.7 macrophages with 1 mg/ml of nano-HA and nano-SiHA produces a significant decrease of the pro-inflammatory M1 (CD80+) population after 72 hours. However, a significant increase of reparative M2 (CD163+) population was observed when compared with control cells in the absence of material. These effects were also obtained after treatment of mouse peritoneal macrophages with these materials in the presence of pro-inflammatory (LPS) or anti-inflammatory (IL-10) stimuli. Different M1 and M2 morphology was observed by confocal microscopy in mouse peritoneal macrophages after 48 hours treatment with LPS and IL-10, in agreement with other authors<sup>3</sup>.

**Figure 1. Effects of nano-HA y nano-SiHA (1mg/ml) on RAW 264.7 macrophage M1 (CD80+) and M2 (CD163+) populations after 72 hours treatment.** Statistical significance: \*\*\*p < 0.005 (compared to the Control without material), ## p < 0.01, ### p < 0.005 (comparison between CD80 and CD163 markers),  $\varphi\varphi\varphi$  p < 0.005 (comparison between nano-HA and nano-SiHA).

### CONCLUSION

The findings of this study allow to conclude that these nanocrystalline hydroxyapatites favour the macrophage polarization toward a M2 reparative phenotype, ensuring an appropriate response in the implantation site of these biomaterials used for bone repair and Tissue Engineering.

## INTRODUCTION

Endothelial cells are in the centre of angiogenic processes which are crucial for the successful integration of implants in the body<sup>1</sup>. Cell-extracellular matrix (ECM) interactions are essential regulators of these processes. Thus, development of ECM mimetic instructive microenvironments supporting endothelial cell function is important to achieve desired tissue responses upon implantation<sup>1,2</sup>.

Supported lipid bilayers (SLBs), which are readily formed on hydrophilic supports, act as biological interfaces mimicking cellular membranes while retaining their physicochemical properties (i.e. phase behaviour). Their differential phase behaviour enables controlling the mobility of the biomolecules on the surfaces for molecular recognition. Also, by forming non-fouling surfaces using neutral (i.e. PC) lipids, SLB functionalization with synthetic ligands (e.g. RGD of ECM) allows to instruct cell behaviour specifically<sup>3</sup>.

## EXPERIMENTAL METHODS

### Surface Preparation

SLBs were formed via a vesicle fusion method on hydrophilic glass substrates. To prepare bio-functional SLBs, vesicles (either of DOPC (fluid) lipids or DPPC (gel) lipids) were conjugated with defined molar ratios of biotinylated PE lipids and after SLB formation, biotinylated RGD ligands were introduced to the surfaces using neutravidin cross-linkers. In addition, bare (non-functional) bilayers that were formed by unconjugated vesicles and fibronectin coated glass were used as control surfaces.

### Characterization of Cell Behaviour on SLBs

Human umbilical vein endothelial cells (HUVECs) at p5 were seeded at a density of 10 000 cells/cm<sup>2</sup> and cultured for different time points on various surfaces. The cell morphology on the surfaces was monitored using bright-field microscopy.

## RESULTS AND DISCUSSION

Our observations indicate that cells marginally adhered onto non-functional SLBs (data not shown) while cells considerably adhered on ligand presenting bilayers. This difference shows that we could specifically direct endothelial cell attachment by controlling the surface composition. Furthermore, we also observed that cells on the gel state (DPPC) SLBs were spreading after 6 h while cells on fluid state (DOPC) SLBs remained round with a lower extent of attachment. This implies that we could also direct cell behaviour by changing the SLB

properties (i.e. (mobile ligands) fluid vs. (immobile ligands) gel state SLBs) while presenting the same chemical composition in the SLBs (Fig.1).

**Fig.1.** HUVECs on 1 mol% ligand presenting (a) DPPC and (b) DOPC based SLBs after 6 h observed with bright-field microscopy (20x magnification, n=3).

Showing the possibility of directing endothelial cell behaviour on these surfaces, understanding the ligand density and time dependent responses in terms of focal adhesion dynamics and cell migration in real time are critical steps that are currently being investigated. Besides, these surfaces introduce a versatile way to present multiple ligands to control endothelial cell behaviour<sup>3</sup>.

## CONCLUSION

In conclusion, our data suggest that endothelial cell behaviour could be directed on SLBs by introduction of ligands on different types of otherwise non-fouling SLB surfaces. In addition, cell contact formation and morphology was dependent on phase behaviour of lipids forming the SLBs. Consequently, our further understanding and exploiting the underlying cellular events will pave the way to develop a biologically active interface for endothelial cells to create smart material coatings on implant surfaces supporting *in vitro* pre-vascularization.

### INTRODUCTION

Magnesium and its alloys have a considerable potential for orthopaedic implants. Its degradability *in vivo* is probably the dominating property which indicates its success. However, still not all the involved mechanisms of the degradation process are fully understood. In this *in vitro* study we aim to elucidate the influence of different physiological and biological parameters on the degradation profile. Here, we wish to clarify the differences between short and long-term exposure to whole blood and plasma, respectively. A second aim is to elucidate the possible role of osteoblasts in changing the chemical composition on the interfaced corrosion layer.

### EXPERIMENTAL METHODS

Pure Mg specimens were prepared by permanent mould casting. Disc-shape samples (10mm x 1.5mm) were cleaned in ethanol and sterilized by gamma-irradiation. To elucidate the influence of inorganic and organic parts of blood, samples were exposed to full blood (90 min. and 6 h) and blood plasma (3 d) in an *in vitro* “closed loop” Chandler-loop system. For comparison the specimens were exposed for 72 h to Hank’s balanced salt solution (HBSS) and Dulbecco’s modified Eagle’s medium (DMEM).

The cell influence was verified on samples which were pre-incubated for 24 h under cell culture conditions in cell culture medium (DMEM). 100,000 human primary osteoblasts (OB) were incubated on these discs for 13 days. During that period medium was changed every 2-3 days. After incubation the samples were fixed in 2.5% glutaraldehyde overnight, followed by 1% osmium tetroxide for 0.5 h to stain the cells. Then different washing steps in isopropanol were performed. As final step samples were dried by critical point drying. These samples were examined using scanning electron microscope (SEM). Then micro cuts on these fixed samples were performed by focused ion beam (FIB) on selected cells with the corrosion layer underneath, the cross sections of these cuts was analysed by EDX area mapping and line scans. Corrosion layer composition was analysed by performing electron induced X-ray emission microanalysis spectroscopy and Fourier transform infrared reflection micro-spectroscopy (FTIR) analysis on the whole sample cross section (10 x 1.5) mm.

### RESULTS AND DISCUSSION

Samples immersed in whole blood show mainly  $\text{MgCO}_3$  associated with calcium-phosphate. Whereas samples immersed in plasma show  $\text{Mg}(\text{OH})_2$  as predominate product, with around 20µm thicker corrosion layer as compared to whole blood immersed samples. Cells on samples had further influence on the degradation profile. On one hand by physically covering the material surface they form kind of a biological corrosion protection layer. In addition they alter the chemical composition for the adjacent corrosion layer, which was detected by line EDX scans revealing more calcium and phosphorous elements.

Fig. 1: Up: Back scattered image of corrosion layers after immersing pure magnesium in two different media; left: in plasma for 72 h; right: in whole blood for 6h; down: SEM image for the cross section cut of OB cell on Mg sample

### CONCLUSION

The results highlight the importance of mimicking the biological environment and its complexity. It was shown in blood plasma that the chemical composition of the corrosion layer was significantly altered, which indicate the role of organic components in the corrosion medium. Furthermore, the biological interaction should be carefully considered, as in our study osteoblasts modified the corrosion profile and possibly mediate a biomineralization process which resulted in higher Ca and P contents on the nearby corrosion layer.

## INTRODUCTION

The spontaneous passivation of Ti6Al4V, one of the most clinically used biomaterials, results on a thin TiO<sub>2</sub> outer surface layer. This layer has recently been shown to confer to Ti6Al4V extraordinary bactericidal properties *in vitro* following its irradiation with UV-C light<sup>1</sup>. The influence of these surface changes on protein adsorption, one of the initial processes that occur upon implantation of a medical device into a body site, has not yet been elucidated at the molecular level. In this study, the structure and mechanical stability of human plasma fibronectin (HFN), a major protein component of blood plasma, is evaluated upon adsorption onto the nonirradiated and irradiated Ti6Al4V through the use of atomic force microscopy (AFM).

## EXPERIMENTAL METHODS

Disks of Ti6Al4V, cut from 25 mm bars supplied by DKSJ Switzerland Ltd., were polished and cleaned as described elsewhere<sup>1</sup>. A set of the samples were exposed to a UV-C source ( $\lambda = 254$  nm) for 15 h receiving an intensity of  $\sim 4.2$  mW/cm<sup>2</sup> prior to experiments. The HFN protein, obtained from Sigma-Aldrich, was suspended in 10 mM PBS at pH 7 to a concentration of 100  $\mu$ g/ml. A volume of 0.5 ml of this solution was allowed to interact with the nonirradiated and irradiated Ti6Al4V samples for 15 min. After the 15 min adsorption time, the protein coated disks were rinsed with PBS and transferred to the AFM.

AFM experiments were performed in PBS using an Agilent AFM 5500 system operating at room temperature and rectangular silicon cantilevers with a tip radius of  $\sim 8$  nm (CSC38 MikroMash). The spring constant of the cantilevers were determined prior to experiments. For each sample, hundreds of force-distance curves were collected at randomly selected locations and used to generate the histograms from which the mean data presented were obtained.

## RESULTS AND DISCUSSION

The mean unfolding force and length obtained upon stretching a single HFN molecule from the nonirradiated Ti6Al4V (Figure 1a) are similar to those obtained by other authors<sup>2</sup>, i.e.  $112 \pm 24$  pN and  $25.6 \pm 3.4$  nm, respectively. These values are typically attributed to the unfolding of the FNIII domains of the protein. The stretching of HFN from the irradiated material, however, reveals a mean unfolding force of  $107 \pm 37$  pN and three different mean unfolding lengths, i.e.  $13.5 \pm 3.2$ ,  $18.1 \pm 1.1$  and  $26.9 \pm 4.8$  nm. These different lengths could be attributed to the unravelling of the FnI, FnII and FnIII domains, assuming

that the disulfide bonds present within the FnI and FnII modules have been likely reduced upon protein adsorption on the irradiated material.

Figure 1. AFM force-plots obtained upon stretching adsorbed HFN from the nonirradiated (a) and irradiated (b) Ti6Al4V

Moreover, a small but significant fraction of the force plots displayed unexpected from transitions (up to three regardless of the substrata) occurring in a stepwise fashion (Figure 2a). Based on the observation that the distance at which the last recorded plateau ends was consistent with the total length of a single molecule, i.e. 160 – 180 nm, it is proposed that the observed behaviour originates from the straitening of a compact molecule (Figure 2b) without the unfolding of its domains. Finally, the mean unravelling forces were found to be lower for the molecules adsorbed on the irradiated than nonirradiated material.

Figure 2. AFM force-plots (a) obtained upon unravelling (b) adsorbed HFN molecules (without the unfolding of its domains) from the nonirradiated and irradiated Ti6Al4V

## CONCLUSION

HFN molecules become structurally looser and mechanically more flexible upon adsorption on the irradiated Ti6Al4V material.

For the first time, force profiles that correlate with the unravelling of a single compact protein without the unfolding of its domains were recorded.

[db614@cam.ac.uk](mailto:db614@cam.ac.uk)

### INTRODUCTION

Electrophoretic deposition is a widely used technique used to form coatings and structures from a solid suspension and has seen wide applications, mainly in ceramic industries. It allows coatings of complex shapes to be formed quickly and evenly on any conductive substrate<sup>1</sup>.

Recently there has been some interest in applying the technique of electrophoretic deposition to a wider variety of materials, including bioceramics and polymeric biomaterials<sup>2</sup>. In this study we attempted to apply the technique of electrophoretic deposition to forming defect free films of insoluble collagen.

### EXPERIMENTAL METHODS

Insoluble collagen was rehydrated in acetic acid and homogenised until a smooth suspension was achieved. The suspension was then degassed under a vacuum and multiple different suspensions were made up of varying collagen wt%, pH, and water content. The water content of the suspension was varied by addition of acetone and ethanol.

Zeta potential measurements were taken to determine which suspensions allowed the largest charge on the collagen molecules and hence which suspensions would be stable and easily deposited.

The suspension was poured into a cell consisting of two stainless steel electrodes separated by silicone rubber spacers and a voltage pulse sequence was applied. The pulse sequences had periods of 1s to 1ms, with a varied percentage of time at 5V applied and the remaining time at 0V. The pulse sequence was applied for a number of time points before the electrodes were removed and allowed to air dry. The films were massed after drying using a balance.

### RESULTS AND DISCUSSION

Figure 1 shows a graph of zeta potential against pH for a collagen suspension. By varying a range of parameters

**Figure 1.** Zeta potential vs pH for 0.1wt% collagen in 0.05M acetic acid.

independently it was possible to select a suspension composition that maximised the zeta potential of the collagen and prevented gas bubbles from coalescing due to electrolysis of the aqueous suspension.

Figure 2 shows a fully detached bubble free collagen film produced by electrophoretic deposition of insoluble collagen suspended in an ethanol/water solution.

**Figure 2.** A free standing collagen film formed by electrophoretic deposition

### CONCLUSION

This study demonstrated that it is possible to apply the technique of electrophoretic deposition to collagen, allowing the rapid production of smooth, bubble free films of a well-controlled thickness. Additionally the films could be detached from the substrate and used as free standing collagen films.

<sup>5</sup>Leibniz Institute for Plasma Science and Technology, Greifswald, Germany

\*schlosse@uni-greifswald.de

## INTRODUCTION

The implantation of medical devices, prostheses and other biomaterials is followed by material-dependent inflammatory reactions, wound healing processes and in the end-stage a foreign body reaction characterized by the occurrence of macrophages and foreign body giant cells (FBGC) formed by fusion of macrophages. Furthermore, FBGC are detectable in the implant surrounding tissue if the implanted material is too large for phagocytosis<sup>1</sup>. Aim of the study was to investigate the occurrence of FBGC after implantation of membranes from different biodegradable materials and of membranes and electrospun fibre meshes of the same material into rats.

## EXPERIMENTAL METHODS

**In vivo study:** In a 1<sup>st</sup> experiment 5×5 mm pieces of a cross-linked acellular porcine dermis collagen matrix (NRX) and Permacol<sup>TM</sup> were implanted intramuscularly into the neck of 24 male Lewis rats. Peri-implant tissue samples of 6 animals for each day were examined 7, 28, 56 and 112 days after implantation. In a 2<sup>nd</sup> series 24 rats received pieces (5×5 mm) of membranes or electrospun meshes from poly(L-lactide-co-D/L-lactide) (PLA) and PLA meshes coated with plasma-polymerized allylamine (PPAAm). After 7, 14 and 56 days peri-implant tissue samples were prepared from 8 animals per experimental day.

**Histological analysis:** Cryosections were stained with Haematoxylin/Eosin (HE) and primary antibodies for CD68<sup>+</sup> macrophages/monocytes (ED1; M1-type) and CD163<sup>+</sup> macrophages (ED2; M2-type), detected using the APAAP system. FBGC were counted in HE-stained slides and calculated as cells per mm<sup>2</sup>.

**Statistical analysis:** The non-parametric Mann-Whitney test and the Wilcoxon matched pairs test were used.

## RESULTS AND DISCUSSION

Day	Permacol <sup>TM</sup>	PLA	NRX
7	0.40 (0.25 – 1.15)	1.00 (0 – 2.00)	0.95 (0.20 – 2.00)
28	0.10 (0 – 0.60)	n.d.	1.85 ** (1.10 – 2.75)
56	0 (0 – 0.10)	0 (0 – 1×10 <sup>-5</sup> )	1.30 ***,++ (0.40 – 3.25)
112	0 (0 – 5×10 <sup>-5</sup> )	n.d.	0.20 (0 – 0.95)

**Tab.1:** Number of FBGC [cells/mm<sup>2</sup>] after implantation of different membranes. Data given as median and interquartile range in brackets; n.d. = not determined; \*\* p<0.05 vs. Permacol<sup>TM</sup>; ++ p<0.05 vs. PLA, Mann-Whitney test

At days 28 and 56 there was a significant higher number of FBGC for NRX membranes compared to Permacol<sup>TM</sup> and at day 56 to PLA, whereas at days 7 and 112 no difference was found. This could either be caused by the material itself and/or by its structure since NRX films are more porous and thicker than Permacol<sup>TM</sup>.

**Fig. 1:** Number of FBGC 7, 14 and 56 days after implantation of PLA membrane (□), PLA mesh (■) and PLA mesh coated with PPAAm (■). \* p<0.05; \*\* p<0.01 vs. PLA membrane, Wilcoxon test

The number of FBGC was significantly higher at all experimental days using both PLA meshes as implant compared to membranes. Thus, an additional surface modification with allylamine did not influence the FBGC reaction. At day 56 for PLA meshes the amount of FBGC was about 4-fold higher than at day 7, whereas using PLA membranes FBGC were no longer detectable.

FBGC were shown to be ED1-positive and ED2-negative, indicating that they are formed by fusion of pro-inflammatory CD68<sup>+</sup> (M1-type) macrophages. This has also been described recently for electrospun polycaprolacton implants<sup>3</sup>.

## CONCLUSION

The foreign body reaction after implantation of biodegradable materials seems to be predominantly influenced by the structure of the implant. Electrospun meshes caused an ongoing stronger reaction compared to membranes of the same material. The FBGC are built by fusion of pro-inflammatory CD68<sup>+</sup> (M1-type) macrophages. This has to be taken into consideration for clinical purposes.

### INTRODUCTION

Proteins are widely used in formulation in the pharmaceutical field and play a major role in biological functions. However, as a widespread phenomenon, the adsorption of proteins on solid surface is always observed for a long-term storage, which will result in a reduced dose of active compound or a loss of biological activity<sup>1</sup>. For instance, insulin losses 52% of its biological activity after 5 minutes contacting with glass surface<sup>2</sup>. The interfacial behavior is also known to trigger aggregation phenomena leading to drastic biological inactivation of proteins during long term storage. In this study, several model proteins has been contacted with multiple type of substrates. Parameters including temperature, concentration, adsorption time, rinsing steps and their influence on amount and conformation of adsorbed proteins have been systematically evaluated.

### EXPERIMENTAL METHODS

#### Proteins

Three model proteins were chosen for this study: bovine serum albumin (BSA), lysozyme (LSZ) and myoglobin (MGB).

#### Kinetic of protein adsorption

High performance liquid chromatography (HPLC) coupled with a Zorbax Bio Series GF-250 column with dimensions of 9.4 (i.d.)×250 mm (Agilent Technologies) was used to quantify protein in solution (phosphate buffer saline, pH 7.4) after contact with glass and polydimethylsiloxane (PDMS) surfaces.

#### Protein conformation determination

Attenuated total reflection infrared (ATR-IR) spectroscopy has been adopted for proteins' structure determination. Spectra for protein have been collected with a model IFS66 spectrometer (Bruker Optics).

### RESULTS AND DISCUSSION

#### Kinetic of protein adsorption on glass surface

**Figure 1.** Adsorption kinetic curves of BSA on glass surface (blue squares) and on PDMS (red circles).

The three proteins which have different intrinsic properties (such as conformation stability) show

characteristic kinetic curves. These curves can be mathematically fitted with Langmuir or two states models (Figure 1: Langmuir model for BSA adsorption). As a more hydrophobic surface, the amount of BSA adsorbed on PDMS after 3 hrs is fivefold more important than on glass.

#### Conformation study of adsorbed protein

##### 1) Influence of the concentration and time

By peak fitting of amide I band, ATR-FTIR is able to give insight on secondary structures of the adsorbed protein. After a short contact time, adsorbed protein lost about half of the  $\alpha$ -helix structures compared to native protein in solution. By increasing protein concentration, the fraction of  $\alpha$ -helix is maintained close to the solution structure, confirming the protective effect of the concentration over denaturation. But this effect can not be effective over a long time: after 2 hrs of contact, the adsorbed proteins at all concentrations showed similar secondary structures.

##### 2) Influence of rinsing step

Rinsing steps are known in the literature to be one parameter responsible for the lack of reproducibility of protein adsorption studies. It appears indeed to have opposite effects after short or long times of contact. By comparing the protein adsorbed with or without rinsing steps on PDMS, we observe that, after 1 min of contact, the rinsing step exposed more denatured molecules whereas it was the opposite after 2 hrs of contact. The rinsing step will act by removing external layer of weakly adsorbed proteins and it is possible that the organization of the protein layer after 2 hrs is more stable, leading to stronger interaction between less denatured molecules.

After having reviewed the relevant parameters for adsorption of proteins, long term adsorption experiments (over 3 months) are currently under investigation. The first results show that initial adsorption process and nature of the surfaces drive the long term behavior of the protein in the formulation and play a role in initiation of aggregation process.

### CONCLUSION

The interfacial behaviour and conformation of adsorbed proteins are highly dependent on parameters such as sorts of proteins, substrate, temperature, adsorption time, concentration, and the rinsing steps. All these parameters are keypoints to enhance the stability of pharmaceutical formulations containing proteins in contact with multiple surfaces during their life time.

## INTRODUCTION

Osseointegration is controlled by a plethora of cellular mechanisms. However, the long-term maintenance of bone at the bone-implant interface is poorly understood. Of great interest is the role of osteocytes (Ot), which via mechanotransduction are responsible for mechanical loading-based remodelling events in bone. Here, the nanoscale structure of the bone-implant and the bone-Ot interfaces was investigated at laser-modified, human dental implants retrieved after 4 years in function<sup>1</sup>.

## EXPERIMENTAL METHODS

The bone-implant materials were processed for electron microscopy. The Ot network was revealed via resin cast etching and visualised by SEM. TEM samples were prepared by the focused ion beam (FIB) *in situ* lift-out technique. High-angle annular dark field STEM (HAADF-STEM) was used for Z-contrast imaging and chemical analysis. The crystalline orientation of bone apatite was investigated by selected area electron diffraction (SAED). Electron energy loss spectroscopy (EELS) was performed for Ca signal mapping. Electron tomography (ET) allowed 3D imaging of the interfaces.

## RESULTS AND DISCUSSION

Cortical-type osteonal lamellar bone filled the implant threads (Fig 1a). The concentrically configured canalicular network connected the central Haversian canal to the nanotextured implant surface through multiple branching canaliculi traversing up to 50  $\mu\text{m}$ . Direct cell-to-cell communication was also observed (Fig 1b). HAADF-STEM of the bone tissue between the implant surface and the Ot lacuna showed highly ordered collagen fibrils (CF) aligned co-parallel to both surfaces (Fig 1c). SAED revealed the crystallographic *c*-axis of apatite approximately parallel to the CF direction. EELS confirmed apatite ingrowth into the nanostructured surface oxide (Fig 1d). ET showed CF forming an immediate boundary to the lacunar space at the bone-Ot interface (Fig 1e), while the bone-implant interface was structurally graded with apatite interdigitation into the surface oxide layer. However, the general morphology at both interfaces was that of CF exhibiting a unidirectional alignment, exhibiting a rope-like twisting motif.

## CONCLUSION

Through Ot processes, an intimate contact is maintained between bone and nanostructured titanium surfaces, even after four years in function. The bone-implant interface ultrastructure reveals gross similarities to the naturally occurring bone-Ot interface. It is proposed that direct mechanical feedback from the osteocytic

network assists in facilitating adaptive osseointegration over the effective lifetime of bone-anchored implants.

**Fig 1:** (a) The bone-implant interface. (b) Ot at the implant surface, exposed by resin cast etching, showed direct cell-to-cell communication (white box). (c) HAADF-STEM image of a FIB-milled sample prepared across the implant-bone-Ot region. The black and white boxes indicate areas selected for ET. (d) EELS Ca map confirmed apatite formation within the nanostructured surface oxide. (e) ET reconstruction of the bone-Ot interface. CF formed a direct boundary to the Ot lacuna.

### INTRODUCTION

Composites materials based on biopolymers and apatite represent appealing extracellular matrix- mimicking scaffolds and therefore their microstructure and cell-interaction are intensively investigated for bone regeneration. We developed gelatin-alginate-apatite materials with various compositions and we explored the role of the biopolymers and the role of the apatite-loading methods onto the microstructure of the resulting composites. In addition, we investigated the interaction of the materials with cells.

### EXPERIMENTAL METHODS

A first type of composite materials was obtained through the alternate soaking of the gelatin-alginate hydrogel scaffolds into calcium and phosphate solutions, as previously reported elsewhere<sup>1</sup>. The number of alternating incubation cycles has been varied from one to six.

The second type of materials was synthesized by the incubation of the phosphate-containing hydrogels into calcium-containing baths.

All the composites were characterized with respect to their microstructure and morphology by Scanning and Transmission Electron Microscopy, equipped with X-ray energy dispersive spectrometer (EDX) and X-ray Diffraction (XRD). The stability of the composites in physiologically-relevant simulated media was also evaluated.

The response of cells to the homogeneity of the samples and to the different microstructural features of the scaffolds were explored at 24 hours and after 7 days using MG-63 cells. The corresponding gelatin-alginate hydrogels were used as control samples.

### RESULTS AND DISCUSSION

The synthesis method and the ratio between the raw materials has a strong influence onto the microstructure and morphology of the obtained composites materials.

The alternate soaking in calcium and phosphate solutions leads to materials with homogeneously distributed apatite nanoparticles within the hydrogel

matrix. Increasing the number of incubation cycles from one to six lead to the formation of denser apatite exterior layers that enhance cell interaction.

The second method, based on the incubation of phosphate-containing hydrogels into calcium-containing baths, leads to more homogeneous composites, with no significant differences in the distribution of apatite nanoparticles in the depth of the scaffold. Better stability of the apatite within the matrix was noticed, when compared to the materials obtained by alternate soaking. Intriguingly, low mineralised islands alternating with strongly-mineralised zones were noticed on some materials (despite the homogeneous composition and treatment during the synthesis). In this respect, the mineral-biopolymer compatibility and adhesion phenomena need further investigation.

MG-63 cells strongly adhered to the mineralized scaffolds. The control gelatin-alginate hydrogels did not promote cell adherence. This was very interesting since we expected the presence of gelatin to stimulate cell adherence, view its collagenous nature. The presence of apatite is the decisive factor determining the adherence and proliferation of MG-63 cells on the studied materials. This confirms the potential of the investigated composites to be used in bone regeneration.

### CONCLUSION

Gelatin-alginate-apatite scaffolds are interesting biomaterials that can be used to generate a wide range of scaffolds. These experiments indicated once more that the control over the morphology and microstructure of such composites is not an easy task and it can strongly influence the biological interactions.

## INTRODUCTION

The cells of the human body are permanently exposed to a variety of mechanical forces, including compression, shear and tensile stress. The importance of this physical microenvironment contributed to an increased demand for new biomimetic systems that more accurately model physiological signals *in vitro*.

In this study we developed a semi-transparent membrane which is optimally adapted to the cultivation of adherent growing cells in a mechanically active environment. The membrane can be colonized on both sides and is porous to allow exchange of signaling molecules and nutrients. Interestingly, it can be used as a barrier for liquid / liquid and gas / liquid interfaces.

## EXPERIMENTAL METHODS

This elastic membrane is made from liquid medical-grade silicone and manufactured on a Mathis Labcoater in a thickness of about 100 microns. The silicone was vulcanized for 4 min at 180 °C. To generate a continuous pore system, PTFE was mixed into the polymer paste and the membrane was stretched after curing. By stretching the polymer tears off the filler, which results in pores with variable diameters. The proportion of the filler is 33 %. In order to promote adhesion of the cells, the membrane was coated with soluble collagen.

## RESULTS AND DISCUSSION

The membrane exhibited good mechanical properties. It has a high elasticity of > 600% and tear strength (> 1.5 N). Importantly, the material is cell compatible as observed in *in vitro* cytotoxicity testing and is tolerated by several different cell types.

The pores of the membrane vary between < 0.5 µm to 15 µm, wherein the filler particles appear in the center of the pores. A migration of cells through the membrane is thus prevented. A complete relaxation of the

membrane leads to the closing of the pores. The membrane must therefore be pre-stretched 1:3.

The cultivation of cells under mechanical strain was examined with the help of a stretching device. For this purpose, the silicone membrane was sterilized with heat, clamped in the device, coated with collagen and seeded with cells. After an incubation period of approximately 16 hours under static conditions, a pulsatile strain at a frequency of 1 Hz was applied.

Cells exhibited significant changes in cell size and shape as it has been described in various cell stretching devices in the literature<sup>1, 2</sup>.

At the moment the membrane is used to mimic the alveolar-capillary interface of a breathing lung. The data indicate that the membrane is suitable to develop biological inspired *in vitro* models.

## CONCLUSION

The successful cultivation of cells demonstrates the suitability of this membrane to generate mechanically active cell culture models.

## INTRODUCTION

Different approaches in osteoporosis treatments include the use of strontium ranelate (SrR), especially indicated in patients unable to tolerate other anti-osteoporotic drugs such as bisphosphonates. However, this treatment presents some long-term safety concerns associated with the risk of blood clots, myocardial infarction and other secondary effects including, disturbances in consciousness, seizures, liver inflammation and reduced number of blood cells<sup>1</sup> leading to severe restriction of the use of this drug by the European Medicines Agency's.<sup>2</sup> Since it is evident that the therapeutic action of SrR is dissociated from the ranelate moiety, we present an alternative compound strontium folate (SrFO) in which the performance of the strontium based drug to stimulate bone formation is enhanced and its capability of skeletal tissue regeneration improved by folate biofunctionality.<sup>3</sup>

## EXPERIMENTAL METHODS

SrFO salt was obtained from folic acid and strontium chloride solutions. Chemical composition of the compound prepared was determined by Mass spectroscopy (MS), elemental analysis (AS) and thermogravimetric analysis (TGA). Structure and coordination mode of folate were elucidated from X-ray diffractograms, infrared and UV-VIS spectroscopy whilst melting point was determined by differential scanning calorimetry (DSC). The same procedure was followed in order to synthesize the calcium based folate derivative (CaFO) as a negative control for *in vitro* tests due to the lack of bone anabolic activity of Ca ions. PEG based scaffolds containing SrFO were prepared and characterised. The *in vitro* behaviour of the folate derivatives were evaluated by standardized MTT and ALP activity assays using osteoblast cell lines (hOb) cultured in presence of SrFO and CaFO salts.

## RESULTS AND DISCUSSION

Pure SrFO and CaFO salts were successfully synthesized in high yield. Spectroscopic analysis indicated that folate crystallized stoichiometrically (1:1) in a bidentate chelating mode of coordination with both Sr and Ca divalent cations through the carboxylate COO<sup>-</sup> groups, presenting four molecules of water of crystallization and thus giving the molecular formulae of SrC<sub>19</sub>N<sub>7</sub>O<sub>10</sub>H<sub>25</sub> (SrFO•4H<sub>2</sub>O, Mw= 599.03 g/mol, Tm = 360 °C) and CaC<sub>19</sub>N<sub>7</sub>O<sub>10</sub>H<sub>25</sub> (CaFO•4H<sub>2</sub>O, Mw= 551.49 g/mol, Tm = 350 °C). Results also indicated that the formation of the folate derivatives do not exhibit the toxic effects related to free Sr<sup>2+</sup> or Ca<sup>2+</sup> ions whilst in the same range the strontium derivative showed an osteogenic activity as indicated by the overexpression of ALP activity.

## CONCLUSION

This study presents for the first time, the synthesis, characterization and the biological behaviour of new strontium folate salts showing evidence of desirable chemical and biological properties with potential as an anti-osteoporotic drug and alternative to the current ranelate based therapies.

### INTRODUCTION

One of the biomaterials used in veterinary dentistry is hydroxyapatite (HAp). It aids the biological process of bone reconstruction and provides the basis on which damaged tissues can be rebuilt. It is also exceptionally biocompatible and bioactive towards bone and other types of tissue. The aim of the present study was to verify the usefulness of hydroxyapatite microporous ceramics for the treatment of periodontal diseases and post-extraction defects. The above material was developed at the Faculty of Materials Science and Ceramics, University of Science and Metallurgy, Krakow, Poland.

### EXPERIMENTAL METHODS

The study was performed on 40 dogs treated at the Department and Clinic of Veterinary Surgery at the University of Life Sciences in Lublin. The dogs were qualified for the in vivo test :-+ 2 study groups and 2 control groups (K1, K2) were created. The first study group comprised 10 dogs diagnosed with moderate to severe gingivitis with 4-8 mm gingival pockets and mobility of mandibular incisors. In order to avoid extraction, hydroxyapatite implantation into the bone pockets was performed. The second study group comprised 10 dogs that required the extraction of mandibular fangs, following which, biomaterial was introduced into the post-extraction cavities. The composition of the control groups reflected that of the respective study groups but without the use of microporous hydroxyapatite.

### RESULTS AND DISCUSSION

In study group 1, considerably better reconstruction of periodontal tissues was observed when compared to the control group K1. The depth of gingival pockets was reduced by 3-4 mm, connective tissue attachment was restored and mobile teeth stabilised. In study group 2, significantly faster healing of bone cavities was stated when compared to the respective control group K2. Moreover, 80% of group K2 patients developed oronasal fistulas while no such cases were observed in the study group.

### CONCLUSION

The study confirmed the validity of using microporous hydroxyapatite granules and shaped blocks in reconstructive periodontal treatment as well as prevention of oronasal fistulas after fang extraction and facilitation of the post-extraction healing process.

## Bone Substitute from Mineralized Phosphate Prestructured Gelatine – Cell Culture and Mechanical Characterization

Benjamin Kruppke, Christiane Heinemann, Jana Farack, Hartmut Worch, Thomas Hanke

Max Bergmann Center of Biomaterials, Institute of Materials Science, Technische Universität Dresden, Germany, [thomas.hanke@tu-dresden.de](mailto:thomas.hanke@tu-dresden.de)

### INTRODUCTION

Bone substitute materials made from mineralized organic molecules are subject of recent research. The restricted mineralization processes through integration of organic molecules is used as an *in vitro* mimic of natural processes. Gelatine is a partial derivative of collagen and is assumed to be able to restrict mineral formation itself. Therefore, prestructuring of gelatine with phosphate ions and the following mineralization process initiated by adding calcium ions was investigated regarding dental repair material by Kollmann *et al.*<sup>1</sup>. Its transformation to bone substitute materials demands a close look on cellular responses of bone cells. This response was investigated by human mesenchymal stem cell (hMSC) monoculture as well as hMSC and monocyte coculture.

### EXPERIMENTAL METHODS

**Preparation.** Mineralization was performed as batch process. First, phosphate-prestructured (PPS) gelatine was produced. For this, a 6 % w/w gelatine suspension was mixed with 0.1 M Na<sub>2</sub>HPO<sub>4</sub> solution in a volume ratio of 3:17. PPS-suspension was adjusted to pH 7.0. The mineralization solutions (1 M) – CaCl<sub>2</sub>·2H<sub>2</sub>O or SrCl<sub>2</sub>·6H<sub>2</sub>O at pH 7.0 – were added to PPS-suspensions at a rate of 2.5 mL/min. During the entire precipitation process, it has been stirred at 300 rpm. Thereafter, the milky suspension was centrifuged and lyophilized. Finally, the pellets were pulverized by a mixer mill. Precipitates were named PPGC and PPGS for phosphate-prestructured gelatine mineralized with calcium and strontium, respectively. The mineral was compacted with uniaxial compression testing machine (Instron 5566, Darmstadt) with a maximum load of 10 kN (100 mg, o. d. 5 mm, 510 MPa). Selected samples were cross-linked by incubation in 100 mM EDC and 50 mM NHS in 80 vol% ethanol. All samples were sterilized with gamma radiation (25 kGy).

**Characterization.** Mineral precipitates were investigated using X-ray diffraction (XRD), infrared spectroscopy (FTIR) as well as scanning electron microscopy (SEM). Mechanical properties were analysed by ball-on-three-balls test and brazilian test.<sup>2</sup> For that, 400 mg and 100 mg mineral were compressed (510 MPa) to disks of 13 mm or 5 mm diameter and 1.5 mm height. Degradation was determined by static incubation of samples in both simulated body fluid (SBF) and phosphate buffered saline (PBS). During degradation, pH and calcium ion concentrations were determined.

Cell culture experiments were performed with hMSC and human monocytes. hMSC monoculture was performed on non-cross-linked PPGC and PPGS samples over 28 days and compared to polystyrene control. Material and control was cultivated with and without CaCl<sub>2</sub> within the cell culture medium as well as with and without osteogenic additives.

Coculture of hMSC and monocytes was performed on cross linked samples. First, cultivation of hMSCs with and without osteoblast induction were cultivated on samples over 10 days. Monocytes were added to differentiated hMSCs without any additives promoting osteoclastic differentiation according to Heinemann *et al.*<sup>3</sup> Phenotype characterization was performed by biochemical methods (DNA, LDH, ALP, TRAP 5b), light microscopy, confocal laser scanning microscopy, and SEM. Statistical analysis was performed using one-way ANOVA.

### RESULTS AND DISCUSSION

PPGC appears to be brushite and monetite regarding its crystal structure with a platelet morphology. PPGS in contrast has spherical morphology and has a comparable FTIR spectrum to PPGC. Degradation of 4 – 8 weight% during 21 days *in vitro* without cells is an adequate rate. hMSC in monoculture showed a low adhesion, but a high proliferation reaching cell numbers of the control after 28 days. Coculture as well showed a restrained response of hMSCs but revealed an osteoclastic differentiation of monocytes without additives like RANKL or M-CSF during cultivation on PPGC.

### CONCLUSION

In contrast to hydroxyapatite (HAp) with its well known high calcium binding capacity – inhibiting osteoblastic activity – PPGC showed promising properties as loadable material. Additionally its time dependent degradation allows bone remodelling under release of physiological degradation products. For bone regeneration the question arises, which cell type is preferred to seed on degradable / resorbable materials. Induction of an osteoclastic response, leading to an active resorption of the material seems to be favourable for the integration of bone substitutes in remodelling processes.

<sup>2</sup>Faculty of Chemical and Process Engineering, Warsaw University of Technology, Poland  
[mitek.tomasz@gmail.com](mailto:mitek.tomasz@gmail.com)

### INTRODUCTION

Intramedullary nailing is a standard treatment for patients with long bone shaft fractures. It a very effective way of treatment, that has currently become a gold standard in this type of fractures. Main advantages of the method are: minimal operative approach, limited tissue trauma and good stability of fracture fixation.

Currently all intramedullary fixation devices are made of metal alloy containing: iron, titanium, cobalt, carbon, nickel, vanadium, chrome, molybdenum. Major flaw of those devises is a need to remove implanted material after about a year. This means another surgical procedure for the patient and additional cost of the therapy.

### EXPERIMENTAL METHODS

20-24 sample implants were created in 6 different solutions series (summary of 132 samples). Half of the samples underwent crosslinking.

In each of the series, crosslinked and not, 4 to 6 implants were degraded and the rest used for bending test analysis and SEM investigation. Alterations in mass, length and diameter of the samples were measured in manufacturing process.

### RESULTS AND DISCUSSION

The diameter of implants in drying process altered 60-67%. There was a tendency toward lower alteration of implant diameter in drying process as the amount of ceramic material addition grew. After cross-linking reaction there is a noticeable reduction of diameter.

There was also no significant differences in length in non-ceramic samples compared to samples with addition of hydroxyapatite forming salt. Cross-linking process did not affect the swelling capacity of samples.

During the seven week degradation process, the length of implants remained stable, with only 1-2% alteration from the initial value.

The analysis of degradation process showed that the change in implant length did not depend on cross-linking.

### CONCLUSION

The results of conducted durability study allow us to state that cross-linking process improved mechanical properties of implants with in situ precipitated ceramic material without affecting mechanical properties of implants without ceramic addition.

It would be beneficial to evaluate the influence of order and pace of adding salt to chitosan solution. Further studies should also focus on producing implant of appropriate dimensions and proving the degradation process on animal model.

Implants tested in this study were characterized by good stability of in vivo degradation and satisfactory mechanical properties. The results of sample testing allow us to plan and develop a biodegradable bone implant.

## INTRODUCTION

Chitosan, a derivative of chitin, the main organic component of the exoskeletons of many marine invertebrates, is a popular biomaterial well known for its cyto- and biocompatibility, antioxidant and antibacterial activity, and its processability into porous scaffolds. Porosity is desirable to facilitate cell and tissue ingrowth. Biomaterials for bone contact should also be bioactive, i.e. capable of forming a direct chemical bond with bone, and also support adhesion and proliferation of bone-forming cells.

In this study, porous chitosan scaffolds were fabricated by a freeze-drying process and subsequently mineralized with calcium carbonate (CaCO<sub>3</sub>) to form composites combining the advantages of the organic and inorganic components. CaCO<sub>3</sub> is the main organic component of many marine invertebrate exoskeletons, hence this approach can be considered to be biomimetic. CaCO<sub>3</sub> has been widely used as a material for bone regeneration and it has performed comparably to the more commonly used materials based on calcium phosphate (CaP). Mineralization with CaCO<sub>3</sub> was expected to lead to mechanical reinforcement with the aim of improving surgical handling and promoting osteogenic differentiation of bone-forming cells. Furthermore, the presence of CaCO<sub>3</sub> is expected to promote bioactivity and adhesion of bone-forming cells. In comparison to pure CaCO<sub>3</sub>, the chitosan-CaCO<sub>3</sub> composites were not expected to be brittle.

Porous scaffolds were fabricated from three different chitosan preparations of varying molecular weight (MW) (low, medium, high) to compare the effect of MW on mineralizability. Mineralization was achieved by alternate soaking of scaffolds in solutions containing calcium and carbonate ions.

## EXPERIMENTAL METHODS

Chitosan of MW 50-190 kD (Low), 190-310 kD (Medium) and > 310 kD (High) were obtained from Sigma-Aldrich. Chitosan was dissolved at 2% (w/v) in 1% (v/v) acetic acid. The solution was frozen at -20° C overnight and lyophilized for 24 h to produce porous scaffolds. Scaffolds were immersed alternately for 10 minutes in 0.333 M CaCl<sub>2</sub> and 0.333 M Na<sub>2</sub>CO<sub>3</sub> solutions. After three alternate soaking cycles, scaffolds were immersed for 24 h in ddH<sub>2</sub>O, weighed, freeze-dried for 24 h and reweighed. Dry mass percentage, i.e. (mass after lyophilization/mass before lyophilization) x 100% served as a measure of mineral formed. Morphology and physicochemical analysis was performed using SEM and ATR-FTIR.

## RESULTS AND DISCUSSION

Calculation of dry mass percentage (Figure 1) revealed that significantly higher amounts of CaCO<sub>3</sub> formed in

scaffolds consisting of high and medium MW chitosan than in low MW chitosan scaffolds. The reasons for this remain unclear at present, however it can be speculated that the medium and MW preparations have a higher affinity for calcium ions.

Figure 1: Dry mass percentages after mineralization

Figure 2: SEM images of medium MW chitosan scaffold mineralized with CaCO<sub>3</sub>. Scale bar: 50 µm (left), 5 µm (right)

Figure 3: ATR-FTIR spectra. C: band indicating calcite. Calcite, the thermodynamically most stable polymorph of CaCO<sub>3</sub>, was detected in all three chitosan scaffold types. This was confirmed by SEM analysis, which revealed rectangular crystals of calcite homogeneously distributed throughout the scaffold (Figure 2). ATR-FTIR analysis (Figure 3) also proved the presence of calcite. Mechanical strength increased markedly after mineralization. No brittleness was observed.

## CONCLUSION

Mineralization of chitosan scaffolds of different MW with CaCO<sub>3</sub> revealed that extent of mineralization was dependent on MW. These results pave the way for *in vitro* and *in vivo* biological testing

### INTRODUCTION

Boron (B) is a notable trace element in human which has stimulating potential on osteogenesis. Recent findings indicate that dietary boron intake has beneficial effect on  $\text{Ca}^{2+}$  metabolism and thus B affects bone calcification and maintenance [1]. The mineral phase of bone is termed biological apatites which contain significant amounts of various ions such as  $\text{Mg}^{2+}$ ,  $\text{Na}^+$ ,  $\text{Zn}^{2+}$ ,  $\text{F}^-$  and  $\text{Cl}^-$ . Until now, a number of methods such as wet precipitation, hydrothermal and sol-gel synthesis have been developed for the preparation of hydroxyapatite (HAp) and ion-doped HAp in a powder form [2]. In addition, there are very few studies in which B was doped into HAp chemically [3]. The aim of this study is to produce boron doped HAp (B-HAp), using biomimetic method supported by different microwave energies.

### EXPERIMENTAL METHODS

To prepare B-HAp, different amounts of boric acid was added into 10xSBF (simulated body fluid) like solution [4] and pH was adjusted to obtain proper pH value for precipitation. In our previous study, we prepared bone-like HAp precipitated by microwave energy [5]. B-HAp was produced by means of interaction of ions within the boron containing 10xSBF (B-SBF) under microwave energy (Milestone Start, Italy). Characterizations of B-HAp and HAp were carried out by SEM, TEM, ATR-FTIR, ICP-OES, Raman, XRD and elemental analysis.

### RESULTS AND DISCUSSION

B-HAp was precipitated from B-SBF containing 10 mg/mL boric acid ( $\text{H}_3\text{BO}_3$ ) by 600 W microwave power. ICP-OES results demonstrated that B-HAp has  $1.15 \pm 0.11$  % (w/w) B, 1.40 (w/w) Ca/P ratio and  $4.30 \pm 0.07$  % (w/w) carbonate content. In Raman spectrum, the strongest line situated at  $961 \text{ cm}^{-1}$  is attributed to the symmetric stretching  $\nu_1$  mode of  $\text{PO}_4^{3-}$ , the bands at  $429 \text{ cm}^{-1}$  and  $591 \text{ cm}^{-1}$  correspond to the  $\nu_2$  bending vibration and  $\nu_4$  mode of the  $\text{PO}_4^{3-}$  group. In the spectrum of B-HAp, an additional weak peak at  $\sim 910 \text{ cm}^{-1}$  has been assigned to the symmetric stretching  $\nu_1$  mode of the  $\text{BO}_3^{3-}$  groups (Fig.1).

**Fig.1.** Raman spectrum of HAp and B-HAp. Black and red arrows indicate the phosphate and borate groups, respectively.

SEM images of HAp and B-HAp powders are illustrated in Fig. 2. They demonstrate many agglomerations of small spherical particles in nano-scale. Their bulk structure were found similar in size and morphology.

**Fig.2.** SEM images of HAp (a and b) and B-HAp (c and d) particles. b and d are ten times bigger than that of a and c, respectively.

### CONCLUSION

In this study, incorporation of B into hydroxyapatite structure using biomimetic method was achieved by means of microwave irradiation.

In conclusion, B-HAp could be a powerful biomaterial to improve regeneration of bone with synergetic effect of boron and hydroxyapatite for bone tissue engineering.

A dynamic distance-based criterion search was used to identify lysine and arginine residues within 5 Å of each other within a tropocollagen. Fully atomistic MD simulations, exploiting the D-band periodicity to replicate the dense fibrillar environment, were then conducted under pseudo physiological conditions in AMBER12.<sup>5,6</sup> A site is a likely candidate for glucosepane formation if the total energy of the tropocollagen molecule is lower in the presence of a bound glucosepane cross-link compared to an unbound glucose molecule. Using the candidate cell and matrix interaction domains map of the collagen fibril produced by Sweeney *et al.*,<sup>7</sup> we then transpose our favourable cross-link positions to determine the biological impact of their presence. Constant velocity steered MD simulations were then conducted to calculate changes in the elastic property of collagen.

Of the 24 positions identified based on the distance criteria, only six were found to be energetically favourable (exothermic binding enthalpies) compared to the unbound glucose collagen model. The local environment around the site has a significant effect on the energetics, with the sites within the gap region being more likely to have favourable formation enthalpies (Figure 1). A number of favourable sites may result in potentially huge implications on the biological function of collagen, as they are within sites where key collagen-biomolecule and collagen-cell interactions occur. For example, the formation of glucosepane was found to be energetically favourable within close proximity of the Matrix Metalloproteinase-1 (MMP1) binding site, which could potentially disrupt collagen degradation. Finally the Young's modulus was also found to change as a result of the presence of the cross-link.

Figure 1. Shows a tropocollagen molecule with A. gap regions highlighted in orange, B. the favourable (green) and unfavourable (red) potential cross-linking sites.

Our 3-dimensional collagen fibril model has identified six likely sites for glucosepane formation within tropocollagen. The positioning of these sites is likely to have a significant effect on tissue function and integrity.

### INTRODUCTION

Poly(butylene succinate) (PBSu), a novel biodegradable aliphatic polyester with excellent processability, is a promising substance for bone and cartilage repair. However, it typically suffers from insufficient bioactivity after implantation into the human body and low mechanical properties, which reduce its application possibilities. Bioactive ceramics include hydroxyapatite (HA), fluorapatite, bioactive glass (BG), and tricalcium phosphate can be either bioactive or bioinert, as they positively affect new bone growth inhibiting resorption and enhancing bone formation<sup>1</sup>. So, in order to overcome this problem, micro-sized bioglass (mBG) or nano-sized hydroxyapatite (nHA) were synthesized and introduced into the polyester via *in situ* polymerization. Regenerative Medicine in orthopedics focuses on research in a wide variety of applications, including bone and cartilage. Biocompatible scaffolds play a key role in successful bone and cartilage regeneration. Cytotoxicity, stability, cell adhesion, proliferation and spreading are factors that influence effectively the use of scaffolds in regenerative medicine applications.

### EXPERIMENTAL METHODS

In this work, indigenous synthetic nano-HA and micro-BG, were developed in the laboratory. Afterwards, PBSu nanocomposites containing 2.5wt% (mBG), 2.5wt% (nHA) and 2.5wt% mBG-nHA were prepared by *in situ* polymerization technique for the first time. We then examine their ability as potential tissue engineering scaffolds. The composites scaffolds were characterized using GPC, SEM, FTIR and XRD. Mechanical testing (Instron 3344) and contact angle measurements were also carried out. Additionally, enzymatic degradation in an aqueous solution containing a mixture of *R. Oryzae* and *P. Cepacia* lipases at 37°C and pH=7.2 and the *in vitro* biomineralization in simulated body fluid (SBF) were studied. Biocompatibility of the composites was assessed using human Mesenchymal stem cells collected by enzymatic digestion of Wharton's Jelly and cultured in osteogenic medium for 28 days. Cell proliferation on the scaffolds was evaluated using fluoresce microscopy. Furthermore MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay was used in order to assess viability of cells on the scaffolds. Finally the morphology of cells on the scaffolds was evaluated by SEM, TEM and photonic microscopy.

### RESULTS AND DISCUSSION

The presence of the bioceramics in the polymerization mixture, affected the reaction, leading to decrease of the final molecular weight (Mw) of the synthesized polymers. Probably extended reactions took place and branched and/or cross-linked macromolecules were formed, due to the surface hydroxyl groups of the filler, which can act as a multifunctional agent, leading to a partially reduction of Mw<sup>2</sup>. Concerning the tensile test it was proved that the presence of the inorganic fillers in the PBSu matrix led to deterioration of its mechanical properties. This decrease could be attributed not only to very low Mw but also, to the absence of any interaction between the bioceramic and the polyester matrix, as was verified from FTIR spectroscopy and thus the adhesion between the different materials is too low. Additionally, enzymatic hydrolysis revealed that all nanocomposites have higher hydrolysis rates than neat PBSu. The presence of hydroxyl groups in HA makes the nanocomposites more hydrophilic than neat PBSu and hence they absorb more water and subsequently degrade more rapidly. XRD study after biomineralization in SBF indicated the appearance of a crystalline phase of hydroxyapatite. In addition to apatite formation enhancement, both bioceramics can induce osteoblast compatibility. The composites have rougher and more hydrophilic surfaces compared to pristine PBS, thereby causing more osteoblasts to adhere and proliferate on them<sup>1</sup>.

### CONCLUSION

PBSu nanocomposites containing 2.5wt% of (mBG), (nHA) or mBG-nHA were prepared and studied as potential materials for tissue engineering applications. Mechanical properties aggravated for all the composite samples, mainly due to decreased Mw as was verified by GPC analysis. It was also found that nanoadditives can accelerate the enzymatic hydrolysis of PBSu increasing hydrophilicity. Both (mBG) and (nHA) can transform the bioinert PBSu surface into a bioactive one, promoting hydroxyapatite formation in SBF solution. Cell biology studies showed that PBS/(mBG)/(nHA) are biocompatible materials.

## INTRODUCTION

In recent years, the clinical demand for bone grafts is extremely large across the population. However, the limited volume of bone grafts and frequent morbidity of patients leads to the need for development of advanced therapeutic strategies for bone regeneration<sup>1,2,3</sup>. The aim of the present work is to study the behavior of pre-osteoblastic MC3T3-E1 cells in a microfluidic system that allows continuous and homogenous feeding of cells, as well as, study of dynamic culture with the use of different biomaterials (gelatin film and collagen fiber networks) inside the microfluidic system.

## EXPERIMENTAL METHODS

### Microfluidic system

The microfluidic system is composed of a pressure pump (Figure 1A) connected with a precisely controlled flow sensor (B) and a chamber (C) including the microfluidic devices. The microfluidic devices are composed of a glass base chip for the cell layer (D) and PMMA chips with PDMS gaskets for loading cells (E) and for flowing fluids across the cells (F).

Figure 1: Illustration of the microfluidic system

### Preparation of gelatin films

A 2% w/v gelatin solution was used for coating the glass base chip of the microfluidic system and dried for 2 hours before seeding the cells.

### Preparation of collagen fiber networks

For the generation of collagen fiber networks, a 3 mg/ml collagen solution was used for the chip coating. Gelation was performed by incubating the collagen solution for 48 hours at 4 °C for thick fibers. Thereafter, collagen gel dried for 3 hours, washed with water and PBS and was completely immersed with culture medium overnight in a CO<sub>2</sub> incubator before seeding the cells.

### Cell culture

8x10<sup>4</sup> pre-osteoblastic cells were cultured on the chip of the microfluidic system and investigated under static and flow conditions with flow rates of 30 and 50 µl/min.

### Osteogenic markers response of MC3T3-E1 cells

We determined the alkaline phosphatase (ALP) activity, and the total soluble collagen contents in the culture medium using an enzymatic activity assay and a modified Sirius red assay, respectively.

## RESULTS AND DISCUSSION

The pre-osteoblastic cells strongly attach and show an osteogenic response inside the microfluidic system. Additionally, we observed that under flow conditions cells appear to be oriented along the direction of flow, whereas cells depict a random orientation under static conditions (Figure 2). The ALP activity was similar between static and flow conditions when using gelatin as a substrate for the cells. Interestingly, when we used collagen fiber networks as a substrate, the ALP activity was higher in dynamic cultures under both flow rates of 30 and 50 µl/min compared to statics. Finally, when gelatin was used as a substrate, the collagen produced in the extracellular matrix under a flow rate of 30 µl/min was significantly higher compared to static conditions, with a remarkably significant increase when applying the flow rate of 50 µl/min.

Figure 2: Morphology of MC3T3-E1 cells inside the microfluidic system under static conditions (A), and under flow conditions applying 30 (B), and 50 µl/min (C) using optical microscopy

## CONCLUSION

Our findings are promising for the cell growth and the osteogenic response of pre-osteoblastic cells demonstrating the potential of using microfluidic systems in bone tissue regeneration applications.

## INTRODUCTION

Porosity is a morphological feature which plays a significant role in new bone generation when bone graft materials are used for filling small or extended bone defects<sup>1</sup>.

Calcium phosphate bone cements (CPBCs) are bone graft materials formed by mixing a powder with a liquid phase. Usually the powder component is  $\alpha$ -TCP whereas the liquid is a sodium phosphate solution. The final product (hardened cement) is composed of calcium deficient apatite. Synthetic hydroxyapatite (HA), a material similar to the basic constituent of bone, has been extensively used in bone tissue regeneration.

The purpose of the present work was to study the effect of HA addition in the initial cement paste on the porosity and pore characteristic of pure and HA reinforced composite CPBCs cements.

## EXPERIMENTAL METHODS

Pure HAP crystals in the form of nanoneedles was prepared by precipitation from aqueous solution using  $\text{CaCl}_2$  0.5M and  $\text{NH}_4\text{H}_2\text{PO}_4$  0.3M as reactants at 70 °C. The pH of the suspension was kept at 9-10 by the addition of concentrated  $\text{NH}_3$ . Preparation of  $\alpha$ -TCP powder, cement setting and hardening was performed using the procedures described elsewhere with slight modifications [2]. Four different CPBCs formulations were prepared: pure  $\alpha$ -TCP cements and cements containing 3, 10 and 20 % HA in the initial paste. X-ray microtomography ( $\mu$ CT) was used to visualize and to quantify pore's size and micro architecture.

The internal microporosity was determined using a  $\mu$ CT equipment (Skyscan 1072), with standard X-ray emission source, where the sample was placed on a rotating base. Images were received with 1024x1024 pixels analysis. Cross-sections ranged between 200-400 in 180 and 360 rotating angle. The following formulations were tested:  $\alpha$ -TCP (control),  $\alpha$ -TCP+HA3%,  $\alpha$ -TCP+HA10%, and  $\alpha$ -TCP + HA20%, expecting to report pore sizes over 80  $\mu\text{m}$ , that are recommended to accelerate and to improve the long in growth within the ceramic<sup>1</sup>. Two cylindrical samples (6mm in diameter and 10mm in height) for each formulation were examined. Five cross-sections, in equal distances, along the sample were received in order to define the mean range of the samples' pore size. The sections were reconstructed in order to determine their inter-connectivity.

## RESULTS AND DISCUSSION

Indicative images ( $\alpha$ -TCP + HAP3%) of microporosity using  $\mu$ CT are presented in Fig 1:

Fig. 1a

Fig. 1b

Fig.1. Cross-sectional (a) and interconnective (b) microporosity

The percentage porosity is as follows: 1.  $\alpha$ -TCP: 17,20%, 2.  $\alpha$ -TCP+HA3%: 34,80%, 3.  $\alpha$ -TCP+HA10%: 40,30%, 4.  $\alpha$ -TCP + HA20%: 44,40%.

Mean range of the pore size for each sample is between 1.  $\alpha$ -TCP: 20 $\mu\text{m}$ -120 $\mu\text{m}$ , 2.  $\alpha$ -TCP+HA3%: 90 $\mu\text{m}$ -150 $\mu\text{m}$ , 3.  $\alpha$ -TCP+HA10%: 150 $\mu\text{m}$ -490  $\mu\text{m}$ , 4.  $\alpha$ -TCP + HA20%: 230 $\mu\text{m}$  -990  $\mu\text{m}$ .

In oral surgery  $\alpha$ -TCP and HA are useful alternative bone graft substitutes to biologic (autografts etc) and natural materials.  $\alpha$ -TCP cement is more soluble and allows for a larger new bone formation area compared to  $\beta$ -TCP granules<sup>2</sup>. Research data for  $\beta$ -TCP grafts report that recommended pore size >80 $\mu\text{m}$  and optimum interconnection size is >80 $\mu\text{m}$  and <150 $\mu\text{m}$ <sup>1</sup>. The pores' inter-connectivity of the sample was neither homogeneous nor satisfactory.

## CONCLUSION

The majority of pores were larger than 80 $\mu\text{m}$ , but there was lack of pore size homogeneity. Although the percentage of samples' porosity was satisfactory, the pores' inter-connectivity was not. Increasing HA portion increases both the percentage porosity and the mean pore size.

## INTRODUCTION

Calcium phosphate cement (CPC) is widely utilized for various clinical applications, such as in bone-substitution materials. The objective of this study was to develop a new CPC with fine injectability, short setting-time, and high strength, and to expand the applications of CPC. Here, we investigated the effect of powder/liquid (P/L) ratio on the properties of CPC.

## EXPERIMENTAL METHODS

$\beta$ -tricalcium phosphate (control TCP; c $\beta$ -TCP) powder was mechano-chemically modified by ball-milling. After milling for 24 h (modified TCP; m $\beta$ -TCP), the powder was mixed with  $\text{CaCl}_2$  solution, and then  $\text{NaH}_2\text{PO}_4$  solution at a P/L ratio of 4:1:1 (R2) or 5:1:1 (R2.5). The P/L ratio for the non-milled c $\beta$ -TCP powder was R2. The mechanical properties of the set cement were measured using the compression strength (CS) test and the diametral tensile strength (DTS) test. The dimensions of the specimens for the CS test were 6 mm in height and 3 mm in diameter, and those for the DTS test were 4 mm in height and 6 mm in diameter. To investigate the initial strength of the cement, CS was measured from 1 to 5 h after mixing. The cement paste was stored for setting in an incubator at 37°C for 14 d, with CS testing at various time points. Fracture surfaces of the specimens stored for 14 d after the DTS test were observed by scanning electron microscopy (SEM).

## RESULTS AND DISCUSSION

The initial CS values from 1 to 5 h after mixing are shown in Fig. 1. The strength of c $\beta$ -TCP cement increased slightly at 3 h after mixing, but showed saturation at 4 h after mixing. m $\beta$ -TCP (R2 and R2.5) cements analysed for more than 1 h after mixing were durable for the tests. The CS of R2 cement increased slightly up to 3 h after mixing, and then increased more substantially between 3 and 4 h after mixing. The CS increased slightly between 4 and 5 h after mixing. R2.5 cement demonstrated significantly higher CS at 1 h after mixing compared to R2 and c $\beta$ -TCP cement. The CS of R2.5 cement continued to increase up to 5 h after mixing. The concomitant acceleration of CS with an increase in setting time might be due to the high dissolution rate of m $\beta$ -TCP powder.

Fig. 2 shows the effect of storage time after mixing on CS in c $\beta$ -TCP and m $\beta$ -TCP cements. R2 and R2.5 cement showed similar CS after 1 d of storage. After 3 d of storage, the CS of R2.5 cement was of higher average value than that of R2 cement. The CS of R2.5 cement showed saturation at more than 3 d of storage, while the CS of R2 cement continued to increase up to 14 d.

Morphology of the fracture surfaces after the DTS test of c $\beta$ -TCP and m $\beta$ -TCP (R2 and R2.5) conducted 14 d after mixing are shown in Fig. 3. Numerous needle-like crystals were observed on the surface of c $\beta$ -TCP, and several pores were observed among the granular structures that resembled urchins. The m $\beta$ -TCP (R2.5) exhibited more clear crystal growth among agglomerate grains than did R2.

Fig. 1 Initial compression strength of cement

Fig. 2 Compression strength of cements after mixing according to storage time

Fig. 3 DTS fracture surfaces of cements 14 d after mixing

## CONCLUSION

These results suggest that the mechano-chemically modified  $\beta$ -TCP powder dissolved rapidly and accelerated hydroxyapatite precipitation, which successfully shortened the cement setting time. Moreover, the m $\beta$ -TCP cement in this study had greater strength at a higher P/L ratio.

## INTRODUCTION

Hydrogels are promising materials for cell-based cartilage repair, as they provide encapsulated cells with a 3D environment that can stimulate differentiation and tissue formation.<sup>1</sup> However, as their mechanical properties are by far inferior to native cartilage tissue, new strategies are required for the reinforcement of hydrogels without compromising chondrocyte performance. Here, we studied the reinforcement of cell-laden gelatine-methacrylamide (gelMA) gels by thermal ageing prior to UV-crosslinking.

## EXPERIMENTAL METHODS

Gelatine was methacrylamide-functionalised as reported previously.<sup>1</sup> Solutions of 10% or 20% gelMA + 0.1 % Irgacure 2959 photo-initiator were crosslinked into gels by exposure to 15 min UV-A, either in the sol state or after thermal ageing at 20 or 5°C. Compressive moduli were measured after 24 h free swelling at 37°C. Chondrocytes were isolated equine articular cartilage and passaged once before encapsulation in gels at 5·10<sup>6</sup> cells/mL under the same conditions as described above. After 24 h, live/dead and Alamar blue assays were performed. Constructs prepared from 10% gelMA gels thermally aged for 3 h were cultured in chondrogenic medium for 6 weeks, then assayed for DNA and glycosaminoglycan (GAG) content using Picogreen and DMMB, respectively.

## RESULTS AND DISCUSSION

After photo-crosslinking, 10% gelMA gels crosslinked from the sol state had a stiffness of 54 kPa. On the contrary, when thermally aged, the stiffness increased up to 235 kPa after photo-crosslinking, reaching similar values as the 20% gelMA gels crosslinked from the sol state (Figure 1).

**Figure 1:** Stiffness development in 10% gelMA hydrogels upon thermal ageing at 20 or 5°C prior to UV-crosslinking. The lower and upper lines represent the compressive modulus of 10% and 20% sol UV-crosslinked gels, respectively.

Encapsulated chondrocytes showed a ~40% reduction in metabolic activity, 24 h after 1-6 hr thermal ageing (Figure 2), however cell viability was not affected (~85%).

**Figure 2:** Metabolic activity of chondrocytes 24 h after encapsulation, as a function of thermal ageing time prior to UV-crosslinking.

After 6 weeks of culture, overall GAG production was increased in the 10% thermal aged gels compared to both 10% and 20% sol gels (Figure 3 left). This could be explained by the increased proliferation of chondrocytes in this condition, as GAG/DNA was similar for all conditions evaluated.

**Figure 3:** GAG production in chondrocyte-laden gelMA gels crosslinked from the sol state or after thermal ageing.

Hydrogels that allow cells to develop new tissue are generally mechanically weak. Here, we present a straightforward method for the reinforcement of cell-laden gelMA gels, which showed both four-fold increase in stiffness and an increased overall GAG production.

## CONCLUSION

Thermal ageing of gelatine-methacrylamide gels prior to UV-initiated crosslinking leads to a fourfold increase in compressive stiffness, while encapsulated chondrocytes remain viable and show proliferation and increased GAG production upon culture.

### INTRODUCTION

Materials for bone tissue engineering should guide and promote the regeneration of bone tissue. Various biocompatible and biodegradable porous scaffolds have been recently designed, with the aim to provide a temporary substitute which mimics bone extracellular matrix structure. Several materials have been recently suggested in the literature as promising candidates, including bioceramics, bioglasses, and hydroxyapatite particles embedded in polymeric scaffolds. Nevertheless, synthetic scaffolds still display many limitations, boosting the search for materials integrating both osteoconductive and osteoinductive properties<sup>1,2</sup>. In this study we formulated and evaluated the in vitro cytotoxicity of a nanocomposite biomaterial for bone regeneration that integrates the structural properties of Halloysite nanotubes (HNT) and the bioactivity of strontium (Sr(II)) included into a biocompatible and biodegradable 3-polyhydroxybutyrate-co-3-hydroxyvalerate (PHBV) matrix.

### EXPERIMENTAL METHODS

HNT powder (Imerys Minerals Ltd; Auckland, New Zealand) was functionalized with a solution of APTES in ethanol (2.5 %wt). The APTES amount was chosen to cover about 20% of the HNT external surface. To upload Sr(II), 100 mg of HNTs were mixed with 10 ml of a 100 mg/ml SrCl<sub>2</sub>·6H<sub>2</sub>O solution. The dispersion was vigorously mixed for 24 h and then centrifuged. The solid was recollected, dried, and then used for the subsequent preparation of the nanocomposites. HNT dispersions were spin coated by means of a P6700 spin coater (Speciality Coating Systems Inc.) onto the glass previously functionalized with APTES, and then a PHBV chloroform solution (2% wt) was spin coated on top of it. The coating process was carried out at r. t. in two stages at constant rotating speed (1500 and 2500 rpm), separated by an acceleration step. The composite morphology was evaluated after degradation in PBS at 37°C for 28 days by SEM microscopy. The retained amount of loaded Sr(II) in HNT-Sr and HNT-Sr-PHBV was evaluated by inductively coupled plasma-atomic emission spectroscopy. For cytotoxicity evaluation, nanocomposite samples were grinded and suspended in distilled water by a Ultra-Turrax® T25 Basic mechanical homogenizer. L929 fibroblasts (4x10<sup>3</sup> cell/well) were incubated with HNT, HNT-Sr, HNT-PHBV and HNT-Sr-PHBV sample solutions (25, 50 and 100 µg/mL) and cell viability was evaluated by MTT and Trypan blue assay after 72 h of incubation, while cell proliferation by BrdU assay at 48 h.

### RESULTS AND DISCUSSION

SEM image (Fig. 1) of the degraded composite evidenced a random bulk erosion process with an increase of exposed HNT respect the control sample, where HNT was almost completely embedded in PHBV matrix.

**Figure 1.** SEM image of the nanocomposite A) freshly prepared; B) degraded for 28 days.

The value of retained amount of loaded Sr(II) was similar in HNT-Sr and HNT-Sr-PHBV samples (~ 60% Sr(II) after 28 days) indicating that PHBV did not affect the release of Sr(II) and simply modulated the exposure of HNT to the surrounding medium.

The cytotoxicity and proliferation assays showed a cell viability (>80%) and proliferation (similar to control) of the cells incubated with HNT, HNT-PHBV and HNT-Sr-PHBV at all concentrations, indicating high biocompatibility of HNT, HNT-PHBV and HNT-Sr-PHBV up to 100 µg/mL. However, the HNT-Sr induces a significant viability reduction and proliferation already at 25 µg/mL, suggesting the need for a barrier to modulate its interaction with cells.

### CONCLUSION

In this study we demonstrated the possibility to use a combination of Halloysite nanotubes and PHBV biopolymer for drug delivery of Sr(II). Furthermore, we have prepared for the first time a HNT-PHBV composite capable of effectively uploading and carrying high doses of Sr(II) with a low cytotoxicity modulated by PHBV coating.

### INTRODUCTION

Biodegradable metallic materials for medical applications have received considerable attention in recent years. The reason is that they provide high potential for fabrication of temporal orthopaedic implants such as bone fixation devices and scaffolds. Magnesium (Mg) is an excellent candidate for biodegradable implants due to its biocompatibility and relevance for biological body functions. Unfortunately, the high Mg degradation rate limits its application in medicine. Apart from necessity of decrease in corrosion rate of Mg, there is need of a robust, reproducible, accurate technique for quantification of *in vitro* and *in vivo* Mg biodegradation and also for evaluation of the effect of various surface treatments, performed to decrease its degradation rate. This research is focused on demonstration of X-ray computed microtomography ( $\mu$ CT) as a non-destructive, quantitative and multi-analytical characterization technique to assess the corrosion progress of high-purity-Mg (HP-Mg). The efficacy of the  $\mu$ CT was compared with that of conventional analytical methods which are commonly used for evaluation of Mg degradation.

### EXPERIMENTAL METHODS

HP-Mg (99.9 %, Goodfellow) discs (D = 15 mm, h = 5 mm), cut from an extruded bar, were used in this study. While the surfaces perpendicular to the disc axe were polished up to #1000 sand paper, the disc edge was tested as supplied. The corrosion behaviour of HP-Mg under simulated physiological conditions was studied by immersion test in Hank's solution at 37 °C up to 8 weeks. Mg degradation was monitored by the mass loss of the samples (after removal of corrosion products), pH variations and increase in Mg concentration in the immersion medium, determined by inductively coupled plasma (ICP). Surface morphology and local chemical composition of samples was studied by light microscope, scanning electron microscope (SEM) and X-ray diffraction (XRD).  $\mu$ CT scans of voxel size 25  $\mu$ m were acquired on state-of-art  $\mu$ CT station GE v|tome|x L 240. 3D visualisations and the analysis were completed using VG Studio MAX 2.2 software.

### RESULTS AND DISCUSSION

After immersion test, visual inspection and SEM images showed an evident clay-like corrosion layer on sample surfaces. The extent and thickness of the layer increased with the immersion time. XRD analysis showed that the corrosion layer was mainly composed of  $\text{Mg}(\text{OH})_2$ . The pH of the immersion media increased, reaching a mean value of  $10.3 \pm 0.1$  along the experiment. It is hypothesised that locally, in the sample surface, the increment of pH was even higher to lead on the formation of  $\text{Mg}(\text{OH})_2$ . Fig. 1 shows the  $\text{Mg}^{2+}$  concentration in the immersion medium and the mass loss of the samples determined both gravimetrically and

from  $\mu$ CT (volume loss). There was a constant release of  $\text{Mg}^{2+}$  to the immersion media, leading on a concentration between 150 and 200 mmol/l after every week, suggesting a constant corrosion rate. In general, there was a match between the mass losses determined by the two methods. Just small differences could be observed at the beginning and the end of the experiment. However, these differences were within the experimental variation between samples (around 5 %). In addition to corroborate that samples corroded monotonically ( $r^2 = 0.973$ ),  $\mu$ CT allowed the determination of the corrosion progress. Discs reconstructions in Fig. 1 show that the edge surface corroded faster than the surfaces perpendicular to the disc axes. This could be explained by the differences in microstructure. While the edge consisted of a columnar grain microstructure, the other surfaces had an equiaxial grain microstructure. Even though the mass loss provides information about overall degradation of the sample,  $\mu$ CT also allows the determination of preferential corrosion zones, useful in particular when testing anti corrosion coatings. Furthermore, applying the proper parameters,  $\mu$ CT allows the assessment of the distribution of corrosion products on the sample surface. The limitation of  $\mu$ CT in resolution to observe the microstructure of the corroded layer can be overcome by combining this technique with SEM.

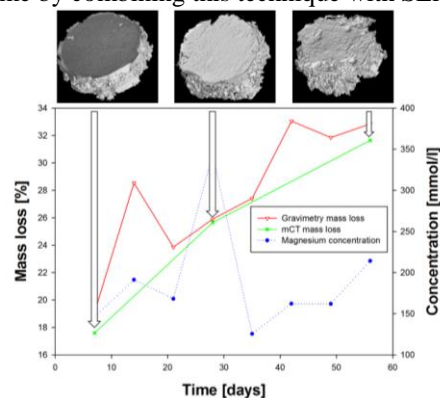

Fig.1:  $\text{Mg}^{2+}$  concentration and mass loss, determined gravimetrically and by means of  $\mu$ CT. Top images show the  $\mu$ CT reconstruction of the samples.

### CONCLUSION

$\mu$ CT can be used for determine Mg corrosion rate and progress. The flexibility and adaptability of the methodology, together with the increasing availability of  $\mu$ CT platforms, make this approach attractive, not only from the scientific aspect, but also in profitability, without losing accuracy in the results.

## INTRODUCTION

Artificial materials which have the ability to spontaneously bond to living bone, when implanted into bone defects, are of great interest as implant materials. It is commonly accepted that a spontaneous formation of a hydroxyapatite (HA) layer on the surface of the material under *in-vivo* conditions is the key step for osseointegration<sup>1</sup>. However, compared to the costly and time-consuming *in-vivo* tests, many *in-vitro* test methods have been developed<sup>2</sup>. In these tests, the material is dipped into an artificially prepared solution, referred to as a Simulated Body Fluid (SBF) for the evaluation of its Apatite Forming Ability (AFA). In many cases, it was shown that these results accurately correlate with the material's bioactivity *in-vivo*<sup>2</sup>. However, despite the success, erroneous prediction of the bioactivity also exists<sup>3</sup>. Thus there is still space for improvement and it would be important to gain more fundamental knowledge about various factors determining the AFA under *in-vitro* conditions.

In this work, we tried to approach the problem in two directions. We explored the effects on AFA due to implant surface properties, e.g. crystalline phase, surface roughness etc. In another effort, we investigated the change in AFA with different SBF compositions. We particularly focused on the effect of proteins (e.g. albumin) since these materials are abundant in human blood plasma and could play a role in the kinetics of either apatite nucleation or growth.

## EXPERIMENTAL METHODS

### Preparation of Titanium Discs

Medical grade titanium bars were bought and cut into discs of ~1.5 cm in diameter. These discs were finely polished by sand papers to have a consistent starting surface. The titanium discs were treated with 65% HNO<sub>3</sub> solution for 30 minutes followed by 24h at 60°C in 5M NaOH or 5M HCl aqueous solution. Some of the samples were also annealed under air for 2h at 550°C.

### Preparation of SBF and Procedures of Bioactivity Tests

The SBF used, based on the suggestions of Bohner and Lemaître<sup>3</sup>, consists of NaCl (117.02mM), CaCl<sub>2</sub>·2H<sub>2</sub>O (2.31mM), NaHCO<sub>3</sub> (22.2mM), Na<sub>2</sub>HPO<sub>4</sub>·2H<sub>2</sub>O (1.39mM) and HCl (1.36mM). Bovine Serum Albumin (BSA) was added to some SBFs with a concentration of 5g/L. During the bioactivity tests, each Ti disc was immersed in ~5mL of SBF with the active surface facing down and a CO<sub>2</sub> partial pressure of 5% atm and a temperature of 37°C was maintained. The samples were taken out for observation by SEM after different periods of time. XRD, XPS and profilometry tests were also conducted.

## RESULTS AND DISCUSSION

The experiments were carried out using statistical experimental design. Differences in AFA were observed for samples with different treatments. Particularly, the HCl treated non-annealed sample did not show AFA. However, for the HCl treated and annealed sample, after the test in SBF, hydroxyapatite was found on the surface. This has clearly shown that surface properties play an important role in determining the AFA.

The effect of proteins in the SBF was investigated using the model system NaOH treated Ti discs. The effect of proteins can be seen in the difference in morphology of HA as well as the amount of deposition. Plate-like structures were found for samples without protein, suggesting a growth in preferential crystal orientation. Samples were also characterized using other methods such as IR and XPS, which will be presented and discussed in detail in the presentation.

**Fig. 1** SEM images of HA on NaOH-treated Ti surface with BSA (left) and without BSA (right) in SBF.

## CONCLUSION

The surface properties of implant materials were proved to be relevant for the deposition of HA onto the surface. The presence of albumin in the SBF also affects the AFA of active materials. The effect can be seen in SEM as well as with other characterization techniques.

## INTRODUCTION

In the bone marrow niche, human bone marrow stromal cells (hBMSC) are surrounded by extracellular matrix (ECM) containing inorganic mineral, collagen I (col) and sulfated glycosaminoglycans (sGAG). Synthetically sulfated hyaluronan (sHA) and oversulfated chondroitin sulfate derivatives (sCS) have been shown to support osteogenesis of BMSC<sup>1,2,3</sup> and to inhibit osteoclastogenesis<sup>3</sup>. In this study we describe the pro-osteogenic effect of artificial ECM (aECM) composed of col and sGAG *in vitro*.<sup>4</sup>

## EXPERIMENTAL METHODS

Artificial ECM were prepared from col and sGAG derivatives varying in the degree of sulfation and the position of sulfate groups (Table 1).<sup>1,2</sup>

GAG	DS <sub>s</sub>	position of sulfate group	MW/ g mol <sup>-1</sup>
HA	0	-	1,17 x 10 <sup>6</sup>
sHA1Δ4S	1	GlcNAc6S	26,400
sHA1Δ6S	1	GlcNAc4S	42,600
sHA2	2	GlcNAc6S/GlcA2',3'diS	26,400
sHA3	3	GlcNAc6,4S/GlcA2',3'diS	47,800
sCS1	1	GalNAc4' (70 %),6'S (30 %)	17,900
sCS2	2	GalNAc6',4'S/GlcA2,3diS	23,200
sCS3	3	GalNAc6'/4'S/GlcA2,3diS	19,900

Table 1: Characteristics of GAG derivatives. DS<sub>s</sub> - degree of sulfation per disaccharide repeating unit, MW - molecular weight. GlcNAc - N-acetylglucosamine, GalNAc - N-acetylgalactosamine, Sulfation (S) simultaneously (/) or partially (,).

The aECM were used as a substrate for osteoblast precursor cells and mature osteoblasts. Human BMSC (osteoblast precursors) were obtained from Bone Marrow Transplantation Centre of University Hospital Dresden. The cells were cultured in DMEM with 10 % FCS and osteogenic supplements were added (10 mM β-glycerophosphate, 300 μM ascorbate, 10 nM dexamethasone) from day 4 after seeding.<sup>1,2</sup> The osteosarcoma cell line SaOS-2 (obtained from ATCC) shows features of mature osteoblasts and was cultured in McCoy's 5A medium with 15 % FCS and starting at day 4 after seeding with 10 mM β-glycerophosphate and 300 μM ascorbate.<sup>4</sup>

For characterization, TNAP (tissue-non-specific alkaline phosphatase) activity was determined in cell lysates with p-nitrophenyl phosphate at day 11 after seeding and calcium deposition was quantified with calcium kit (Greiner Diagnostics, Bahlingen, Germany) at day 22.<sup>1</sup>

## RESULTS AND DISCUSSION

Artificial ECM containing sCS2, sCS3, sHA1Δ4S, sHA2 and sHA3 induced a significant increase of

TNAP in hBMSC (Figure 1)<sup>4</sup>. The calcium deposition – a second indicator for osteogenic differentiation – was determined at day 22 and showed the same pattern.

Figure 1: Influence of aECM on specific TNAP activity of hBMSC at day 11 after seeding. Values shown as mean ± standard error of the mean, c (P < 0.001) calculated by one-way ANOVA analysis with Bonferroni's posttest, n = 4.

As seen in figure 1, the pro-osteogenic effect of GAG derivatives was independent of kind of disaccharide unit and the absolute number of sulfate groups. But the C-6 position of the N-acetylglucosamine seems to be necessary. Furthermore, the osteoinduction is specific for osteoblast precursor cells as sGAG did not affect mature osteoblasts SaOS-2 in the same manner.

The molecular mechanism of this specific pro-osteogenic effect is still unknown. However, there are hints that sGAG derivatives interfere with matrix remodelling e.g. by decreasing endogenous col synthesis<sup>5</sup>, reducing formation<sup>5</sup> and activity of matrix metalloproteinases (MMPs) and increasing formation of tissue inhibitors of metalloproteinases (TIMPs).

## CONCLUSION

The manifold effect of sGAG and sGAG containing aECM (e.g. osteoinduction of osteoblast precursor cells, influence on matrix remodelling) makes them to an interesting tool for tissue engineering approaches.

### INTRODUCTION

Bone augmentation materials should combine both, biodegradation and adequate mechanical properties to provide fast bone regeneration and therefore early rehabilitation of patients. In this context, struvite forming magnesium substituted calcium phosphate cements (CMC) seem to be promising materials due to their biocompatibility, biodegradability and high compressive strength. The aim of this study was to prepare injectable and ready-to-use CMC pastes, which can be shaped as required. Furthermore, the application of such cement pastes as a controlled release system for antibiotics was evaluated.

### EXPERIMENTAL METHODS

CMC pastes (InnoTERE GmbH, Germany) consisted of  $\text{Ca}_x\text{Mg}_{(3-x)}(\text{PO}_4)_2$  powder with  $x=0.5$  or  $x=0.75$ , a biocompatible carrier liquid, and  $3.5\text{M}(\text{NH}_4)_2\text{HPO}_4$  (N-CMC) or a mixture of  $3\text{M}\text{KH}_2\text{PO}_4$  and  $0.5\text{M}\text{K}_2\text{HPO}_4$  (K-CMC) as binder components. The pastes were either applied as 1-component or as 2-component system in which a second aqueous phase was homogeneously mixed with the cement paste at a 1:4 volume ratio by using a static mixing device (Figure 1). For drug elution experiments cement modification with Vancomycin (VHCl) was performed (1) by mixing 1.24wt% solid antibiotic with the paste during manufacturing or (2) by dissolving 10.0 wt.% antibiotic in the aqueous phase of the 2-component system. Samples were prepared by filling the paste into  $6\times6\times12\text{mm}^3$  silicon molds, followed by curing for 24h at  $37^\circ\text{C}$  and  $>90\%$  humidity and subsequent immersion in phosphate buffered solution (PBS). The compressive strength, porosity, microstructure, chemical composition, and drug release were analyzed after several time points.

### RESULTS AND DISCUSSION

The present study demonstrates the preparation of injectable and premixed pastes based on CMC. The cement setting reaction proceeds only in a humid environment due to the substitution of the carrier liquid by water. Depending on the type of phosphate providing salt, different cements were obtained. For N-CMC, cured samples consisted of unreacted raw materials farringtonite and stanfieldite as well as of the reaction products struvite, calciumpyrophosphate and newberyite. Usage of a mixture of potassium phosphates as binding agent (K-CMC) leads to the reduction of struvite content in favor of newberyite. Compressive strength increased during immersion in PBS over 56 days from 8-10 MPa after 5 days to 24 MPa for N-CMC and from 12 MPa to 18 MPa for K-CMC, respectively (Table 1). According to this,

porosity decreased with proceeding immersion time but was independent of chemical composition. Bioactive VHCl was released in a first order kinetic over a period of 28 days for N-CMC and 3 days for K-CMC, respectively. Cement properties like microstructure, porosity, and mechanical strength were not influenced by the addition of the drug. Thus, the different release kinetics may be attributed to differences in the setting reaction and thus final chemical composition of the two cement types.

Figure 1: Application and handling of calcium magnesium phosphate cement paste.

Cement paste composition	Compressive strength [MPa]
$\text{Ca}_{0.5}\text{Mg}_{2.5}(\text{PO}_4)_2$ K-CMC 1-component	$18 \pm 3$
$\text{Ca}_{0.5}\text{Mg}_{2.5}(\text{PO}_4)_2$ N-CMC 1-component	$24 \pm 3$
$\text{Ca}_{0.75}\text{Mg}_{2.25}(\text{PO}_4)_2$ N-CMC 1-component	$24 \pm 4$
$\text{Ca}_{0.75}\text{Mg}_{2.25}(\text{PO}_4)_2$ N-CMC 2-components	$10 \pm 2$

Table 1: Compressive strength of drug loaded cement pastes after 56 days in PBS.

### CONCLUSION

The results suggest that premixed CMC pastes are promising bone filling materials with high mechanical stability and drug elution option for the treatment or prevention of osteomyelitis or infection.

## INTRODUCTION

Calcium carbonate (CaCO<sub>3</sub>) has been widely applied in scaffold form as a material for bone regeneration. In microparticle form, CaCO<sub>3</sub> is a popular drug delivery vehicle. Magnesium (Mg) has been incorporated in calcium phosphate (CaP)-based materials for bone regeneration to promote bone cell adhesion, proliferation and differentiation *in vitro* as well as integration with surrounding bone *in vivo*. However, Mg-enriched CaCO<sub>3</sub> and magnesium carbonate (MgCO<sub>3</sub>) have attracted far less attention.

In this study, microparticles of MgCO<sub>3</sub>, Mg-enriched CaCO<sub>3</sub> (hereafter referred to as (Mg/Ca)CO<sub>3</sub>) were synthesised and compared to CaCO<sub>3</sub>.

Microparticles were characterized with respect to morphology, both directly after synthesis and after incubation in ddH<sub>2</sub>O. Furthermore, self-gelling, injectable composites for bone regeneration were generated by mixing microparticles with solutions of the polysaccharide Gellan Gum (GG). It is known that GG hydrogels can be formed by crosslinking with calcium (Ca) or Mg ions<sup>1</sup>. We hypothesized that the higher solubility of MgCO<sub>3</sub> and (Mg/Ca)CO<sub>3</sub> compared to CaCO<sub>3</sub> would result in faster gelation.

## EXPERIMENTAL METHODS

MgCO<sub>3</sub>, (Mg/Ca)CO<sub>3</sub> and CaCO<sub>3</sub> microparticles were prepared by mixing equal volumes of solution 1 (consisting of Na<sub>2</sub>CO<sub>3</sub>) and solution 2 (consisting of CaCl<sub>2</sub> and/or MgCl<sub>2</sub>), as shown in Table 1, at room temperature using stirring. Microparticles formed instantly, were isolated by centrifugation, subjected to washing with ddH<sub>2</sub>O and dried in an oven at 38 °C. Particles were also incubated in ddH<sub>2</sub>O for 7 days. Particle morphology was examined by SEM. To produce self-gelling GG-microparticle composites, 0.875% GG was sterilized by autoclaving. Microparticle suspension was mixed into the GG solution to obtain a composite containing 0.7% w/v GG and 0.4% w/v microparticles.

Table 1. Concentrations of solutions mixed to produce microparticles (all values mol dm<sup>-3</sup>)

Microparticle type	Solution 1	Solution 2	
	Na <sub>2</sub> CO <sub>3</sub>	CaCl <sub>2</sub>	MgCl <sub>2</sub>
MgCO <sub>3</sub>	0.333	0.333	0
(Mg/Ca)CO <sub>3</sub>	0.333	0.167	0.167
CaCO <sub>3</sub>	0.333	0	0.333

## RESULTS AND DISCUSSION

Morphology of dried microparticles is shown in Fig. 1. CaCO<sub>3</sub> (fig. 1A) microparticles had a spherical morphology, typical for deposits of the polymorph vaterite. Some cubic deposits of the polymorph calcite were seen. (Mg/Ca)CO<sub>3</sub> microparticles (fig. 1B) were larger and consisted of crystal-like structures of non-uniform morphology. MgCO<sub>3</sub> microparticles had an irregular, non-crystalline morphology. After incubation in ddH<sub>2</sub>O for 7 days, CaCO<sub>3</sub> microparticles (fig. 2A)

converted to calcite, while (Mg/Ca)CO<sub>3</sub> microparticles (fig. 2B) became spherical with a vaterite-like morphology. This may suggest a phase change and Mg release. MgCO<sub>3</sub> microparticles changed after incubation but remained irregular and inhomogeneous.

Figure 1: SEM images of CaCO<sub>3</sub> (A) and (Mg/Ca)CO<sub>3</sub> microparticles (B) after drying. Scale bar: 10 µm.

Figure 2: SEM images of CaCO<sub>3</sub> (A) and (Mg/Ca)CO<sub>3</sub> microparticles (B) after incubation in ddH<sub>2</sub>O for 7 days. Scale bar: 10 µm (A), 20 µm (B).

Regarding GG-microparticle composites, addition of MgCO<sub>3</sub> microparticles to GG-solution led to very rapid gelation (within 1 min). Resulting composites were transparent, which may signify dissolution of MgCO<sub>3</sub> microparticles. Addition of (Mg/Ca)CO<sub>3</sub> microparticles to GG-solution led to slower gelation (approx. 3 min) and non-transparent composites. Addition of CaCO<sub>3</sub> microparticles to GG-solution did not cause gelation and resulted in particle sedimentation. Hence, it appears likely that Mg release from microparticles is causing GG hydrogel formation. These self-gelling composites are injectable.

## CONCLUSION

CaCO<sub>3</sub>, (Mg/Ca)CO<sub>3</sub> and MgCO<sub>3</sub> microparticles were synthesized. Addition of microparticles containing Mg to GG solutions induced hydrogel formation, most rapidly in the case of MgCO<sub>3</sub> microparticles. Further work on these self-gelling, injectable materials will focus on their suitability as bone regeneration materials and drug delivery systems, e.g. by incorporation of cells and biologically active molecules, cyto- and biocompatibility testing.

### INTRODUCTION

It has been observed that isolated cells are unable to form new bone tissue with the right mechanical and physiological characteristics. As consequence, tissue engineering involves the use of porous, bioresorbable materials as temporary 3D scaffolds to promote cell attachment, differentiation and proliferation<sup>1</sup>.

Ideally the scaffold would degrade slowly enough to maintain structural support during the initial stages of bone formation, but fast enough to allow space for continuous growth of new bone<sup>2</sup>.

The association of a bone cement based on calcium phosphate (Ca-P) and of biodegradable polymer like PCL (Polycaprolactone) leads to a composite material with improved mechanical properties and a decrease of the intrinsic fragility of bioceramic materials.

### EXPERIMENTAL METHODS

PCL plotted scaffolds, with oriented layer at 0/90° and 45°, diameter of wire 0.3 mm, square pores 0.09mm<sup>2</sup>, were fabricated using a Bioscaffolder® (Sys-Eng, Germany) device. The composites were obtained for infiltration of injectable liquid bone cement based on brushite, with and without plasma oxygen pretreatment, in order to change the hydrophobicity of the PCL and then the wetting with the cement. Putting a small amount of cement on the scaffold surface with a spatula, the fluid paste penetrated for gravity through small hits and finally further amount of cement was spreaded on the scaffold to fill completely the structure. The brushite was prepared by mixing  $\beta$ -TCP (tricalcium phosphate) with MCPM (mono-calcium phosphate monohydrated) in stoichiometric proportion and then adding a water solution of Na-citrate 0.5M (solid-liquid ratio 1.5:1). Mechanical properties of the samples (dynamic tensile and dynamic compression tests) were obtained with a homemade instrument<sup>3</sup>. Also measures of scaffolds and composites degradation (weight loss in water and PBS) and a preliminary biological evaluation (only on the PCL scaffold) were also performed.

A primary human osteoblast cells (HOBs) model was used<sup>4</sup> and proliferation of cells was determined using the Alamar-Blue™ assay (Life technologies), which is a redox indicator that measures proliferation quantitatively. Cells were micro seeded at a total density of 1x10<sup>5</sup> cell per scaffold placed in a 24 well plate. The culture period covered 21 days. The test was performed on days 1, 3, 7, 14 and 21. The cell culture media was changed after 24 h and every 3 days subsequently. Thermanox™ (Nalge NUNC International, Rochester, USA) dishes were used as standard positive controls.

### RESULTS AND DISCUSSION

The Complex Modulus analysis for PCL scaffolds highlights that their mechanical properties are lower than the ones of the trabecular bone in tensile test and even more in compression test. However higher is the solid fraction of the scaffold higher is the storage modulus,  $E'$ . The ox. plasma treatment of the scaffolds leads to an increase of  $E'$  only with the best combination of exposure time and power applied, probably due to a higher interaction between PCL and brushite.

Mechanical tests on PCL/brushite composite show an increase of  $E'$  due to the presence of the ceramic, with a higher improvement in compression test (Tab. 1).

	Solid fract.	Tensile $E'$ (MPa)	Compression $E'$ (MPa)	
		PCL scaffold	Composite	
PCL	61%	112	39	369
PCL ox plasma	68%	118	45	150
PCL (45°)	47%	56	19	178

Table 1.

From the degradation study on PCL/brushite it is possible to observe a real loss of weight after 15 days. PCL scaffold instead has not been affected by the solution during the six weeks of analysis.

The Alamar Blue assay showed an increase in cell number comparing the first and the last time point (21 days). SEM analysis performed after 3 days from the cell seeding showed the ability of the cells to attach and spread onto the fabricated scaffold.

### CONCLUSION

PCL infiltrated with brushite shows an elastic modulus comparable with the one of cancellous bone and very higher than the PCL scaffold. Due to the positive cell tendency to proliferation and a good cell adhesion to a PCL surfaces, combined with the biocompatibility and osteoconductivity of the brushite, the composite PCL/brushite seems promising for applications in bone replacement and repair.

## INTRODUCTION

Calcium phosphate bone cements are well known biomaterials widely applied in small bone reparation. In particular, brushite phase ( $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$ ) is often the best choice to produce a cement paste, which can be injected or moulded to fill damaged bone sites. Its use is also preferred to hydroxiapatite based materials, due to the faster resorption time<sup>1</sup>.

In this work, a series of composite materials was prepared, in which aminoacids have been introduced in the structure following two synthesis methods: i) by impregnation from an aqueous solution on the bone cement after setting and ii) directly by incorporation.

The aim was to understand the interaction between the organic and the inorganic moieties and to evaluate the properties of these new materials.

## EXPERIMENTAL METHODS

Brushite cements were prepared by mixing  $\beta$ -TCP (tricalcium phosphate) with MCPM (mono-calcium phosphate monohydrated) in stoichiometric proportion and then adding a water solution of Na-citrate, 0.1M, used as retardant, according the reaction:

Samples with solid-liquid ratio 2:1 and 1.6:1 were prepared.

Glycine, lysine and proline aminoacids have been chosen as the major components of collagen protein.

Two different methods were adopted to prepare the composite materials: i) by impregnation from an aqueous solution on the bone cement after setting and ii) directly by incorporation of the solid aminoacid with calcium phosphate salts before mixing with the liquid.

All the samples was analysed with FT-IR technique (Nexus Thermo Nicolet FT instrument, OMNIC software).

## RESULTS AND DISCUSSION

FT IR studies show that brushite phase is predominantly produced also in the presence of aminoacids in the solid phase, thus no changes are induced in the solid structure.

The resulting biomaterials show good workability and setting time suitable for mouldable or injectable cement according the solid/liquid rapport. Moreover, the addition of aminoacid could improve the adhesion cell capacity and the bio-degradability of brushite matrix, favouring the bone growth at the exposed surface.

In particular, glycine addition in the solid phase, without adding retardant in the aqueous solution, leads to a cement paste having suitable setting times, possibly due to a coordinating effect of the amino acid towards brushite Ca ions. In fact, FT-IR data (Fig. 1) evidenced changes in shape and position of the NH and C=O stretching modes of the amino and carboxylic groups in glycine structure, suggesting the interaction of the aminoacid with the inorganic matrix mainly through coordination of the carboxylate group (acting as ligand) with inorganic matrix cations<sup>2</sup>.

Fig. 1. FT-IR spectra of brushite (reference material) and of the composites Brushite-glycine (glycine in the solid phase). Inset: subtraction spectrum in comparison with pure glycine spectrum.

## CONCLUSION

A retardant effect on setting of calcium phosphate cement due to the interaction between aminoacid and inorganic compound was evidenced. This does not yield to significant changes in the brushite produced, that remain the predominant phase.

## INTRODUCTION

Calcium phosphates obtained by biomimetic routes, such as calcium deficient hydroxyapatite (CDHA), are widely used as bone substitutes due to their similarity with the mineral phase of bone, not only in composition, but also in other relevant properties such as crystallinity, specific surface area and reactivity. However, in spite of exhibiting excellent *in vivo* performance, CDHA has been shown to present poor *in vitro* behaviour<sup>1</sup>. Ionic exchange, which is more pronounced in this material compared to sintered ceramics, due to low crystallinity and high specific surface area, has been pointed out as one of the possible causes, together with the spiky microstructure of these materials<sup>1,2</sup>. However, the role of the two parameters is unclear, due to the difficulty to analyse them separately. The aim of this study was to assess to what extent ionic exchange affected cell response, by performing cell culture studies with different material/cell culture medium ratio. This was an effective way to isolate the effect of ionic exchange from that of surface topography on *in vitro* cell behaviour.

## EXPERIMENTAL METHODS

CDHA discs with different dimensions were prepared by mixing  $\alpha$ -tricalcium phosphate ( $\alpha$ -TCP) powder with an aqueous solution of 2.5 wt.% disodium hydrogen phosphate at liquid/powder ratio of 0.4 mL/g. Rat mesenchymal stem cells (rMSCs) were seeded at a 300 cells/mm<sup>2</sup> density on the CDHA discs using AdvDMEM cell culture medium. Two culture conditions were used: a) Large discs (15 mm  $\varnothing$  x 2 mm height) were immersed in 1 mL medium, b) Small discs (5.5 mm  $\varnothing$  x 300  $\mu$ m height) were immersed in 2.5 mL medium. Thus, the ratio between biomaterial volume and cell culture volume was  $V_B/V_{CM} = 0.35$  and 0.01 respectively for the a) and b) conditions. TCPS with 1 mL and 2.5 mL of medium were used as controls. During cell culture, the  $Ca^{2+}$  and  $P_i$  concentrations as well as protein content were quantified using colorimetric methods, and pH was also monitored. Cell number was determined at 6h, 3, 7 and 14 d by LDH quantification. The differentiation of rMSCs to osteoblastic phenotype in direct contact with the material (condition b), was assessed by measuring gene expression by qRT-PCR. After 6h of adhesion the medium was replaced by osteogenic medium and levels of RUNX2, ALP, COLL I, OC, ON, OPN and BMP-2 were quantified at 6h, 1 and 3d. ACTB was used as housekeeping gene.

## RESULTS AND DISCUSSION

A strong decrease in calcium was observed when  $V_B/V_{CM}$  was 0.35, whereas the levels of calcium remained unaltered, similar to those of tissue culture

plastic, when  $V_B/V_{CM}$  was 0.01 (Fig. 1).

Figure 1. a) Proliferation of rMSCs on CDHA with  $V_B/V_{CM}=0.35$  and  $V_B/V_{CM}=0.01$  b) Evolution of  $Ca^{2+}$  in the cell culture medium. Dashed line indicates experimental values of  $Ca^{2+}$  of AdvDMEM.

Cell behaviour was very different in the two culture conditions (Fig. 1). Although rMSC adhesion on the material was good in the two cases, the number of cells decreased with time when  $V_B/V_{CM}$  was 0.35. In contrast, cells did proliferate when  $V_B/V_{CM}$  was reduced to 0.01. No effect of medium volume (1 mL or 2.5 mL) on cell proliferation in TCPS was observed. Gene expression of rMSCs cultured with  $V_B/V_{CM} = 0.01$  is summarized in Fig 2. An earlier expression of BMP-2, OP, OC and ON was found, with higher levels than the control with osteogenic medium at 6h and 1 day.

Figure 2. Gene expression levels of rMSCs cultured on TCPS or CDHA with  $V_B/V_{CM}=0.01$ . The presence or absence of osteogenic medium was marked as +OG or -OG, respectively.

## CONCLUSION

The ratio between biomaterial and cell culture volume had a strong influence on proliferation of rMSCs, suggesting a predominant effect of ionic exchange on *in vitro* cell survival. When ionic fluctuations were minimised, cells proliferated, and the overexpression of genes involved in osteogenic processes pointed out the relevance of surface topography on promoting cell differentiation.

### INTRODUCTION

Traumatic injury and age-related degenerative diseases associated with cartilage are major health problems worldwide. The articular cartilage is comprised of a relatively small number of cells, which have a relatively slow rate of turnover. Therefore, damaged articular cartilage has a limited capacity for self-repair<sup>1</sup>. New clinical methods have been designed to achieve better repair of injured cartilage. However, there is no treatment that enables full restoration of it.

The aim of this study was to evaluate how collagen gel with bone marrow mesenchymal stem cells (MSCs) and collagen gel alone will influence on the hip cartilage repair after injury.

### EXPERIMENTAL METHODS

Collagen type I was isolated from rats' tails and cross-linked with N-hydroxysuccinimide in 24-hour process. MSCs were isolated from rats' bone marrow. The experiments were conducted according to the guidelines for animal experiments of Ethics Committee. Fifteen 8-week-old Wistar rats were used in this study. All animals received hip joint surgery with a total of 30 created cartilage defects. Then, animals were randomly divided into three groups and filled, respectively, with collagen gel (group I), collagen gel cultured with MSCs (group II) or left untreated as a control (control group). Immunohistochemistry and radiological evaluation was carried out 11 weeks post implantation.

### RESULTS AND DISCUSSION

It has been proved that the surface of the matrix is non-toxic, and its porosity promotes cell adhesion and growth. However, the *in vivo* regeneration process was poor. We observed the low integration rate of biomaterial. Immunohistochemical evaluation of cartilage

after 11 weeks of treatment showed low II and high X collagen expression in two tested groups in comparison to the control one, in which we observed the high II collagen expression. What is more, after radiological analysis, we observed the best regeneration process in control group. The biomaterial construct and mesenchymal stem cells, as well as the use of the biomaterial itself was not sufficient to regenerate the hip cartilage surfaces.

### CONCLUSION

These results suggest that the collagen gel based biomaterials, even with MSCs, are not satisfactory in repair of hip cartilage defect. However, additional evaluation is needed to confirm these results.

## Osteointegration of a Macroporous Cement Designed to Repair Large Cancellous Bone Defects

Bruno Cimatti<sup>1</sup>, Wendell Monteiro Barboza<sup>1</sup>, Marcelo Henrique Nogueira-Barbosa<sup>2</sup>, Edgard Eduard Engel<sup>1</sup>

<sup>1</sup> Laboratory of Bioengineering, Ribeirão Preto Medical School, University of São Paulo, Brazil

<sup>2</sup> Division of Radiology, Ribeirão Preto Medical School, University of São Paulo, Brazil

[engel@fmrp.usp.br](mailto:engel@fmrp.usp.br)

### INTRODUCTION

Porous cements have been extensively studied for tissue engineering as scaffolds or for small bone defects commonly seen in Dentistry. Large bone defects such as those created after benign bone tumor curettage are usually filled with solid bone cement. The frequent formation of a thin layer of fibrosis around the cement block may cause bone fracture and subsequent arthrosis, mainly when the defect is periarticular<sup>1</sup>. Hirn *et al.* demonstrated that even large bone defects are filled with new bone, but depending on its size, the fracture risk is unacceptable<sup>2</sup>. A bone substitute with large pores that can be molded during surgery, allows bone ingrowth and prevent fracture could be a reasonable alternative<sup>3</sup>.

Polymethylmethacrylate (PMMA) cement mixed to the effervescent components sodium bicarbonate and citric acid, forms large interconnected pores and has physical and mechanical characteristics similar to cancellous bone<sup>3</sup>. The objective of the study was to evaluate the osteointegration capacity of this cement.

### EXPERIMENTAL METHODS

A 15x10mm cylindrical defect was created in 36 sheep tibias and filled with porous PMMA cement in group 1, with solid PMMA cement in group 2 and left empty in group 3. Porous cement was created by adding 20% of effervescent components sodium bicarbonate and citric acid to polymethylmethacrylate cement (PMMA).

Euthanasia was performed 3 months after surgery and the operated region was analyzed with micro-computed tomography scanning ( $\mu$ CT) (high-resolution  $\mu$ CT model 1172, Bruker, Belgium).

### RESULTS AND DISCUSSION

Group 1. In all samples, bone ingrowth could be demonstrated. New bone formation can be seen invading the interconnected pores mainly in the same direction of the mechanical axis.

Group 2. In all samples, a thin layer separates the cement block from bone.

Group 3. Bone ingrowth can be seen in the defect, but it is randomly distributed.

None of the specimens presented fractures of any group.

Figure 1 demonstrates new bone formation in an empty defect of Group 3.

Figure 2 demonstrates the "loose" cement block in Group 2.

Figure 3 demonstrates the bone ingrowth in Group 1.

Clear line in the inferior region of the cement.

### CONCLUSION

PMMA porous bone cement allows bone ingrowth that can be detected 3 months after surgery.

### **INTRODUCTION**

Large metaphyseal bone defects created after benign bone tumor curettage are usually treated by solid bone cement (PMMA) implantation. Porous and absorbable cements are expected to improve clinical results by lowering incidence of aseptic loosening, heat promoted bone necrosis, mechanical buttress failure and absence of bone integration<sup>1</sup>.

Effervescent components like sodium bicarbonate and citric acid can be mixed to PMMA producing porous cement that fits intraoperative requirements. Furthermore, castor oil polyurethane is a well-known absorbable cement that can be mixed to effervescent components to produce porous and absorbable bone cement<sup>2</sup>.

*In vivo* and *in vitro* toxicity of both products have never been tested to support its clinical use. The spurious production of toxic elements and the effect of citrate, an anticoagulant byproduct of the effervescent components reaction, were analyzed.

### **EXPERIMENTAL METHODS**

#### ***In vitro* experiments**

The three experimental groups consisted of PMMA or one of the two commercially available castor oil polyurethane cements (Poliquil® or Bioosteo®) mixed to the effervescent components specimens. These groups were compared to classic PMMA solid cement specimens. All the elements produced during preparation and incubation of the cements were analyzed by High Efficiency Liquid Chromatography coupled to Mass Spectrometry and Resazurine microplate assay of NIH/3T3 and MRC-5 fibroblasts strains culture.

#### ***In vivo* experiments**

Femoral defects were created in six rabbits per group and filled with PMMA or Poliquil® porous cements or left empty. Magnetic resonance of the limb, histology of the limb, kidneys and liver and coagulation parameters of blood samples collected immediately after and 1, 4 and 7 days after surgery were analyzed.

### **RESULTS AND DISCUSSION**

Castor oil polyurethane of both brands (Bioósteo® and Poliquil®) released 4,4'-diaminodiphenylmethane. The Poliquil® brand released 4,4'-diphenylmethane diisocyanate too. Both compounds are considered toxic and inhalation and ingestion should be avoided<sup>3</sup>. The MRC-5 and NIH3T3 cell strains proliferation was decreased in less than 80% in contact with polyurethane cements and less than 65% with PMMA, compared to the control group. Dilution of the medium diminished

this effect. We believe that the acidity of the medium due to incomplete reaction of the effervescent components may be the cause of this finding.

Liver and kidneys histology showed some slight changes in the same proportion as the control group. We infer that the cements do not cause acute systemic toxicity.

In all groups, histologic analysis of the operated area showed small hematomas and a slight foreign body reaction. Significant inflammatory reaction could not be found in any of the study groups. Citrate formation from the effervescent components reaction seems to not interfere with coagulation. Inflammatory reaction around porous cements is similar to that of classic solid PMMA cement. The cytotoxic effect observed *in vitro*, could not be detected *in vivo*.

Coagulation parameters did not changed at any time after surgery. The evaluation by magnetic resonance imaging confirmed that there was no formation of larger hematomas than in specimens of the control group.

### **CONCLUSION**

Our data suggest that the porous cement produced by mixing effervescent components are well tolerated, produce little inflammatory reaction and do not cause coagulation disorders. However, the reaction of the effervescent components and castor oil polyurethane based cement yields potentially toxic products that deserves a specific investigation.

### INTRODUCTION

Calcium phosphate biomaterials have been widely used as bone substitute materials in clinical applications due to their good biocompatibility and osteoconduction. However, they are usually plagued by low inherent mechanical properties.

### EXPERIMENTAL METHODS

During this study we synthesized and analyzed nanostructured calcium phosphate bone cements based on  $\alpha$ -tricalcium phosphate ( $\alpha$ -TCP) [1] reinforced with nanoneedles of hydroxyapatite (HAP) (1, 3, 5, 10 and 20%) with strictly controlled porosity so as to optimize both mechanical properties and osteoblast nesting. We further analyzed the ability of the new biocements to induce the proliferation and survival of the pre-osteoblast cell line MC3T3E1 through DNA quantification and cell counting. In addition, cell morphology was observed with Scanning electron microscope (SEM) and fluorescence microscopy. Moreover, the osteoblastic induction was quantified by alkaline phosphatase (ALP) activity measurements and the morphology of the cells with SEM after 14 days of culture in the presence of the osteogenic factors, ascorbic acid and  $\beta$ -glycerophosphate.

### RESULTS AND DISCUSSION

SEM images showed that the surface microstructure of the cements after hardening was composed of plate-like crystals. The compressive strength of pure cements was at  $34.3 \pm 1.7$  MPa while in the case of composite cements is strongly depended upon the HAP content. By increasing the HAP content until 20 % the compressive strength drastically decreased until  $4.9 \pm 0.2$  MPa which was within the cancellous bone ranges

between 1.5 and 45 MPa. As regards the attachment, survival and differentiation of the pre-osteoblast MC3T3E1 cells on the surface of biocements, our results so far indicate that biocements with certain ratio of  $\alpha$ -TCP-HAP composite are tolerated as well as pure  $\alpha$ -TCP with regard to their osteoinductive and osteogenic properties.

### CONCLUSION

In conclusion, pure or HAP loaded calcium phosphate bone cements are suitable for low stress loading locations and display biocompatibility.

### INTRODUCTION

To address skeletal defect, several polymeric and composite scaffolds has been developed towards bone graft material. In spite of astounding micro-architecture and fabrication, foreign body reaction during in vivo transplantation is one of the limiting factor with such polymeric scaffolds. The formation of a dense collagenous capsule causes inadequate mass transport and cell communication between scaffold and host. To address such challenges natural origin biopolymer has been functionalized. This functionalized biopolymer (FBP) has zwitterionic properties causing ultra-low-fouling activity, which resist formation of avascular capsule during subcutaneous implantation. FBP further composite with synthetic polymer to develop a bioactive anisotropic 3D scaffold by designing aligned nanofiber sheet through electrospinning and subsequent multi-scalar 3D scaffold formation via micro-fabrication strategy.

### EXPERIMENTAL METHODS

Here, we represent a method for functionalization of natural origin biopolymer. This FBP fabricated into aligned nanofibers sheet via electrospinning. Further, three dimensional multi-scalar scaffold was formed micro-fabrication techniques. Physio-chemical characterization of scaffolds carried out using SEM, EDS, XRD, FTIR, TG-DTA and stereo-zoom microscope. In vitro cells attachment, migration study, proliferation, differentiation studies were performed. Further, in vivo studies were conducted in rabbit animal model.

### RESULTS AND DISCUSSION

Natural sources were successfully used for synthesis of resorbable functionalized polymer, nano-fibrous scaffolds. Natural origin, multiphasic CaP were printed successfully and got highly interconnected multi-scalar porous, fibrous hybrid composite scaffold. As hybrid composite mesenchymal stem cells (MSCs) revealed a higher ALP activity with increased RNA expression of collagen I and osteocalcin. In vivo studies found promising results of bone regeneration after implantation.

### CONCLUSION

In present study, CaP provide high mechanical support and interphase for bone tissue growth, where functionalized polymer act as niche for MSCs differentiation and impart rapid mineralization. Nano-micro architectural hybrid composite scaffolds can be used as a bone graft replacement in a cost effective way using biological waste as raw material.

## INTRODUCTION

Degradable orthopaedic implants can be used as temporary fixations e.g. in case of complicated fractures. The gradual degradation eliminates the need of reoperation to remove the implant after bone healing. This means saving costs and reducing risk of surgical complications. Currently used polymers lack sufficient mechanical properties required for orthopaedic applications and therefore, metallic materials, mainly magnesium-based alloys have been extensively developed and studied for these purposes<sup>1</sup>. The main aim is to decrease the corrosion rate using various alloying elements and also by altering the microstructure as the grain size significantly influences the corrosion rate<sup>2</sup>. Equal channel angular pressing (ECAP) is one of the methods of severe plastic deformation leading to ultra-fine grain materials<sup>3</sup>. It was observed that grain refinement of magnesium-based materials can increase<sup>4</sup> as well as decrease<sup>5</sup> the corrosion resistance.

Our aim was to investigate whether the ultra-fine structures of AE42 and LAE442 Mg-alloys achieved by ECAP processing increased the corrosion resistance of the materials and subsequently evaluate the effect of the treatment on changes of their *in vitro* toxicity.

## EXPERIMENTAL METHODS

Commercial Mg-alloys AE42 and LAE442 were extruded and further processed by ECAP by eight or twelve passes, respectively. Three replicates of each sample were used. Corrosion tests were performed in simulated body fluid (SBF). SBF was prepared according to Kokubo *et al.*<sup>6</sup> and samples were incubated for one week at 37 °C in closed vessels at agitation of 125 rpm. Surface to volume ratio was 3.5 mm<sup>2</sup>·ml<sup>-1</sup>. Released ions were measured using AAS. The corrosion rate after extrusion and after additional ECAP was compared. Statistical analysis was conducted with R software. Differences before and after the processing were analyzed using two sample t-test.

## RESULTS AND DISCUSSION

Figure 1 shows concentration of magnesium in extracts of alloys before and after ECAP. Processing through ECAP resulted in significantly reduced corrosion rate in both tested alloys. These results are in accordance with electrochemical measurements. Moreover, the protective corrosion layer on the surface observed by SEM was two times thicker after ECAP treatment<sup>7, 8</sup>. Microstructure characterization by SEM and TEM showed substantial grain refinement due to the ECAP processing that confirms the effect of the microstructure on the degradation rate of these alloys<sup>9</sup>.

Nevertheless, these observations need to be confirmed by *in vitro* experiments using appropriate cell models.

Fig. 1 Mg concentration [mg·l<sup>-1</sup>] in extracts of AE42 and LAE442 before and after ECAP treatment expressed as mean±SSD, n = 3, asterisks indicate p<0.05 in t-test.

Indirect *in vitro* cytotoxicity test will be performed according to ISO 10993-5 standard. Alloys will be incubated in cultivation medium and concentration of ions in extracts will be measured using ICP-MS. Cytotoxicity of extracts will be tested *in vitro* using U-2 OS and L929 cell lines via microculture tetrazolium assay (WST-1).

## CONCLUSION

ECAP treatment reduced corrosion rates of AE42 and LAE 442 magnesium alloys. Cytotoxicity tests need to be performed in order to confirm that decrease in corrosion rate is sufficient for *in vitro* system.

### INTRODUCTION

Biodegradable polymeric devices for bone repair have been proposed as an alternative to metallic materials since they overcome the need of a second surgical event for removal, especially in pediatric patients. For many years, there have been deep concerns about the weak mechanical properties and rapid degradation of polymeric devices. Moreover, clinical results reveal insufficient osseointegration, adverse tissue reactions and/or osteolysis at the implantation site after almost complete resorption of the biodegradable implant (1). Magnesium (Mg) and its alloys are among the most interesting alternative options to biopolymers because of their mechanical strength and stiffness, which are close to those of natural bone, and good biocompatibility (2). The main concerns regarding the use of Mg biodegradable implants rely on the hydrogen release and the alkalization of the surface. This study investigates the incorporation of Mg particles within a poly-L-D-lactic acid (PLDA) matrix as a way to improve the mechanical properties and biocompatibility of the polymer. We focused on the influence of Mg reinforcement of PLDA on the *in vitro* response of osteoblastic precursors and inflammatory cells.

### EXPERIMENTAL METHODS

PLA 2002D from NatureWorks® was used as the matrix. Commercial purity Mg particles of about 50 µm were provided by Goodfellow. Composites specimens were manufactured in a BOY XS Injection Moulding machine. Mass fractions of 0.2 and 1% Mg were selected to manufacture the composites. Mechanical properties were assessed by compression tests. Mg ion released from the composites into culture medium was quantified by a coupled enzyme assay. Human mesenchymal stem cells (MSCs) and TPA-differentiated THP-1 (dTHP-1) cells were used for cytocompatibility studies. Cell viability was monitored using the AlamarBlue assay and cell morphology was analysed by SEM. Nuclear morphology and actin filaments were revealed after staining MSCs with DAPI or phalloidine-TRITC, respectively. The degree of cell layer maturation was investigated in MSCs cultured in osteogenic medium on the samples or incubated with composite extracts by determination of ALP activity. Soluble factors levels in media of MSCs cultured on the composites or THP-1 exposed to composite extracts were quantified using CBA Flex Sets (BD Biosciences) and ELISA Kits.

### RESULTS AND DISCUSSION

Materials reinforced with Mg particles exhibited higher compressive strength than the neat polymer. PLDA/Mg composites incubated under standard cell culture conditions released Mg into culture medium, and the amount was higher in matrices reinforced with 1% than with 0.2% Mg particles. Viability of MSCs cultured on the composites also increased with Mg content. Confocal images of DAPI-stained MSCs revealed normal nuclear morphologies on all samples. MSCs grown on the materials formed a cell monolayer and exhibited a clearly expanded typically elongated shape. Actin polymerized in a dense meshwork of well-defined stress fibers distributed through the cell body of cells on the three polymer-based materials. Composites induced an increase in FN content and ALP activity in cell layers, being the levels higher on PLDA loaded with 0.2% than with 1% Mg particles. A similar pattern of ALP activity was observed in MSCs cultured in the presence of degradation products of the composites. Compared to unloaded PLDA, MSCs cultured on matrices loaded with 1% Mg particles secreted higher levels of MCP-1 and VEGF. Regarding the effect of composite extracts on inflammatory cytokine release from dTHP-1, our data show that TNF-α and IL-10 secretion were unaffected by degradation products of any of the materials tested. MCP-1 and RANTES secretion levels were also unaffected by composite extracts but increased by degradation products of unloaded PLDA.

### CONCLUSION

Mg reinforcement of PLDA matrices enhances viability and osteoblastic maturation of MSCs as well as secretion of MCP-1 and VEGF. Degradation products of PLDA/Mg composites do not increase levels of inflammatory cytokines released from macrophage-like cells.

### INTRODUCTION

Biphasic calcium phosphate (BCP) as bone grafting substitute can be used for reinforcement of osteoporotic bone and for promotion of bone healing and bone defect filling<sup>1</sup>. Experimental and clinical data showed bioactivity of BCP<sup>2,3</sup>. In current study the BCP ceramic granules with HAp/b-TCP ratio of 90/10 was selected as appropriate. It is supposed that the minor amount of b-TCP in the composition due to relatively faster resorption rate compared to HAp will ensure the initial burst of releasing calcium and orthophosphate ions into the biological medium, thus seeding new bone formation. The majority of HAp remaining after resorption of b-TCP will act as a tissue scaffold for the complete formation of new bone. Objective of our study was to evaluate by immunohistochemical method local bone tissue response to BCP ceramic granules implanted in experimental animals. Investigation of osteocalcin (OC) and osteopontin (OP) expression helps to understand bone tissue regeneration potential and remodeling after BCP implantation.

### EXPERIMENTAL METHODS

Experimental osteoporosis was induced in 10 female rabbits (age 2 years) by ovariectomy and following injections of methylprednisolone 1 mg/kg daily for 8 weeks<sup>4</sup>. On 6 animals 3mm hole was created in proximal end of the hip bone and filled with a BCP bioceramic granules 1 to 1.4 mm of size, containing hydroxyapatite (HAp) and  $\beta$ -tricalcium phosphate ( $\beta$ -TCP) in ratio 90/10 synthesized in Rudolfs Cimdins Riga Biomaterials innovations and development center of Riga Technical University by aqueous precipitation technique<sup>5</sup>. The control group consisted of 3 rabbits with the analogous defect of osteoporotic bone without implantation of BCP bioceramic granules. After 3 months animals were euthanased and bone samples collected and prepared by routine histological method. Tissue samples were stained according the standart immunohistochemical methods and expression of OC and OP was examined. Distribution of these factors was evaluated semiquantitatively by counting positive structures in the visual field: 0/+ - occasional, + - few, ++ - medium, +++ - many<sup>6</sup>.

### RESULTS AND DISCUSSION

Histological samples from control group showed local bone atrophy proving development of osteoporosis. In experimental group we found partially resorbed granuli

enrolled by osteoclasts and connective tissue capsule. In experimental group bone trabeculae were more developed.

In control group bone formation marker OC was found occasionally in visual field suggesting low bone tissue regeneration potential. In experimental group revealed stable increase of OC expression in all cases. Also OP what is active in bone remodeling was found occasionally in control group and increased in all samples of experimental group, but less obviously as osteocalcin. Probable the difference of OC and OP expression depends on the time of its assessment; greater OP expression happens on early stages of osteogenesis as adhesion of cells on the surface of a biomaterial takes place, OC, in turn, is an indicator of metabolic activity, whose increase would be found in the phase of bone mineralization<sup>7</sup>.

### CONCLUSION

Biphasic calcium phosphate bioceramic granules implanted in osteoporotic bone show good and stable local bone tissue regeneration and remodeling potential by increase of osteocalcin and osteopontin.

### INTRODUCTION

Aim of the presented research was to analyze and compare the tissue reactions to two different xenogeneic bone substitute materials dependent on the different sintering temperatures, preclinically *in vivo* and clinically.

### EXPERIMENTAL METHODS

The two bone substitute materials were implanted subcutaneously in CD-1 mice for up to 60 days additionally to their clinical for sinus augmentation in the upper jaw. Tissue formation, implant bed vascularization and numbers of multinucleated giant cells were investigated histologically and histomorphometrically.

### RESULTS AND DISCUSSION

Both bone substitute materials showed good integration within the peri-implant tissue and no signs of adverse inflammatory effects. In the preclinical *in vivo* study both groups presented an increasing vascularization over the whole study period. Within the implantation bed of the bone substitute of low sintering temperature (LST) few multinucleated giant were obvious on the surface of small sized bone substitute granules in the early integration period, while the tissue reaction to the bigger granules at later stages consisted mainly of mononuclear cells. In contrast, the tissue reaction to the bone substitute material of high sintering temperature (HST) consisted of biomaterial surface associated multinucleated giant cells. The clinical analysis confirmed the different cellular mechanisms

to the investigating biomaterials, mainly differing in the expression of a foreign body giant cell reaction.

### CONCLUSION

The tissue reactions to the investigated low and high sintering temperature bone substitute materials showed distinct differences *in vivo* and clinically, mainly in the formation and migration of multinucleated giant cells. As both biomaterials have the same origin, the observed differences seem to be related to the different processing techniques and the resulting different physico-chemical structures.

<sup>2</sup>Johan Gadolin Process Chemistry Centre, Åbo Akademi University, Finland

[peter.uppstu@abo.fi](mailto:peter.uppstu@abo.fi)

### INTRODUCTION

Bioactive glass scaffolds can be favourably used for the regeneration of bone<sup>1</sup>. However, because of the inherent brittleness of glass, polymer/glass composite scaffolds may be better suited for bone regeneration purposes than scaffolds based only on glass, especially in load-bearing sites<sup>2</sup>. Amorphous polylactide (PLA) coating has been shown to considerably increase the compression strength of porous glass scaffolds<sup>3</sup>. PLA stereocomplexes (sc-PLA) are known to increase mechanical properties and retard hydrolytic degradation compared to amorphous PLA or PLA homocrystals<sup>4</sup>. The aim of this study was to evaluate the impact of sc-PLA coatings on mechanical and degradation properties of porous bioactive glass scaffolds. As reference, glass scaffolds were coated with homocrystalline poly(L-lactide) (PLLA) or amorphous poly(D,L-lactide) (PDLLA).

### EXPERIMENTAL METHODS

Porous scaffolds of the bioactive glass 13-93 were manufactured with the foam replication method. The glass scaffolds were dip-coated with amorphous PDLLA, homocrystalline PLLA or an equimolar mixture of PLLA and poly(D-lactide) (PDLA) for stereocomplex formation. After drying the scaffolds were annealed in order to increase the amount of stereocomplex crystals in the coating. In vitro degradation of the scaffolds in simulated body fluid (SBF) was studied for up to 10 weeks. Compression strength was measured both before and after in vitro degradation. Water uptake, mass loss and pH of the SBF were measured. Morphological characterization was performed with SEM to evaluate scaffold porosity and coating thickness. Studies were performed with 5 parallel samples.

### RESULTS AND DISCUSSION

The effect of sc-PLA coatings on compression strength both before and after in vitro degradation, compared to amorphous and homocrystalline PLA coating, will be discussed in detail. The findings are compared to results of amorphous PLA coating of porous glass scaffolds published elsewhere. Mechanical properties and the in vitro degradation properties of the amorphous, homocrystalline and stereocomplex PLA coatings are shown.

Figure 1. Uncoated (left) and coated (right) glass scaffold.

### CONCLUSIONS

This work gives important insight into the applicability of sc-PLA for adjusting the mechanical and degradation properties of scaffolds for tissue regeneration.

### INTRODUCTION

Tissue engineering has greatly benefited from growth factor-based regenerative systems[1,2]. Many matrix-based systems for growth factor delivery[3,4] using natural polymers reported and tried to apply in medical field because their merits such as, safety, easy availability, and. However, long-term efficiency low in natural polymer is a still problem. In this study, we have engineered a delivery system for localized, long-sustained growth factor from alginate nanoparticles containing Bone Morphogenetic Proteins-2(BMP-2) for osteogenesis.

### EXPERIMENTAL METHODS

We observed effect of controlled release BMP-2 from alginate nanoparticles on in vitro osteogenic differentiation of Bone marrow stromal cells (BMSCs), by RT-PCR, western blots, immuno-cell-chemical and several stains. In vivo study, four groups were prepared; fibrin glue for control, fibrin glue with BMSCs, fibrin glue with alginate nanoparticles containing BMP-2 (ANP), and fibrin glue with BMSCs and ANP. These groups were applied in 4mm calvarial defects of nude mice. For evaluation of bone formation effect in each group, the specimens were harvested at 1, 8, and 16 weeks after surgery. The samples were analyzed with micro-CT and histological findings using H&E, von-kossa staining, and immunohistochemistry.

### RESULTS AND DISCUSSION

In vitro data, only BMSCs in culture medium was not expressed osteocalcin in RT-PCR and western blot. BMSCs in osteogenic medium, BMSCs in culture medium with ANP, and BMSCs in osteogenic medium with ANP were expressed osteocalcin in RT-PCR and western blot. Immuno-cell-chemical and several stains were positive in each group respectively except BMSCs in culture medium group.

In vivo study, fibrin glue with BMSCs, fibrin glue with ANP, and fibrin glue with BMSCs and ANP groups were formed bone structure at 8 week. In 16 weeks, bone-forming process kept going in all groups except control. By micro-CT and immunohistochemistry analysis, fibrin glue with BMSCs and ANP group showed most abundant bone formation.

Fig. 1. SEM photographs of the ANP prepared by diffusing water for (a) 10 min and (b) 3 days.

Fig. 2. Micro-computer tomography of critical size calvarial defect model; (a) 1 week, (b) 8 weeks of hBMSCs in fibrin glue group, (c) 1 week, (d) 14 weeks of hBMSCs and ANP in fibrin glue group.

### CONCLUSION

Alginate nanoparticles loaded BMP-2 in this study can be effective to the bone formation by enhanced and long steady release of growth factors. It is expected the application of this delivery system is as a good alternative for osteogenesis in regenerative medicine fields.

## INTRODUCTION

Porous membrane materials allow selective permeability of some nutrients, growth factors and proteins into a tissue defect. These materials also guarantee optimal conditions for cells to adhere and proliferate within the regenerating tissue. For these reasons membranes have been used in stomatology (periodontology), traumatology and orthopedic medicine. In case of a bone defect which size is larger than the critical bone defect a membrane works as a factor stimulating faster bone regeneration. Gradient pores, modification of membrane materials in a bulk (e.g. with ceramic nanoparticles) or at a surface (e.g. with proteins, PRP) are sufficient parameters to create the cellular response [1]. The most popular materials used in forming of membrane implants are synthetic resorbable polymers such as; polylactide (PLA), poliglicolide (PGLA), polycaprolactone (PCL) and their copolymers, or natural polymers such as collagen [2]. When the nanoparticles are present in the polymer matrix such polymer-ceramic composition exhibits novel properties. Bulk modification of the polymer can result in its bioactivity (BG, HAp, TCP), faster degradation (MMT), higher strength (Hap, SiO<sub>2</sub>) and better biocompatibility than the pure polymer. It is a good reason to use the nanocomposite membrane materials as a bone defect separator (e.g. after removal of cysts) or barrier providing optimal conditions for regeneration of a bone defect (e.g. ACL reconstruction).

This work presents results of investigations on polymer-ceramic nanocomposite membranes modified by osteoconductive (SiO<sub>2</sub>) and osteoinductive (TCP) ceramic nanoparticles.

## EXPERIMENTAL METHODS

Porous nanocomposite materials based on resorbable poly-ε-caprolactone (Sigma Aldrich) and ceramic nanoparticles: silica-SiO<sub>2</sub> (5-10 nm, Sigma Aldrich) and tricalcium phosphate-TCP (20-30 nm, Sigma Aldrich) were obtained by the phase inversion method. Porous microstructure of the nanocomposites was investigated using SEM/EDS. Physicochemical properties of the materials surface were investigated by means of wettability and surface energy measurements (DSA 10 Kruss). Mechanical properties of the membranes (strength and Young's modulus) were tested in a stretching test (Zwick 1435). Durability of the materials in *in vitro* conditions was estimated using phosphate buffer solution (PBS). Monitoring of their degradation was performed by the thermal analysis (TG/DSC).

## RESULTS AND DISCUSSION

Microstructures of both manufactured membranes were porous. Size and shape of the pores strongly depended on the applied nanoparticles i.e.; pores in the PCL/SiO<sub>2</sub> membrane were round and had larger diameters (12 - 25 μm) while pores in the PCL/TCP membrane were smaller (7 - 15 μm) and irregular. Additionally, the nanoparticles influenced mechanical properties of the membranes which strength (~140 MPa) and Young's modulus (~14 MPa) were two times larger than those of the pure polymer membrane (Fig 1.). The PCL/SiO<sub>2</sub> as well as the PCL/TCP showed bioactivity because after 3 days in SBF solution on their surface apatite structure could be observed. The membrane with nano-silica apatite structure were observed after 10 days in SBF solution. Degradation test showed that the membrane materials after two weeks of PBS incubation were characterised by larger crystallites than before the test, after 4 weeks the crystallite size of PCL decreased of about 50%, and after 10 weeks the membrane materials collapsed.

Fig 1. Mechanical properties of the membrane materials

## CONCLUSIONS

Nanocomposite membrane materials based on PCL and modified with SiO<sub>2</sub> or TCP nanoparticles give great possibility to design many materials futures such as: shape and size of pores, bioactivity and wettability. Conventional polymeric membranes lose mechanical properties, but addition of ceramic nanofiller can improve them. It means that the nanocomposite membranes can be potential materials for space-making implant in bone tissue defect regeneration.

### INTRODUCTION

There is a big need for broken bone fixation systems targeted at small animals treatment. Metallic plates, which are commonly used for such purpose, have many drawbacks e.g. corrosion, accumulation of metal ions in tissues, too high Young modulus. Degradable plates made of polymer composites reinforced with carbon fibres may offer an interesting alternative. In this work a research on biofunctionality of novel fixation plates made of polylactide based composites are presented.

### EXPERIMENTAL METHODS

Fixation plates were manufactured with two types of forming processes: a hot-press of the prepregs ( $T \sim 200^\circ\text{C}$ ) and an injection moulding ( $T \sim 190^\circ\text{C}$ , system pressure  $80\text{kg/cm}^3$ ). As a matrix the resorbable polylactide Purasorb PLDL 7028 (Purac) was used. Hot-pressed plates were reinforced with 60wt% woven fabric CF2D (Tenax) impregnated with PLDL dissolved in dichlorometane (1/10) (Fig.1a). Continuous carbon fibres CF1D (Tenax) were previously shaped in loops to create a peripheral circumferential reinforcement of injected samples (Fig.1b).

Fig.1 Degradable internal fixation plates:  
a) PLDL/CF2D, b) PLDL/CF1D

Obtained plates were incubated for 6 weeks in distilled water ( $37^\circ\text{C}$ ). Such period of time is suggested in the literature as a minimal for primary ossification. Mechanical testing (3pts bending) of the simulated model allowed to verify biofunctionality of the fixation system. Plates before and after incubation were compared. They were installed with metallic screws to the notched rabbit femoral bones and were bent (Fig.2). Observations of destroyed samples were conducted under stereoscopic microscope. The possibilities of applications of developed plates for veterinary orthopedics were evaluated on analysis of the results.

Fig. 2 Three-points bending test - model of simulated fixation system on rabbit femoral bone

### RESULTS AND DISCUSSION

After the mechanical testing it was found that much better results were achieved for PLDL/CF2D samples than for PLDL/CF1D. Introduction of high volume of woven fabric of carbon fibers strongly increased the stiffness of the fixation model and as a result total deformation was much smaller. There was observed an impact of the six-weeks incubation on mechanical properties of the PLDL/CF2D plates (30% decrease of bending strength) in contrary to PLDL/CF1D where such result was not recorded (Fig.3).

Fig.3 Comparison of bending strength of PLDL/CF plates before and after incubation.

### CONCLUSION

Even though there was a downgrade of bending strength of woven reinforced plates after incubation the value still was twice higher then bending strength of the plate reinforced with carbon fibre circumferential loop. It may indicate that this type of the plate will maintain a high strength and a proper stiffness of the osteosynthesis. It provides the correct amount of strength when necessary. In a presence of body fluids it harmlessly degrades over time and the load can be safely transferred to the healed bone giving the impulse to the bone tissue to remodel the structure according to the Wolff's law.

## The Influence of Poly(ethylene glycol) with Different Molecular Weight on the Properties of Acrylic Bone Cements

Klaudia Król, Kinga Pielichowska

Faculty of Materials Science and Ceramics, Department of Biomaterials,  
AGH University of Science and Technology, Poland  
[kingapie@agh.edu.pl](mailto:kingapie@agh.edu.pl)

### INTRODUCTION

Acrylic bone cement is commonly used for orthopaedic prosthesis fixation, since 1958<sup>1</sup>. The main problem that has been noticed with the use of acrylic bone cement is thermal necrosis of surrounding tissues, due to the high amount of heat being generated during the curing process<sup>2</sup>. Many attempts have been made to reduce too high curing temperature of PMMA bone cement. In this study, acrylic bone cement was modified with poly(ethylene glycol) (PEG), well-known, biocompatible phase change material (PCM), to decrease too high temperature of acrylic bone cement<sup>3,4</sup>.

### EXPERIMENTAL METHODS

Acrylic bone cement was modified with 15% of PEG with different molecular weight of 1450 - 10 000. The liquid to powder ratio (L/P ratio) of 0.37 ml/g was used. The setting time was measured using the Gillmore needle test. The curing parameters (maximum temperature  $T_{max}$  and setting time  $t_{set}$ ) were measured in accordance with ISO 5833 standard. The thermal analysis (DSC, TG), mechanical tests (compression testing and ultrasonic testing), microstructure studies (fluorescence microscopy, SEM) were performed to characterize the new material. Moreover, samples were incubated at 37 °C according to EN ISO 10993-13 for 3 months in distilled water. The pH, conductivity, and mass changes were measured during the incubation process.

### RESULTS AND DISCUSSION

The setting time of acrylic bone cements is given in Table 1. Bone cements modified with PEG showed longer setting time than the pure cement. In all cases, the curing process lasted in approximately 30–60s.

Tab. 1 Setting time of acrylic bone cements modified with poly(ethylene glycol) (Gillmore Needle method)

Sample	Setting time	
	Initial time	Final time
Pure cement	7 min 9s	8 min 8s
Cement + PEG 4000	14 min 30s	15min 30s
Cement + PEG 8000	11min 15s	12min 30s
Cement + PEG 10000	12min 30s	13min

An increase in setting time, determined according to ISO 5833:2002 standard, is an evidence for retardation of the polymerization reaction rate, caused by PEG phase change process.

Fig. 1. shows the temperature-time profiles. The maximum polymerization temperature of pure cement was 60.9°C.

A significant decrease in maximum temperature of modified bone cements was observed and it depends on PEG molecular weight. The largest temperature decrease was found for cement containing PEG 4000.

Fig. 1 Polymerization exotherms of acrylic bone cement modified with PEG

PMMA releases large amounts of heat during the polymerization. This thermal energy is utilized by PEG phase change, causing a decrease in the temperature of polymerization and an increase in setting time of acrylic bone cement. Depending on molecular weight of PEG, different amounts of heat can be stored.

### CONCLUSION

The aim of this study was to verify the effect of PEG on polymerization temperature of acrylic bone cement. A considerable decrease in curing temperature together with an increase in the setting time was observed. Importantly, the curing parameters still fulfilled the requirements of ISO 5833 standard.

## Optimizing Tibial Fractures Treatment with Carbon-Plate Fixator – CARBOELASTOFIX

Maciej Ambroziak<sup>1</sup>, Jan Chłopek<sup>2</sup>, Anna Morawska-Chochół<sup>2</sup>, Wojciech Żakiewicz<sup>1</sup>

<sup>1</sup>Chair and Department of Orthopedics and Traumatology of Locomotor System,  
Medical University of Warsaw, ul. Lindleya 4, 02-005 Warszawa, Poland

<sup>2</sup>AGH University of Science and Technology, Faculty of Materials Science and Ceramics,  
Department of Biomaterials, al. Mickiewicza 30, 30-059 Kraków, Poland

### INTRODUCTION

The paper focuses on optimizing the treatment of tibial fractures with a new type of carbon external fixator, named "Carboelastofix" by the design team based on its construction and mechanical properties.

Experimental and clinical research conducted for a number of years at the Clinic of Orthopaedics and Traumatology of the Medical University of Warsaw has shown the advantages of the "Carboelastofix" external fixator in healing tibial fractures.

The authors' main objective was to construct a bone fixation system which lacked the drawbacks of metal constructions. The novel method takes into account the forces transmitted by the fixator and the maximum loading of the fracture healing site at a given stage, which allows to choose the individual initial characteristics of the fixator.

### EXPERIMENTAL METHODS

The innovative external fixator was used to treat tibial fractures (type 42-A1 and 43-A2 according to AO classification) in 30 patients between 2002 and 2006.

All the cases succeeded in fracture healing. Results were based on clinical assessment and conventional X-rays. In addition, the progress of fracture healing was analyzed with ultrasonometry tests and in some cases density analysis of optical digital radiography images.

Fracture healing is a dynamic process and every stage requires different local mechanical and biological conditions. A special measuring device was constructed to assess the stiffness of the fixator - bone interface and it allowed to modify the flexibility (dynamization of fixation) consistently during the course of treatment. As fracture healing progressed and the interfragmentary stiffness increased, the stiffness of the fixator was gradually reduced. Treating fractures with a dynamic method such as these attempts to ensure iso-elasticity of the fixation during the whole healing process, as the principles of orthopaedic trauma suggested for many years to be optimal in achieving bone consolidation.

In addition, as the carbon plates are radiolucent, precise monitoring of fracture site healing and assessment of potential complications is possible.

### CONCLUSION

The presented optimized version of the Polish "Carboelastofix" carbon external fixator and obtained clinical results prove its high effectiveness in treating spiral and oblique tibial fractures. With its mechanical properties (gradual dynamization) and radiolucence this type of fixator has definite advantages over traditional external fixation constructions and may be considered an alternative.

## The Influence of Chain Extender on Properties of Polyurethane-Based Composites as Potential Injectable Bone Substitutes

Piotr Szczepańczyk, Kinga Pielichowska, Jan Chłopek

AGH University of Science and Technology, Faculty of Materials Science and Ceramics, Department of Biomaterials, Poland

[pszczepa@agh.edu.pl](mailto:pszczepa@agh.edu.pl)

### INTRODUCTION

Polyurethanes have potential application in nerve regeneration, cartilage and bone tissue repair, skin and vascular regeneration. Polyurethanes can be fabricated as either rigid or flexible foams. Their interconnected porous structure is beneficial for cell migration and proliferation. Open-celled pores also enable vascularisation and communication between cells. Segmented structure makes it possible to tune their physicochemical, mechanical and biological properties (1). Chain extender influences both structure and properties of the polymer material. For example increasing content of chain extender may cause higher density (2). Molecular weight distribution may be controlled by chain extender concentration (3). Chain extenders influence the elastic modulus and glass transition temperature of the adhesive through the hard/soft segment relationship (4). Their chemical structure also affects the crystallinity (5). Polysaccharide chain extenders such as chitin accelerate the degradation rate. Simultaneously the thermal stability was found to increase with increasing chitin content. Chitin-based polyurethanes exhibited enhanced stiffness, heat resistance, molecular rigidity and strength. The wide range of material properties that were achieved through modifications in chemistry makes these degradable polymers applicable for biomedical applications (6). The aim of this study was to modify polyurethanes reinforced by  $\beta$ -tricalcium phosphate ( $\beta$ -TCP) microparticles by adding chitosan to facilitate biodegradation (7). It has also been proved that polyurethane chains containing either monosaccharides or sugar alcohols do not degrade into toxic by-products (8). The effect of chitosan/1,4-butanediol used as crosslinking agent/chain extender was investigated. The composite foams were synthesized using various amounts of  $\beta$ -TCP. It was found that incorporation of  $\beta$ -TCP and chitosan influenced microstructure of composites.

### EXPERIMENTAL METHODS

The effect of varying  $\beta$ -TCP content and chitosan/1,4-butanediol ratio was investigated using infrared spectroscopy, differential scanning calorimetry, drop shape analysis and microscopic methods. *In vitro* tests

were carried out to study the influence of bioceramics and crosslinking agent/chain extenders on biodegradation as well as a preliminary investigation of the *in vitro* bioactivity.

### RESULTS AND DISCUSSION

Scanning electron microscopy showed presence of the apatites deposition after 4-week incubation in simulated body fluid (Figure 1). Incorporation of  $\beta$ -TCP microparticles improved modulus.

Figure 1 SEM image of PU/ $\beta$ -TCP after SBF incubation

### CONCLUSION

Synthesis of the composites included different  $\beta$ -tricalcium phosphate content and chitosan/1,4-butanediol ratio. The effect of  $\beta$ -TCP and chain extenders was studied by spectroscopic, thermal and microscopic methods. The addition of  $\beta$ -TCP and chitosan influenced thermal stability. Introduction of  $\beta$ -TCP strengthened the hydrophilic nature of polyurethane foams. Both  $\beta$ -TCP and chitosan could be able to tailor properties of the composites so they could be closer to fulfil the requirements of tissue engineering. However, further investigation is necessary to study another factors connected with *in vivo* bone healing.

### INTRODUCTION

The human amniotic membrane (hAM) is a highly abundant and readily available tissue that may be helpful as a support for bone regeneration. Human Amniotic Membrane may be an alternative to induced membrane in the case of critical size bone defects to replace the periosteum. This membrane contains two different cell types: human Amnion Epithelial Cells (hAECs) and human Amnion Mesenchymal Stem Cells (hAMSCs) that have a strong osteoinductive potential<sup>1,2</sup>. Moreover, AEC introduced in tibia bone defect survived in the site of implantation for 45 days and supported consistent bone neoformation<sup>3</sup>. The aim of this project was to analyze bone regeneration potential of hAM implanted in mice calvaria bone defect. We have investigated i) the role of epithelial and mesenchymal layers on bone regeneration efficiency in a model of calvarial critical defect and ii) the consequences of cryopreservation.

### MATERIAL and METHODS

hAM cryopreservation vs fresh membranes: hAM were recovered after elective cesarian surgery and either used as fresh tissue or cryopreserved in RPMI/Glycerol (1/1).

In vivo procedure: Critical bone defects (3.3mm diameter) were performed in adult mice calvaria. Defects remained free or were covered by an hAM fragment, either fresh or cryopreserved in each orientation (hAECs or hAMSCs, n = 8-10 in each group). Sacrifice was performed after 8 weeks and bone regeneration was quantified by X-rays (faxitron). Kruskal & Wallis with Mann & Whitney comparisons were utilized. Decalcified histological analysis was done using trichrome Masson staining.

In vitro: Human Bone Marrow Mesenchymal Stem cells (hBMSCs) were cultured on cryopreserved hAM fragments in basal medium during two weeks; hAM cell survival after cryopreservation and hBMSC viability were analyzed with live/dead staining.

### RESULTS AND DISCUSSION

Preliminary results of faxitron analysis showed that no defect was regenerated *ad integrum*. However, mineralized nodule formations were observed, mainly for cryopreserved hAM. Quantitative analysis suggested that cryopreserved hAM (hAECs side)(1) induced mineralized nodule formation with a higher efficiency as compared with fresh hAM or absence of any hAM (2).

Fig 1 : Faxitron showing the defect remaining after 8 weeks of healing.

Histological analysis has shown that hAM did not induced important inflammatory reaction. New bone formation was exceptionally observed at the periphery of the defect.

Live/dead cells viability assays showed very few hAM cells alived after thawing (1). However, after 7 days, dividing cells were detected (AECs and hAMSCs) (2). Preliminary results revealed that hBMSCs could adhere to hAM and survive (3).

### CONCLUSION

hAM alone did not allow regeneration *ad integrum* of critical calvaria bone defect in mice. Cryopreserved hAM with epithelial side in contact with the defect have produced more mineralized nodules than other conditions. In vitro analyses have shown that hAM epithelial side was suitable for hBMSC proliferation. We proposed now to investigate the osteogenic potential of hAM associated with hydroxyapatite in the same model.

## INTRODUCTION

The requirements for novel biomaterials for medical applications are still changing and increasing. Apart from bioactivity and appropriate mechanical properties, novel biomaterials should have be biodegradable, have cell immobilization properties and ability to be a drug delivery system for cure of disease or support of healing process, e.g. limit inflammation<sup>1</sup>. Natural based polymers seem to be the best biomaterials to fulfil those requirements. Chitosan is one of them<sup>2</sup>. This polymer is commonly used as a bioresorbable matrix for wound dressing, drug delivery system and as a scaffolds material. It exhibits promising non-toxic, bioactive and cell attachment properties<sup>3</sup>. Synthetic nanoclay commercially named Laponite<sup>®</sup> was used in the research to enhance its properties. Its structure is very similar to commonly used montmorillonite, but synthetic origin guarantees stable and recurrent composition and less content of heavy metal ions in comparison with natural montmorillonite.

## EXPERIMENTAL METHODS

Low molecular weight chitosan was dissolved in three solvents: commonly used acetic acid, ascorbic acid and lactic acid. The concentration of solvents and chitosan were the same, it was 2,5% of chitosan in 2% aqueous acidic solutions. To obtain composites, cross-linker was dispersed first in an aqueous environment and mixed with chitosan. Obtained gels were precipitated in polyphosphate counterions solution to achieve a form of beads. Then, they were air dried and vacuum dried. DSC measurements have been performed using standard procedure 10°C/min in nitrogen atmosphere. Cell culture tests were performed to confirm bioactive properties of the composites.

## RESULTS AND DISCUSSION

The obtained nanocomposites show differences in thermal properties depending on cross-linker concentration and solvent used in the preparation. Significant differences are visible in Figure 1. Curve CL (from chitosan dissolved in ascorbic acid) and LL (from chitosan dissolved in lactic acid) have similar course till 80°C, then there are big differences, especially for chitosan from ascorbic acid solution. Large endothermal

peak is probably caused by evaporation of entrapped water. This suggests that ascorbic acid solution causes stronger water entrapment in chitosan hydrogel structure.

Figure 1. DSC curves of chitosan hydrogels (LL-lactic acid; CL-ascorbic acid).

## CONCLUSION

Synthesis environment is a crucial element influencing properties of obtained material. In DSC curves, there are significant differences in thermal properties chitosan dissolved in aqueous solutions of different organic acids.

## Why Incorporation of Poly(Ethylene Glycol) into Polyurethane Chain is an Attractive Way to Improve Its Physicochemical Properties for Bone Regeneration?

Michalina Marzec, Justyna Kucińska-Lipka, Helena Janik,

Department of Polymer Technology, Chemical Faculty, Gdansk University of Technology, Poland

[michalina.marzec@pg.gda.pl](mailto:michalina.marzec@pg.gda.pl)

### INTRODUCTION

Polyurethanes (PUs) have unique segmented structure, due to which diverse properties can be obtained using relevant raw materials and additives. Moreover, it is known that PUs undergo calcification when implanted into human body. The ability to promote calcium phosphates (CP) formation is one of the unique properties that stands out PU from other biomaterials and speaks for using PU in bone regeneration. However, calcification occurs only after long-term implantation. In this study, poly(ethylene glycol) (PEG), because of its exceptional properties such as biocompatibility and biodegradability, was chosen to speed up calcification process. We examined the influence of different amount of PEG incorporated into chain on PU properties.

### EXPERIMENTAL METHODS

Five series of PU from poly(ethylene-butylene) adipate diol, poly(ethylene glycol) (PEG), 1,6-hexamethylene diisocyanate and 1,4-buthanediol were synthesized.

*In vitro* calcification was carried out for 80 days. PUs were incubated in Golomb & Wagner's solution. Scanning electron microscope analysis (SEM) was used to examine PU surface before and after incubation. Calcium concentration in solutions after removing samples was measured by atomic absorption spectrometry (AAS). Tensile strength were performed according to PN-EN ISO: 1799 : 2009. The hydrophilic properties were determined by the water contact angle measurement with a sessile drop technique.

### RESULTS AND DISCUSSION

From data presented in table 1 it is clear that incorporation of PEG into PU chain improves mechanical properties, the tensile strength increased from 10 MPa to 26 MPa. The water contact angle decreased with the increase of PEG, what indicates that by PEG incorporation it is possible to obtain more hydrophilic material. Noteworthy, in all series we obtained highly hydrophilic materials. Figure 1 shows that addition of PEG into PU caused calcium phosphate formation already after 16 days of incubation in Golomb & Wagner solution.

Tab. 1 Physical properties of PUs synthesised with different PEG content.

PEG content (wt. %)	0	5	10	20	25
Tensile strength (MPa)	10	17	21	26	22
Water contact angle (°)	15	15	11	10	9

Fig. 1 SEM photographs of the PU surface samples A – PU without PEG, B – PU with 20 wt % of PEG after 16 days of incubation.

The mechanism of calcification is still unknown, but it was discussed in terms of presence of ester and/or ether groups, hydrophilic/hydrophobic properties and hard segment content. In this study we proved that the presence of ether groups and higher isocyanate index enhance calcification, what is in agreement with. However the statement in the literature that hydrophilicity promotes nucleation of CP is not always the case. We found that both materials had comparable contact angles but only sample that possessed ether groups speeded up calcification (Fig. 1, Tab. 1).

### CONCLUSION

Incorporation of poly(ethylene glycol) into polyurethane chain is an attractive way to improve biological properties, mechanical strength and supports formation of new bone. Introducing ether groups speeds up calcification.

## Construction of a Functional Bone Implant to Direct the Biomineralization Process

Inas Ozcan<sup>1</sup>, Kursad Kazmanli<sup>2</sup>, Fatma Nese Kok<sup>1</sup>

<sup>1</sup>Molecular Biology Genetics and Biotechnology Programme, Istanbul Technical University, Turkey

<sup>2</sup>Metallurgical and Materials Engineering Department, Istanbul Technical University, Turkey

[ins.ozcn@gmail.com](mailto:ins.ozcn@gmail.com)

### INTRODUCTION

The aim of this study is to design a biodegradable, biocompatible hard tissue implant to trigger and direct the biomineralization process. To construct the implant, silk fibroin from *Bombyx mori* and its blend with other polymers such as gelatin and poly(L-lactic acid) (PLLA) was chosen as the main for their superior properties in bone tissue related applications<sup>1-2</sup>. To direct the biomineralization process a short-peptide derived from osteocalcin will be used<sup>3</sup>. As the structure/crystallinity of biominerals are important for their biological activity, the biomineralization process in the constructed implants will be examined by different techniques (SEM-EDC; XPS, etc) both in the absence and the presence of the human fetal osteoblastic cells (fHOB).

### EXPERIMENTAL METHODS

Silk fibroin protein was obtained from *Bombyx mori* cocoons (a modified procedure was adapted from Rockwood et al)<sup>4</sup> with 4-6 % w/v yield (Fig.1). The fibroin solution was aliquoted (5mL), freeze at -20°C overnight and subsequently lyophilized for 48 h. Silk fibroin solutions (2%, 3%, 6% w/v) with or without addition of gelatin (1%; 1:1 v/v) were prepared swelling behavior, porosity and morphology were examined.

Figure 1. Silk fibroin solution from *B.mori* cocoons and lyophilized-fibroin scaffolds

Silk fibroin scaffolds were cut into 12mm diameter and 6mm thickness were weighted, then immersed in phosphate buffer saline (PBS) at room temperature and weighed again after 1 h, 3h, 5h and 24h. Swelling ratio %S was determined via Ws (swollen scaffold)-Wd (dry scaffold) values and were calculated as follows:

$$\%S = \frac{(W_s - W_d)}{W_d} \times 100$$

Hexane, being a nonsolvent for silk fibroin was used for porosity measurements. The known volume of hexane (V1), hexane-impregnated scaffold along with hexane (V2), the residual hexane volume (V3) were used to calculate the porosity of scaffolds (ε) obtained by:

$$\epsilon(\%) = \frac{V_1 - V_3}{V_2 - V_3} \times 100$$

### RESULTS AND DISCUSSION

Swelling behavior for silk fibroin and silk fibroin/gelatin composite scaffolds were given at Fig.2. It could be noticed that scaffolds with gelatin had low

swelling ratio compared to SF scaffolds. Highest swelling ratio was obtained by 2 and 3% SF scaffolds.

Figure 2. Swelling ratio of SF and SF:GEL scaffolds in PBS

Porosity studies showed that increasing the polymer amount lead to a decrease in porosity for SF implants. Addition of gelatin seems to alter this behavior. All scaffolds had illustrated higher than 60% porosity. Difference in SF amount and addition of gelatin seemed to yield scaffolds with different morphologies (Fig 3).

Figure 3. SEM micrographs of the scaffolds

### CONCLUSION

Preparation of silk fibroin/PLLA with different polymer ratios is an ongoing work. After the selection of best candidates, peptides will be immobilized and biomineralization studies will be started.

This paper describes practical surface treatments demonstrated for PEEK and titanium alloy orthopedic implants that significantly improve the osseointegration potential of these materials. The surface treatment provides a biocompatible surface that enables subsequent covalent functionalisation with bioactive molecules. The processes rely on energetic ion bombardment from a plasma to create a nanoscale interfacial layer containing pi-conjugated carbon clusters which serves as a reservoir for radicals. Covalent coupling of tropoelastin molecules by reaction with these embedded radicals is achieved in a one-step application of the biomolecules in buffer solution to the surfaces. The immobilized molecules promote bone cell adhesion and proliferation as observed in assays using MG63 and SAOS cell lines. We take significant steps towards making this a practical treatment with commercial potential by demonstrating 1) sterilization of the tropoelastin-coated devices in packaging without impacting the bioactivity of the protein; 2) robustness of the interlayer against scratching under load, and 3) that the plasma-based processes used can be applied to the complex shaped structures typical of orthopedic implants in a straight-forward way. The utility of the coatings in promoting bone integration is demonstrated by in-vitro cell assays and in-vivo experiments.

### INTRODUCTION

As the population ages and life expectancies continue to increase, the need for orthopedic implants, such as hip and knee replacements and spinal implants, is increasing rapidly. Traditionally titanium alloys have been the preferred materials for such implants. Titanium has a relatively biocompatible surface, which is often modified to help facilitate bone integration using coatings based on hydroxyapatite.

Polyetheretherketone (PEEK) is a polymer whose mechanical properties provide a much better match to bone. It has been introduced as a material for orthopedic implants to combat the problem of stress shielding and has been deployed commercially particularly in spinal implants, however it provides poor integration with surrounding bone tissues. Following improvements of bone integration achieved for titanium by the application of hydroxyapatite (HA) coatings, composites of PEEK with hydroxyapatite (HA) have improved its bioactivity but typically at the expense of the excellent mechanical properties. Coating with titanium has been proposed as a way to improve its ability to integrate with bone tissue.

### EXPERIMENTAL METHODS

Plasma immersion ion implantation in a nitrogen plasma is used to activate the surfaces of polymers, such as PEEK. In this process the sample is immersed in an RF plasma and surrounded by a mesh electrode of appropriate geometry. High voltage negative bias (up to 20kV) pulses are applied to the electrode to accelerate nitrogen ions from the plasma into the surface of the polymer.

For treatment of metals, such as Ti alloys, acetylene and argon are added to the plasma to facilitate deposition of a carbon containing surface layer. The metal workpiece to be modified is connected directly to a high voltage pulsed power supply. Ions accelerated from the plasma provide interface mixing for excellent adhesion as well as creating radicals embedded in the deposited coating.

In each case the treated surface layer is <100nm in thickness and contains sufficient radicals to covalently couple a dense bioactive layer of protein/peptide to the surface by simple contact with a solution containing the biomolecules.

### RESULTS AND DISCUSSION

Mechanical stability of the surfaces was demonstrated by scratching under load and subsequent incubation in heated ionic solutions. The surfaces, as examined under SEM, showed that the modified layer was only removed at the sites where scratched by the indenter. No delamination was observed in surrounding areas.

Covalent immobilisation of bioactive adhesion of signalling proteins and peptides was demonstrated using molecules such as tropoelastin and its derivatives. Resistance to elevated temperature SDS washing showed that the biomolecules were immobilised covalently. Sterilization by gamma irradiation was demonstrated and did not alter the layers' bioactivity.

Cell assays showed that the biomolecules retained their cell adhesive and signalling capabilities when immobilised to these surfaces and significantly enhanced the adhesion and proliferation of cells seeded on them.

Bone cell markers such as alkaline phosphatase showed good bone cell activity and that the surfaces would support bone integration.

### CONCLUSION

We have created a practical and industry scalable platform technology for the bioactivation of surfaces to promote the tissue integration of bone contacting biomaterials.

## Exploring Osteoclastogenesis in a Co-Culture System

Sabine Schulze<sup>1</sup>, Peter Dieter<sup>1</sup>, Ute Hempel<sup>1</sup>

<sup>1</sup>Institute of Physiological Chemistry, TU Dresden, Germany  
[Sabine.Schulze1@mailbox.tu-dresden.de](mailto:Sabine.Schulze1@mailbox.tu-dresden.de)

### INTRODUCTION

Bone is a highly dynamic tissue which is characterised by continuous remodelling. Bone mass and bone density are maintained by precise activation and repression of bone-resorbing osteoclasts (OC) and bone-forming osteoblasts (OB). OB secrete M-CSF and RANKL which induce fusion and activation OC precursors. Vice versa, OB are recruited to sites of prior bone resorption by OC-generated factors to refill resorption cavities<sup>1</sup>. For balanced bone formation and resorption it is of great importance to address both cell types in research on implant materials and drugs. Therefore, we established a direct *in vitro* co-culture of OB and OC using a natural OB-derived matrix as a substrate and avoiding any further osteogenic supplements.

### EXPERIMENTAL METHODS

PBMC isolated from buffy coats were seeded on a native extracellular matrix generated by SaOS-2 cells<sup>2</sup> and treated with M-CSF to ensure their survival. Mesenchymal stroma cells (MSC) were incubated with  $\beta$ -glycerophosphate and ascorbic acid. After eight days of predifferentiation MSC were either co-cultured with PBMC or were seeded alone on SaOS-2 matrix. To estimate the impact of cell-cell contact on osteoclastogenesis PBMC medium was supplemented with supernatant from MSC culture. Vice versa, MSC were cultured in medium containing PBMC supernatant. Medium was refreshed twice a week. After two weeks of (co-)culture OC and OB markers were measured. Differentiation of PBMC into OC was verified by resorption pit formation and analysis of the OC marker tartrate-resistant acid phosphatase (TRAP). Osteogenic differentiation of MSC was evaluated by alkaline phosphatase activity.

### RESULTS AND DISCUSSION

Fig.1: Quantitative resorption assay. PBMC in co-culture with MSC resorbed as much as RANKL-stimulated PBMC. Unstimulated PBMC cultured with MSC supernatant show significantly less resorption.

Fig.2: Microscopic images of stimulated PBMC (A), co-culture (B) and PBMC cultured with MSC supernatant (C). Resorption pits are highlighted by white arrows. In PBMC culture with MSC supernatants huge OC occur after PBMC fusion, but no resorption pits are visible.

These data imply that RANKL-dependent bone resorption is enhanced by direct OC-OB contact which enables the exclusive interaction of membrane-bound RANKL (on OB) with its receptor RANK (on OC). In the indirect co-culture system OC are reliant on the release of soluble RANKL by OB which seems to be not sufficient for a OC activity comparable to direct co-culture. Our results confirm previous publications<sup>3,4</sup>.

### CONCLUSION

For actively resorbing osteoclasts cell-cell contact with osteoblasts is essentially required. Therefore, we established a well-tuned co-culture system on a smart calcium phosphate matrix.

### INTRODUCTION

The low capacity of articular cartilage for self-repair and regeneration is extremely poor which contributes to the degradation of articular cartilage associated with osteoarthritis (OA).<sup>1</sup> Regenerative medicine offers great potential as an alternative to joint replacement to treat OA patients. We have previously shown the chondrogenic potential of human bone marrow mesenchymal stem cells (BM-MSCs) derived from OA patients in chitosan-coated poly(L-Lactic Acid) (PLLA-CHT) scaffolds after long-term culture.<sup>2</sup> This present study is aimed at analyzing the effect of the physicochemical properties of the scaffolds during the different stages of the chondrogenic differentiation process in order to give better insight of the dependence of the biological response of BM-MSCs on scaffolds' structure and composition.

### EXPERIMENTAL METHODS

Human BM-MSCs ( $2.5 \times 10^5$ ) derived from OA patients, were seeded on pure or chitosan-coated PLLA scaffolds under a defined chondrogenic differentiation medium (CM) composed by DMEM supplemented with knock-out serum (15%), ascorbic acid (10  $\mu$ l/ml), transferrin (6  $\mu$ l/ml), dexamethasone (10  $\mu$ M), retinoic acid ( $10^{-7}$  M) and transforming growth factor beta 3 (TGF- $\beta$ 3, 10 ng/ml), during 7, 14 and 21 days, using a conventional pellet-culture system as control. At each time point the expression of cartilage interest markers at molecular and protein level was studied using rt-PCR and immunohistochemistry (col1a1, col2a1, col10a1, sox9, aggrecan, PRG4, CILP, POSTN and RPL13a as housekeeping gene). The quality of the synthesized extracellular matrix was analyzed by histological staining (toluidine blue (TB), safranin-O (SO)).

### RESULTS AND DISCUSSION

Controlling extraction-gelation parameters allows to create different structures on PLLA-CHT scaffolds, such as hydrogel-(PLLA-CHT1) or fiber-like coatings (PLLA-CHT2) that can directly influence the chondrogenic differentiation process of BM-MSCs. We observed the chondrogenic differentiation of cells and the formation and maturation of an extracellular matrix with deposition of proteoglycans (Fig.1 TB and SO) and zone-specific molecules such as lubricin (PRG4, superficial zone) and cartilage intermediate layer protein (CILP, intermediate zone), although negative for periostin (POSTN, deep layer). Chitosan incorporation negatively affected the chondrogenic

process of BM-MSCs observed at mRNA and protein expression, with a significant decrease on aggrecan and col2a, as well as, PRG4 and CILP, when compared to pure PLLA. A hydrogel-like tissue led to a more heterogeneous tissue whilst fiber-coating to a more homogeneous distribution of the tissue formed. Moreover, the presence of chitosan seems to be accelerating an hypertrophic phenotype, with an early increase on the expression of col10a1, at day 14. The expression of col1a1 remained downregulated at all time points which discards fibrocartilage formation (data not shown).

Figure 1. Histological analysis (TB and SO) in cross-sections of pure and CHT-coated PLLA scaffolds (scale bar: 200  $\mu$ m).

### CONCLUSION

BM-MSCs chondrogenic differentiation can be influenced by the composition and structure of pure and CHT-coated PLLA scaffolds, although in our case the composition effect seems to have a higher impact than structural modifications.

## INTRODUCTION

Bone tissue defects, especially those with critical size, are treated with autologous or allogenic grafts or scaffold biomaterials. Designing scaffolds, that mimic structure of bone extracellular matrix (ECM), and provide optimal architecture and chemistry for cell proliferation, migration and differentiation are the goals of many studies<sup>1</sup>. Another approach is the use of drugs that are known to enhance bone growth. In this study we propose to combine both approaches: resorbable scaffolds and drug delivery system based on resorbable microparticles (MPs).

In detail, we prepared poly(L-lactide-co-glycolide) (PLGA) scaffolds and modify them with PLGA MPs containing sodium alendronate (Aln). Our intention was to provide support for osteoprogenitors and osteoblasts adhesion/proliferation/differentiation and concomitantly to inhibit osteoclasts by sustained local delivery of Aln. Aln was chosen because it is widely used for the treatment of several bone diseases like osteoporosis, Paget's disease, bone tumors and recently it has been proposed as osteointegration-enhancing drug<sup>2</sup>.

## EXPERIMENTAL METHODS

PLGA scaffolds were produced by solvent casting/particulate leaching technique. Sodium chloride particles (400 – 600 µm) were used as a porogen. After PLGA dissolution the mixture was transferred into 5-mL syringes and dried. Next the rigid salt/polymer mixture was cut into slices (2 mm) and washed in ultra-high-purity water till conductivity of the water was about 2 µS/cm. Aln-loaded PLGA MPs were prepared by double-emulsification technique. MPs were dispersed in human recombinant collagen solution type I (Collage<sup>TM</sup>, Aldrich, 3 mg/mL) and immobilized on PLGA scaffolds, previously hydrophilized with ethanol, by drop seeding procedure. Morphometric analysis (for empty and Aln-loaded MPs) was done under inverted optical microscope. Scaffolds microstructure was characterized by SEM. Encapsulation and loading efficiencies and drug release kinetics were evaluated by an orthophthaldialdehyde (OPA) assay with the use of fluorescence spectroscopy<sup>3</sup>. Degradation kinetics of MPs in phosphate buffered saline (PBS) was also studied. Cytotoxicity test performed on extracts from scaffolds with MPs was conducted with the use of MG-63 osteoblast-like cells. AlamarBlue (Sigma) and live/dead staining (Aldrich) were used to test proliferation, viability and morphology of the cells<sup>2</sup>.

## RESULTS AND DISCUSSION

Morphometric analysis showed differences between loaded and un-loaded MPs. The average diameters were  $6.8 \pm 2.2$  µm and  $4.2 \pm 2.3$  µm for Aln-MPs and for empty MPs, respectively. The Aln-MPs were characterized by a high solubilization of 90% and drug loading efficiency of  $13.6 \pm 0.3\%$ . Immobilization of MPs on the pore walls with the use of rh-collagen solution was found effective as shown by SEM studies (Fig. 1).

Fig. 1 SEM microphotographs of PLGA scaffolds containing MPs immobilized with rh-collagen type I; mag. 100x (A.) and 300x (B.).

The results of release study show initial slow burst followed by sustained release of Aln; it was correlated with hydrolytic degradation kinetics of MPs. *In vitro* tests confirmed cytocompatibility of PLGA scaffolds modified with Aln-MPs: similar metabolic activity, viability and morphology was found when osteoblast-like MG-63 cells were cultured in the extracts or in pure culture medium.

## CONCLUSION

The study showed that immobilization of MPs loaded with Aln on PLGA scaffolds was successful. Prolonged drug release was achieved and whole system was cytocompatible with osteoblast-like cells. The results suggest that resorbable PLGA scaffolds containing Aln-loaded MPs are promising approach for the treatment of large critical-size bone tissue defects.

### INTRODUCTION

Modification of bioactive glasses with strontium oxide has been shown to impart osteoconductive properties through the release of strontium ions in solution, showing potential for use in the treatment of osteoporotic fractures. For use as a biomaterial, a balance must be struck between network disintegration and stability, to provide both ionic release and mechanical stability. Borate based glasses have been shown to be highly tailorable in their degradation, providing potential in this field<sup>1</sup>. Our understanding of borate glass structure however lags behind that of other glass building systems, representing only 2% of publications in the field<sup>2</sup>. Better understanding of the effect of modified content on borate glass structure is needed to understand the changes seen in glass reactivity, specifically in the range of 20-30% modifier additions, where the borate anomaly occurs<sup>3</sup>. This study aims to investigate the effect of compositional changes in a borate glass through the substitution of, therapeutically active SrO, with Na<sub>2</sub>O.

### EXPERIMENTAL METHODS

#### Glass synthesis

Nine tertiary borate glasses were synthesised through equimolar substitution of Na<sub>2</sub>O (0 to 16%) for SrO (30 to 14%). Glass powders were heated to 600°C, for 1 hour, then melted at 1100°C for a further hour before splat quenching. Glass was ground to <45µm and analysed through DSC, XRD (n=3).

#### Structural Analysis

<sup>11</sup>B MAS NMR was performed using a Bruker Avance NMR (11B Larmor frequency = 224.67 MHz) at spinning speeds of 25 and 10 KHz for the centre and sidebands (32 and 4 transients collected respectively).

#### Compositional Analysis

Glass samples were digested using 50 mg of glass powder in 10 ml of 30% ultra trace HCl for 2 hours at 40°C (n=3). Digested glasses were then analysed by ICP-OES for B, Sr and Na content.

### RESULTS AND DISCUSSION

All compositions investigated formed an amorphous glass without evidence of crystallization or APS when analysed through XRD and DSC. While T<sub>g</sub> decreased linearly from 641°C to 520°C with the addition of Na<sub>2</sub>O, significant differences could only be found between the two extremes of the compositional range. The fraction of N4 coordinated boron in the glass network varied from 39.2% to 43.2% in the nine glasses investigated. No definitive effect of the boron anomaly could be seen in the region investigated.

Table 1 shows the post firing compositional changes found in the glass series. A significant change in the borate content was only seen with the 16% strontium composition. Losses of sodium content were greatest in the low sodium glasses; contrary to previous reports of high losses with increasing alkali metal content<sup>3</sup>.

Table 1: Changes in glass composition during glass synthesis expressed in molar percentage

Theoretical Composition			Final Composition		
B <sub>2</sub> O <sub>3</sub>	SrO	Na <sub>2</sub> O	B <sub>2</sub> O <sub>3</sub>	SrO	Na <sub>2</sub> O
70	30	0	67.5	32.5	0
70	28	2	68.4	31.4	0.2
70	26	4	68.9	27.6	3.5
70	24	6	67.8	25.4	6.8
70	22	8	68.5	23.8	7.7
70	20	10	69.2	21.1	9.7
70	18	12	69.7	18.0	12.3
70	16	14	66.0	17.3	16.7
70	14	16	67.4	15.5	17.1

Compositional dependence of glass transition temperature was improved by the use of post firing compositions, shown by regression error mean square values from 8.97 to 6.58. Similarly improvements in linear correlation between boron coordination and composition increased when using for firing compositional analysis with a decrease in regression error mean square values from 1.22 to 1.13.

### CONCLUSION

Significant changes to borate glass composition occur during glass firing process. As glass structure and properties are understood to be composition dependent it is not surprising that these changes affect our ability to predict the relationship between composition, structure and properties. To better understand compositional effects on glass behaviour post fabrication compositional analysis is a valuable tool.

## INTRODUCTION

An artificial bone for laboratory practices<sup>1</sup> is an advanced composite material that is very useful for many applications such as testing dental implants or orthodontic devices<sup>2</sup>. Three principal advantages can be considered: i) to obtain samples with specific features of trabecular density and cortical thickness that in real bones are subjected to the casualty, ii) to have a bone that maintains its designed properties for long time because it is not subjected to a rapid degrade as in the real case and, finally, iii) to dispose promptly of samples that reproduce the characteristics of different typologies of both animal and human bones.

The first step of this research was to prepare two types of polymeric composites with mechanical properties (flexural and compression elastic modulus) close to the ones of the cancellous and of the cortical human bone. Thereafter bilayer samples - prepared with compact composites polymer and porous polymer, simulating the cortical and the trabecular bone respectively - were evaluated through the measurements of the insertion torque of orthodontic temporary anchorage devices (TADs)<sup>3</sup> and then through their primary stability.

## EXPERIMENTAL METHODS

Trabecular bone was obtained with PMMA polymerized from Methyl Methacrylate monomer (Sigma-Aldrich) and commercial sucrose, 50vol.%, used as porogen. The liquid phase was before added with benzoyl peroxide (4wt.%) used as activator and N,N-methyl-para-toluidine (0.8wt.%) as catalyst and manually mixed with sucrose by mean of a spatula. Then it was inserted in a plastic syringe and compacted and finally maintained at low temperature (4°C) for 24 hours. To remove the porogen, specimens have been leached in hot water for many cycles of low pressure (0.02atm) and atmospheric pressure in order to permit water to penetrate inside the matrix pores.

Compact bone was set with PMMA and alumina trihydrate (ATH), 50vol.%, as reinforcement. To improve the interface between filler and matrix, the manufacturer used an adhesion-promoting additive<sup>4</sup>.

Both the trabecular and compact artificial bone specimens were tested in compression and in flexion with Zwick/Roell Z010 machine (maximum load 10KN), obtaining the stress-strain curve and the elastic modulus of the material.

Final bones samples were prepared spreading a MMA film on the compact bone layer in order to make it adhere to the trabecular specimens. Three kinds of artificial bone with cortical thickness of 1mm, 1.5mm and 2mm were prepared. Inserting torque of TADs on

these samples was evaluated with a digital torsion dynamometer (Cedar, Sugisaki Meter Co. LTD, Japan). Their primary stability was measured with the Zwick/Roell Z0.5 machine (maximum load 500N), after that the bone sample was immobilized to the base of the apparatus, while the TADs abutment was fixed to the mobile head of the machine through a dedicated device. The TADs were submitted to a cycle of load, oscillating at 0.1Hz according to a triangular profile in the range - 5N and +5N. In the meanwhile the TADs displacement was recorded.

## RESULTS AND DISCUSSION

The porous PMMA used as trabecular bone shows an elastic modulus according to the literature values<sup>3</sup>, the 9 samples tested have an mean elastic modulus of 173.0MPa with standard deviation of 39.6.

The composite PMMA-ATH used as compact bone shows an elastic modulus of 10GPa while from literature<sup>5</sup> the mean values are 18.3GPa for mandible and 14.9GPa for maxilla. The mean torque value of the TADs tested is 5Ncm, and their mean value of primary stability is 2.8µm/N as expected.

## CONCLUSION

Artificial bone with porosity and mechanical characteristics comparable to the human bone was prepared. This advanced material also displays a behaviour, evaluated as insertion torque and primary stability of TADs, similar to the one of a natural bone. This material appears therefore very promising as testing bone for mechanical laboratory experiments on TADs.

## INTRODUCTION

The magnetic electrospun mats were established as an innovative biomaterial for hyperthermia treatment of cancer therapy lately<sup>1,2</sup>. Unlike those surface-modified magnetic nanoparticles that may not firmly adhere onto the tumor site for long-term duration, the magnetic mats with nanofibrous structure can promote cell adhesion and kill the tumor cells directly within an alternating magnetic field (AMF). However, most published magnetic electrospun mats were fabricated using non-biodegradable polymers and organic solvents, which has caused the problem of removal after therapy as well as the suspected biotoxicity issue associated with the residual solvent. Alginate (SA) was utilized in this investigation as the main material for electrospinning because of being biodegradable and water-soluble. The alginate-based electrospun mats were then treated by an ionic or a covalent crosslinking method, then followed by chelation with  $\text{Fe}^{2+}/\text{Fe}^{3+}$  for chemical coprecipitation of  $\text{Fe}_3\text{O}_4$  magnetic nanoparticles. Various qualitative and quantitative analyses for the mats as well as the cytotoxicity and in vitro hyperthermia assay on the  $\text{Fe}_3\text{O}_4$ -SA/PEO (ionic-crosslinked mat) and  $\text{Fe}_3\text{O}_4$ -SA/PVA (covalent-crosslinked mat) were examined.

## EXPERIMENTAL METHODS

SA solution (3%, w/w), PEO solution (4%, w/w) and PVA solution (17%, w/w) were prepared. To prepare two kinds of electrospinning solutions, SA/PEO and GA/SA/PEO/PVA solutions with solid content weight ratios of 1/2.5 and 1.7/1/0.5/2 were used, respectively. For the  $\text{Fe}^{2+}$  ionic crosslinking method, the SA/PEO mat was immersed in  $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$  and  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  ( $\text{Fe}^{2+}/\text{Fe}^{3+}$  molar ratio: 1/2) for 2 hr in nitrogen purging condition. To prepare the covalently crosslinked mat, the GA/SA/PEO/PVA mat was crosslinked in the presence of  $\text{HCl}(\text{aq})$  vapour in a sealed petri dish at  $45^\circ\text{C}$  for 24 hr. The obtained crosslinked GA/SA/PEO/PVA mat was then immersed in ultrapure water at  $37^\circ\text{C}$  for 3 days to remove most amount of PEO, uncrosslinked SA and PVA, unreacted GA and HCl.

For the fabrication of magnetic electrospun mats, the SA/PEO and the SA/PVA mats were separately immersed in stoichiometric excess amounts of  $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$  and  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  ( $\text{Fe}^{2+}/\text{Fe}^{3+}$  molar ratio: 1/2) for 2 hr with nitrogen purging. The 37%  $\text{NH}_4\text{OH}$  solution was added drop-wise to the mixture with vigorous stir for 5 min and 30 min, respectively, to form  $\text{Fe}_3\text{O}_4$  *in situ*.

The magnetic electrospun mats were characterized by FTIR, SEM, TEM, thin film X-ray diffraction ICP and

SQUID. The cytotoxicity assay was performed with MTT method. The *in vitro* hyperthermia effect of the samples were carried out in the AMF in which the tube was filled with 0.5 mL culture medium containing  $3 \times 10^5$  A-549 cells. The heating process was performed for 15 min and the temperature was maintained at  $44\text{--}45^\circ\text{C}$ .

## RESULTS AND DISCUSSION

The TEM micrographs as well as the ICP results and XRD pattern of the alginate-based magnetic electrospun mats indicated the successful incorporation of magnetic nanoparticles. In addition, the FTIR results have shown that the PEO added has been removed after immersion in different aqueous solution for electrospun mats. In addition, the ionic crosslinked magnetic electrospun  $\text{Fe}_3\text{O}_4$ -SA/PEO mat started swelling after contacting with the culture medium and cracked into small pieces after 1-day culture. Henceforth, only the covalent crosslinked  $\text{Fe}_3\text{O}_4$ -SA/PVA mat was analyzed for in vitro hyperthermia experiments.

The hyperthermia experiment indicated that the cell viability for all samples containing  $\text{Fe}_3\text{O}_4$  were greatly reduced after the use of AMF heating. (Fig 1)

Fig 1. The in vitro hyperthermia effect of the control (PBS only), SA/PVA mat,  $\text{Fe}_3\text{O}_4$  nanoparticles and  $\text{Fe}_3\text{O}_4$ -SA/PVA mat.

## CONCLUSION

The hyperthermia effect showed the  $\text{Fe}_3\text{O}_4$ -SA/PVA mat had greater impact to tumor cells than the  $\text{Fe}_3\text{O}_4$  nanoparticles. Such magnetic mats could effectively lower the viability of tumor cells in the AMF and are of potential for hyperthermic treatment.

### INTRODUCTION

Sarcomas such as osteosarcoma are treated with surgery and chemotherapy by anticancer drugs. The anticancer drugs cause various severe side effects, and prospective enough effects may not be obtained. So-called nano-particles smaller than cells have a property to enter cells and they are expected as drug delivery system (DDS)<sup>1</sup>. We heretofore reported biocompatibility and safety of the carbon nanotubes (CNT)<sup>2, 3</sup>. We report potential as DDS for chemotherapy to osteosarcoma cells with CNTs.

### EXPERIMENTAL METHODS

The 143B cells (human osteosarcoma cell line) were seeded at  $5.0 \times 10^5$  cells/10cm culture plate. After 24 hours, the culture medium was renewed to the medium contained 1  $\mu\text{g/ml}$  or 10  $\mu\text{g/ml}$  multi-walled CNT (MWCNT). Doxorubicin hydrochloride (DOX) (0.1  $\mu\text{M}$ , 1.0  $\mu\text{M}$ , 5.0  $\mu\text{M}$ ) was used as positive control. Each group was  $n=3$ . After more 24 hours, we observed the cells with light microscope and counted the number of 143B cells of each plate.

### RESULTS AND DISCUSSION

In the light microscope images of the 143B cells that we added MWCNTs before 24 hours, the MWCNTs were taken in the cells. In the MWCNT 10  $\mu\text{g/ml}$  group, much MWCNTs were taken in the 143B cells than the MWCNT 1  $\mu\text{g/ml}$  group. The cell number after 24 hours culture was  $23.3 \times 10^5$  cells/plate in control,  $10.3 \times 10^5$  cells/plate in DOX 0.1  $\mu\text{M}$  group,  $5.6 \times 10^5$  cells/plate in 1.0  $\mu\text{M}$  group,  $2.8 \times 10^5$  cells/plate in 5.0  $\mu\text{M}$  group,  $21.3 \times 10^5$  cells/plate MWCNT 1  $\mu\text{g/ml}$  group and  $16.3 \times 10^5$  cells/plate MWCNT 10  $\mu\text{g/ml}$  group (Fig1).

Because CNTs enter into sarcoma cells, we think that CNTs have possibility to improve antitumor effects of chemotherapy as DDS of anticancer drugs.

Number of the 143B cells

Fig1. Number of the 143B cells. PS; Polysorbate (surfactant). DOX; Doxorubicin. CNT; Multi-walled Carbon nanotube. MWCNTs inhibited the cellular proliferation in concentration-dependency

### CONCLUSION

When the MWCNTs are added to the osteosarcoma cell line; 143B cells, the MWCNTs are taken into the cells and inhibited the cellular proliferation in concentration-dependency. By adhering anticancer drugs to the MWCNTs, we expect to improve invasive efficiency to sarcoma cells of the anticancer drugs, to enhance the chemotherapeutic effect and to reduce the chemotherapeutic side effects

## INTRODUCTION

Chemotherapy, in which potent drugs are used to destroy cancer cells, carries a high risk of damage to the healthy tissues. The reduction of harmful effects of this method of cancer treatment can be achieved through the use of regional chemotherapy – comprising the administration of anti-cancer agents directly at the tumour site<sup>1</sup>. It is crucial to provide a method of controlled delivery in which both the amount of drug and the time of administration can be regulated.

Conjugated polymers are considered promising materials for use as matrices for drug delivery systems. In contrast to the physical entrapment, conjugated polymers allow controlled, reversible electrostatic immobilisation of a wide range of biologically active compounds<sup>2,3</sup>. Change in their reduction-oxidation state as a result of electrical stimulation is followed by the release of a precise amount of drug<sup>4</sup>.

In this study, we describe the synthesis and performance of conjugated polymer matrix as a reservoir for betulin – naturally occurring triterpene with high anti-cancer activity<sup>5</sup>.

Scheme 1. Chemical structure of betulin.

## EXPERIMENTAL METHODS

Betulin was purchased from “Natchem” company<sup>6</sup>. Cyclic voltammetry (CV) was utilised for the fabrication and in situ analysis of conjugated polymer/betulin composite layers. The release of betulin from the composite was followed by time-resolved UV-Vis spectroscopy. The biological activity of released betulin solutions was determined using chosen cancer cell lines. SEM images were collected and used to track the changes of composite morphology in the process of drug release.

## RESULTS AND DISCUSSION

The in-situ entrapment of betulin into the structure of growing polymer matrix was proven to be an efficient method of immobilization resulting in the formation of conjugated polymer/betulin composite.

Fig.1. The schematic representation of ion-exchange properties of conjugated polymers.

The release of betulin immobilised in conjugated polymer matrix was performed under spontaneous (passive) and electro-assisted (active) modes in PBS. Through the modification of synthesis conditions it was possible to modify the drug capacity of matrix as well as the proportions of drug released *via* passive and active modes. The range of applied reduction potentials have been optimized – low enough to start the process of release but not too low, to prevent the process of matrix degradation.

## CONCLUSION

Conjugated polymer/betulin composite was shown to be a promising material for electrically-triggered delivery systems applied in regional chemotherapy.

### INTRODUCTION

Liposomes are widely studied as drug delivery systems in cancer treatment. The use of drug delivery systems (DDSs) such as liposomes can alter drug pharmacokinetics and biodistribution. The multidrug resistance remains (MDR) a major obstacle of chemotherapy. The resistance mechanism in MDR cells is mainly overexpression of P-glycoprotein (P-gp) on the plasma membrane. Itraconazole (ITZ)- triazole antifungal agent against a broad spectrum of fungal species has potential for modulating MDR [1]. The folate receptor (FR) is often overexpressed in cancers – it has frequently been exploited for the specific delivery of folate-linked drugs into cancer cells.

The aim of our study was to create hybrid drug delivery system: 5-fluorouracil (5-FU, antineoplastic drug) encapsulated in liposomes itraconazole and folic acid modified. The interaction between liposomes and itraconazole was checked using various methods. To evaluate the therapeutic effect of studied hybrid system the biological studies was performed.

### EXPERIMENTAL METHODS

Liposomes were prepared by hydration of the dry lipid film, followed by sonication. The lipid bilayers composed of 2-oleoyl-1-palmitoyl-sn-glycero-3-phosphocholine (POPC) and itraconazole at various molar ratios. Folate-targeted liposomes consisted of 99,5 mole % POPC and 0,5 mole % folate-PEG2000-lipid. Langmuir monolayer experiments and Brewster angle microscopy (BAM) of the POPC/ITZ mixtures displayed the highest content of ITZ in lipid monolayer. Fluorescence methods were used to estimate the position of ITZ in PC bilayer. To check the stability and estimate the size of liposomes with different content of ITZ the dynamic light scattering measurements were used. The morphology of bilayer structures formed in dispersions was inspected using a cryogenic transmission electron microscopy and atomic force microscopy. Encapsulation efficiency of 5-FU in liposomes were determined by spectroscopy Uv-Vis[2]. The cytotoxic activities of hybrid drug delivery system (DDS) in Caco-2 cancer cells were determined by MTS assay. Cellular uptake studies of DDS was measured by fluorescence microscopy.

### RESULTS AND DISCUSSION

Based on the results obtained with the application of BAM microscopy was found that the monolayers containing 10-15 mol% of itraconazole are completely mixes with POPC. At higher concentrations of ITZ the interactions between POPC and itraconazole are unfavorable, which leads to the phase separation and expelling of itraconazole from POPC film. Using fluorescence method and doxil-spin labeled molecules have been shown that the ITZ is located at ca. 13 Å from the center of the bilayer [3]. The ITZ modified liposomes and unmodified liposomes are comparatively stable. The antiproliferative effect of studied DDS in Caco-2 cells is similar to free 5-FU.

### CONCLUSION

In conclusion, we have demonstrated the use of folic acid as a ligand for targeting of liposomes to tumor cells. Incorporating itraconazole into liposomes with 5-fluorouracil could be an attractive approach not only for improving drug efficacy and reduction of side effects but mainly to reverse P-gp- mediated drug resistance.

[mchalanqui01@qub.ac.uk](mailto:mchalanqui01@qub.ac.uk)

### INTRODUCTION

Prostate cancer (PCa) is one of the most common types of cancer, affecting 15% of the male population worldwide, and a major cause of cancer-related mortality in men<sup>1</sup>. This high rate of mortality is primarily due to metastasis of the primary tumor<sup>2</sup>, 70% of which is primarily localized in the bone.<sup>3</sup>

Metastatic prostate cancer cells have the ability to disrupt the equilibrium of normal bone remodeling processes and can be characterized as either osteolytic or osteoblastic<sup>4</sup>. Metastatic lesions from prostate cancer are predominantly osteoblastic<sup>4</sup>. During osteoblastic bone metastases, the equilibrium between bone resorption and bone formation is disrupted in favor of bone formation<sup>4</sup>. Patients suffer severe bone pain and the poor bone quality often leads to bone fractures<sup>4</sup>. Once tumors metastasise to bone, they are effectively incurable. For patients with bone metastatic disease current therapeutic strategies are limited to palliative treatments to minimise the rate of bone degradation and patient pain<sup>5</sup>.

Aberrant microRNA (miRNA) expression is a common feature of human cancer<sup>5</sup>. miRNA34a (miR-34a) has previously been shown to be down-regulated in PCa cells<sup>6</sup>. Due to its strong anti-tumor and anti-metastatic effects<sup>5</sup>, and consequential potential as a negative regulator of PCa cells, miR-34a represents a promising target to modulate PCa induced-bone metastatic disease.

Therefore up-regulation of miR-34a via nanoparticles (NPs) from a biomaterial scaffold should elicit a therapeutic effect in disseminated PCa. In this study we propose a novel, thermo-responsive alginate-g-PNIPAAm (Alg-g-P(NIPAAm)) hydrogel for non-invasive local delivery of NPs incorporating an amphipathic peptide (RALA) that serves as a delivery vehicle for DNA expressing miR-34a.

### EXPERIMENTAL METHODS

*Preparation of hydrogel:* Alginate (Alg) and NIPAAm were synthesized via free radical polymerisation to form a Alg-g-P(NIPAAm) hydrogel.

*Formulation of RALA/miR-34a NPs:* The RALA/miR-34a NPs are formed by self-assembly via electrostatic interactions. Particle size and zeta potential (ZP) were measured using a Malvern Zetasizer Nano ZS to determine the physiochemical characteristics.

*Clonogenic Assay:* Colony forming assay was performed using the crystal violet method. Confluent

PC-3 prostate cancer cells were transfected with RALA/miR-34a NPs for 6 h then returned to growth media. After 48 h cells were seeded in a 6-well plate at a density of 200 and 500 cells per well. Cells were cultured for 2 weeks before crystal violet staining.

*Drug delivery study:* P(Alg-g-NIPAAm) was loaded with RALA/miR-34a plasmid. These drug delivery systems were placed in trans-wells adapted for 24-well plate and immersed in water or culture media at 37°C. The release profile of the miR-34a was assessed by withdrawing the supernatant at different time points and measuring nucleic acid content using the picogreen assay.

### RESULTS AND DISCUSSION

Preliminary studies demonstrate that the Alg-g-P(NIPAAm) solution exhibits a thermo-responsive behaviour with a lower critical solution transition (LCST) about 32°C. Thus, the hydrogel is liquid at temperatures below 32°C and gels at higher temperatures. Consequently, the hydrogel can be injected into the body and act as a depot for the delivery of the therapeutic NPs. Work is currently ongoing to characterize the size, charge and shape of the RALA/miR-34a NPs. This is necessary to ensure the NPs exhibit optimal physical characteristics to ensure efficient transfection. Release studies are ongoing to determine the NP delivery from the Alg-g-P(NIPAAm) hydrogel. For our therapy we are aiming to have an initial burst release of the NPs, followed by a maintenance effect, ideally for several months. We are also examining the molecular effects of the miR34a therapy on PC-3 tumours.

### CONCLUSION

miR-34a has exhibits a potent anti-cancer effect *in vitro* and *in vivo*. The development of a new formulation for local delivery to bone sites using a thermo-responsive hydrogel presents a therapeutic treatment for those with disseminated prostate cancer.

## INTRODUCTION

Antigen-specific CD8<sup>+</sup> cytotoxic T lymphocytes (CTLs) are key factors of immunological rejection in transplantation as well as cancer immunotherapy<sup>1</sup>. However, Most of tumors are not immunologically rejected because they have self antigens<sup>2</sup>. In this study, we hypothesized that “foreignizing” tumor cells by delivering non-self foreign antigens into the tumors would result in rejection by foreign antigen-reactive CTLs. In an attempt to demonstrate this hypothesis, we prepared a polymeric conjugate consisting of hyaluronic acid (HA) as the tumor targeting ligand and ovalbumin (OVA) as a model foreign antigen.

## EXPERIMENTAL METHODS

HA-OVA conjugate was prepared by using reductive amination in presence of NaBH<sub>3</sub>CN as a reducing agent. Fluorescein isothiocyanate (FITC) labelled HA-OVA conjugates were used for further experiments.

Cellular uptake behaviour of HA-OVA was monitored using OVA-FITC and HA-OVA-FITC in HPV-16 E7-expressing mouse cervical cancer model (TC-1) cells for 2hr.

*In vitro* antigen presentation and CTL-mediated apoptosis of TC-1 cells were observed using FACS Calibur flow cytometry. *In vivo* biodistribution and anti-tumor efficacy of conjugate were carried out to evaluate *in vivo* effect of HA-OVA conjugate using tumor-bearing mice.

## RESULTS AND DISCUSSION

In this study, OVA were chemically conjugated to HA via reductive amination between the reducing end group of HA and the amino group of OVA in the presence of NaBH<sub>3</sub>CN as a reducing agent.

In cellular uptake experiment, HA-OVA-FITC showed stronger fluorescence signal at the intracellular level than OVA-FITC (figure 1-a). The cellular uptake of conjugate was quantified by using flow cytometry (figure 1-b). These result showed that the HA surface of conjugate accelerated its uptake by TC-1 tumor cells via receptor-mediated endocytosis.

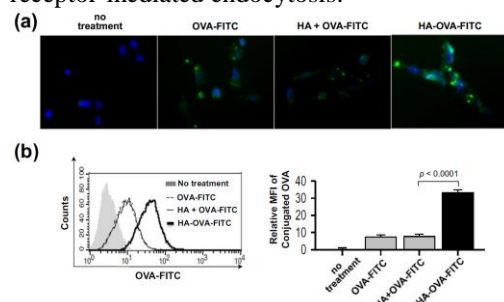

Figure 1. Cellular uptake behavior of the conjugate.

(a) Cellular images were observed by using fluorescence microscopy and (b) the cellular uptake was quantified by flow cytometry.

We carried out whether the delivered OVA could be processed and presented on the TC-1 cell surface (figure 2-a) and whether the conjugate could facilitate OVA-specific CTL-mediated killing of tumor cells (figure 2-b). These results suggest that the *in vitro* delivery of OVA by using conjugated ligand (HA) efficiently provokes CTL-induced apoptotic death of target tumor cells.

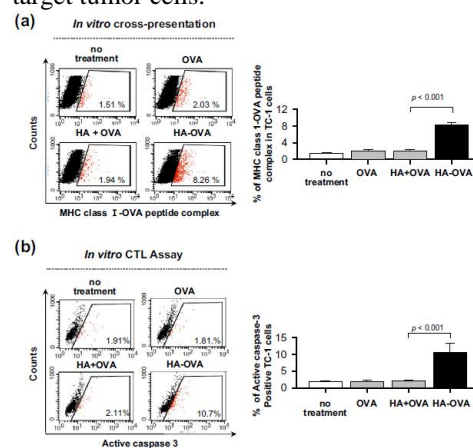

Figure 2. (a) *In vitro* antigen presentation. (b) CTL-mediated apoptosis of TC-1 tumor cells was analysed by flow cytometry.

## CONCLUSION

In this study, we demonstrate that a foreign antigen (OVA) decorated with HA is capable of targeting tumor site and generating anti-tumor effect by provoking immune rejection against tumor that present foreign antigens. This foreign antigen-delivery system may play a role as a platform technology for treatment of various intractable diseases.

## INTRODUCTION

Photodynamic therapy (PDT) is a well-established treatment for certain forms of cancer and skin diseases [1]. It is a noninvasive alternative to conventional treatments like surgical tumor resection, chemo- and radiotherapy. Cancerous cells are lysed by the combined action of light, oxygen present in the tissues and dye molecules (photosensitizers) which are administered intravenously or topically. The photosensitizer is activated by a light of a suitable wavelength which after its excitation to the singlet excited state ( $S_1$ ) is followed by intersystem crossing (ISC) resulting in the formation of highly populated triplet state ( $T_0$ ) photosensitizer. The excited triplet state of a given photosensitizer may undergo two different processes. The first process results in the production of singlet oxygen (type II), via energy transfer, while the other leads to the formation of radicals (viz.  $OH^\bullet$ ,  $HO_2^\bullet$ ,  $O_2^{\bullet-}$ ) via electron transfer (Type I and III). Formation of oxygen-containing radicals requires the photosensitizer to undergo oxidation. The knowledge of the ability of the photosensitizer to undergo redox processes (redox potentials) is crucial for the understanding of the photosensitization process.

Figure 1. Structures of the studied photosensitizers.

## EXPERIMENTAL METHODS

Two newly synthesized photosensitizers were used, viz. **ZnPc(t-Bu)<sub>4</sub>I** and **ZnPc(t-Bu)<sub>4</sub>(CF<sub>3</sub>)<sub>4</sub>**. Their redox potentials were compared. Cyclic voltammetry (CV) was performed on PalmSens<sup>3</sup> potentiostat/galvanostat and was conducted in deoxygenated dichloromethane or N,N-dimethylformamide. Tetrabutylammonium tetrafluoroborate (TBAF, Fluka,  $\geq 99.0\%$  electrochemical grade) was used as a supporting electrolyte (0.1 M). Cyclic voltammetry experiments were performed on saturated solutions (5 mL) of the respective phthalocyanines (Pcs). The working electrode was either platinum disc (1.6 mm in diameter) or carbon glassy electrode (5 mm in diameter). Spectroelectrochemical experiments were performed in a quartz cell of 0.5 mm optical length with the Pt gauze working electrode, the Pt counter electrode and the Ag/Ag<sup>+</sup> reference electrode (connected to a PalmSens<sup>3</sup>).

## RESULTS AND DISCUSSION

Cyclic voltammograms (CV) of the studied photosensitizers showed a number of one-electron redox processes, all of them being ring-centered events (Fig.2).

Figure 2. Cyclic voltammogram of **ZnPc(t-Bu)<sub>4</sub>I<sub>4</sub>**.

CV measurements of the CF<sub>3</sub> substituted zinc phthalocyanine, viz. **ZnPc(t-Bu)<sub>4</sub>(CF<sub>3</sub>)<sub>4</sub>**, revealed four one-electron reductions and two one-electron oxidations. In general, the CF<sub>3</sub> substituted phthalocyanine is easier to reduce and harder to oxidize than the phthalocyanine counterpart having no CF<sub>3</sub> groups, viz. **ZnPc(t-Bu)<sub>4</sub>**, supporting the notion that trifluoromethyl substituents have a strong electron-withdrawing effect on the phthalocyanine macrocycle. CV measurements of **ZnPc(t-Bu)<sub>4</sub>I<sub>4</sub>** revealed three one-electron reductions and two one-electron oxidations. Spectroelectrochemistry allowed for direct observation of both  $\pi$ -cation and  $\pi$ -anion radicals which formed electrochemically.

## CONCLUSION

CV measurements and spectroelectrochemistry revealed that all studied Pcs undergo only ring-centered redox processes. The  $\pi$ -cations of **ZnPc(t-Bu)<sub>4</sub>(CF<sub>3</sub>)<sub>4</sub>** proved to be stable species, while electrochemical oxidation of **ZnPc(t-Bu)<sub>4</sub>I<sub>4</sub>** resulted in gradual degradation of the phthalocyanine photosensitizer.

### INTRODUCTION

EMT is a biologic process in which epithelial cells (E) lose their polarity and specialized cell-cell contacts, acquiring a mesenchymal phenotype (M) with enhanced migratory and invasion capacity<sup>1</sup>. EMT is crucial for cancer invasion, and reversion of this phenotype is decisive for metastases establishment. Several evidences point to the inter-conversion between E and M states in cancer, with acquisition of a metastable and potentially more aggressive phenotype. The study of such transitions and their implications in cancer progression could greatly benefit from advanced 3D *in vitro* models of EMT. By creating greater similarity with *in vivo* scenarios, such 3D models are likely to generate useful tools to efficiently identify and test anti-cancer therapeutics. Here we propose a new *in vitro* model of EMT and its reversion, combining inducible epithelial cell lines (EpH4) with tunable 3D matrices. Alginate hydrogels modified with cell-adhesion moieties (RGD peptides) were used to partially recapitulate the complexity of the native extracellular matrix (ECM)<sup>2</sup>.

### EXPERIMENTAL METHODS

Near-normal mouse mammary epithelial cells (EpH-4, E cells) were entrapped within 1wt-% RGD-modified alginate hydrogels prepared by internal gelation<sup>3</sup>. To induce EMT, cell-loaded alginate matrices were cultured in the presence of TGF- $\beta$ 1 during 1 week (M cells). As a control, E cells were maintained in cell culture medium without TGF- $\beta$ 1. For reversion, M cells were further cultured for 7 days in culture medium without TGF- $\beta$ 1. To monitor the occurrence of EMT and its reversion in 3D, cell behavior was analysed at different levels, namely in terms of viability (Live/Dead assay); metabolic activity (resazurin assay); proliferation (Ki-67 immunostaining), organization (F-actin staining); phenotype (expression of E markers, E-cadherin; and M markers, fibronectin,  $\alpha$ -SMA); MMPs activity (gelatin zymography). Gene expression of epithelial (CDH1, Occludin) and mesenchymal (CDH2, vimentin) markers, and EMT inducers (Zeb2 and Twist1) was analysed by real-time PCR.

### RESULTS AND DISCUSSION

The mild alginate cross-linking conditions enabled the establishment of 3D cultures with high cell viability. In non-induced cells, E cells proliferated along 7 days in culture (Ki-67 positive) and formed multicellular spheroids. Moreover, E cells expressed E-cadherin at the membrane. After 7 days in culture, several E cells

spheroids showed a central clearing and formation of lumen surrounded by a layer of cells, characteristic of epithelial morphogenesis. On the other hand, induced cells formed smaller cell aggregates and presented lower metabolic activity than E cells. M cells presented E-cadherin delocalization to the cytoplasm and expressed fibronectin and  $\alpha$ -SMA, which are features of mesenchymal-like cells. At the gene level, there were no significant alterations in the expression of epithelial markers, CDH1 and Occludin, between E and M cells. On the other hand, both mesenchymal markers (CDH2 and vimentin) and EMT-related transcription factor Zeb-2 were significantly upregulated in M cells. The ability of induced cells to secrete MMPs was also evaluated. The results showed an enhancement in MMP9 secretion by M cells comparing to E cells at day 7, which has been associated with cell migration and invasion of carcinoma cells. By removing the TGF- $\beta$ 1 stimulus after EMT, i.e. after 7 days of culture, we observed a partial reversion from a mesenchymal to an epithelial-like phenotype with cells presenting an intermediate state between E and M. For instance, we observed E-cadherin presence at cell membrane and  $\alpha$ -SMA expression in the cell cytoplasm and a decrease in MMP9 secretion.

### CONCLUSION

In conclusion, we were able to establish a 3D *in vitro* model of TGF- $\beta$ 1-induced EMT and its reversion, using RGD-modified alginate hydrogels that provide a well-defined and tunable ECM-like microenvironment.

# Modelling of Antimetastatic Agent NAMI-A Fate after Serum Administration

Klaudyna Śpiewak, Małgorzata Brindell

Faculty Chemistry, Jagiellonian University of Kraków, Poland  
[klaudyna.spiewak@gmail.com](mailto:klaudyna.spiewak@gmail.com)

## INTRODUCTION

Imidazolium trans-tetrachlorodimethylsulfoxide-imidazolruthenate(III), NAMI-A, a novel antimetastatic ruthenium complex which successfully completed phase I clinical trial<sup>1</sup>. NAMI-A was investigated towards affinity to transferrin (Tf), whether Tf-Ru adducts might be formed after its intravenous injection. Studies were focused on the holotransferrin due to its favoured binding to transferrin receptor. Transferrin receptor can be a targeting molecule for cancer therapy due to its overexpression in rapidly proliferating cells. In this study undermentioned issues were addressed: i) the influence of the iron occupied binding site on the overall association constant and Ru content in ruthenated Tf, ii) the competition in NAMI-A binding to Tf vs. HSA, and finally iii) the effect of low- and high-molecular-mass constituents of human serum on NAMI-A binding to Tf.

## EXPERIMENTAL METHODS

### Spectrofluorimetric titration

Fluorescence measurements were performed on a spectrofluorimeter PerkinElmer LS55. The emission spectra were recorded between 305 and 500 nm upon excitation at 295 nm.

### Separation of protein fractions

The chromatographic system ÄKTA Pure was used for separation. Anion exchanged Mono Q 5/50 GL column was applied to the separation of ruthenated proteins. 0.02 M BIS-TRIS/HCl pH 7.0, A, and 0.02 M BIS-TRIS/HCl, 1 M NaCl pH 7.0, B, were used as eluents. Separation conditions: injection volume: 100 µl, target concentration of B: 50%, gradient length: 20 CV, flow rate: 1 ml/min. CaptureSelect™ Transferrin Affinity Matrix was used for a one-step transferrin purification from human serum. Equilibration buffer: PBS, pH 7.4. 400 µl of sample was injected into the column. Unbound serum components were washed with 5 CV of equilibration buffer. Transferrin was eluted with 5 CV of the elution buffer: 20 mM Tris, 50% (v/v) propylene glycol, 1.0 M NaCl, pH 7.4.

### Determination of protein and ruthenium concentration

The Tf and HSA concentrations in the studied systems were determined using human Tf or HSA ELISA kits, respectively. The total protein concentration in human plasma was measured by Bradford method. The total Ru content in samples was measured by the application of ICP-MS using ELAN 6100 Perkin Elmer spectrometer

## RESULTS AND DISCUSSION

The calculated value of  $K_{SV}$  was found to be  $10\,300 \pm 100\text{ M}^{-1}$  at  $37\text{ }^{\circ}\text{C}$ . The analysis of ruthenium distribution have shown, that both apo- and holo-Tf are able to sequester Ru ions from HSA, though albumin is still the major location of Ru ions.

Fig.1. Serum models compositions (pH 7.4).<sup>2</sup>

Tabele 1. Ru fraction in ruthenated proteins produced after incubation of NAMI-A, Tf and HSA for 24 h at molar ratio at 20:1:18.<sup>2</sup>

Model	Tf saturation	Ru/Tf [mol/mol]	Ru/HSA [mol/mol]
0*	100%	$0.50 \pm 0.08$	$0.50 \pm 0.06$
0	30%	$0.52 \pm 0.07$	$0.51 \pm 0.05$
1	30%	$2.0 \pm 0.2$	$1.2 \pm 0.1$
2	30%	$2.9 \pm 0.5$	$1.1 \pm 0.1$

The addition of low-molecular-weight components of human serum included in Model 1 and 2 gave rise to evident increase in fraction of Ru equivalents in both proteins (Tabele1), while the fraction of free Ru species was negligible. The enhancement of Ru species binding to serum proteins can arise from transformation of NAMI-A into more active Ru species or/and modulation of protein surface making the binding sites more accessible.

## CONCLUSION

Here, we showed that holotransferrin is able to bind NAMI-A as easily as apotransferrin. The presence of physiological concentration of albumin (ca. 18-fold excess over Tf) resulted in a twofold decrease of ruthenium binding to Tf. Interestingly, the introducing of low-molecular-mass components of serum dramatically increased the ruthenation of Tf. Intermolecular competition binding studies between transferrin and albumin showed that both proteins bound similar amount of ruthenium species. Investigation of NAMI-A binding to Tf in human serum showed that this protein was not the major binding partner for Ru complex. However, in spite of many competing proteins still the ruthenation of Tf was observed.<sup>2</sup>

### INTRODUCTION

Lack of adequate venous material for autologous grafts constitutes a common problem in the coronary artery bypass surgery. Developing small vascular grafts with a luminal endothelial surface which would mimic anti-thrombogenic effect of an autologous “living” graft is one of the most urgent tasks in tissue-engineering<sup>1</sup>. In this study, we have investigated the growth of vascular cells on different alginate-based biomatrices to evaluate their potential for vascular scaffolds.

### EXPERIMENTAL METHODS

Different formulations containing alginate solution (2%, w/v) blended with protein solutions (silk fibroin, gelatin, keratin, or elastin) at 1% w/v, were prepared in form of hydrogels and extensively characterized with regard to physico-chemical features<sup>2</sup>. Human umbilical vein endothelial cells (EC), human umbilical artery smooth muscle cells (SMCs) and normal human fibroblasts were seeded on different biomatrices placed in 24-well cell culture plates and cultivated for up to 10 days. Cell growth was monitored microscopically after 3, 7 and 10 days of culture. The numbers of viable cells on each hydrogel were compared by fluorescent staining (calcein/DAPI) and the metabolic activity of the cells was analysed using WST-8 assay. All cell types were investigated in three independent experiments, each with quadruplicate samples.

### RESULTS AND DISCUSSION

Alginate is the biomaterial of choice for various tissue engineering applications due to its ability to form hydrogel. However, alginate has unfavourable degradation characteristics and does not promote the cell adhesion. Our studies show that in comparison to pure alginate hydrogels, vascular cell growth was improved on alginate-protein blend hydrogels. In particular, the alginate-silk fibroin and alginate-keratin<sup>2</sup> provided good surfaces for ECs (Fig. 1), supporting the attachment, growth and spreading of ECs for up to 10 days of culture.

SMCs showed best colonization and growth on alginate-keratin hydrogels, and fibroblasts on silk fibroin, elastin and keratin-containing hydrogels, as shown by actin and calcein staining, as well as WST assay. Interestingly, in contrast to our previous studies with alginate dialdehyde-gelatin crosslinked gels<sup>3</sup>, alginate-gelatin blend provided a less favourable scaffold for fibroblasts growth.

Figure 1. Fluorescent microscopy images of HUVECs on alginate (a), alginate/keratin (b), alginate/silk fibroin (c) and alginate/elastin (d) hydrogel films after 3 days of culture. The cells were stained for calcein (green) and nucleus (blue).

### CONCLUSIONS

Designing a scaffold which supports endothelialisation is an important step for the development of anti-thrombogenic small vascular grafts with improved patency. Due to their good vascular compatibility, alginate-based protein-containing hydrogels constitute good candidates for applications in cardiovascular surgery. Further studies are necessary to evaluate the mechanical stability and behaviour of these scaffolds *in vivo*.

### INTRODUCTION

Titanium nitride (TiN) offers particular possibilities for the development of implants with improved haemocompatibility [1, 2]. Data presented in literature shows that nanoscale features of biomaterial surfaces influence on cells response [3, 4]. Materials used so far does not allow to obtain the optimum conditions for adhesion and proliferation of vascular endothelial cells. Thus, recent materials do not promote proper proliferation of endothelial cells.

The aim of study was verified, the effect of the nanocrystalline TiN outer zone of nitrated surface layers with different topography produced under glow discharge conditions in terms biocompatibility with endothelial cells.

### EXPERIMENTAL METHODS

The TiN+Ti<sub>2</sub>N+αTi(N) surface layers (TiN) on Ti6Al4V titanium alloy at low temperature (680°C) under glow discharge nitriding processes at the cathode potential (TiNK) and plasma region (active screen plasma nitriding) (TiNP) were produced.

The TiN surface layers properties in terms of surface roughness and wettability by deionized water were examined using atomic force microscopy (AFM, Veeco) and imaging Nikon Coolpix 4500 and measurement with the use of DROP3 program, respectively.

The biomimetic biofilm was produced on biomaterials surfaces by incubation with albumin and collagen III.

The human umbilical vein endothelial cells (EC) were incubated on biomaterials samples, than fixed cells, and stained with antibody anti-human vinculin and Alexa Fluor 488, TRITC-conjugated Phalloidin, and DAPI were investigated under confocal microscope and morphometrically analyzed using Cell Sense program (both, Olympus). Results were expressed as mean ± SD and statistically analyzed using a Student's t-Test.

### RESULTS AND DISCUSSION

Studies have shown a lower roughness of TiNP in range of parameters Ra, Rq, Rt than TiNK and wettability comparable to TiNK. This was followed by enhance vascular cells adhesion on TiNP (Fig.1, 2). Images documented presence on TiNP large, polymorphic EC with numerous focal adhesion forming discs on cell membrane in contact with the material surface. EC on TiNK in contrast to those on TiNP were much smaller, mostly spindle-shaped with focal adhesions located on the cell edges. In addition, actin in EC on TiNP formed cytoskeleton fibers arranged parallel to the cell border,

while in cells on TiNK the cytoskeleton was blurred distributed in accordance with the cell axis.

Fig.1. Endothelial cells morphology on TiNP (A) and TiNK (B) surface layers. F-actin stained in red, vinculin –green, and nuclei – blue. Mag.40x zoom 4.

Fig.2. Analysis of endothelial cells number adhered on TiNP and TiNK.

### CONCLUSION

This study results suggest TiNP promising properties for cardiovascular applications by demonstrating strong positive effect of its surface nanotopography, however with additive interaction of produced biofilm.

## Electrospun Polylactide-Polycaprolactone Copolymer for Vascular Tissue Engineering

Jana Horakova<sup>1</sup>, Petr Mikes<sup>1</sup>, Ales Saman<sup>1</sup>, Michal Ackermann<sup>2</sup>

<sup>1</sup>Department of Nonwovens and Nanofibrous Materials/Technical University of Liberec, Czech Republic

<sup>2</sup>Department of Applied Mechanics/Technical University of Liberec, Czech Republic

[jana.horakova@tul.cz](mailto:jana.horakova@tul.cz)

Small diameter vascular grafts were produced by electrospinning of polylactide and polycaprolactone copolymer (PLC). The morphology of resulting fibers was uniform with fiber diameter about 1  $\mu\text{m}$ . Scaffolds were mechanically tested showing very good strength and elasticity. The scaffold supports endothelial cell growth on the surface.

### INTRODUCTION

There is a pressing need to develop vascular grafts that can replace failed small diameter arteries. Synthetic vascular grafts made from ePTFE, Dacron, or polyurethane work well as replacements for large diameter vascular grafts (>6 mm) with high blood flow<sup>1</sup>. However, they often fail when used to replace small diameter vessels due to acute thrombogenicity, anastomotic intimal hyperplasia, and aneurysm formation<sup>2</sup>. Biodegradable polymers, such as poly- $\epsilon$ -caprolactone or poly-L-lactic acid have been successfully used for tissue engineering applications, including vascular replacement<sup>3,4</sup>.

### EXPERIMENTAL METHODS

Small diameter vascular grafts were produced by electrospinning of PLC solution. Fibers were collected on rotating mandrel to obtain tubular scaffold. The structure was analyzed by scanning electron microscopy (SEM) and image analysis.

Mechanical properties of the tubular scaffold were measured using tensile tester. The graft was clamped to the tensile tester and stretched until break. Stress-strain curves were recorded for each tested graft ( $n=3$ ). Scaffolds made from PLC were seeded with human umbilical vein endothelial cells. Adhesion and proliferation of the cells was evaluated after 1, 3, 7 and 14 days using MTT test, fluorescence and SEM.

### RESULTS AND DISCUSSION

Tubular scaffolds with inner diameter in range from 1 to 6 mm were produced by electrospinning. The diameter of PLC fibers was  $1.09 \pm 0.40 \mu\text{m}$ . Wall thickness of vascular graft was controlled by time of electrospinning to obtain the thickness of 100  $\mu\text{m}$ .

Fig.1: SEM photo of outer site of PLC vascular graft (a), cross section of vascular graft (b).

Copolymer PLC showed excellent mechanical properties in terms of stress and strain as depicted in Figure 2.

Fig.2: Stress-strain curves of electrospun PLC vascular graft with 4 mm inner diameter ( $n=3$ ).

Scaffolds were seeded with endothelial cells showing good cell adhesion followed by proliferation of the cells on the surface of the electrospun layer.

Electrospinning is well-known method for production of scaffolds for tissue engineering. To meet the requirements for small diameter vascular grafts, proper material and technology has to be used. We have showed that electrospun copolymer PLC fulfil the requirements in terms of sufficient mechanical strength and elongation at break. The scaffold also supports endothelialization of the graft that is crucial to prevent thrombosis, the most common failure of small diameter vascular grafts. Further in vivo tests are ongoing to prove the usage of such grafts.

### CONCLUSION

New material was introduced as a potential candidate for vascular tissue engineering applications. Electrospun copolymer PLC showed excellent mechanical and biological properties, the main requirements for small diameter vascular grafts.

## Combination of Vinpocetine and AcSDKP for Developing Drug Eluting Stent with Anti-inflammatory Function

Seong Ho Seo<sup>1,2</sup>, Kwang-Sook Park<sup>1</sup>, Samy Olivier Gobaa<sup>1</sup>, Yoon Ki Joung<sup>1</sup>, Ik Hwan Kim<sup>2</sup>, Dong Keun Han<sup>1</sup>

<sup>1</sup>Center for Biomaterials, Korea Institute of Science and Technology, Seoul 136-791, Korea

<sup>2</sup>College of Life Sciences and Biotechnology, Korea University, Korea

[dkh@kist.re.kr](mailto:dkh@kist.re.kr)

### INTRODUCTION

Anti-inflammatory drugs have been applied to improve the function of stent, so called 'drug-eluting stents'. Many researchers reported that the reduction in neointimal hyperplasia and restenosis in stent could be accomplished by stent-based delivery of anti-immune drugs, such as sirolimus, paclitaxel and so on. However, the application of these drugs still has some major concerns.<sup>1</sup> For example, these drugs cause the endothelial toxicity to attenuate re-endothelialization, resulting in increasing stent thrombosis. In this study, we hypothesized that the combinational treatment of vinpocetine and AcSDKP inhibits the inflammatory response of endothelial cells and smooth muscle cells (SMC) without the endothelial toxicity. Additionally, it was examined the effect of this combination on macrophage infiltration and SMC proliferation. As a result, it was observed that combinational treatment of vinpocetine and AcSDKP decreased pro-inflammatory cytokines and macrophage infiltration. Also, it could reduce the SMC proliferation.

### EXPERIMENTAL METHODS

The U-937 cells and HUVECs were treated with the degradable polymer byproduct and/or vinpocetine and AcSDKP were stained with a calcein (HUVEC) and PKH26 (U-937).<sup>2,3</sup> Treated cells were rinsed with PBS solution and incubated in staining solution at 37°C for 30 min, followed by washing with PBS. The constructs were then visualized by fluorescent microscopy (U-RFL-T(CKX41), Olympus, Japan).

### RESULTS AND DISCUSSION

In the byproduct-treated sample, the significant number of U-937 cells adhered to HUVECs. While the group added to vinpocetine or AcSDKP showed the decrease in the adhesion of U-937 cells. Furthermore, the group

treated with both indicated that U-937 cells rarely adhered on HUVECs.

Fig. 1. Effect of vinpocetine and AcSDKP on the adhesion of U-937 cells on HUVEC.

### CONCLUSION

The significant concentration of vinpocetine was found for the inhibition of IL-6 expression and SMC proliferation, but the assurance of EC viability and proliferation. It was confirmed that vinpocetine can induce re-endothelialization, suppressing the adhesion of macrophages on EC by AcSDKP in the wound-healing process.

# Capture of Late Endothelial Progenitor Cell by Anti-CD146 Antibody Immobilization on Nano-filamentous Silicone-coated Stent

Sung Nam Kang<sup>1,2</sup>, Yoon Ki Joung<sup>1,2</sup>, Dong Keun Han<sup>1,2</sup>

<sup>1</sup>Center for Biomaterials, Korea Institute of Science and Technology, Seoul 136-791, Korea

<sup>2</sup>Department of Biomedical engineering, Korea University of Science and Technology, Daejeon, Korea  
[dkh@kist.re.kr](mailto:dkh@kist.re.kr)

## INTRODUCTION

Restoration of damaged endothelium might be a well-built way to prevent late stent thrombosis and restenosis. It has been reported that late endothelial progenitor cell (late EPC) can differentiate to endothelial cell and then facilitate re-endothelialization. In this study, we focused on CD146 as a target surface biomarker for late EPC capture. CD146 is a transmembrane glycoprotein that is constitutively expressed in the whole human endothelium.<sup>1</sup> Silicone nanofilament (SiNf) was modified on metal surface for increasing the amount of antibody immobilized on surface.<sup>2</sup> We demonstrated that anti-CD146 antibody (Ab)-immobilized stent can effectively capture circulating late EPCs and may restore a damaged endothelium.

## EXPERIMENTAL METHODS

SiNf surface was prepared using a trichloromethylsilane (TCMS) and modified by 3-aminopropyl triethoxysilane (APTES) for introducing the amine group as shown in Fig. 1. Morphology of SiNf surface was confirmed by SEM. SiNf, anti-CD34 Ab, and anti-CD146 Ab-immobilized surfaces were evaluated by immunofluorescence staining, scanning electron microscopy (SEM), ATR-FTIR, water contact angle, and EDX. The impact of Anti-CD146 Ab-immobilized SiNf surface on cell capture was evaluated by late EPC capture assay.

## RESULTS AND DISCUSSION

SiNf treatment changed a comparatively hydrophilic Co-Cr surface to a hydrophobic one and the SEM images showed tangled filaments with nano scale (Fig. 2A). Fluorescence staining demonstrated that anti-CD146 Ab was homogeneously covered on the surface. Capture assay exhibited that late EPCs were more significantly captured on anti-CD146 Ab-immobilized surface than bare surface and anti-CD34 Ab-immobilized one (Fig. 2B). This is probably attributed to the specific binding to CD146 marker on late EPC and larger surface area of SiNf. Early EPC do not express CD 146 but late EPC express CD 146, as mature endothelial cells. Anti-CD 146 Ab immobilized surface is able to capture more late EPCs than early

EPCs and this give rise to inducing rapid re-endothelialization to damaged endothelium lesion.

Fig. 1. Schematic procedure of antibody immobilized SiNf formation.

Fig. 2. (A) SEM images of SiNf on Co-Cr surface and (B) fluorescence images of late EPCs captured on modified surfaces.

## CONCLUSION

Structure of SiNf and immobilization of anti-CD146 Ab provided an effective surface for capturing specifically late EPC. Further studies are ongoing to demonstrate growth and differentiation of captured late EPC *in vitro* and their impact *in vivo*. This approach will become a promising way for preventing from restenosis and thrombosis of existing stents by accelerating re-endothelialization after stenting.

# Magnetic Susceptibility and Hardness of Alloys of Au and Group V Elements (Nb, Ta) for MRI Artifact-free Biomedical Applications

Kenichi Hamada, Shihoko Inui, Emi Uyama and Eiichi Honda

Institute of Health Biosciences, Tokushima University, Japan

[hamada.dent@tokushima-u.ac.jp](mailto:hamada.dent@tokushima-u.ac.jp)

## INTRODUCTION

Mismatch between the volume magnetic susceptibility ( $\chi_v$ ) of biomedical metal devices and the surrounding tissue in a human body is a major artifact in magnetic resonance imaging (MRI). The authors have developed Au–Pt–Nb alloys with  $\chi_v$  values similar to that of human tissue [approximately  $-9 \times 10^{-6}$ , (-9 ppm)] and with excellent mechanical properties<sup>1</sup>. However, the alloys exhibit insufficient deformability and improving the deformability is challenging because of the difficulty in performing a solid-solution treatment. To develop new MRI artifact-free alloys with both high strength and high deformability, a feasible solid-solution treatment is necessary. In this study, alloys of Au and group V elements (Nb and Ta) with excellent biocompatibility, were fabricated, and their  $\chi_v$ , Vickers hardness (Hv) and phase constitution were investigated.

## EXPERIMENTAL METHODS

Au–xNb (x = 4–12) and Au–yTa (y = 10–30) alloy ingots were fabricated by argon-arc-melting. The ingots were cold-rolled to a thickness of approximately 1–1.5 mm. The total rolling reduction was 50–70%. The rolled Au–Nb and Au–Ta alloy plates were homogenized at 1273 K for 20 h. Aging treatments were performed at 873 K. For all the samples, the  $\chi_v$  values were measured using a magnetic susceptibility balance; the Hv was measured under a load of 100 g for

30 s; and the phase constitution was analysed using X-ray diffractometry (XRD).

## RESULTS AND DISCUSSION

Fig. 1 shows the effect of Nb or Ta content on the  $\chi_v$  of homogenized Au–Nb or Au–Ta alloys. The  $\chi_v$  of both homogenized alloys increased linearly with increasing Nb or Ta content. The Au–6Nb and Au–15Ta alloys exhibited  $\chi_v$  values close to -9 ppm. Although the XRD profile of the Au–12Nb alloy, shown in Fig. 2, indicated the presence of a binary phase structure with Au–Nb solid-solution and Au<sub>2</sub>Nb, the linear dependence, shown in Fig. 1, did not change. In addition, the Au–8Nb alloy after aging at 873 K for 5 h showed the precipitation of Au<sub>2</sub>Nb without a significant change in  $\chi_v$ . These results suggest that the amount of Au<sub>2</sub>Nb precipitation was small and/or the  $\chi_v$  of Au<sub>2</sub>Nb was close to that of Au–Nb solid-solution. To clarify, an Au–19.1Nb alloy was fabricated and homogenized at 1323 K for 50 h. The XRD profile of the Au–19.1Nb alloy indicated clear peaks of Au<sub>2</sub>Nb with only slight peaks of Au–Nb solid-solution. Therefore, the  $\chi_v$  value of the Au–19.1Nb alloy is inferred to be equal to that of Au<sub>2</sub>Nb. Furthermore, the  $\chi_v$  value measured was -20 ppm, a value close to that of the Au–4Nb alloy, and thus, Au<sub>2</sub>Nb precipitation did not drastically change the  $\chi_v$  value of Au–Nb alloys when Nb content was less than 12%. Au–Ta alloys, where Ta content is above 20%, also indicated a binary phase structure with Au–Ta solid-solution and AuTa. This result suggests that the  $\chi_v$  value of AuTa is close to that of Au–Ta solid-solution; however, single phase AuTa was not successfully fabricated in this research.

Hv for the Au–6Nb and Au–15Ta alloys were 117 and 132, respectively, and did not increase after aging at 873 K. These results suggest that Nb and Ta are not the appropriate alloying elements to increase the Hv of Au effectively.

## CONCLUSION

Addition of Nb or Ta is not effective for increasing the Hv of Au alloy, but helps achieve the required  $\chi_v$  value to improve compatibility with human tissues, and thereby reduce MRI artifacts.

Institute of Health Biosciences, Tokushima University, Japan

[c301251012@tokushima-u.ac.jp](mailto:c301251012@tokushima-u.ac.jp)

### INTRODUCTION

Mismatch between the volume magnetic susceptibilities ( $\chi_v$ ) of a biomedical metal device and the surrounding human tissue is the main cause of metal artifact in magnetic resonance imaging (MRI). The authors have developed Au–Pt–Nb alloys as candidates for MRI artifact-free alloys with  $\chi_v$  values similar to that of human tissue [approximately  $-9 \times 10^{-6}$  (-9 ppm)] and with excellent mechanical properties<sup>1</sup>. However, the alloys exhibit insufficient deformability for certain types of biomedical applications. Improving the deformability of these alloys is challenging as it is difficult to perform a solid-solution treatment on them. A feasible solid-solution treatment is required to develop new MRI artifact-free alloys with both high strength and high deformability. In this study, alloys of Au and group IV elements (Ti and Zr) that have excellent biocompatibility, were fabricated, and their  $\chi_v$ , Vickers hardness (Hv), and phase constitution were investigated.

### EXPERIMENTAL METHODS

Au–xTi (x = 0.5–5.0 mass%) and Au–yZr (y = 1.0–5.0) alloy ingots were fabricated by argon-arc-melting. The ingots were rolled to a thickness of approximately 1–1.5 mm. The total rolling reduction was 50–70%. The rolled Au–Ti and Au–Zr alloy plates were homogenized at 1273 K and 1123 K, respectively, for 20 h. Aging treatments were performed at 873 K. For all the samples, the  $\chi_v$  was measured using a magnetic susceptibility balance; the Hv was measured under a load of 100 g for 30 s; and the phase constitution was analysed using X-ray diffractometry (XRD).

### RESULTS AND DISCUSSION

Fig. 1 shows the effect of Ti content on the  $\chi_v$  of Au–Ti alloys. The  $\chi_v$  increased drastically with 0.5% Ti addition; however, with further increase in Ti content,  $\chi_v$  increased gradually. The XRD patterns showed that the precipitation of Au<sub>4</sub>Ti was enhanced with an increase in Ti content. The Au–5Ti alloy exhibited  $\chi_v$  close to -9 ppm; however, it also indicated significant embrittlement and was difficult to be rolled. Aging at 873 K for 10 min did not change the  $\chi_v$  of the alloys.

Fig. 2 shows the effect of Ti content on the Hv of Au–Ti alloys. The Hv value increased gradually with Ti content under 1% Ti, increased steeply with Ti content from 1% to 2% Ti, and decreased gradually above 2% Ti. The XRD profile of Au–Ti alloys with more than 2% Ti indicated the precipitation of Au<sub>4</sub>Ti. After aging at 873 K for 10 min, the Au–1Ti alloy exhibited a drastic increase in Hv, while the XRD profiles showed no phase constitution change. These results suggest that a small amount of Au<sub>4</sub>Ti precipitation effectively

Fig.1 Effect of Ti content on  $\chi_v$  of Au–Ti alloys.

Fig. 2 Effect of Ti content on Hv of Au–Ti alloys.

increased the Hv of Au–1Ti alloy but did not change its  $\chi_v$ . The results also suggest that an increase in Au<sub>4</sub>Ti precipitation made the alloy brittle and reduced its deformability.

The Au–Zr alloys showed a similar dependence of  $\chi_v$  and Hv on Zr content. The saturated  $\chi_v$  value was smaller than that for the Au–Ti alloys and the saturated Hv value was similar to that for the Au–Ti alloys.

### CONCLUSION

A small amount of Ti or Zr addition effectively increases the Hv of an Au alloy without severe embrittlement. However, the addition of a suitable third alloying element is required to achieve the required value of  $\chi_v$ .

## INTRODUCTION

Stents provide biological support in body conduits and are useful for counteracting stenosis (constriction) in cardiovascular, gastrointestinal, urethral and airway passages<sup>1</sup>. However, the current widespread use of permanent metal stents that remain throughout the lifespan of a patient, threaten restenosis, thrombosis, or physical irritation if not surgically removed.

In infants the clinical requirement is for a stent that retains structural integrity for periods of several weeks up to many months *in vivo* during host tissue restoration<sup>2</sup> and from a materials perspective this requires an implant with appropriate mechanical and degradation characteristics.

Bioresorbable phosphate glass fibres have shown enormous potential for temporary implants and tissue repair, owing to their mechanical properties and solubility in aqueous media which can be modified by addition of various oxide compounds<sup>3,4</sup>. Further, when combined with degradable polymers the resulting glass fibre polymer composites (GFRP) become ductile allowing them to be forged into supporting scaffolds with suitable mechanical and dissolution properties. To date however, their use for stenting applications has not been investigated possibly due to major difficulties of processing these compositions into fibre form.

In this study, two phosphate glass fibre compositions containing SiO<sub>2</sub> (silica) and B<sub>2</sub>O<sub>3</sub> (Boron) were fabricated to test the hypothesis that B<sub>2</sub>O<sub>3</sub> containing phosphate glass fibres present enhanced mechanical and dissolution behaviour for use as a degradable stent.

## EXPERIMENTAL METHODS

**Glass fibres:** GF330 (Silica based) and GF331 (Boron) continuous fibre with target diameters ranging from 10–20µm were obtained (Giltch Ayrshire, UK).

**Fibre dissolution and pH study:** 200mg fibre bundles for each fibre formulation were immersed in 10ml glass vials containing phosphate buffered saline (Sigma Aldrich UK). Each sample (n=6 per formulation) was weighed (Denver Instrument) and the dissolution media pH recorded (Accument Basic AB15) before and after 3 and 7 days of incubation at 37°C. Before weighing, samples were dried in an air circulating oven at 60°C for 4 hours.

**Tensile tests:** Individual fibre filaments were placed on a paper frame (fig 2) with a gauge length of 25mm and the ends of each fibre attached to the frame using cyanoacrylate adhesive. Glass fibre diameters (n=20) were measured using optical microscopy (Zeiss Axiovert). Samples were mounted onto the specimen grips of a test machine (Instron 8841) fitted with a 10N load cell and tested at room temperature at 1mm/min. Tensile modulus and strength were calculated and Student's t-test were performed using Prism v.5

## RESULTS AND DISCUSSION

**Fig1:** Dissolution media pH (left) and % mass loss (centre) for GF330 and GF331 compositions after immersion in PBS, with light microscope images (right)

**Fig2:** Stress-strain curves for B<sub>2</sub>O<sub>3</sub> based glass fibres (left) and paper frame and mounting technique (right)

Degradation media of the boron based GF331 displayed a more dramatic decline in pH after 7 days  $4.09 \pm 0.76$  compared with GF330  $6.20 \pm 0.23$  (fig1), however a greater quantity of fibre mass was lost in the Silica based composition after 7 days of immersion in PBS. On average boron containing glass fibres demonstrated a statistically significantly higher tensile strength and tensile modulus than silica based fibres ( $p < 0.05$ ) and this maybe attributed to increased cross link density in glass fibres containing B<sub>2</sub>O<sub>3</sub> additions<sup>5</sup>.

## CONCLUSIONS

Despite creating a noticeably higher acidic environment B<sub>2</sub>O<sub>3</sub> fibres retain greater mass after days of immersion in PBS and are likely to perform with longer mechanical integrity *in vivo* than SiO<sub>2</sub> based fibres when used as part of a GFRP composite stent material.

### INTRODUCTION

Different approaches and biomaterials have been applied to solve thrombosis and intimal hyperplasia associated with failure of small diameter grafts.

Electrospinning is a technique able to produce vascular graft with fibers in the nanometer range that resembles the extracellular matrix of native tissues, thus supporting endothelial cell attachment, alignment, proliferation and maintenance of their *in vivo* function [1, 2]. Moreover spray, phase-inversion technique was successfully employed to fabricate microporous polyurethane vascular graft able to support wall thickness cell colonization in 3D structure [3-4]. With the aim to take the advantage of both techniques we produced a bilayered polyurethane vascular graft combining electrospinning and spray technique.

### EXPERIMENTAL METHODS

A 12% (w/v) solution of Poly(ether urethane) Estane<sup>®</sup> 5714 (hereinafter PU) was prepared by dissolving the PU in a solvent mixture of tetrahydrofurane (THF), N,N-dimethylformamide (DMF) and deionized water (58/40/2, v/v/v) for electrospinning. The electrospun inner-layer of the composite graft (ID 5 mm, length 200 mm) was produced using a custom-made electrospinning apparatus equipped with a rotating cylindrical collector [5]. Electrospinning was performed using needle-to-collector distance of 22 cm, solution flow rate of 0.5 mL/h and voltage of 26kV. Electrospun fibers were deposited on a grounded stainless steel rod rotating at 125 rpm to produce a tubular mat. The process was prolonged for 2 h to obtain a 100 µm thick electrospun network.

The external layer was obtained using spray, phase-inversion method as previously described [3]. A 0.2% (w/v) PU solution was prepared by dissolving PU in THF:1,4-dioxane (DX) (1:1, v/v) added with 17% (v/v) of distilled water. The PU solution and distilled water were sprayed on the electrospun scaffold rotating at 88 rpm at a flow rate of 2 mL/min for 50 min. After fabrication, grafts were maintained for 24 h in distilled water.

For ultrastructural evaluation SEM micrographs were acquired and analyzed with ImageJ to quantify the thickness of electrospun and sprayed layers and the diameters of PU nanofibers.

A peel tests, were performed according to modified ASTM method D 903-93 with dynamometric tension/compression machine (Z1.0, Zwick/Roell Germany) equipped with a 100 N load to evaluated adhesion strengths between electrospun and sprayed layers. After the peeling test the grafts were analyzed by SEM to evaluated morphological structure.

### RESULTS AND DISCUSSION

Bilayered graft after fabrication appeared porous and without any gross defects. SEM images of the grafts evidenced different morphologies (Fig. 1A): 1) a nanofibrous inner layer with  $101 \pm 6$  µm of thicknesses; 2) a microporous external layer with  $130 \pm 13$  µm of thicknesses and a pore size measuring  $90 \pm 55$  nm (Fig. 1C); 3) an intermediate layer with a structure containing a mixing of electrospun and sprayed structures. No significant difference of electrospun layer thickness and fiber diameter was observed before and after spray deposition (Fig. 1B).

The peel test between the electrospun and sprayed layers showed a  $27 \pm 1.7$  g/mm<sup>2</sup> adhesion force.

The SEM analysis of morphological structure of electrospun surface after peel test revealed a firm adhesion of sprayed layer onto the electrospun surface of graft indicated by the presence a thin layer of the microporous structure attached to the underlining electrospun layer.

**Fig. 1.** Representative SEM images of polymeric graft. (A) cross-section of bilayered graft; (B) internal surface of the graft; (C) external surface of the graft.

### CONCLUSION

This study demonstrated the possibility to combine two different consolidated techniques to manufacture a bilayered polyurethane vascular graft with a homogeneous microporous layer firmly attached on electrospun layer with the aim to supply a provisional cell template for *in situ* tissue regeneration.

[yamtet@ncvc.go.jp](mailto:yamtet@ncvc.go.jp)

### INTRODUCTION

Rapid and complete neointima formation on biomaterials is extremely important for suppressing late stent thrombosis and for high patency of the small-diameter blood vessels. We have been studying peptide-immobilization methods onto different substrate and succeeded to improve the in vitro adhesion of endothelial cells and endothelial progenitor cells on peptide-modified biomaterials surface by immobilizing REDV tetrapeptide sequence. REDV was reported as a specific sequence against  $\alpha_4\beta_1$  integrin<sup>1</sup> that is expressed by the endothelial cells and also by the circulating endothelial progenitor cells.

In the present study we tried to achieve the patency of small diameter vascular acellular grafts by using REDV-sequence immobilization technology. Small-caliber vascular grafts with the diameter less than 4 mm have not been utilized in the clinical stage because of the thrombogenic formation and rapid stenosis. Many studies on the small-caliber grafts have been carried out so far, but their size and aspect ratio was not satisfactory. We then challenged the patency of the thin and long grafts by immobilizing peptide onto the acellular tissues.

### EXPERIMENTAL METHODS

Carotid arteries of african black ostriches weighing 90–130 kg were selected as the base materials due to their straight and non-branched shape. They were trimmed, washed, packed with saline in plastic bag, and pressurized at 9800MPa for 10min to decellularize them. The treated blood vessels with the inner diameter (ID) of 2mm and the length of 20-30cm were immersed in saline containing 40 U/mL of DNase I, 20 mM MgCl<sub>2</sub>, and antibiotics for 3 days under 37°C, washed with saline, and preserved in the same medium until experimental use. The remaining DNA was quantified with DNeasy Blood & Tissue Kit, and fluorescence DNA quantification Kit.

The tissues were embedded in paraffin, sectioned, and stained with hematoxylin-eosin, Elastica van Gieson, or von Willebrand factor. The mechanical properties were tested and compared with the native arteries.

Modification peptide composed of collagen binding sequence and integrin  $\alpha_4\beta_1$  ligand (REDV) was used to immobilize REDV to the luminal surface of acellular blood vessel. A control peptide of which the collagen binding sequence was converted is also used. Acellular carotid arteries were immersed in 10 $\mu$ M peptide solution and incubated at 60°C for 1h.

The in vitro specific cell affinity of the modified surface was evaluated by seeding human endothelial cells or human endothelial progenitor cells. The number of adhering cells and their morphology was studied.

All animal experiments were conducted in accordance with the Guidelines for Animal Experiments established by the Ministry of Health, Labor, and Welfare of Japan and by the National Cerebral and Cardiovascular Center Research Institute in Japan. Goettingen minipigs were anesthetized with propofol. The left and right femoral arteries were exposed and clamped with single-use microvessel clamps. Six peptide-modified decellularized carotid arteries and three unmodified decellularized carotid arteries were transplanted in a femoral-femoral bypass manner. Blood velocity was recorded using laser Doppler flowmetry.

### RESULTS AND DISCUSSION

First of all, to evaluate the early stage thrombogenesis, the grafts were exposed to blood flow for 60 min by connecting them to a pump oxygenator, and the luminal surfaces were observed under SEM. It was revealed that the thrombus formation was greatly suppressed by the POG7G3REDV modification. This may be due to the shielding effect of the peptide against the thrombogenicity of the collagen.

Surprisingly, five POG7G3REDV-modified grafts in 6 total transplantations were patent for 3 weeks. We confirmed the presence of a von Willebrand-positive and a Vimentin-positive layer at the luminal surface without any thrombosis one week after transplantation (Figure 6b). In contrast, all unmodified grafts were occluded in a couple of days.

### CONCLUSION

The REDV peptide modification suppressed the early thrombus formation and lead to very quick neointima formation. These effects achieved the surprisingly high patency of the acellular vascular grafts with this thin and long vascular grafts, which are the clinically applicable size and aspect ratio.

## Interaction Of Nanocomposites Containing Carbon Fillers With Different Degradation Media

Agnieszka Piegat, Zygmunt Staniszewski, Mirosława El Fray

West Pomeranian University of Technology, Polymer Institute,  
Division of Biomaterials and Microbiological Technologies, 45 Piastów Ave, Szczecin, Poland  
[apiegat@zut.edu.pl](mailto:apiegat@zut.edu.pl)

### INTRODUCTION

Polymer chemistry is the major factor determining material susceptibility to degradation. In case of biomaterials contacting with body fluids, the predominant mechanism is hydrolysis, accelerating degradation by the presence of enzymes and oxidative agents. In some applications the degradation is desirable process (e.g. absorbable sutures), while in others is main problem occurring during handling.

Polyurethane thermoplastic elastomers (TPU) are known as bio- and blood compatible, biostable materials. Their specific interaction with circulating blood is mainly connected with two-phase microdomain structure, in which domains of hard segments are dispersed in a continuous matrix of soft segments<sup>1</sup>. Depending on the chemical structure of soft segments (polyether, polyester, polycarbonate) those materials undergo hydrolytic degradation, autooxidation and environmental stress cracking<sup>2</sup>.

In this paper we analysed the influence of different degradation media on selected properties of carbon nanofillers in the polyester thermoplastic elastomer matrix (containing dimerized fatty acid (PET-DLA)), and compared to TPU medical grade material as a reference. The addition of carbon nanofiller *in situ* during the synthesis was aimed to stabilize polymer structure, by enhancing microphase separation.

### METHODS

In this work, copolymers of poly(ethylene terephthalate) and dimerized fatty acid with two different hard:soft segments ratio were evaluated, namely 40:60 and 60:40 wt%. Degradation of selected materials containing different carbon nanofillers (from 0.05 to 1 wt%): multiwall carbon nanotubes (MWCNT), carbon black (CB) and graphene (GR) was carried out in simulated body fluid prepared according to Kokubo formulation, phosphate buffer solution and oxidative solution of 20% hydrogen peroxide and cobalt chloride (0.1 M), usually used as *in vitro* oxidation medium<sup>3</sup>. The degradation was carried out for 4 weeks at 37°C. Samples were analyzed after 7, 14, 21 and 28 days in shaking incubator. Chemical structure was analysed by ATR FTIR method, additional DSC analysis was carried out in order to investigate the changes in bulk properties of degraded materials. The surface morphology of materials was analyzed with scanning electron microscope and EDX analysis. Due to the specific application of composite materials, mechanical properties were evaluated on thin film samples (0,5 mm thickness).

### RESULTS AND DISCUSSION

The changes of the chemical structure of copolymers and their composites were more noticeable for materials containing 40 wt% of hard segments. Figure 1 present FTIR spectra of neat copolymer before and after incubation in SBF.

Fig.1. ATR FTIR spectra of a) 40:60, b) 60:40 PET-DLA copolymers

Similar results were found for materials with different carbon fillers - stronger changes were observed in case of 40 wt% of hard segments matrix. Thus could suggest that materials with lower content of hard segments are more susceptible to hydrolytic degradation due to the higher content of amorphous phase.

### CONCLUSIONS

PET-DLA copolymer and its composites with lower content of hard segments is more susceptible to changes in bulk properties, due to the better penetration of degradation media into the amorphous regions of polymer matrix.

[ziabka@agh.edu.pl](mailto:ziabka@agh.edu.pl)

### INTRODUCTION

Durability of polymer insulations applied in endocardial leads is a subject of researches during last years [1, 2, 3]. During long term insertion in human body external polymer insulation is damaged and metal wire is exposed. There are many reasons of such abrasions, however interaction between two leads, lead and pacer or insulation and metal wire are considered as the most common [1]. Leads continuously move during their normal work cycle, overlap on each other and are damaged in points of contact and bounding. Leads are removed using endovenous techniques. Very often insulation is additionally damaged during removal of leads what also makes more difficult defining the real cause of their damage. The aim of performed research is to show abrasions of insulation which appear on leads during long term insertion in human body using scanning electron microscopy and chemical analysis as confirmation methods.

### EXPERIMENTAL METHODS

The silicon leads (*Medtronic CapSureFix*) extracted by simple traction from 8 patients at the age of  $74.7 \pm 8.6$  (5 males and 3 females) were examined using optical microscopy (Nikon A2 100) and scanning electron microscopy (Nova Nano SEM 200, FEI Company). Testing have been committed with an attachment for the chemical analysis of specimens in microareas with energy dispersive x-ray spectroscopy (EDX, EDAX). The observations were carried out in low vacuum conditions in the secondary electron mode.

### RESULTS AND DISCUSSION

Table 1 shows optical (A) and SEM (B) microphotographs of leads surface, chemical analysis inside the abrasion on polymer surface (C) and on wire surface (D). In both pictures it is visible that outer silicone insulation is damaged. The silicon continuity is interrupted by the oval abrasion. Inside the abrasion the electrode wire is exposed.

Chemical analysis proved presence of tissue on surface of all tested polymer insulations. Moreover, analysis showed presence of tissue on internal surface of silicon insulation (1 on fig. B), which was confirmed by higher concentration of carbon (C), presence of nitrogen (N) and sulphur (S) and low signal from the silicon (Si).

Committed testing showed dependency between level of damage and period of time - the longer the lead was

implanted, the greater damage was observed. Damage were not caused during implantation or reimplantation procedures. Round shape of abrasion proved also that the polymer surface was damage during mutual overlap and abrasion of two leads.

### CONCLUSION

Combination of scanning electron microscopy and energy dispersive x-ray spectroscopy is a useful method for investigation damages on extracted leads. Both techniques are effective in distinguishing and classifying damages of polymer insulation.

## Investigation into Surface Characteristics of Coronary Stents

Sarah Morgan<sup>1</sup>, Richard A. Black<sup>1</sup>, Christopher McCormick<sup>1</sup>.

<sup>1</sup>Department of Biomedical Engineering, University of Strathclyde, Scotland, UK  
[sarah.morgan@strath.ac.uk](mailto:sarah.morgan@strath.ac.uk)

### INTRODUCTION

Advanced Coronary Heart Disease (CHD) is commonly treated by insertion of a Drug-eluting Stent (DES) into a previously blocked coronary artery, helping restore blood flow to the heart. DESs are Bare Metal Stents (BMSs) that have been coated with a drug (often encased within a polymer), which is slowly released to prevent excessive cellular proliferation within the artery wall. Despite their success, DESs are not suitable for all patients and have been linked to delayed healing of the endothelial cell layer that is crucial to normal artery function.

Research efforts are now focused on the development of stents which encourage rapid endothelial cell re-growth. Surface topography has been shown to influence cell adhesion, proliferation and migration<sup>1</sup>. Additionally, surface stiffness has been shown to influence cell behaviour<sup>2</sup>. This is particularly relevant for drug eluting stents whose surfaces may exhibit variations in surface stiffness due to heterogenous distributions of drug and polymer on the surface. Conducting polymers are emerging as a potential drug-eluting stent coating<sup>3</sup> although there has been little detailed investigation of their surface topography in this context.

We investigated the surface characteristics of four well-established coronary stent types and compared the results to those obtained for a conducting polymer coating we have recently produced.

### EXPERIMENTAL METHODS

#### Surface Analyses

Atomic Force Microscopy (AFM) (Asylum Research MFP-3D, AC in air, AC160 TS cantilever, 1Hz, 5  $\mu\text{m}$ ) was used to analyse the surfaces of clinically relevant BMSs and DESs. Three stents of each type were examined (n=2 for Yukon<sup>®</sup> stent) with four random points analysed per sample. The surface topography and cantilever phase signal was recorded for each surface, from which values for Root Mean Squared Roughness ( $R_{\text{RMS}}$ ) and Surface Area (SA) were calculated.

#### Electropolymerisation

Polypyrrole coatings were produced on stainless steel wire (AISI 316L, diameter 0.2mm) by means of electropolymerisation: Potentiostatic, Voltage: 0.9V, Duration: 15-25min, Electrolyte solution: 0.1M Pyrrole, 0.1M NaSa. N=3.

### RESULTS AND DISCUSSION

Average values of  $R_{\text{RMS}}$  and SA are displayed in Table 1, demonstrating the differences in surface topography between the BMSs and DESs. Surface roughness values of the polypyrrole coating were also shown to be in line with these values. A height retrace overlaid with phase

retrace image of the surface of a Taxus<sup>®</sup> Express<sup>2</sup> stent is displayed in Figure 1, illustrating the difference in surface stiffness and height between the paclitaxel particles in blue and the polymer in red.

Table 1:  $R_{\text{RMS}}$  and SA values for surfaces of materials examined.

Sample	Average $R_{\text{RMS}} \pm \text{SD (nm)}$	Average SA $\pm \text{SD } (\mu\text{m}^2)$
Gazelle <sup>TM</sup> (BMS)	$14.39 \pm 11.24$	$25.15 \pm 0.14$
Yukon <sup>®</sup> (SES) *post drug elution	$182.02 \pm 37.04$	$28.02 \pm 0.98$
Cypher <sup>®</sup> (SES)	$34.67 \pm 34.77$	$25.20 \pm 0.34$
Taxus <sup>®</sup> Express <sup>2</sup> (PES)	$33.36 \pm 30.02$	$25.27 \pm 0.69$
PPy (0.9V, 25min)	$135.06 \pm 37.26$	$28.51 \pm 1.81$

Figure 1: Representative AFM height retrace overlaid with phase retrace images (scan size 5  $\mu\text{m}$ ). Top: Taxus<sup>®</sup> Express<sup>2</sup>. Bottom: Cypher<sup>®</sup>.

### CONCLUSION

With these differences in surface characteristics, we anticipate that endothelial cells will behave differently on each stent surface, thus affecting healing following stent implantation, which is the subject of our ongoing work.

## Influence of Preservative on the Tensile Strength of the Tissue of Porcine Circulatory System

Alicja Stanislawska, Kinga Dawidowska

Department of Materials Science and Welding Engineering  
Technical University of Gdansk, Poland  
[alistanislawska@gmail.com](mailto:alistanislawska@gmail.com)

### INTRODUCTION

Currently one of the leading causes of death worldwide are heart diseases which include calcification of heart valves and vascular aneurysm. There are many biomaterials that can substitute pathologically altered tissue, however, none of them is as perfect as a native tissue. Currently, scientists are looking for new biomaterials that can be successfully implanted without exposing the patient to reoperation. We compare the tensile strength of the porcine tissues of the circulatory system that were stored in saline solution, with the same tissue-curing in a solution of glutaraldehyde. According to the literature glutaraldehyde results in the mechanical reinforcement by the binding of the so-called collagen cross-linking [1] so biological heart valve before implantation are keeping in glutaraldehyde solution. Subsequently, the tensile strength of the porcine tissues will be compared with tensile strength of Polish bionanocellulose produced by BoWil as implanting material used in cardiac surgery and vascular surgery.

### EXPERIMENTAL METHODS

We used flakes of the aortic valve (left coronary petal, right coronary petal and coronaryless petal), pericardium and porcine aortic patches (lobe). The tissues were divided into two groups. On the day of the study, all tissues were thawed and immersed for a period of about 2 hours in 0.95% sodium chloride solution. Test of the tension of the first part of the samples was carried out after the immediate removal from the sodium chloride, and the tension test of the second part was performed after keeping them in 0.05% glutaraldehyde solution for 10 min. Tensile test was carried out at the company testing machine INSTRON model 1112. Three samples of each type of material were made. Each sample came from another heart.

### RESULTS AND DISCUSSION

The studies show that the tensile strength of the left and right coronary petal and pericardium which were fixed in glutaraldehyde is characterized by higher strength properties relative to the same tissue stored in saline solution. Coronaryless petal and lobe of aorta fixed with aldehyde obtained slightly lower tensile strength values, relative to the same tissues stored in the saline, which may be due to errors resulting for example from a very fusing material and thus insufficient reagent bound collagen. The thickness of the tissue affects the binding of collagen. In the case of thinner tissue, for example pericardium, a significant increase in tensile strength was observed in comparison with the aorta, whose thickness is several times higher. In the case of application of the materials of various thickness at the same time of fixation, results consistent with expectations were obtained, because the thicker tissue requires longer time to total collagen cross-linking. The big standard deviation of the results for coronaryless petal could be due to the fact that the tissues were taken from a slaughterhouse, which does not guarantee the same conditions of rearing pigs. However, studies show that the impact of the reagent coming into contact with the test material affects its mechanical strength.

### CONCLUSION

Studies show that the impact of the reagent coming into contact with the test material affects its mechanical strength. Fixing the biological material with an aldehyde results in the mechanical reinforcement by the binding of the so-called collagen cross-linking. The results discussed in this article allow further studies on the comparison of the mechanical properties of natural tissues with bionanocellulose material. Such a material would be an interesting alternative for the currently used biomaterials in medicine.

## Encapsulation of Anti-inflammatory Drug into PCL Based Electrospun Fibres for Nerve Regeneration

Valentina Cirillo, Vincenzo Guarino, Annunziata Cummaro, Olimpia Oliviero, Luigi Ambrosio

Institute for Polymers, Composites and Biomaterials, Department of Chemical Sciences & Materials Technology,  
National Research Council of Italy, V.le Kennedy 54, Naples, Italy

[vincenzo.guarino@cnr.it](mailto:vincenzo.guarino@cnr.it)

### INTRODUCTION

Inflammation plays an important role in nerve regeneration strategies. Acute inflammation is the innate immune system's first line defence, intended to eliminate or segregate the foreign material. A strong inflammatory response can lead to the implant failure and disrupt nerve regeneration process. In this context, a large variety of synthetic grafts has been tested as promising solution to get fully nerve regeneration *in vivo*<sup>1</sup>. However, no matter how biocompatible a synthetic material is, the body will still give an immune response to it. Recently, several studies have remarked that active molecules (i.e., neurotrophins, antibiotics) can be efficiently incorporated in 3D scaffolds to locally hinder the inhibitory microenvironment occurring after lesion of peripheral nerve<sup>2</sup>. In particular, an anti-inflammatory drug in synthetic grafts may be locally delivered to the injury site to reduce the inflammatory response, avoiding capsule formation and cell infiltration into the lumen of conduits, so improving regeneration process.

For this purpose, in this study, Polycaprolactone (PCL) and PCL/Gelatin electrospun fibres have been prepared with and without the non-steroidal anti-inflammatory drug diclofenac sodium salt (DicNa). Electrospun fibrous scaffolds were then studied in order to evaluate the drug release profile to assess the best candidate as drug loaded electrospun grafts.

### EXPERIMENTAL METHODS

PCL and PCL/Gelatin fibres loaded with DicNa (Sigma Aldrich, Italy), were produced by electrospinning technique starting from different polymeric solutions: firstly, PCL (0.1 g/ml) and DicNa (5 mg/ml) were dissolved in 1,1,1,3,3,3 hexafluoropropanol (HFIP), secondly PCL and Gelatin (total polymer concentration 0.1 g/ml) were both mixed in HFIP with DicNa (5 mg/ml). Process parameters were changed to optimize fibres morphology. Fibrous platforms were examined by SEM/EDS, providing a complete detail on fibres size and composition.

Thermal analysis (TGA) has been performed in order to assess the inclusion of the drug. Moreover drug encapsulation and drug release profiles have been evaluated to underline the differences due to the use of mono and bicomponent systems. The drug-loaded fibrous mat was weighed and placed in PBS, incubated at 37°C and shaken. The amount of released drug, for several time intervals up to 15 days, was determined by UV-vis spectroscopy at 280 nm.

Cytotoxicity was preliminarily analysed by Alamar Blue test performed in hMSC culture via direct and indirect way.

### RESULTS AND DISCUSSION

SEM observations allowed for the correlation of final fibre morphology to process parameters set. Process parameters, such as flow rate, distance and voltage, were varied in order to identify the optimal set to obtain defect free fibres. By Image J analysis software, mean fibres diameter has found to be  $(0.12 \pm 0.02) \mu\text{m}$  and  $(0.41 \pm 0.05) \mu\text{m}$  for mono and bicomponent systems, respectively.

Moreover, in order to qualitatively verify the encapsulation of drug into the mono and bicomponent fibres, EDS spectroscopic analysis was also performed. It confirmed drug inclusion in the electrospun fibres as also showed by TGA thermograms. The encapsulation efficiency was about 50% for PCL alone and more than 80% for PCL/Gelatin.

Before reaching a plateau value, release profiles showed a strong initial burst in both cases, for the bicomponent it is strongly affected by gelatin depletion in aqueous medium while for monocomponent system it is related to the accumulation of the drug on the fibres surface. A preliminary screening of cell response until 7 days also showed a good response of hMSC in the presence of both drug loaded fibres, thus evidencing a reduction in cytotoxicity respect to the controls, namely, drug into the plate without electrospun fibers.

### CONCLUSION

PCL and bicomponent PCL/Gelatin electrospun fibres have been studied as anti-inflammatory drug release systems. Since gelatin concurs to influence the mechanism of drug release, bicomponent fibres released the drugs fairly fast and nearly completely, while monocomponent system, after an initial burst, could hold the drugs much longer. These results suggest new ideas for the fabrication of drug loaded electrospun conduits for peripheral nerve regeneration.

# Preparation of Biomedical Poly( $\epsilon$ -caprolactone) via Ring Opening Polymerization Catalyzed by *Candida antarctica* Lipase B in Ionic Liquids

Urszula Piotrowska, Marcin Sobczak, Ewa Olędzka

Medical University of Warsaw, Faculty of Pharmacy, Department of Inorganic and Analytical Chemistry, Banacha 1,

## INTRODUCTION

Enzyme catalysis has provided an environmentally friendly synthetic strategy for a variety of useful biomaterials, most of which would be difficult to produce using conventional chemical catalysts<sup>1</sup>.

Poly( $\epsilon$ -caprolactone) (PCL) is widely utilized aliphatic polyester for medical applications, such as drug delivery systems (DDS) or tissue engineering scaffolds due to its good biocompatibility and lack of toxicity. PCL has been successfully synthesized by polycondensation or by ring opening polymerization (ROP). ROP gives polyesters with a higher purity and low polydispersity, so it is the preferred route in the controlled release technology<sup>2</sup>.

A number of research topics develop an enzymatic ROP of cyclic monomers in organic solvent (e.g. toluene and heptane). Due to the toxicity of their vapor, recent literature reports suggest the possibility of using thermally stable and nonflammable ionic liquids (ILs) as the reaction medium. ILs have increasingly attracted attention as non-aqueous media for biocatalytic polymer synthesis. ILs can improve the solubility of monomers and/or polymers, provide better enzyme stability, activity and selectivity<sup>3,4</sup>.

The aim of this study was to obtain a low-molecular weight polyesters, terminated by functional groups (hydroxyl and carboxyl), with respect to their further applications as DDS. In order to this, ROP of  $\epsilon$ -caprolactone ( $\epsilon$ -CL) in the presence of non-toxic catalyst - *Candida antarctica* lipase B (CALB) in ILs media was carried out. The preliminary studies of several possible combinations of ILs anion's type, temperature and time on the polymerization process have been evaluated.

## EXPERIMENTAL METHODS

$\epsilon$ -CL, CALB and ILs were placed in 10 mL glass ampoules under an argon atmosphere. The vials were placed in a thermostated bath at predetermined temperature. After thermostated, the product was extracted with toluene and the enzyme was filtered off. Toluene was removed by evaporation in room temperature at reduced pressure.

Fig.1. Ring opening polymerization of  $\epsilon$ -CL

<sup>1</sup>H NMR spectra of PCL were obtained on Varian 300 MHz spectrometer using CDCl<sub>3</sub> as a solvent. The MALDI-TOF MS spectra were performed in the linear mode on a Kompact MALDI 4 Kratos analytical spectrometer using a nitrogen gas laser and 2-[(4-hydroxyphenyl)diazenyl] benzoic acid as a matrix.

## RESULTS AND DISCUSSION

The ROP process was carried out in the presence of three ILs composed of the same cation (1-butyl-3-methylimidazolium) and three different anions (tetrafluoroborate, hexafluorophosphate, bis((trifluoromethyl)-sulfonyl)imide).

CALB has shown an activity in all types of ILs using different reactions conditions.

Polyesters with a number average molecular weight ( $M_n$ ) in the range of 1200-4200 g·mol<sup>-1</sup> were obtained.

The structure of the obtained polymers was determined by MALDI-TOF MS and spectroscopy methods. It has been found that during ROP process both linear and cyclic polymers were formed. The frequency of cycle formation is affected by both kind of ILs, temperature and reaction time. The polydispersity index (*PDI*) of the obtained polymers determined by the MALDI-TOF MS method was low and ranged from 1.03 to 1.22.

## CONCLUSION

The enzyme-catalyzed ROP of CL in ILs seems to be a promising method of the synthesis of biomedical polyester. The polymer structure was strongly dependent on ILs species, temperature and reaction time. The obtained results demonstrated that ILs offer new possibilities for solvent engineering in an enzymatic polymerization.

## The Biomimetic Hydrogel Matrix for Long-term Cell Culturing

Agata Stefanek<sup>1</sup>, Tomasz Ciach<sup>2</sup>

<sup>1,2</sup>Department of Chemical and Process Engineering, Warsaw University of Technology, Poland  
[a.stefanek@ichip.pw.edu.pl](mailto:a.stefanek@ichip.pw.edu.pl)

### INTRODUCTION

Recently, there is a lack of techniques for long-term, three dimensional cell culture both in vivo and in vitro<sup>1,2</sup>. The insufficient transport rate of nutrients (glucose, oxygen) inside the 3D cell structures is the biggest obstacle for three dimensional cell culturing<sup>3</sup>. The aim of this work was to develop the method of production the biomimetic hydrogel matrix containing synthetic oxygen carrier for long-term cell culture both in vivo and in vitro. The research involves also cytotoxicity evaluation of produced material. The matrix is designed to mimic the natural originated extracellular matrix (ECM)- it forms a microcapsules of a diameter below 400  $\mu\text{m}$  with perfluorocarbon core (synthetic oxygen carrier) and alginate layer. The cells are suspended in hydrogel layer. Moreover the structure of the matrix provides free diffusion of nutrients inside the matrix and at the same time secretion of the metabolites of the encapsulated cells and immunoisolation<sup>4</sup>. The synthetic oxygen carrier in the matrix is employed to face the widely reported problem appearing in 3D cell cultures- insufficient oxygen level and occurring necrotic zones in cell aggregates<sup>5</sup>. Nowadays, development of the techniques and materials enabling long-term stable cell culture both in vitro and in vivo is a key challenge for the tissue engineering area.

### EXPERIMENTAL METHODS

#### Microcapsules production

Microcapsules were produced by the use of the encapsulator (B-395 Pro, Buchi) with concentric nozzle which enables producing core/shell structures in sterile conditions. All parameters of the process (nozzles size, liquids flow rate, gas pressure, vibration frequency, the electrode voltage) are settable, which provides good microcapsules size control. The process parameters were adjust to obtain uniform structures of define size app. 400  $\mu\text{m}$ .

#### Cytotoxicity

For cytotoxicity investigation of produced complex biomaterial, the procedure recommended in the "ISO 10993-5:2009 Biological evaluation of medical devices- Part 5: Tests for in vitro cytotoxicity" norm was applied. The MTT assay was used to evaluate the percentage of viable cells with respect to the control cell culture.

### RESULTS AND DISCUSSION

The parameters of microcapsules production process were adjust (Table 1). The process enables production uniform microcapsules of predictable diameter.

Table 1. The parameters of the microcapsules production process

Outer/inner nozzle diameter [ $\mu\text{m}$ ]	150/200
Flow rate [ml/min]	3,3
Vibration frequency [Hz]	1500
Gas pressure [mbar]	236
Diameter [ $\mu\text{m}$ ]	404,52 $\pm$ 35,74

The cytotoxicity tests proved that material has no cytotoxic potential. The viability of the L929 cells contacted with material extracts (after 24 h and 72 h of medium incubation with material) was above 70% according to the cells cultured in supplemented medium. The results of MTT assay are presented on the Figure 1.

Figure 1. The MTT assay results

### CONCLUSION

The production process of uniform hydrogel microcapsules containing perfluorocarbon core was developed. The process could be employed to producing biomimetic hydrogel matrixes for long-term cell culturing both in vitro and in vivo. Moreover, the results of MTT assay proved lack of cytotoxic potential in produced microcapsules containing perfluorocarbon core.

## Microencapsulation and Nano Coating of Pancreatic Beta Cells

Niusha Nikravesh<sup>1</sup>, Gurpreet Chouhan<sup>1</sup>, Anita Ghag<sup>1</sup>, and Liam Grover<sup>1</sup>

<sup>1</sup>School of chemical engineering, University of Birmingham, UK  
[NXN372@bham.ac.uk](mailto:NXN372@bham.ac.uk)

### INTRODUCTION

Transplantation of pancreatic islets proposes a promising method for treating patients with type 1 diabetes mellitus (T1DM). It is currently, however, restricted by various problems including the shortage of donors, poor revascularization, immune rejection, and the need for life long immunosuppressive drugs. To address these issues, microencapsulation of islets has been introduced as a method to avoid host immune response by utilising a semi-permeable membrane, which provides a mechanical barrier for separating the graft from host antibodies and immune cells<sup>1</sup>. Despite significant progress being made in recent decades concerning the knowledge of microencapsulation devices, there are still several obstacles involved with the procedure. For example, relatively large number of microcapsules, and inefficiency in oxygen and nutrient diffusion due to the thickness of polymeric membrane around the cells<sup>2</sup>. In this study we aim to camouflage the surface of uniformly aggregated pseudo islets with polyelectrolyte nano coatings using the layer-by-layer (LBL) technique in order to reduce the membrane thickness around the islets, and to compare the results with traditional microencapsulated single cells.

### EXPERIMENTAL METHODS

Beta-TC-6 were cultured in Dulbecco's modified Eagle medium (DMEM) supplemented with 10% FBS, 2.5% HEPES, 1% penicillin/streptomycin, and 2.5% L-glutamine. Concave micro well arrays were developed to form uniform-sized islet spheroids. Cell survival was tested by MTT assay. As first method, cell encapsulation was conducted using encapsulator (B-390 pro) and medium viscosity alginate was cross-linked by calcium chloride. For the second encapsulation technique, cultured pseudo islets were coated with alternative layers of polycation (Poly-L-lysine) and polyanion (alginate). Furthermore, cell viability was assessed by incubating the encapsulated islets with live/dead staining in culture medium for 40mins at 37°C, and then imaged with a fluorescent microscope.

### RESULTS AND DISCUSSION

Manipulation of encapsulator parameters such as frequency, nozzle size, and pump flow rate resulted in the formation of alginate microparticles with an average diameter of <300µm (Fig.1-A). Also the result showed the effect of concave micro well on spheroid formation, demonstrating that concave micro wells more effectively generate uniform islet spheroids. The

viability of islets was assessed by staining with 5µl calcein AM, which stains live cells green, and 25µl propidium iodide, a red dye that can only permeate dead cells membrane. A high viability of coated pseudo islets was observed during the 14 day viability study (Fig.2-A, B)

Fig 1: Morphology and viability of encapsulated cells. (A) Void alginate microparticles with average diameter of 268.63µm (frequency=2300HZ, pump flow rate=6ml/min, nozzle size=80µm). (B) Encapsulated single islet cells in alginate microsphere. (C) Pseudoislets coated with 3 bilayer of alginate-PLL.

Fig 2: Cell viability assessed with live/dead staining on day 14. (A) Alginate microencapsulated islet cells. (B) Nanocoated pseudo islets.

### CONCLUSION

In this study two different approaches for encapsulation of islet cells were evaluated. Microencapsulation of islet cells, despite being studied for several years, have had issues with longevity of transplanted cells. The aim of this study is to show that coated islets produced using the LBL method have the potential to increase coverage of encapsulated cells. Minimising the capsule thickness reduces the distance for diffusion of oxygen, nutrients, and small molecules resulting in improved cell viability and functionality.

### INTRODUCTION

In addition to tissue engineering applications, synthetic tissue-like constructs can be used as *in vitro* models for 3D cell culture [1]. If a suitable synthetic environment that closely mimics human tissue physiology can be created, then costly and ethically questionable *in vivo* animal studies could largely be avoided. In the context of bone tissue engineering, we have already investigated this concept in a preliminary study looking into the ability of alginate beads mineralized with hydroxyapatite (HA) to support a culture of primary human osteoblasts and osteoprogenitor cells [2]. This work validated the concept of supporting osteoblast cultures and the ability to form synthetic bone like constructs using mineralized alginate. However, natural human bone undergoes continuous remodelling by a co-ordinated process involving three main cell types: bone formation is mediated by osteoblasts and osteocytes and bone resorption by osteoclasts, with all the cell types affecting each other. Imbalances in this process may cause pathological loss of bone mass as seen in conditions of delayed bone healing after fracture, osteoporosis and metabolic bone diseases. As this imbalance cannot be considered in mono-cellular systems, this represents one of the major limitations for *in vitro* testing of novel therapeutics for bone. Therefore, a primary goal of this study was to develop a co-culture of osteoblasts and osteoclasts to create a synthetic bone-like 3D platform using mineralised alginate microbeads.

### EXPERIMENTAL METHODS

Mineralised alginate hydrogel microbeads were synthesised using electrostatic extrusion as described previously [3]. SCP-1 cells were encapsulated at a concentration of  $1 \times 10^6$  cells / mL. THP-1 cells were stimulated with phorbol 12-myristate 13-acetate (PMA) for 48hrs to form adherent macrophage cells and then encapsulated in or seeded onto mineralised alginate microbeads. Co-cultures of microbeads were maintained in trans-well dishes. TRAP activity was measured after 14 days culture. Cell numbers were normalised using a resazurin assay for measuring cell metabolism.

### RESULTS AND DISCUSSION

Cells were either encapsulated in the microbeads or seeded onto the mineralised surface of the hydrogel. Mineralisation with HA was essential for cell attachment to the surface (Fig 1A). In this way binary compositions of cells could be created in 3D. In order to study the effect of co-cultures of osteoblast and osteoclast cells, microbeads with encapsulated SCP-1 pre-osteoblast cells were cultured in trans-well plates in

the presence of THP-1 osteoclast-like cells which had either been encapsulated in or seeded on mineralised alginate microbeads. Samples were cultured with and without osteoblast stimulating media. Measurements of tartrate resistant acid phosphatase (TRAP) activity, (an enzyme produced exclusively by osteoclast cells) indicated that co-culture was necessary for THP-1 cells to differentiate into osteoclast cells and this was only possible when the cells were cultured on the surface of the beads and not encapsulated within them. Addition of osteoblast differentiation medium significantly enhanced TRAP activity levels (Fig 1B).

**Fig. 1. A:** Fluorescent micrograph showing SCP-1 cells adhered to a mineralised alginate microbead (actin red, nuclei blue) and not to surrounding unmineralised surfaces (grey). **B:** TRAP activity of THP-1 cells in co-culture with encapsulated SCP-1 cells after 14 days with (red) and without (blue) osteoblast differentiation media compared to negative control (green). Mann-Whitney t test \$ P = 0.002, \* P = 0.006.

### CONCLUSION

Here, previous work regarding cell attachment to mineralised hydrogels has been validated. In addition, a cell culture system to study co-cultures of cells relevant to bone biology in 3D has been developed with implications for both *in vitro* characterisation and the development of bone tissue engineering scaffolds using hydrogel-mineral composite materials. Work is now focussed on studying bone formation using this system and miniaturising the mineralised hydrogel dimensions for use in flow chambers.

### INTRODUCTION

Pancreatic islet transplantation is a promising strategy for the treatment of Type 1 diabetes (T1D), but the necessity of life-long systemic immunosuppression limits its clinical application. In order to protect the islet graft, several encapsulation strategies have been studied since islet transplantation became a feasible therapy, to strengthen the efficacy<sup>1</sup>. Poly(ethylene glycol) (PEG) hydrogels are one of the most widely utilized biomaterial systems, thanks to their soft tissue-like properties<sup>2</sup>. Additionally, because of their intrinsic resistance to protein adsorption and cell adhesion, PEG hydrogels seem to be the most suitable bioinert material that is ideal for use in drug delivery vehicles, blood-contacting devices, for controlled cell differentiation and cell encapsulation for transplantation<sup>3</sup>. In this work, PEGDA hydrogels were synthesized by UV crosslinking and characterized for cell encapsulation. PEGDA coating should be designed to prevent islet destruction by immune-reactive cells and antibodies, while at the same time allowing sufficient physiological exchange to prevent hypoxia, minimize the stress state of the islets and maintain a controlled glycaemic level, through proper diffusion of insulin. Macroscopic properties such as water content and compressive modulus are influenced by gel crosslinking, so we investigated how simple changes in composition of precursor solution and time of irradiation modify such important properties in the design of the coating. PEGDA hydrogels are susceptible to slow degradation *in vitro* and *in vivo*, thus hydrogel degradation properties were evaluated to understand their behaviour over time.

### EXPERIMENTAL METHODS

**Synthesis of PEGDA hydrogels.** 700Da Poly(ethylene glycol)-diacrylate was dissolved in distilled water at three different concentrations (7.5 – 10 – 15 % w/v) and a photoinitiator (Darocur® 1173) was added to the solution at 3% w/w with respect to the PEG macromer and polymerized through UV irradiation (365 nm at 2 mW cm<sup>-2</sup>) for different time lengths (1, 3, and 5 minutes). **Characterization experiments.** Swelling studies and mechanical analysis were carried out to evaluate hydrogel reticular parameters. Degradation tests were performed to study how parameters change over time. Protein release profiles were used to estimate diffusion coefficients for insulin. Cytotoxicity of the hydrogels was evaluated *in vitro* using 3T3 cell line, by means of MTT assay.

### RESULTS AND DISCUSSION

Increasing PEGDA concentration in starting polymer solution and/or UV time exposure reduced the

equilibrated swelling ratio of the hydrogels, while increased mechanical properties. This finding can be explained considering that higher crosslinking densities involve shorter mesh size of the hydrogel (Figure 1).

**Figure 1.** Effect of PEGDA % and UV time exposure on mesh size.

Hydrogel degradation happens through breakage of networked groups, leading to a reduced crosslink density over time and increased mesh size (Table 1).

duration	% increase of mesh size, ξ		
	PEGDA 7.5% (6 weeks)	PEGDA 10% (10 weeks)	PEGDA 15% (10 weeks)
UV 1 min	18.25±4.24	24.77±2.65	34.71±4.04
UV 3 min	27.40±3.15	22.07±4.91	32.53±3.12
UV 5 min	35.42±2.78	33.78±4.32	32.32±4.98

**Table 1.** Percentage increase of mesh size after degradation.

In islet encapsulation, it would be crucial to know how the mesh size changes over time, to evaluate which molecules can diffuse through the gel coating. Insulin release profiles gave a diffusion coefficient in the order of 10<sup>-6</sup>-10<sup>-7</sup> cm<sup>2</sup>/s. The hydrogels cytocompatibility was satisfactory, showing a slight decrease of cell viability when reducing the UV exposure time. This evidence can be explained considering that the less UV-exposed hydrogel give more unreacted polymers.

### CONCLUSION

The results obtained in this study suggest the possibility to use PEGDA hydrogels as cytocompatible coatings for islet encapsulation. Swelling ratio, mechanical properties and degradation can be conveniently and finely modulated, by controlling macromer composition and time of irradiation. Moreover, insulin diffusion within the gels is suitable for the intended application.

### INTRODUCTION

Stem cell therapy has been increasingly used in lung diseases for various inflammatory conditions and pulmonary hypertension<sup>1,2</sup>. This expanding application does not yet include lung injury caused by burns or inhalation of smoke in fire incidents, which is known to be a leading cause of death in burn patients<sup>3</sup>. Current regimes for the treatment of inhalation injury mostly rely on the self-regeneration of the injured tissues and general treatments such as inhaled anticoagulation and oxygen therapy<sup>4</sup>. Amniotic fluid mesenchymal stem cells have been shown to have anti-inflammatory properties and also the capacity to differentiate into epithelial lung lineages<sup>5</sup>. Current cell therapies for the lungs are administered by injection and the cells are expected to reach the lungs. The current study aims to deliver the cells directly to the lungs for repair and regeneration.

### EXPERIMENTAL METHODS

Aerosolised suspensions of A549 human lung epithelial cells were used to optimise conditions of cell spraying with two devices, PennCentury MicroSprayer<sup>®</sup> Aerosoliser and LMA MiniMAD<sup>™</sup>. Cells were sprayed onto poly-L-lysine or collagen-coated plastic, gelatin 10% gel or media. A natural protein keratose extracted from Merino wool dissolved at 0.1mg/ml in media was used to explore the benefits in homing of cells. Human amniotic fluid mesenchymal stem cells (hAFMSCs) were used thereafter. To examine the survival of cells during the process of spraying, cell viability was measured using live/dead cell staining kit and live cell imaging on IncuCyte Zoom<sup>®</sup> together with cell viability assays such as alamarBlue<sup>®</sup> and Cell Counting Kit-8. All data were produced in triplicates ( $n = 3$ ) for reliability. Data were analyzed and presented as means  $\pm$  standard deviation.

### RESULTS AND DISCUSSION

Cell attachment after aerosolisation varied depending on the device used, the type of coating and hardness of the recipient surface as verified by live cell imaging and live/dead cell staining assays. At 8 hours after aerosolisation of hAFMSCs most cells recovered and attached to poly-L-lysine coated plastic after “soft landing” onto media (Fig. 1. *left*) whereas a larger proportion of cells died after being sprayed onto hard plastic (Fig. 1. *right*). The mechanical stress of the cell aerosolisation process was dependent on the device used. PennCentury MicroSprayer<sup>®</sup> Aerosoliser yielded

smaller particle size compared to LMA MiniMAD<sup>™</sup> and thus was less favourable for cell viability.

**Fig 1.** Images from a live/dead cell staining assay performed 8 hours after spraying human amniotic fluid mesenchymal stem cells onto media (*left*) and poly-L-lysine coated plastic (*right*) using LMA MiniMAD<sup>™</sup>. Green and red represent live and dead cells respectively. The type of coating and hardness of the recipient surface determines the cell viability. Scale bar represents 500  $\mu$ m.

Additional studies including cell viability assays and live cell imaging demonstrated that the cells were capable of recovering from the mechanical stress and proliferated normally after aerosolisation. In order to enhance cell homing capacity to the injured site, poly-L-lysine, collagen or keratin was used, of which collagen showed highest levels of cell attachment and proliferation. These materials also have potential to assist in the regeneration process for the lung tissues<sup>6</sup>.

### CONCLUSION

This study shows the possibility of delivering stem cells directly to the lungs for cell based therapy for the regeneration of the lung tissues. Furthermore, it has been demonstrated that the presence of keratin or collagen enhances the cell proliferation after spraying, which may have a role in regeneration of tissues after lung injury.

<sup>1</sup>Faculty of Pharmacy, Silpakorn University, Nakhon Pathom, Thailand

[charoept@gmail.com](mailto:charoept@gmail.com)

### INTRODUCTION

Dermal and transdermal delivery of Tretinoin (Tr) has been used to treat acne and photodamaged skin and to manage keratinization disorders such as ichthyosis and keratosis follicularis. However, the chemical instability of Tr, the drug is unstable when exposed to heat and light. Moreover, Tr is a poorly water soluble drug<sup>1</sup>. The new-state-of-art in drug delivery is important to overcome these problems. Many researches showed the benefit of lipid nanocarriers in the dermal and transdermal applications<sup>2</sup>. Limonene (L) has been classified as a lipophilic terpene type permeation enhancer which obtained from *Citrus lemon*<sup>3</sup>. The aims of this study were to develop Limonene composed lipid nanocarriers (solid lipid nanoparticles (SLN), nanostructured lipid carriers (NLC) and nanoemulsions (NE)) to enhance the skin permeation of Tr and examined the effect of different Limonene composed lipid nanoparticles formulations (10% L-SLN, 10% L-NLC and 10% L-NE) on the physicochemical properties (size and zeta potential), drug loading, cytotoxicity, and skin permeation of Tr.

### EXPERIMENTAL METHODS

Tr-loaded 10% L-SLN, 10% L-NLC and 10% L-NE were prepared using a *de-novo* emulsification method. The dispersed phase consisted of 0.3% Tr, lipid matrix core (SLN: Cetyl palmitate, NLC-Cetyl palmitate and Oleic acids and NE: Oleic acids and Medium chain triglycerides), 10% L, Transcutol P and Butylated hydroxytoluene. Droplet size and zeta potential of Tr-loaded lipid nanocarriers were determined at 25°C by using a Zetasizer Nano ZS. The percent yield of Tr incorporated into lipid nanocarriers and the Tr content was investigated after disrupted with Propa-2-ol and analyzed by HPLC. *In vitro* skin permeation through shed snake (*Naja kaouthia*) was determined using a Franz diffusion cell with a water jacket connected to water bath at 32°C. The cytotoxicity of the nanocarriers in Normal Human Fibroblast (NHF) was evaluated based on a procedure adapted from the ISO10993-5 standard test method. Statistical significance was evaluated using a one-way-analysis of variance (ANOVA). The significance level was set at a p value < 0.05.

### RESULTS AND DISCUSSION

All Tr loaded lipid-based nanocarriers had mean size less than 200 nm (140 to 146 nm) with narrow polydispersity index (PDI). The zeta potential of particles was high and negative (-29 to -45 mV) which implied to electrostatic repulsion of lipid droplets in the system. The incorporation efficiency of Tr loaded of all formulations was higher than 80%, and Tr content was higher than 8 mg/g. This result showed all Limonene composed lipid-based nanocarriers had a high capacity

loading for lipophilic drugs. The flux of Tr from Limonene composed lipid nanocarriers was in the order of 10% L-SLN > 10% L-NLC > 10% L-NE > suspension. Furthermore, Tr cumulative at 24 h from Limonene composed lipid nanocarriers was much significant higher than suspension. The cytotoxicity level of all Limonene loaded nanocarriers was low because the IC<sub>50</sub> value was higher than 1,000 µg/ml. The result from the cytotoxicity study implies that lipid nanocarriers decrease Tr toxicity to fibroblast cells.

**Figure 1** The *in vitro* skin permeation of Tretinoin-loaded (●) 10% L-SLN, (■) 10% L-NLC, (◆) 10% L-NE and (X) suspension.

Formulations	IC <sub>50</sub> (µg/ml) ± SD
Tretinoin powder	350 ± 25
Tretinoin 10% Limonene-SLN	10000 ± 1000*
Tretinoin 10% Limonene -NLC	1500 ± 200*
Tretinoin 10% Limonene -NE	2500 ± 200*

**Table 1** IC<sub>50</sub> value of Tretinoin powder, Tretinoin loaded 10% L-SLN, 10% L-NLC and 10% L-NE. (\*Compared with the Tretinoin powder (p < 0.05)).

### CONCLUSION

Limonene composed SLN, NLC and NE preparations were achieved by *de-novo* emulsification method. All formulations had a size in nano-meter range with a good capacity of Tr loading. The skin permeations study showed the lipid nanocarriers can improve Tr permeation into the skin when compared to suspension formulation. Moreover, Limonene composed lipid nanocarriers also exhibited a low toxicity to NHF. From our study implied that limonene composed lipid nanocarriers were promising dermal drug carriers for Tretinoin.

### INTRODUCTION

Gene delivery from a scaffold represents a promising approach to efficiently control stem cell fate. With this in mind, we designed an optimized tissue engineering construct for cartilage repair, based on custom made cross-linker free collagen microspheres ( $\mu$ Coll) impregnated with TGF- $\beta$ 3. This injectable biomimetic scaffold associated to mesenchymal stem cells (MSC) successfully induced a chondrocyte phenotype and the formation of neocartilage both *in vitro* and *in vivo*<sup>1</sup>. However, *in vivo* experiments suggested the late apparition of hypertrophic differentiation markers, which must be avoided for the cartilage neo-tissue to be fully functional. To maintain a mature chondrocyte phenotype, we investigate a complementary approach based on RNA interference of RunX2, a transcription factor involved in chondrocyte terminal differentiation. To ensure good transfection levels of the MSC, siRNAs were formulated into non-viral vectors: environment responsive PIC micelles<sup>2</sup>. The combination of such non viral gene vectors onto a collagen matrix, called Gene Activated Matrix, is expected to improve MSC differentiation control.

### EXPERIMENTAL METHODS

**Formulation of PIC micelles:** Double Hydrophilic Block Copolymers (DHBC) PEO<sub>x</sub>-PMAA<sub>y</sub> were formulated into micelles by polyelectrolyte complexation with either PLL or PEI. The encapsulation of siRNA into the PIC micelles was investigated as a function of loaded amount, pH, and polyacid block size. **Transfection of MSC:** Internalization of the micelles in MSC was assessed by flow cytometry, using a fluorescently labeled siRNA-TAMRA. Gene extinction efficiency of RunX2 was assessed by RT-qPCR. **Synthesis of collagen microspheres ( $\mu$ Coll):** a microfluidic set up with T-junction was used to form an emulsion between an acidic type I collagen solution and perfluorated oil. Microparticles of fibrillar collagen were obtained through a sol-gel transition induced in the aqueous droplets by vapor diffusion. **Association of micelles and microspheres:** Loading of vectors was investigated by impregnation of FITC-labelled micelles into  $\mu$ Coll and the release profile established by diffusion in PBS.

### RESULTS AND DISCUSSION

We obtained micelles with a diameter of  $60 \pm 5$  nm and a weakly positive zeta potential of  $14 \pm 2$  mV which are stable at physiological pH. To suit gene therapy applications, the pH-trigger value for micelles

dissociation and release of siRNA was chosen close to that found in endosomes (5.5), by selecting the appropriate DHBC moiety. The micelles were shown to be efficiently associated with MSC (Fig. 1) by flow cytometry. Preliminary RT-qPCR data showing a notable extinction of the targeted gene Runx2 call for further investigation. Finally, collagen microspheres with a narrow diameter distribution (mean =  $225 \pm 24$   $\mu$ m) were prepared using a custom microfluidic set-up and efficiently loaded with siRNA-micelles (Fig.2).

Fig. 1 Internalization of SiRNA-TAMRA into MSC (50pmol of siRNA per well, 6 well plates, 100000 cells per well)

Fig.2 Association of fluorescent micelles with  $\mu$ Coll.

### CONCLUSION

Our work shows that PIC micelles can be formulated to efficiently encapsulate siRNA and disassemble at acidic (endosomal) pH. These non-viral vectors are able to deliver siRNAs inside MSCs, thereby down-regulating the hypertrophic factor Runx2. Ongoing experiments are aiming at evaluating the potential of  $\mu$ Coll to serve both as an injectable MSC carrier and as a reservoir for their long-term transfection. The latest results will be presented, notably regarding the expected improvement in transfection efficiency owing to the 3D biomimetic environment of these Gene Activated Matrices.

## Skin Penetration Enhancement of Hydrophilic Macromolecules using Microneedles Combination with Electroporation and Sonophoresis: Effect of Molecular Weight on Skin Permeation

Maleenart Petchsangai, Praneet Opanasopit, Theerasak Rojanarata, and Tanasait Ngawhirunpat

Faculty of Pharmacy, Silpakorn University, Nakhon Pathom, Thailand

[p\\_maleenart@hotmail.com](mailto:p_maleenart@hotmail.com)

### INTRODUCTION

Limitations of transdermal drug delivery system are significantly associated with the skin's barrier function which restricts the amount of drug absorbed across the skin. As a result, physical enhancement methods such as microneedles (MN), electroporation (EP), and sonophoresis (SN), have been used to improve skin permeability. MN are micron-sized needles which can breach stratum corneum, the skin's outermost layer, to create holes big enough for the molecules to pass through. EP is the transitory structural perturbation of lipid bilayer membranes causing a rearrangement of lipid bilayer in cell membrane or in more complex structure such as stratum corneum, leading to an increase in skin permeability. SN, also known as phonophoresis, is the use of ultrasound to deliver various compounds through the skin. The three combined method, MN+EP+SN, has been shown a great effectiveness for improving skin permeation of hydrophilic macromolecules. The objective of this study was to investigate the effect of molecular weight (MW) of hydrophilic macromolecules on skin permeation using this three combined method, MN+EP+SN.

### EXPERIMENTAL METHODS

Porcine skin was used as an animal skin model in this study. 1,000  $\mu\text{m}$ -long MN+EP arrays were prepared using nine acupuncture needles (**Figure 1**). Fluorescein isothiocyanate (FITC)-dextrans with various MW; FD-4 (4 kDa), FD-20 (20 kDa), and FD-40 (40 kDa) were used as model drugs. *In vitro* skin permeation of all compounds was performed using Franz diffusion cell apparatus. First, skin was punctured with the MN+EP array using 10 N forces for 2 min. Next, 300 V of electrical current was applied to the skin using a square wave pulse generator. The MN+EP-treated skin was mounted, and 625  $\mu\text{M}$  of FD-4, FD-20, and FD-40 was instantly added to each of the diffusion cell.

(a)

(b)

**Figure 1** A schematic diagram of the MN+EP array (a) and a homemade MN+EP array which each of needle was systematically connected by copper wire (b).

Ultrasonic energy was then applied continuously using an ultrasonic transducer for 2 min. The concentration of FD was determined using a spectrofluorophotometer.

### RESULTS AND DISCUSSION

To study the effect of MW on the macromolecular delivery through the skin treated with MN+EP+SN, the skin permeation of FD-4, FD-20, and FD-40 were investigated. The results showed that the cumulative amount of FD permeated can be ranked as follow; FD-4 > FD-20 > FD-40 (**Figure 2**). This result suggested that the higher MW of penetrant contributed to the lower skin permeation.

**Figure 2** *In vitro* permeation profiles of FD with various MW across porcine skin: FD-4 (■), FD-20 (●), and FD-40 (▲).

### CONCLUSION

The homemade MN+EP arrays with the length of 1,000  $\mu\text{m}$  were successfully fabricated using nine acupuncture needles. They showed the potential to deliver hydrophilic macromolecules with MW up to 40 kDa, into the skin. Nevertheless, the MW of penetrant affected the skin permeation using this three combined method. The higher MW of FD was applied, the lower skin permeability could be obtained.

## Poly-L-lysine Based Covalently Crosslinked Bionanocomposites with Controlled Drug Release and Cell Adhesion Properties

Minkle Jain, Kazuaki Matsumura

School of Materials Science, Japan Advanced Institute of Science and Technology, Japan

[s1340151@jaist.ac.jp](mailto:s1340151@jaist.ac.jp)

### INTRODUCTION

Engineered tissues are great substitutes for treating organ failures associated with disease, injury and degeneration<sup>1</sup>. However, challenging task is to mimic the complex cell-microenvironmental interactions to regulate the formation of functional tissue. Designing of the new biomaterials with controlled release profile and cell adhesion characteristics can be useful to precisely control cell behaviour and facilitate the formation of specific functional tissues<sup>2</sup>. In order to recapitulate the native structures various nanofillers are used with in the polymeric network. In this context injectable hydrogels are good choice with aforementioned properties. In the current study we have formulated the system based on succinylated poly-L-lysine (PLL-SA) which is chemically crosslinked using 4-arm polyethylene glycol with N-hydroxy succinimide ester (PEG-NHS). Previously, we have reported that PLL-SA is a potent cryoprotectant<sup>3</sup>. The uniqueness of this gel is that the degradation of this can be tuned from few days to months. Incorporation of synthetic clay laponite (XLG) can introduce biocompatibility. Modification of the system with nanoclay also modulates the mechanical and degradation property. Overall this hydrogel could be used for biomedical applications that require spatial control of cell adhesion and controlled release of cationic drugs.

### EXPERIMENTAL METHODS

PLL-SA was synthesised by reacting PLL aqueous solution with succinic anhydride in different mole ratios from 0-80%. This PLL-SA was then mixed with laponite and PEG-ester in appropriate amounts to formulate the hydrogel. Parameters were varied to tune the mechanical and degradation properties like concentration of the polymer, crosslinker and nanoclay. These hydrogels were analysed by XRD and ATR-IR. Dynamic mechanical analysis (DMA) was also carried out.

### RESULTS AND DISCUSSION

PLL-SA was mixed with crosslinker in various concentrations to tune the degradation profile of the system (Figure 1). Incorporation of laponite in this helps us to tailor the cell adhesion and mechanical property of the gel. Mechanical property of the gel can be tuned from 5 kPa to 25 kPa by just incorporation of nanoclay and varying the crosslinker concentration (Figure 2).

**Figure 1** Degradation profile of the gel with various crosslinker concentration.

**Figure 2** Mechanical property tuning of the gel by varying crosslinker concentration after incorporation of laponite.

### CONCLUSION

The current study clearly demonstrates that covalently crosslinked PLL-SA-PEG based system exhibit tunable mechanical property and cell adhesion properties. Incorporation of nanoclay results in tough hydrogels. This system can be used as injectable hydrogels. Thus, this hydrogel enables the development of cell material platforms that can be applied and tailored to specific functions for tissue engineering and drug delivery applications.

### INTRODUCTION

20(S)-Camptothecin (CAMPT) has been verified as a broad range of anti-cancer activity in animal models including lung, prostate, breast, colon, stomach, bladder, ovarian and melanoma cancers<sup>1,2</sup>. However, its therapeutic application is hindered by a low solubility, high toxicity and rapid inactivation through lactone ring hydrolysis at a physiological pH<sup>1,2</sup>.

Fig. 1. 20(S)-Camptothecin

The polymeric conjugates of CAMPT could act as a transport form for this drug and enhance its biodistribution. In the past few years, the covalent conjugates of CAMPT with polymers have been developed and characterized<sup>3</sup>.

The main problem with the obtained carriers is probably owing to the not fully controlled release of CAMPT. Therefore, polymer chemists are still actively involved in the investigating of new effective drug delivery systems containing CAMPT<sup>1-3</sup>.

The aim of this study was to prepare new polyesters or poly(ester-carbonate)s conjugates containing CAMPT. The preliminary studies of the influence of polymeric chain structure on the release process of CAMPT were presented.

### EXPERIMENTAL METHODS

The polymerization of cyclic esters or carbonates were carried out under an argon atmosphere. The polymeric products were dissolved in methylene chloride and then washed with methanol and dilute hydrochloric acid.<sup>3</sup>

The toxicity tests were carried out according to procedures described in our early papers<sup>3</sup>.

Polymeric conjugates of CAMPT were synthesized using two-step methods under argon atmosphere<sup>3</sup>.

The obtained macromolecular conjugates of CAMPT were put into PBS (pH 7.4) at 37°C, and the initial UV measurement was carried out.

### RESULTS AND DISCUSSION

The macromolecular matrices were obtained by the ring-opening polymerization (ROP) of cyclic esters ( $\epsilon$ -

caprolactone, glycolide and *rac*-lactide) and cyclic carbonate (trimethylene carbonate). The ROP process was carried out in the presence of PEG as macro-co-initiators and tin (II) or gallium catalytic systems.

The cytotoxicity evaluation of the obtained polymers was studied using the luminescent bacteria *V. fischeri* and two ciliated protozoans *S. ambiguum* and *T. thermophila*. It was found that the obtained matrices were not toxic to all test bionts, both bacteria and protozoa.

In the second step of this study, the macromolecular conjugates of CAMPT were obtained. The polymers and CAMPT were coupled *via* 1,6-diisocyanatohexane. *In vitro* CAMPT release from the macromolecular conjugates was carried out in PBS buffer at 37 °C for 1-12 weeks. It has been found that many factors are influencing the release of CAMPT from the obtained macromolecular conjugates, namely the copolymers structure, co-monomer unit content in the polymer chain and  $M_n$  of macro-coinitiators.

### CONCLUSION

The obtained novel biodegradable matrixes were not toxic. The rates of CAMPT release were shown to be directly dependent on the nature of the received copolymers. The kinetic rates of CAMPT released was seen to be faster for the polymeric conjugates contained ester units as compared to those with carbonate units. The obtained results demonstrate that the polyesters or poly(ester-carbonate)s are interesting and promising materials for the controlled release of CAMPT.

### INTRODUCTION

Non-viral vectors such as polycations or cationic lipids have been developed to mediate the gene transfection. Although these cationic reagents can lead to high gene expression in cultured cells, they showed very limited in vivo transfection efficiency. The complexes of plasmid DNA with these vectors usually have positive charge on their surface, which invites nonspecific interactions with blood components or cells. We found that hyaluronic acid (HA) could deposit onto the DNA/polycation (or cationic lipid) complexes to recharge their surface to negative, and effectively diminished the adverse interactions<sup>1, 2</sup>. DNA/polycation/HA ternary complex was highly biocompatible, and could be targeted to malignant cells. HA-coating also improved the transcription efficiency of the DNA complex<sup>1</sup>. Moreover, we found that the DNA/polyethyleneimine (PEI)/HA ternary complex could be freeze-dried without any cryoprotectant maintaining their gene transfection activity under precise conditions<sup>3</sup>. It enabled the preparation of very small DNA complex particles with relatively high concentration by preparing the complex at highly dilute conditions followed by condensation by lyophilizing, and rehydration with small amount of water. Small DNA/polycation/HA complexes were then prepared with plasmid DNAs coding cytokines, and were injected into tumor-bearing mice. They showed strong suppression of the tumor growth, and the small tumors completely disappeared<sup>3</sup>. In those experiments, multiple injections of the complexes were required to achieve the satisfactory therapeutic effect, and single dose rarely induced high response, probably owing to the short duration of the gene expression by such artificial vectors. Multiple injections are sometimes difficult depending on the injection site. Slow release system would, thus, be desired to get high therapeutic effect by a few times-administration.

On the other hand, calcium phosphate (CaP) such as a hydroxyapatite has been explored as biodegradable and biocompatible drug-releasing devices. In this study, we developed novel CaP nanocapsules including DNA/PEI/HA ternary complexes (CaP-DNA/PEI/HA), and their durable gene expression and anti-tumor effect were examined.

### EXPERIMENTAL METHODS

CaP-DNA/PEI/HA capsule was prepared by immersing fine pDNA/PEI/HA ternary complex particles, which had been obtained by the method described above, in 1.5 times concentrated simulated body fluid (SBF). To examine the transfection efficiency of the CaP-coated

DNA complex, CaP-DNA(GFP)/PEI/HA was prepared with plasmid coding GFP, and added to cultured B16 cells. GFP gene expression was then observed by fluorescence microscopy. Cellular uptake of the DNA complex by the cells was also examined using the complex with DNA fluorescently labeled by YOYO-1. Fluorescence intensity of GFP or YOYO-1 was evaluated by image analysis.

Tumor-bearing mice were prepared by subcutaneous inoculation of B16 cells. When the tumor size increased to 4 mm, CaP-DNA(GM-CSF)/PEI/HA, prepared with plasmid coding GM-CSF, was injected into the tumor just once, and tumor size was measured for 100 days.

### RESULTS AND DISCUSSION

SBF has a similar inorganic ion concentration to that of human blood plasma, and is supersaturated against hydroxyapatite. When a material having surface containing phosphoric acid or carboxylic acid groups are immersed in SBF, it is known that an apatite layer would be formed on it. The DNA complex surrounded by HA could also be coated by CaP layer, when the complex was mixed with 1.5-times concentrated SBF, and CaP capsule enclosing the DNA complex was obtained.

Cellular uptake of DNA/PEI/HA complex by B16 cells reached maximum 1-2 days after the addition of the complex, regardless of whether coated with CaP or not. Although uptake profile was similar, the CaP-DNA/PEI/HA showed much prolonged gene expression (>2 weeks) than that without CaP-coating.

The therapeutic effect of the slow-releasing system was then examined in tumor model mice. Durable gene expression invited much higher therapeutic efficacy, and single dose of CaP-DNA(GM-CSF)/PEI/HA completely inhibited the tumor growth in most mice.

### CONCLUSION

A CaP-encapsulated DNA complex could be obtained by immersing the hyaluronic acid-coated DNA/PEI complex in SBF. It showed highly durable gene expression. Those comprising pDNA(GM-CSF) had a significant tumor-growth suppression effect, and single injection induced complete disappearance of the tumor. DNA complex coated by CaP layer seems promising as a sustained-gene expression device.

## Thermally Responsive Core-shell Nanocapsules with Independent Dual Drug Release Profiles for Combined Therapy of Osteoarthritis

Mi Lan Kang, Ji Eun Kim, Gun Il Im\*

Department of Orthopaedics, Dongguk University Ilsan Hospital, Korea

\*[gunil@duih.org](mailto:gunil@duih.org)

### INTRODUCTION

Kartogenin (KGN) is a recently characterized material that promotes the selective differentiation of mesenchymal stem cells (MSCs) into chondrocytes, thus stimulating cartilage regeneration<sup>1</sup>. Diclofenac (DCF) belongs to a class of medicines called non-steroidal anti-inflammatory drugs (NSAIDs) and helps to reduce inflammation and pain. In this study, DCF and KGN were choosing as the combined osteoarthritis (OA) therapy to induce anti-inflammatory activity and cartilage regeneration.

We developed a dual drug delivery system that can release two drugs independently by thermal responsiveness. The nanoparticles consisting of chitosan oligosaccharide (COS) and carboxyl group-terminated pluronic F127 (F127) was synthesized by covalent cross-linking. KGN was covalently conjugated to COS before the nanoparticle synthesis. DCF was encapsulated in the inner core of the nanoparticle.

The aim of this study was to (1) characterize the nanocapsules for controlled dual release by temperature change and (2) evaluate the combined therapeutic effects of the nanocapsules *in vitro*.

### EXPERIMENTAL METHODS

**Preparation of nanocapsules** Carboxylated F127 (F127-COOH) can be obtained according to the reported work with succinic acid. Conjugation of F127-COOH and KGN with COS was carried out by EDC/NHS during the nanocapsules synthesis process using emulsification/solvent evaporation method. DCF was encapsulated inside of the nanocapsules by change of wall-permeability according to temperature control. The chemical conjugation was confirmed by FTIR and <sup>1</sup>H-NMR. Size and morphology of the nanocapsules were characterized by DLS and FE-SEM, respectively.

**Controlled dual release by temperature change** *In vitro* release study of the F127-COS-KGN NCs loading DCF was carried out by temperature change. The amounts of KGN and DCF released from the NCs were determined by HPLC chromatography.

***In vitro* chondrogenic differentiation** The hBMSCs (2.5×10<sup>5</sup> cells, passage 3-5) were made by pellets and then the nanoparticles were added. After 14-21 days, pellets were analysed for DNA contents, GAG amount, and the expression of chondrogenic markers.

***In vitro* anti-inflammatory activity** After induction of inflammation with LPS in human U937 cells and primary chondrocyte, the nanoparticles were treated to the cells. The concentration of secreted IL-6 and TNF-α were determined ELISA.

### RESULTS AND DISCUSSION

**Preparation of nanocapsules** The nanocapsules are ~300 nm at 37 °C and expand to ~650 nm when cooled at 4 °C in aqueous solution. Temperature-controlled size variation was reduced according to increase of molar ratio of KGN to COS. The molar ratio of F127 to COS was increased, the range of size change according to temperature control was grown.

***In vitro* release study** While the encapsulated DCF showed burst release for 9 hours after cold shock, the conjugated KGN showed sustained release for 14 days even though temperature change. When the molar ratio of F127 decreased in the F127-COS-KGN NCs formulations, more sustained release of KGN was observed.

***In vitro* chondrogenic differentiation** While DNA levels did not change significantly, GAG per DNA content increased significantly, when exposed to nanocapsules versus no treatment or unconjugated KGN (p < 0.05). There was no significant difference whether cold shock is treated or not in nanocapsules treated groups. Safranin-O staining showed the greater intensity in the pellets treated with nanocapsules than those of pellets treated with unconjugated KGN. The gene expression of *COL2A1* and *aggrecan* increased in hBMSCs pellets exposed to unconjugated KGN and both nanocapsules for 21 days compared with those of untreated hBMSCs. In particular, nanocapsules treated pellets exposing to cold shock showed significant increases in both chondrogenic proteins compared with other pellets treated with either unconjugated KGN or nanocapsules without cold shock.

***In vitro* anti-inflammatory activity** After cold shock treatment, the nanocapsules treated chondrocyte showed rapid decrease of IL-6 secretion. A similar phenomenon was confirmed on U937 showing decrease of TNF-α.

### CONCLUSION

Both KGN and DCF were released independently from the F127-COS-KGN NCs loading DCF by temperature control. The DCF showed burst release for 6 hour respecting rapid anti-inflammatory analgesic effect, while the KGN was released sustainably and continuously from the NCs respecting effective regeneration. The F127-COS-KGN NCs loading DCF can be effective combined therapeutic for OA by thermally controlled dual drug delivery.

[eoledzka@wum.edu.pl](mailto:eoledzka@wum.edu.pl)

### INTRODUCTION

In the last years, the tendency in the development of biomaterials for implantology indicates the growing importance of composite materials based on polymers<sup>1,2</sup>. Nonetheless, inimical mechanical properties of the polymeric materials, such as mechanical strength, Young's modulus, fracture toughness, limited their application as implants. Hydroxyapatite (HA) is known as biocompatible and bioactive material, thus was commonly used for the fabrication of highly porous, interconnected scaffolds and isotropic pore structures recently<sup>3</sup>. This material might be also applied as a coating for orthopaedic and dental implants sustaining their surface properties and the bone-implant interface leading to the improvement in its osseointegration<sup>4</sup>. Selenium is one of the essential constituents of the human diet. Furthermore, it plays a significant role in diverse metabolic processes and that it, is a constituent of selenoproteins as well as of glutathione peroxidase<sup>5</sup>. Pamidronate - alkyl-amino bisphosphonate is considered standard of care therapy for nonresectable skeletal metastases in human cancer patients<sup>6</sup>.

Therefore, the aim of this study was to develop a novel combined scaffold composed of hydroxyapatite doped with selenium ions/biodegradable polymer (linear or branched) and contained pamidronate as a model drug. We assume that the fabricated scaffolds could serve as a promising bone replacement material for patients with bone tumours or bone metastasis (jaw bone).

### EXPERIMENTAL METHODS

The polymerization of linear and branched polymers was carried out under an argon atmosphere. The polymeric products were dissolved in methylene chloride and then precipitated twice from a cold mixture hexane/diethyl ether and dried under vacuum for 72 h.

The cytotoxicity assays were carried out with the luminescent bacteria *Vibrio fischeri* and the ciliate protozoan *Spirostomum ambiguum*.

The obtained combined scaffolds for both, *in vitro* release and hydrolytic degradation studies, have been manufactured in the tablet form.

The *in vitro* release study of pamidronate was performed to measure the concentration of drug released at pH 7.00±0.05 at 37°C.

### RESULTS AND DISCUSSION

In the first step of this study, linear and branched biodegradable polymers have been synthesized and characterized. The polymerization in various molar ratio took place easily under the designated conditions.

<sup>1</sup>H and <sup>13</sup>C NMR analysis demonstrated that used initiators successfully initiated ROP of  $\epsilon$ -caprolactone and D,L-lactide. Moreover, they were effectively incorporated into macromolecule.

The combined scaffolds were manufactured in the tablets form, by a direct compression of substituted hydroxyapatite, synthesized polymer and pamidronate. It has been found that the kinetic release of drug from the scaffolds tested *in vitro*, is strongly dependent on the physicochemical properties and an average molecular weight of the polymers. Furthermore, it was well- correlated with the hydrolytic biodegradation results of the scaffolds fabricated without drug.

### CONCLUSION

A combined scaffold composed of hydroxyapatite doped with selenium ions and biodegradable polymer and containing pamidronate was successfully developed. In order to prepare biodegradable polymers, bulk ROP of  $\epsilon$ -caprolactone and D,L-lactide was carried out. The structure and physicochemical properties of the obtained products were confirmed by analytical methods. The cytotoxicity showed that the obtained polymers are not cytotoxic. *In vitro* results showed that the percentage of the released pamidronate was affected by the physicochemical properties of the synthesized polymeric matrices. Consequently, this newly developed combined scaffold might be applied as a promising material for patients with bone tumours or bone metastasis (jawbone).

# Poly(lactic-co-glycolic acid)-based Nanoparticles as Drug Delivery Systems for Doxycycline Hyclate and Simvastatin for the Treatment of Inflammation-caused Bone Resorption

Manuel Schweikle, Hanna Tiainen, Håvard Haugen

Department of Biomaterials/Institute of Clinical Dentistry, University of Oslo, Norway

[manuel.schweikle@odont.uio.no](mailto:manuel.schweikle@odont.uio.no)

## INTRODUCTION

Hard tissue regeneration in bone defects caused by periodontitis and periimplantitis can be challenging due to critical defect size and high risk of recurrent bacterial infections. Synthetic titanium dioxide (TiO<sub>2</sub>) scaffolds have shown to feature good osteoconductive capacities paired with high compressive strength which allows mechanical loading shortly after implantation<sup>1</sup>.

However, they are lacking the osteoinductive properties of autologous bone graft material. For that reason they should be combined with poly(lactic-co-glycolic acid) (PLGA) nanoparticles as a drug delivery system for doxycycline hyclate (DOX) which in addition it's antibiotic action has shown to feature bone growth promoting effects when presented in adequate concentrations<sup>2</sup>.

## EXPERIMENTAL METHODS

DOX-loaded PLGA nanoparticles were produced by a double-emulsion water in oil in water technique as previously described<sup>3</sup>.

Size and morphology of the fabricated particles were characterized qualitatively and quantitatively by AFM, SEM and DLS. UV-vis and FT-IR were used to characterize and quantify the encapsulated drugs. Several process modifications were investigated to manipulate particle morphology and drug diffusion during particle formation. Furthermore, the developed method was slightly adapted to produce particles loaded with the hydrophobic drug simvastatin (SIM), which has shown to have similar bone growth properties as DOX.

## RESULTS AND DISCUSSION

The introduced fabrication method was found successful for the production of smooth, spherical nanoparticles within the size range of 200 to 800 nm (see Fig. 1). Particle size and morphology could to some extent be controlled by altering different emulsification parameters.

However, maximal encapsulation efficiency (EE) for hydrophilic DOX was just below 2 %. At the same time hydrophobic SIM could be entrapped at up to 80 % EE. These findings stand in contrast to the comparatively high EEs for small hydrophilic molecules in PLGA nanoparticles reported elsewhere<sup>3</sup>.

It can be assumed that large quantities of hydrophilic DOX diffuse into the outer water phase during particle preparation due to the weak intermolecular interaction between drug and matrix. Various process

modifications were tested to decrease the loss of DOX during the fabrication process by means of accelerating polymer precipitation and retarding diffusion kinetics, but did not significantly increase the EE.

Fig. 1: SEM-images of (a) DOX- and (b) SIM-loaded PLGA nanoparticles featuring smooth, spherical shape and size distribution measured by DLS. Scale bar 10  $\mu$ m.

## CONCLUSION

No significant amounts of hydrophilic DOX could be immobilized in the produced PLGA nanoparticles. A huge discrepancy could be observed for the EE of DOX and SIM. The results question the suitability of a water based double-emulsion process for the encapsulation of small hydrophilic molecules within hydrophobic matrices.

## Upsalite®: Novel Mesoporous Drug Delivery System

Peng Zhang, Teresa Zardán Gómez de la Torre, Johan Forsgren, and Maria Strømme

Ångström Laboratory, Uppsala University, Uppsala, Sweden

[peng.zhang@angstrom.uu.se](mailto:peng.zhang@angstrom.uu.se)

### INTRODUCTION

Currently, poor aqueous solubility of active pharmaceutical ingredients (APIs) has been one of the most challenging issues for the pharmaceutical industry since this often results in limited oral bioavailability of these APIs which in turn limits their therapeutic effect. About 40% of newly marketed drugs have poor solubility and 80-90% of drug candidates in the R&D pipeline fail because of solubility problems. Therefore, improvement of the solubility of highly permeable but poorly soluble APIs, i.e. BCS II (Biopharmaceutics Classification System II) drugs, has been in the focus of research during the last decade.

One attractive approach to increase the aqueous solubility and thus the bioavailability of poorly soluble drugs is to formulate the poorly aqueous soluble compounds in their amorphous state since amorphous compounds generally exhibit higher apparent solubilities than the crystal form of the same substance<sup>1</sup>. However, because of their metastable nature, amorphous APIs are driven by thermodynamics to crystallise, depending on factors like the glass transition temperature ( $T_g$ ) and moisture content of the formulation. Thus, the amorphous APIs need to be stabilised in the formulation in order to prevent crystallisation.

Due to the small pore size, mesoporous structures (pores with a diameter between 2 and 50nm) have the ability to stabilize amorphous substances, which is an attractive approach to improve the solubility of drugs with poor aqueous solubility<sup>2</sup>. In the current study we aimed to investigate if Upsalite®, a mesoporous  $MgCO_3$  material, could suppress crystallisation of the BCS (Biopharmaceutics Classification System) class-II drug Ibuprofen (IBU) and hence increase the apparent solubility of the substance.

### EXPERIMENTAL METHODS

Upsalite® was synthesized as described earlier<sup>3</sup>. IBU was incorporated into the material via a soaking method and dried at 70 °C. X-ray powder diffraction (XRD), Fourier transform infrared spectroscopy,  $N_2$  sorption analysis, thermal gravimetric analysis (TGA) and differential scanning calorimetry (DSC) were employed to characterize the drug loaded material. The release of IBU was studied by the USP-II paddle method in phosphate buffer (pH=6.8) and the released concentration of IBU was monitored by UV/vis absorbance spectroscopy.

### RESULTS AND DISCUSSION

From the XRD patterns and the DSC curves (Figure 1), it could be confirmed that the IBU incorporated in Upsalite® was present in an amorphous

state demonstrating that the mesoporous structure of Upsalite® completely suppressed crystallisation of the incorporated drug.

Figure 1. XRD patterns (left), DSC curves (right) for the studied samples.

The release profiles of free IBU and IBU incorporated in Upsalite® can be seen in Figure 2. Clearly, the release rate of the amorphous IBU inside the Upsalite® is more rapid than that of the free substance. The release rate of the amorphous IBU from Upsalite® is three times faster during the first 5 minutes compared to the dissolution rate of the crystalline free substance. As well, 50% of the IBU is dissolved and released from the carrier within 12 minutes while it takes 30 minutes for the free substance to reach the same level.

Figure 2. IBU Release Profiles.

### CONCLUSION

This work shows that the mesoporous magnesium carbonate, Upsalite®, can be used as an excipient in pharmaceutical formulations to increase the release rate and solubility of poorly soluble substances.

## INTRODUCTION

Multiple clinical trials have indicated that anti-platelet treatment can reduce the likelihood of a recurrent stroke event<sup>1</sup>. Drug delivery systems (DDSs), made of biodegradable polymers, have the potential to control drug release. Electrospinning is a simple technique that can produce 3D structures capable of releasing pharmaceuticals in a controllable manner<sup>2</sup>. The main goal of this work was to study the properties of an electrospun DDS, made of polycaprolactone (PCL) and polyethylene glycol (PEG), and encapsulating acetylsalicylic acid (ASA).

## EXPERIMENTAL METHODS

All reagents and polymers were purchased from Sigma-Aldrich. The concentration of ASA in the core solution was 15 mg/ml (ASA specimens). PCL (Mn 70000 – 90000) was used in both core and shell solutions at concentrations of 150 mg/ml and 100 mg/ml, respectively. PEG (Mn 4000) was used only in the shell solution at a concentration of 50 mg/ml. Specimens without ASA encapsulated were also prepared (non-ASA specimens). Electrospinning was performed using a custom-made coaxial nozzle at an electrical field of 1 kV/cm. The flow rates of the core and shell solutions were 1 and 3 ml/h respectively. The morphology of the fibrous scaffolds was examined by scanning electron microscopy (SEM). The mechanical properties of the scaffolds were assessed under both dynamic uniaxial tensile testing and quasi-static uniaxial tensile loading to failure. The dynamic tests were conducted under 0-20% strain at 1 Hz, using a horizontal BOSE tensile testing device (LM1 Testbench), whereas the quasi-static tests were performed at a strain rate of 20 mm/min using an INSTRON tensile testing device (5967 Dual Column). Six rectangular specimens of 15 mm gauge length and 10 mm width were used for each measurement, cut along the electrospinning orientation. A thickness gauge (Quick mini, Mitutoyo) was used to measure the thickness. Both types of tests were performed at room temperature and humidity. The performance of the specimens was assessed from the recorded stress-strain data, which was used to obtain the maximum tensile stress and strain, and Young's modulus. Cytotoxicity experiments were performed according to the ISO10993-5:2009 with L929 murine fibroblasts to assess the biocompatibility of the scaffolds. A contact assay was performed in triplicates using cyanoacrylate (superglue) as the positive and collagen gel (2 mg/ml) as the negative control. Statistical analysis was performed using Origin Pro 8.5 (One-way ANOVA with post-hoc Tukey), whereas statistical significance was determined at a 0.05 level.

## RESULTS AND DISCUSSION

Morphologically, the electrospun fibres presented a smooth, cylindrical shape with random orientations and an average diameter of  $0.67 \pm 0.29 \mu\text{m}$  and  $0.49 \pm 0.10 \mu\text{m}$  for the ASA and non-ASA specimens, respectively ( $p=0.018$ ). The values of Young's modulus obtained from the quasi-static tensile tests ranged from  $68.55 \pm 15.62 \text{ MPa}$  for the non-ASA specimens to  $100.76 \pm 14.74 \text{ MPa}$  for the ASA specimens ( $p<0.05$ ). Accordingly, the values obtained from the dynamic uniaxial tests ranged from  $65.87 \pm 6.66 \text{ MPa}$  for non-ASA specimens to  $107.705 \pm 9.29 \text{ MPa}$  for the ASA specimens ( $p<0.05$ ). No statistically significant difference was found between the two testing methods ( $p>0.05$ ). Moreover, the ultimate tensile strength (UTS) was increased from  $11.32 \pm 1.93 \text{ MPa}$  for the non-ASA specimens to  $13.94 \pm 1.87 \text{ MPa}$  for the ones with ASA ( $p>0.05$ ). The maximum tensile strain values were  $0.38 \pm 0.04$  and  $0.30 \pm 0.02 \text{ mm/mm}$  for the non-ASA and ASA specimens, respectively ( $p=0.18$ ). The mechanical properties of the electrospun constructs were comparable to the mechanical properties of native tissues investigated in previous studies<sup>3</sup>. This highlights the capacity of the electrospun constructs to be tailored in terms of their mechanics to match a range of tissues for biomedical applications. Moreover, none of the specimens (with/without ASA) revealed any cytotoxic effect on the cell viability or morphology of L929 murine fibroblasts.

## CONCLUSION

The addition of ASA led to thinner fibres with significantly higher stiffness and lower ductility in comparison with fibres without ASA encapsulated. Core/shell fibre mats could be potential candidates for DDSs, used to control delivery of anti-platelet agents against recurrent stroke.

### INTRODUCTION

The herpes simplex virus is one of the most frequent pathogen acquired by humans. According to the statistics, more than 50% of people are infected by that virus<sup>1</sup>. Acyclovir is a widely used antiviral agent due to of its high efficacy in the treatment of herpes simplex virus infections. Acyclovir blocks viral DNA polymerase, inhibiting replication of DNA. Its application reduces the frequency of relapses and alleviates troublesome symptoms of primary infection<sup>2</sup>. The acyclovir therapy suffers from the low solubility of the drug in aqueous media and resulting low bioavailability, short half-life (about 2.5 h) and large variability in its absorption between patients. Thus the therapy has many adverse effects and can result in neurotoxicity, urticaria, diarrhea or swoon. Therefore, it is important to find new formulations that allow for increasing the effectiveness of the drug in order to decrease the required dose and make the treatment safer.

Our work aims at studying the potential use of cytosine – modified polymer matrix as a new carrier designed for acyclovir delivery. The new polymer was obtained by modifying sodium alginate, natural polysaccharide, with cytosine. It is expected that the synthesized derivative will interact specifically with guanine group present in acyclovir's structure by creating hydrogen bonds. This should increase encapsulation efficiency of the polymeric delivery system based on aforementioned derivative and allow for a better control over the release process.

### EXPERIMENTAL METHODS

The resulting derivative was obtained by using microwave irradiation. Sodium alginate, cytosine and potassium persulfate were dissolved in water, mixed thoroughly and the whole mixture was heated to 85°C prior to subjecting to microwaves. The reaction was performed at 85°C in microwave reactor for 30 min. The product was isolated from the reaction mixture by precipitation to isopropanol followed by filtration and drying. The obtained polymer was then characterized using physicochemical methods: elemental analysis, <sup>1</sup>H and <sup>13</sup>C NMR (in D<sub>2</sub>O at room temperature) spectrometry and UV/Vis spectrophotometry. The latter was performed in water at room temperature using 1 cm quartz cuvette.

### RESULTS AND DISCUSSION

Sodium alginate was modified by cytosine using microwave irradiation according to Scheme 1. The success of the reaction was first confirmed by the presence of nitrogen in the elemental analysis results.

**Scheme 1.** Reaction scheme for modification of sodium alginate with cytosine

This element is absent in the alginate structure and its presence can be associated with the introduction of cytosine into the polymeric structure of alginate. <sup>13</sup>C NMR spectrum of obtained derivative showed four signals at: 94.42, 144.52, 154.83 and 163.94 ppm which can be ascribed to the carbons of cytosine. Finally the presence of the absorption maximum at 252 nm, characteristic for acyclovir, in the UV-VIS spectrum of the synthesized derivative of alginate confirmed further the successful incorporation of the drug into the polymeric matrix. The obtained derivative was formed into microbeads using calcium ions as the cross-linking agent. Acyclovir was encapsulated into the matrix. The influence of the specific cytosine-guanine interactions on the release process was verified using unmodified alginate microbeads as a reference.

### CONCLUSION

New cytosine-modified alginate was synthesized using microwave irradiation. The physicochemical characterization of the obtained derivative was performed, including NMR spectroscopy, UV-Vis spectrophotometry and elemental analysis. All the methods confirmed the success of the modification. The obtained derivative was then used to form microbeads. Acyclovir was successfully entrapped in the polymeric matrix and the influence of the specific cytosine-guanine interactions on its release profile was demonstrated.

## INTRODUCTION

Inhalation as a non-invasive route for systemic delivery of a variety of drugs, including biopharmaceutics, gained a new breath in the last decades<sup>1</sup>. We propose the use of amphiphilic polymers for the development of powder formulations intended for the pulmonary delivery of biopharmaceutics, using insulin as a model protein. Previously, we successfully developed and characterized insulin-loaded micelles of Soluplus® (SOL), Pluronic® F68, F108 and F127. Lyophilized micelles shown to be physically stable upon storage up to 6 months both at 4°C and 20°C, with negligible loss of the secondary structure of the protein<sup>2</sup>. This work aimed to assess the *in vitro* toxicity, pulmonary permeability, and phagocytosis by macrophages; and study the pharmacological activity and toxicity profile of formulations in diabetic animal models.

## EXPERIMENTAL METHODS

Powders obtained by freeze-drying of insulin-micelles. The geometrical particle size distribution was determined by laser diffraction and the aerodynamic diameter (*d<sub>ae</sub>*) estimated using powders' tap density. IC<sub>50</sub> and CC<sub>50</sub> values of formulation in Calu-3 and A549, and Raw 264.7 cells after 24h of contact was assessed using the MTT conversion assay and LDH leakage assay. The permeability of free and formulated insulin through alveolar and bronchial epithelium was assessed using A549 and Calu-3 cell monolayers. The uptake by THP-1 and U937 macrophages was assessed qualitatively by confocal microscopy and quantitatively by flow cytometry. *In vivo* pharmacological activity and sub-acute toxicity of formulations were assessed using streptozocin-induced diabetic male Han:Wistar rats. Insulin was administered subcutaneously as solution and endotracheally as powders and solution. Plasma glucose and insulin levels were determined at different time-points. For toxicity assessment, formulations were administered every two days during 14-days. PBS and insulin solution were used as controls. After euthanasia, blood samples were collected and bronchoalveolar lavage performed. BALF screened for toxicity markers and plasma for insulin-autoantibodies.

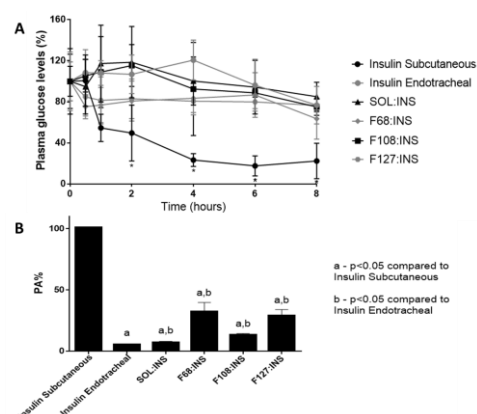

## RESULTS AND DISCUSSION

Formulations presented *d<sub>ae</sub>* values compatible with lung deposition (Table 1). IC<sub>50</sub> and CC<sub>50</sub> of the formulations were superior to the concentration of formulation expected in the lungs.

**Table 1.** Particle size distribution over the volume and aerodynamic diameter of insulin-based formulations (mean values ± SD, n=3).

Sample	D <sub>0.1</sub> (μm)	D <sub>0.5</sub> (μm)	D <sub>0.9</sub> (μm)	d <sub>ae</sub> (μm)
SOL:Ins	4.5±1.1	15.3±0.2	44.3±3.3	3.1±0.3
F68:Ins	9.5±4.0	39.1±19.6	328.9±221.4	13.8±8.0
F108:Ins	6.5±0.8	23.4±4.8	358.3±527.5	5.8±0.4
F127:Ins	6.7±2.0	21.6±6.3	81.9±53.7	5.6±1.4

All the formulations were partially internalized by macrophages, F127-micelles shown the lower percentage of uptake (12-13%), correlating to the small size of micelles. Pulmonary administration of insulin promoted lower hypoglycaemic effect than subcutaneous injection (Fig. 1A); however, the encapsulation of insulin increased its pharmacological availability (Fig. 1B). Additionally, no signs of inflammation and tissue damage were observed. Blood samples were negative for insulin auto-antibodies.

**Figure 1.** Percentage of blood glucose (A) and pharmacological availability (B) of controls and formulations (mean values ± SD, n=6).

## CONCLUSION

Powder formulations based on polymeric micelles presenting promising characteristics for the delivery of biopharmaceutics by inhalation were developed and characterized.

### INTRODUCTION

Creating hybrid systems for controlled drug delivery is essential for developing new forms of medicine that are more available and effective with minimal adverse event [1]. One of the forms of controlled drug delivery systems are microspheres, about 1-500  $\mu\text{m}$  in diameter, in which the medicinal substance is incorporated into the polymer matrix [2]. Microspheres are small porous single-phase polymer balls, often homogeneously gelled, with high biocompatibility and thanks to the adequately picked biodegradable polymer matrix, exhibit elongated curve of release of active substances.

In recent years the interest in research on natural polymers has dramatically increased due to their low costs, compatibility with various medicine and minimal release of organic solvents during the manufacturing of microspheres. Special attention is drawn to chitosan, (deacetylated chitin) thanks to its unique properties such as biodegradability, biocompatibility, bioactivity, and non-toxicity [3]. Production of chitosan microspheres is possible due to its ability to form gel in  $\text{pH} > 6.5$ . By adjusting the rate of deacetylation of chitin and its molecular weight one can change the size of the microspheres as well as rate of the drug release. Morphology, particle size, size distributions and efficiency of the process depend on the method and parameters of fabrication process. However the flaw of this method is low stability of the microspheres after the synthesis. This is why the aim of the study was to develop a method of producing stable chitosan microspheres with controlled particle size that can be used as a vessel for drug delivery.

### EXPERIMENTAL METHODS

Chitosan (CHN) microspheres have been obtained by emulsion polymerization with potassium tri-phosphates (TPP) and a cross-linking agent glutaraldehyde (GLT). Chitosan was dissolved in 2% acetic acid to obtain 2% polymer solution. As an emulsifier the sorbitan monooleate was used which served as a 1% oil phase. In our studies different TPP/CHN v/v ratio (1:1, 2:1 and 3:1) was used. In order to improve stability 50% of cross-linking agent glutaraldehyde has been used.

### RESULTS AND DISCUSSION

Chitosan microspheres have been obtained by emulsion polymerization, thanks to the ionic interactions between chitosan positive amino groups and potassium tri-phosphates negative phosphate ion group. In this method liquid polymer solution has been connected to organic phase by surfactant creating emulsion. Using oil phase has stopped microsphere agglomeration.

In addition, all of the obtained microspheres have been cross-linked with GLT that improved stability of the chitosan microspheres in liquid as well as after drying at room temperature.

The morphology of microspheres was characterized by SEM. Size of the particle immersed in liquid has been evaluated by laser diffraction. Best results have been obtained with volume fraction of TPP to CHN 2:1. The obtained microspheres after drying exhibit globular shape with porous internal structure (Fig. 1). They are small in diameter (10  $\mu\text{m}$ ) and show narrow size distribution (Fig.2).

The microstructures of the obtained materials have been examined by Atomic Force Microscopy and FTIR. The drug incorporation efficiency into CHN microspheres was also examined.

Fig.1 SEM images of the microstructure of microspheres for volume fraction of TPP to CHN 2:1

Fig.2 Particle size distribution evaluated by laser diffraction of microspheres for volume fraction of TPP to CHN 2:1

### CONCLUSION

Stable microspheres have been successfully obtained with controlled size distribution and can be used as a drug delivery vessel.

### INTRODUCTION

Postoperative endophthalmitis after cataract surgery and intraocular lens (IOL) implantation is a potential blinding complication.<sup>1</sup> The most common forms of prophylaxis are topical administration of antibiotic eyedrops 1 to 3 days before and during one week after surgery, and intracameral injection immediately after surgery.<sup>2,3</sup> As eyedrops have several disadvantages, such as rapid antibiotic absorption into the bloodstream and patient-compliance problems, antibiotic-loaded IOLs have been proposed as an alternative to both eyedrops and intracameral injection,<sup>4</sup> although they are not yet commercially available. The main objective of this study was to develop efficient antibiotic release systems for the treatment of post-surgical endophthalmitis, employing moxifloxacin (MFX), a fluoroquinolone used in endophthalmitis prophylaxis,<sup>2</sup> and materials used in commercial IOLs. Surface-modification by plasma grafting was employed to alter the drug loading capacity of the discs and their release kinetics.

### EXPERIMENTAL METHODS

**Argon plasma grafting.** Poly[(2-hydroxyethyl methacrylate)-co-(methyl methacrylate)]-based discs for IOLs (from PhysiOL SA, Liège, Belgium; diameter: 5 mm) were exposed to Ar plasma for 3 min (power: 100 W; gas pressure: 0.6 mbar), were immediately immersed into a 10% (v/v) aqueous HEMA (2-hydroxyethyl methacrylate) solution containing 5 mg/mL of MFX, and were left to react for 1 h at 60 °C.

**Drug loading and release studies.** Discs were immersed into a 5 mg/mL MFX solution in Hank's Balanced Salt Solution (HBSS) for 24 or 72 h, at 4 °C. The drug release study was carried out at 37 °C, in batch, under shaking (100 rpm) in either 3 mL of HBSS, with daily periodic removal of 500 µL aliquots for MFX quantification (at 290 nm) and replacement by the same volume of HBSS, or in a microfluidic cell containing 250 µL of HBSS renovated at 0.25 µL/min, with MFX quantification by HPLC. Results were expressed as mean ± standard deviation ( $n = 3$ ).

**Discs characterization.** Characterization of the discs before and after modification was carried out by contact angle goniometry, SEM/EDX (Scanning Electron Microscopy with Energy Dispersive X-ray spectrometry), and by determination of their water swelling capacity.

### RESULTS AND DISCUSSION

Loaded discs which were plasma-grafted with PHEMA in the presence of MFX (System 14) released more MFX than unmodified loaded discs and did it for a longer period of time (20 days, at least). A disc similarly modified but reloaded with MFX after the modification (System 15) released even more MFX during the same period of time. A further increase in the amount of released drug was obtained with an unloaded disc which was plasma-grafted with PHEMA in the presence of MFX and subsequently loaded with MFX (System 17). In order to infer about the efficiency of these systems in the eye, the release study was carried out in a microfluidic cell which reproduced the hydrodynamic conditions in the eye. All three systems released MFX at a concentration above MFX's Minimum Inhibitory Concentration (MIC) for *Staphylococcus aureus*, *S. epidermidis* and *Streptococcus pneumoniae* for at least 6 days, but only System 17 released MFX for more than 10 days above the MIC, the target time period.

### CONCLUSION

Grafting of PHEMA on the discs in the presence of MFX allowed the preparation of systems which release MFX during at least 6 days above the MIC and, the best system, could sustain the release of MFX for more than 10 days above the MIC. Thus, this system is a promising option for the development of antibiotic-eluting IOLs.

### INTRODUCTION

Silk biomaterial combines superb mechanical properties, biocompatibility and biodegradability, thus it has a great potential for application in biomedical field. Moreover, silk can be processed into different morphological forms such as film, fiber, hydrogel, scaffold, capsules, and micro- and nanospheres which may serve as drug carriers. Although, spider silk is not easily accessible from nature, the genetic engineering and biotechnology production resolve the accessibility problem. The synthetic silk genes are designed. Their sequences are based on the consensus motifs of the corresponding natural equivalents<sup>1</sup>. Their further genetic modification enables the generation of bioengineered silk of altered property.

The objective of the study was to generate the bioengineered spider silk to modify its affinity for drugs, followed by studies of drug loading and release.

### EXPERIMENTAL METHODS

The bioengineered spider silk proteins were designed MS2 and EMS2. MS2 was obtained by ligation of 15 repeat units of consensus motif derived from the *N. clavipes* spidroin MaSp2, while EMS2 was based on MS2, however a glutamic acid residue was added to the each repeat unit of MS2. Bioengineered proteins were produced in *E.coli* expression system and then purified by thermal denaturation method<sup>2</sup>. To prepare silk spheres the proteins solutions were mixed with potassium phosphate<sup>3</sup> at different conditions depending on 1) concentration of potassium phosphate, 2) pH of potassium phosphate buffer, 3) concentration of silk proteins. Physical properties of the particles were characterized using scanning electron microscopy, infrared spectrometry and zeta potential measurements. The cytotoxicity of spheres was investigated by MTT assay. Two drugs mitoxantrone and etoposide were loaded into silk particles using post-loading method. The levels of drug incorporation and release profiles of drugs were studied spectrophotometrically.

### RESULTS AND DISCUSSION

Bioengineered spider silks - MS2 and EMS2 were constructed, produced and purified. Both silk variants formed spheres in conditions above a critical potassium phosphate concentration i.e. 1 and 2 M for MS2 and EMS2 protein, respectively. The type of protein and its concentration affected the size and size distribution of the obtained spheres. Zeta potential of both spheres was negative, however for spheres made of MS2 it was between -1.6 and -14mV while for EMS2 it was from -

31 to -35 mV depending on the method applied for the sphere preparation. The cytotoxicity analysis demonstrated that MS2 and EMS2 spheres were not toxic.

Figure 1: (A) Scanning electron image of the EMS2 and (B) MS2 spheres. Scale bars 1µm.

EMS2 spheres showed stronger affinity to positively charged mitoxantrone, while loading of neutral etoposide was similar for both silk particles. Both drugs showed a pH-dependent release profile from the particles.

### CONCLUSIONS

The genetic engineering gives a possibility to generate a new variants of bioengineered silk. By replacing, adding or/and removing a particular amino acid residue the property of bioengineered spider silk can be modified. We generated EMS2 variant of MS2 bioengineered silk protein. EMS2 retained the self-assembly property and formed spheres. By adding 15 residues of glutamic acid the, EMS2 affinity to a positively charged mitoxantrone was increased. Silk as a non-toxic and biodegradable protein polymer is an ideal biomaterial for drug delivery. By modifying the silk sequence, the affinity to drugs can be controlled.

### INTRODUCTION

Silk as a biomaterial of outstanding physico-chemical properties, biocompatible and biodegradable has great potential as a carrier of therapeutic agents. Due to the self-assembly property, silk can be processed into several morphological forms such as fibres, scaffolds, films, hydrogels, capsules and spheres. Moreover, the genetic engineering enabled the functionalization of silk by adding peptide moieties of desired attribute<sup>1</sup>. Functionalization of silk by adding nucleic acid binding domain enables development of siRNA delivery system. Efficient and specific delivery of siRNA remains a formidable challenge. Recently, the naked CpG-siRNA conjugates were used to deliver therapeutic siRNAs into target immune cells<sup>2</sup>. The CpG-STAT3siRNA conjugates showed good efficacy in preclinical tumor models<sup>3</sup>, however, further clinical translation of this strategy requires optimization for systemic delivery. Embedding siRNA into silk spheres may improve the serum stability of siRNA molecule in body fluids. The aim of this study was the development CpG-siRNA delivery system based on bioengineered spider silk functionalized with nucleic acid binding domain.

### EXPERIMENTAL METHODS

Bioengineered spider silk (MS2) was designed based on the consensus motif derived from the *N. clavipes* spidroin MaSp2. MS2 was functionalized by adding nucleic acid binding domain (KN). MS2 and hybrid KNMS2 were produced in bacterial expression system and purified using thermal denaturation method<sup>4</sup>. CpG-siRNA against oncogenic and immunosuppressive STAT3 transcription factor was used in this study<sup>3</sup>. The binding of CpG-siRNA to silk was analyzed by agarose gel electrophoresis. The silk spheres loaded with CpG-siRNA were prepared by salting out process<sup>5</sup>. For serum stability assays, the MS2KN complexes and spheres loaded with CpG-siRNA were incubated in presence of mouse serum and then analyzed in acrylamide gel. The uptake of spheres by murine macrophages was analyzed using flow cytometry and confocal microscopy.

### RESULTS AND DISCUSSION

Bioengineered spider silk MS2 and its hybrid variant MS2KN were constructed, produced and purified. CpG-siRNA efficiently bound to MS2KN in contrary to control protein MS2. The functionalization did not impede the self-assembly property of bioengineered silk, enabling the processing of MS2KN silk protein into spheres. Both complexes and spheres protected siRNA from degradation in serum. MS2KN spheres

loaded with CpG-siRNA were efficiently internalized by macrophages; both nucleic acid and silk protein were localized inside the cells.

Figure 1: Analysis of the stability of CpG-siRNA-MS2KN complexes in serum. CpG-siRNA alone (3, 6, 9) or complexed with MS2KN (4, 7, 10) was incubated in 30% mouse serum for 0, 1 and 3 hours in 37° C. The control CpG-siRNA (2, 5, 8) was not treated with serum. After incubation samples were analyzed in 15% Urea-PAGE (1 - DNA ladder 50bp).

### CONCLUSION

Functionalization of silk by adding nucleic acid binding domain enabled efficient loading of CpG-siRNA into silk spheres. Silk improved the serum stability of siRNA molecule and allowed for cell-specific uptake of CpG-siRNA.

The obtained results indicated a great potential of the functionalized bioengineered spider silk for the delivery of a therapeutic nucleic acids.

## INTRODUCTION

The encapsulation enhances the stability of drug molecules, improves the targeting properties and prolongs pharmacological activity *via* continuous local release of active molecules [1]. The aim of this study is to encapsulate, L-ascorbic acid, in biopolymers in order to obtain (i) enhancing its encapsulation efficiency (ii) increasing drug release ratio using different pH mediums. Microspheres based on polycaprolactone (PCL), polyethylene glycol (PEG), and casein (CS) is prepared by spray drying technique. Drug loaded microparticles are characterized in terms of morphology, encapsulation efficiency, and drug release. In this manner, the importance of the study is producing of a stable and effective drug encapsulation system by PCL-PEG-CS polymer mixture. First part is to define best effective drug loading terms. Final part of the study is about drug release experiments and calculation drug release ratios in different solution mediums. At the end of studies, we achieved minimum 84.05% maximum drug loading, and 68.92% drug release ratio at 9.6 pH medium. By this way, our drug loaded microparticles can be proposed as alternative or adjuvants for controlling release of L-ascorbic acid in human or animal. In particular, PCL-PEG-CS microspheres can be used for L-ascorbic acid (vitamin C) carriers.

## EXPERIMENTAL METHODS

Polymer solutions are fed to spray dryer and drying conditions are at 135 °C, 3 ml/min feed ratio.

Secondly, L-ascorbic acid in different weight ratios are loaded for microsphere which have the lowest particle diameter. L-ascorbic acid loading studies are done by indirect loading of drug to microspheres at 25 °C and 200 rpm. L-ascorbic acid contents are 5 wt%, 10 wt%, and 15 wt%, respectively.

Liquid phase is analyzed by UV at 518 nm to calculated [16-19]. Calculations in drug release step of the study are also done by UV. 0.5 mg blend/1 mL release medium (pH 2.8, 7.4, and 9.6) ratio is used.

## RESULTS AND DISCUSSION

Drug encapsulation studies are performed under three different L-ascorbic acid concentrations (5 wt%, 10 wt%, and 15 wt%) with different loading time and PCL-PEG-CS particle amounts. Figure 1 and Figure 2 indicate that how much L-ascorbic acid is encapsulated due to the time and particle amount, respectively.

Figure 1 shows drug absorbance is achieved peak value (84.05% loading efficiency) in one hour; thereafter smoothly decreased in all L-ascorbic acid solutions.

Although there is no significant difference, Figure 2 indicates that the encapsulation efficiency tended to increase from 0.5 to 2.0 mg particle/mL L-ascorbic acid solution. On the contrary, increasing weight percent of L-ascorbic acid in solution significantly increased loading rates. It changes from 49.93% to 84.05% by

PCL-PEG-CS microsphere amounts from 0.5 to 2.0 mg particle/mL solution.

**Figure 1.** Effects of drug loading time on encapsulation of L-ascorbic acid.

It is also facts that low diameter and well distributed structure of microspheres are reasons to gain high L-ascorbic acid loading values. Thus, when highly water-soluble drugs, such as L-ascorbic acid, are encapsulated using ternary polymer blends, % encapsulations achieved are expectably high.

In-vitro release profiles of L-ascorbic acid from the microspheres produced by PCL-PEG-CS are shown in Figure 3. Experimental uncertainties in the % drug released, based on three replicates, are approximately changed from 3.4% to 5.7%.

**Figure 2.** Effects of particle amount on encapsulation of L-ascorbic acid.

**Figure 3.** L-ascorbic acid release with different pH mediums in 8 hours.

The % drug release initially in 2 h is  $17.21 \pm 3.36$  at pH 2.8,  $13.84 \pm 3.50$  at pH 7.4 and  $33.39 \pm 5.7$  at pH 9.6. Maximum drug release ratio achieved in 6 h is  $68.21 \pm 5.7$  at pH 9.6. The results indicate that L-ascorbic acid coat in the bioblend based microspheres are easily degraded higher pH values particularly at basic scale.

## CONCLUSION

The dissolution rates of the drugs from PCL-PEG-CS microspheres are clearly improved at higher pH as compared to neutral and acidic pH values. Because of unstable and very sensitive L-ascorbic acid, producing vitamin C drugs are really difficult. Towards the aim of the study, improving the vitamin C drugs, our method provides easily procurable and effective solution.

## Silicone Stabilized Liposomes as Novel Nanostructural Drug Carriers

Joanna Lewandowska-Lańcucka, Katarzyna Mystek, Maria Nowakowska

Faculty of Chemistry, Jagiellonian University, Poland  
[lewandow@chemia.uj.edu.pl](mailto:lewandow@chemia.uj.edu.pl)

### INTRODUCTION

Recently, there has been a growing interest in development of novel advanced drug delivery systems. In general, DDS are expected to increase therapeutical efficacy while reducing toxicity of the biologically active molecule. Liposomes – artificially constructed phospholipid vesicles are probably the most frequently studied DDS. That is due to their unique properties such as nontoxicity, biodegradability, as well as simplicity of preparation and control over the composition and size<sup>1</sup>. Unfortunately, the major problem with practical application of liposomes is related to their low stability during storage resulted from their high tendency for aggregation, degradation, and fusion leading to uncontrolled leakage of the entrapped compounds<sup>2</sup>. Various strategies have been proposed to overcome that problem. The main approaches involve optimization of the lipid composition in the membrane, adsorption of polymeric material at the liposomal surfaces<sup>3</sup>, and covalent grafting of hydrophilic polymers onto the head groups of phospholipids<sup>4</sup>. In our study we have proposed the new stabilization method of the liposomes using silicone as a protective and stabilizing agent<sup>6</sup>. Silicones are among the important biomaterials used in prosthetic devices such as implant for breast enlargement, tissue augmentation and for treatment of hydrocephalus. They exhibit interesting properties including low toxicity, low surface tension, and thermal stability in the broad range of temperatures as well as an excellent gas permeability. Thus the silicone layer will ensure high mechanical, thermal and chemical stability for the fragile liposome vesicles while not compromising biocompatibility

### EXPERIMENTAL METHODS

The cationic liposomes were obtained from egg yolk phosphatidylcholines (PC) and a cationic double-tailed surfactant, dimethyldioctadecylammonium bromide (DODAB). The surfactant was introduced to modify the surface potential of the liposomes, so the base-catalyzed polymerization/ polycondensation processes of the monomer can occur at the surface. In order to obtain the liposome dispersion of low polydispersity, the lipid vesicles were extruded through filters with 100-nm pores. 1,3,5,7-tetramethylcyclotetrasiloxane (D<sub>4</sub><sup>H</sup>) and its derivatives were employed as silicone precursors. The silicone precursors were introduced into the liposome dispersions and the polycondensation/ polymerization process was initiated by changes in pH. The stability of the obtained nanostructures were evaluated using the spectrophotometric titration with Triton X-100, measurements of zeta potential and determination of the hydrodynamic diameters (Dynamic

Light Scattering). The model hydrophilic drug, calceine was then entrapped in the nanocarriers prepared. The release of calceine molecules into the aqueous phase was monitored by fluorescence spectroscopy.

### RESULTS AND DISCUSSION

Silicone-stabilized liposomes were successfully obtained using base catalyzed polycondensation/ polymerization processes of the silicone precursors. The polycondensation process was followed by FTIR analysis of the prepared and isolated silicone materials. Depending on the type of the precursor used, the stabilized silicone layers were created on the outer side of the vesicles or in the lipid bilayer. The conditions of the synthesis were optimized in terms of the amount of the precursors used, temperatures and the pH values of the reaction. Using the silicone precursors with various numbers of the groups participating in the sol-gel reaction it was possible to obtain stable nanocarriers with the tunable permeability characteristic. They also differ in size, zeta potential and stability. The sol-gel reaction was carried out at two different pH, namely 8.5 and 10.2. The cryo-TEM micrographs proved that silicone-coated liposomes were obtained but at the higher pH, a fraction of disintegrated liposomes was also observed. The experiments with surfactant-lysis and calcein-release studies have confirmed that the silicone coated liposomes are definitely more stable than pristine cationic liposomes.

### CONCLUSION

Novel method for stabilization of liposomes by formation of silicone coating was proposed. By choosing the sol-gel reaction conditions and selection of silicone precursors it was possible to obtain the stable liposomal nanocarriers with the tunable permeability. Moreover, manipulation with the degree of silanol polymerization affects the zeta potential value of the nanocarriers resulting in reduction of their aggregation.

## INTRODUCTION

Efficient drug delivery is one of the most important challenges in cancer treatment<sup>1</sup>. Considerable efforts focus on the preparation of targeted vehicle to transport drugs to tumour cells.<sup>2</sup> Such delivery system requires i) good encapsulation properties, ii) efficient drug targeting/release, iii) biocompatibility and, iv) facile elimination from the body.<sup>3</sup>

Stimuli-responsive microgels, which are submicrometer-sized particles that can be swollen by change of pH, have gained growing attractions as drug delivery systems. Herein, we report the design of folic acid-functionalised microgels that can transport hydrophobic compounds to the tumour cells and release their cargo during endocytosis at lysosomal pH.

## EXPERIMENTAL METHODS

**Microgel synthesis via aqueous emulsion polymerization.** 2,2'-(diisopropylamino)ethyl methacrylate [DPA] was polymerized in water in the presence of *N*-(3-aminopropyl)-2-methylacrylamide hydrochloride (APMA) comonomer, 2-methylene-1,3,6-trioxocane (MTC), ethylene glycol diacrylate (EGDA) cross-linker, poly(ethylene glycol) ethyl ether methacrylate stabilizer (PEGMA) and ammonium persulfate (APS) initiator via aqueous emulsion polymerization at 70 °C to obtain PEGMA-PDPA particles. PDPA particles were decorated with folic acid.

**Dynamic Light Scattering (DLS) and Zeta potential** studies were carried out using Malvern Zetasizer Nano ZS on particles dispersion at 0.01 wt. % in PBS.

**PDPA particles cytotoxicity** was investigated via MTS and Live/Dead assays in the presence of HDF cells.

Cellular uptake was carried out via confocale microscopy using HeLa cell as model of cancer cells.

## RESULTS AND DISCUSSION

Lightly cross-linked PEGMA-PDPA particles of around 200 nm were obtained via aqueous emulsion polymerization.

**Figure 1.** DLS (♦) and Zeta potential (■) of PEGMA-PDPA particles in function of the solution pH in PBS solution.

As judged by DLS, PEGMA-PDPA particles exhibited a latex-to-microgel transition at pH 6.5 due to the protonation of the tertiary amine of the DPA residues (**Figure 1**). This indicates that PEGMA-PDPA will swell up with water to 550 nm during the endocytosis process as originally targeted. The presence of PEGMA stabilizer is absolutely required to ensure colloidal stability in physiological conditions. Moreover, the copolymerization of MTC comonomer offered hydrolysable bonds into the particles facilitating particle degradation after 1 week in the presence of lipase at physiological conditions into shorter polymer chains easily eliminated by the kidney.

PEGMA-PDPA particles did not exhibit cytotoxicity in the presence of HDF cells (**Figure 2**). Moreover, Doxorubicin could be encapsulated into the particles and the presence of folic acid at the particle surface allowed cellular uptake by HeLa cells where DOX was efficiently released as judged by fluorescence microscopy.

**Figure 2.** Viability (left) and Live/Dead assays (right) of HeLa cells in the presence of PEGMA-PDPA particles (50 µg L<sup>-1</sup>) after 3 days (scale bar: 100 µm).

## CONCLUSION

Stable, biodegradable and biocompatible pH-responsive microgels easily functionalised with targeting molecules were easily prepared by emulsion polymerization. Hydrophobic compounds could be encapsulated at physiological condition and efficiently released during endocytosis due to the swelling of the particles occurring at lysosomal pH.

[line.a.omtvedt@ntnu.no](mailto:line.a.omtvedt@ntnu.no)

### INTRODUCTION

Alginate is a linear polysaccharide composed of  $\beta$ -D-mannuronic acid (M) and  $\alpha$ -L-guluronic acid (G), where mainly G-blocks give alginate its ability to form a gel with divalent cations<sup>1</sup>. Cyclodextrins (CyD) consists of  $\alpha$ -(1 $\rightarrow$ 4) linked  $\alpha$ -D-glucosyl units, which have a hydrophilic exterior and a hydrophobic cavity<sup>2</sup>. This enables CyD to form inclusion complexes with various hydrophobic molecules and moieties<sup>2</sup>. The aim of this study was to combine the gel forming ability of the alginate with the capability of CyD to form inclusion complexes with hydrophobic molecules. This can potentially be used as a controlled release system of biomedically relevant molecules such as drugs, proteins and peptides.  $\beta$ -CyD has previously been grafted to the carboxyl-groups in alginate<sup>3,4</sup>. Here,  $\beta$ -CyD was grafted to partially oxidized alginate.

### EXPERIMENTAL METHODS

Alginate was grafted with  $\beta$ -CyD in three succeeding steps: High-G alginate ( $F_G = 0.68$ ) was partially oxidized with metaperiodate (step one), and the resulting aldehyde groups was thereafter bound to an alkyne linker using reductive amination (step two). Finally, the copper(I)-catalyzed azide-alkyne cycloaddition (CuAAC) click-reaction was used to covalently bind 6-O-monodeoxy-6-monoazido- $\beta$ -CyD ( $N_3$ - $\beta$ CyD) to the alkyne-substituted alginate (step three). The gelation ability of the alginate grafted with  $\beta$ -CyD was examined by the formation of calcium gel-beads composed of both high-G alginate ( $F_G = 0.68$ ) and alginate grafted with  $\beta$ -CyD. The release of a model compound, methyl orange, from the gel beads was studied and compared to release from non-grafted high-G alginate beads with and without free  $\beta$ -CyD.

### RESULTS AND DISCUSSION

The covalent binding of alginate and  $\beta$ -CyD was confirmed with <sup>1</sup>H-NMR and DOSY. Degrees of substitution (DS) for the alginate grafted with  $\beta$ -CyD were determined by <sup>1</sup>H-NMR. Gel-beads composed of both high-G alginate ( $F_G = 0.68$ ) and alginate grafted with  $\beta$ -CyD was successfully made. Alginate gel-beads incorporated with the grafted alginate showed a prolonged release of methyl orange compared to both reference beads made of non-modified alginate, and beads made of alginate mixed with non-grafted  $\beta$ -CyD (figure 1). In addition, faster dissolution of the gel-beads incorporated with the grafted alginate was observed.

The properties of the gels formed by alginate grafted with CyD can be tuned by varying the DS: The amount of immobilized  $\beta$ -CyD grafted to the alginate can be adjusted, as well as the gelation ability of the alginate due to ring opening of oxidized monomers<sup>5</sup> in the alginate chain.

**Figure 1:** Solutions coloured by methyl orange: (L) Colour of load solution (start concentration of 0.05 mg/ml methyl orange) after removal of alginate-beads, and (1-6) colour of treatment solutions after the alginate beads loaded with methyl orange was left one hour in 0.9 % (w/v) saline treatment solutions and removed. A-D denotes the alginate beads consisting of: (A) high-G alginate ( $F_G = 0.68$ ), (B) high-G alginate ( $F_G = 0.68$ ) and free  $\beta$ -CyD, (C - D) different ratios of high-G alginate ( $F_G = 0.68$ ) and alginate grafted with  $\beta$ -CyD, were beads given in C had a lower ratio of the grafted alginate compared to the beads given in D.

### CONCLUSION

Alginate was successfully grafted with  $\beta$ -CyD and retained the gelation ability. The grafted CyD gave slower release of methyl orange than alginate gels without CyD or with non-grafted CyD. Combining the gelling properties of alginate with the CyD affinity towards hydrophobic molecules allows for further tailoring of the system related to mechanical properties to obtain a controlled release system for biomedically relevant molecules.

[i-nakase@21c.osakafu-u.ac.jp](mailto:i-nakase@21c.osakafu-u.ac.jp)

### INTRODUCTION

Exosomes are ~100-nm vesicles that consist of a lipid bilayer<sup>1</sup> and are secreted from various cell types. They carry bioactive molecules between cells, including microRNAs, which mediate cell functions.<sup>1</sup> Endocytosis is a major pathway for the cellular uptake of exosomes; however, the detailed internalization mechanisms are still unknown. In this research, we studied the contribution of the macropinocytosis (accompanied by actin reorganization, ruffling of the plasma membrane, and engulfment of large volumes of extracellular fluid<sup>2</sup>) to exosome uptake. We found that the active induction of macropinocytosis via stimulation of cancer-related receptors and expression of oncogenic Ras significantly increases the cellular uptake of exosomes.

### EXPERIMENTAL METHODS

HeLa cells stably expressing GFP-fused CD63 (exosome membrane marker protein) to secrete CD63-GFP-containing exosomes (CD63-GFP exosomes) were prepared by transfection with the CD63-GFP plasmid (System Biosciences) and antibiotic selection using puromycin. Secreted exosomes were isolated by Total Exosome Isolation Kit (from cell culture media) (Invitrogen) or ultracentrifugation, as previously reported.<sup>3</sup> To artificially load saporin in exosomes, CD63-GFP exosomes were mixed with saporin in PBS, prior to electroporation using a Super Electroporator NEPA21 Type II system (NEPA Genes), and unencapsulated saporin was removed by washing and filtration using Amicon Ultra Centrifugal Filters (100K device, Merck Millipore).

### RESULTS AND DISCUSSION

Endocytosis is reported to be a major pathway for the cellular uptake of exosomes; however, it has a cargo size limitation (~120 nm) for cellular uptake.<sup>4</sup> Because of this size limitation, endocytosis is considered to have low efficacy for the cellular uptake of exosomes (~100 nm). Macropinocytosis induces the engulfment of large volumes, and this pathway enables the cellular uptake of large-sized cargo (~1 µm).<sup>4</sup> The contribution of this pathway to exosomal uptake is almost unknown.

The stimulation of epidermal growth factor receptor (EGFR) by treatment with the receptor ligand EGF induces macropinocytosis signal transduction. When A431 (human epidermoid carcinoma) cells were treated with CD63-GFP exosomes (20 µg/ml) for 24 h at 37 °C, cellular uptake of the exosomes was significantly increased by the addition of EGF (i.e., cellular uptake was approximately 27-fold higher for

cells treated with 500 nM EGF than untreated cells, as analysed by a flow cytometer).

In tumour cells, the expression of the oncogenic Ras protein has been shown to induce macropinocytosis. MIA PaCa-2 (human pancreatic adenocarcinoma) cells are homozygous for the K-Ras<sup>G12C</sup> allele. As an important route of nutrient uptake, the cells induce macropinocytosis.<sup>5</sup> The relative cellular uptake of CD63-GFP exosomes (20 µg/ml) by MIA PaCa-2 or BxPC-3 (expressing wild-type K-Ras) for 24 h at 37 °C was analysed using a flow cytometer. MIA PaCa-2 cells showed superior cellular uptake efficiency of the exosomes (approximately 14-fold) relative to that of BxPC-3 cells, suggesting that increased macropinocytosis via oncogenic Ras enhances the cellular uptake efficacy of exosomes in tumour cells.

In addition, we tested the delivery of bioactive molecules by encapsulation in exosomes. Saporin is a ribosome-inactivating protein that inhibits protein synthesis and cell growth. A431 cells were treated with saporin-encapsulated exosomes (4 µg/ml of the total exosomes) for 48 h at 37 °C, prior to a WST-1 assay. For saporin-encapsulated exosomes, the addition of EGF (500 nM) resulted in significantly increased cytotoxicity compared to the absence of EGF, suggesting that macropinocytosis induction via EGF stimulation increases the cellular uptake of saporin-encapsulated exosomes and saporin bioactivity.

### CONCLUSION

In this study, we found important roles of macropinocytosis in the efficient cellular uptake of exosomes. These findings will contribute to our understanding of the biological functionality of exosomes in various cellular events (e.g., cell-to-cell communication, cancer and other diseases, and infection) under stimulated macropinocytosis conditions, and to the development of exosome-mediated delivery systems for future therapeutic and diagnostic applications.

## Electrospraying of Aliphatic Polyesters for Drug Delivery Systems

Aleš Šaman<sup>1</sup>, Jana Horáková<sup>1</sup>, Kateřina Pilařová<sup>1</sup>, Petr Mikeš<sup>1</sup>

<sup>1</sup>Department of Nonwovens and Nanofibrous Materials/Technical University of Liberec, Czech Republic  
[ales.saman@tul.cz](mailto:ales.saman@tul.cz)

Small diameter particles were produced by electrospraying of copolymer of poly(lactide-co-polycaprolactone), (PLC) and poly(lactic-co-glycolic acid), (PLGA). The particles were diameter about 5-20  $\mu\text{m}$ , the particles had spherical shape and irregular surface. The Particles contained small particles polyvinylalcohol (PVA) which can contain water or alcohol soluble substrates. Model substrates was rhodamine B.

### INTRODUCTION

Today, we are facing a constant search for solutions to health-related problems. Solution, which would be facilitated by the functionalization of nanofibrous materials, is targeted drug delivery systems. These mostly small polymer particles are produced may be different methods, but in recent years is gaining prominence method electrospraying. This method is suitable, because can generate small particles ( $> 20 \mu\text{m}$ ) but also below one micron<sup>1</sup>. The shape and size of the resulting particles can be influenced depending on the chosen polymer, solvent and parameters in electrospraying<sup>2</sup>. Biodegradable polymers, especially aliphatic polyesters, which can be controlled by the ratio of degradation of the individual components of the copolymer<sup>3</sup>. The whole process can be modeled truncated degradation by enzymes which catalyze the hydrolysis. Advantage electrospraying is also that it can be directly combined with electrospinning as it is in the article<sup>4</sup>. This combination can take advantage of such scaffolds are small fiber diameters, fiber orientation, size and porosity. The particles then enrich the scaffold and controlled release of active substances.

### EXPERIMENTAL METHODS

Small diameter particles were produced by electrospraying of PLC and PLGA solution. First step was preparing PVA solution, which contain active soluble substrate. PVA solution was used electrospraying technology sprayed on aluminium foil. This way prepared particles were ultrasounds disperse into PLC and PLGA solution. After follow again electrospraying. The resultant particles were combined into nanofibers scaffolds. This technology was produced on a rotating cylinder, where on one side was electrospraying needle and on the other side was the electrospinning needle. The structure was analysed by scanning electrons microscopy and image analysis.

### RESULTS AND DISCUSSION

The size of the resulting particles produced from aliphatic polyesters amounted tens of micrometres. using image analyse was measured, that PLC had  $12.06 \pm 6.69 \mu\text{m}$ , PLGA had  $13.57 \pm 7.26 \mu\text{m}$  and polyvinyl alcohol had  $272.26 \pm 167.39 \text{ nm}$ , but with fluorescence microscopy shows that the particles formed agglomerates, as seen on Fig. 2.

**Fig.1:** SEM photo of PLGA (left), Fluorescent microscopy photo of PLGA contain PVA agglomerates with Rhodamine B (right).

As seen of Fig. 2 can with a rotating conductive roller having a cylinder diameter 50 mm and one turn per minute, can be achieved uniformly dispersed particles in scaffold. By enzymatic degradation was found that after several days packaging PLGA and PLC started degraded. Absorption spectrophotometer recorded increasing absorbance caused rhodamine B in degradation bath.

**Fig.2:** Cross section of scaffold, where is combine PCL nanofiber with PLGA Particles on paper as background material.

### CONCLUSION

New material and his combine with known materials are potential candidate for drug delivery systems in connect scaffold for tissue engineering. Electrospraying copolymer PLC and PLGA showed great control release with use lipase. Advantage this technology is big loading particles PVA and great possibilities control released active substrates. Possible disadvantage for specific applications are bigger size particles.

### INTRODUCTION

In situ-forming gels, with a phase transition temperature near to body temperature, appear particularly interesting as platforms for drug delivery applications. Being liquid at room temperature, indeed, they can be simply injected into the body but, once in place, they gelify thus allowing a time-controlled release of the active. In this context, due to their ability to undergo thermal gelation, thermosensitive amphiphilic block copolymers, namely polyethylene oxide–polypropylene oxide copolymers (pluronic PPO-PEO-PPO), have been widely used in biomedical field, particularly as a dispersing medium for drugs. However, to encapsulate hydrophobic drugs and/or to obtain a controlled release the use of a protective matrix for the drug is more convenient. To this aim Mesoporous Silica Nanoparticles (MSNs) with their highly-ordered structures having uniform but size-adjustable pores have shown high efficiency either for loading or controlled drug release<sup>1</sup>. The main target of this work is to design composite injectable *in situ* forming gels based on blends of PPO-PEO-PPO copolymers reinforced by a natural polysaccharide, hyaluronic acid (HA), and mesoporous silica nanoparticles (MSNs) functionalised with HA, as platforms for the controlled release of chemotherapeutics. The presence of the HA promotes the interaction between poloxamers blends and MSNs. Thanks to their gel nature these platforms could be potentially used to fill the cavity after tumor resection. Preliminarily, drug loading efficiency onto MSNs was optimised and *in vitro* release kinetics of a widely employed chemotherapeutic (Irinotecan) was also studied.

### EXPERIMENTAL METHODS

The dispersing medium platforms were prepared by mixing Pluronic F127 and F68 with small amounts of HA. The composition of the medium was optimised to obtain a gelification temperature ( $T_{gel}$ ) around body temperature. The medium mixture was characterised for the rheological properties and assessed for its capability of suspending efficiently MSNs.

The MSNs were synthesized and eventually functionalized with HA according to Yu et al.<sup>2</sup>, then characterized in terms of morphology, size and porous dimensions, through N<sub>2</sub> adsorption/desorption isotherms SAXS and TEM techniques<sup>3</sup>.

The first drug entrapment experiments were performed by suspending the MSNs particles in a DMSO solution of Irinotecan. Subsequently ethanol was added to promote the adsorption of Irinotecan (5 mg/ml) on the MSNs particles. After overnight stirring, the suspension was sonicated and centrifugated. The immobilized amount of the drug was determined through UV-Vis analysis ( $\lambda = 368\text{ nm}$ ) of the supernatant. Preliminary *in vitro* release experiments were performed suspending MSNs in 10 ml of release medium (PBS at

pH 7.4) at 37 °C. At scheduled time intervals, 1 ml aliquots were withdrawn and replaced with the same volume of fresh media. The aliquots were ultracentrifugated and the supernatant was analyzed through spectrophotometric analysis ( $\lambda = 368\text{ nm}$ ) to assess the content of Irinotecan.

### RESULTS AND DISCUSSION

Separate Pluronic F127 and F68 solutions do not show a gelling temperature close to the body one in the concentration range from 10 to 30% w/w (gelling temperatures higher than 40°C or lower than 25°C). By formulating Pluronic F127/F68 blends at specific concentrations, it was possible to obtain a medium with a  $T_{gel}$  close to the body temperature. The addition of low molecular weight HA at different concentrations had only a slight influence on  $T_{gel}$ , but very interestingly, improved significantly the viscoelastic properties of the final gel as determined through rheological measurements. The Irinotecan loading efficiency was optimized in terms of dissolving medium and was found to be the highest (about 5%) for the medium 50% DMSO-50% ethanol. Very promising results were obtained from the first experiments aimed to achieve stable suspensions of Irinotecan loaded MSNs in the new thermosensitive medium mixture. Stability of suspensions is very high in the gel above the  $T_{gel}$ . The main problem is related to the stability of the suspension below the sol-gel transition temperature. Indeed, below the  $T_{gel}$  the polydispersity in the size of the MSNs represents an important instability factor: the use of HA functionalized MSNs might improve the stability of the suspension also at room temperature. Work is in progress. In any case, the preliminary *in vitro* drug release experiments, simply performed with the MSNs suspended in PBS, showed that a controlled Irinotecan release occurred during about 7 days.

### CONCLUSION

Here we are presenting preliminary but very promising results aimed to build a sustained drug delivery composite platform based on pluronics, HA and MSNs, potentially useful to carry chemotherapeutic agents.

### INTRODUCTION

Nanoparticles created systems have received increasing interest, because the high surface to volume ratio ensures well-tailorable properties<sup>1</sup>. The formulations in nanoparticles could reduce the risk of toxicity and the side effects of active-agents, and could increase the efficiency, specificity, and the tolerability, so the therapeutic index of different drugs<sup>2-3</sup>.

Poly-gamma-glutamic acid ( $\gamma$ -PGA) is a poly-amino acid, what is negatively charged in an aqueous solutions and it is biodegradable, edible and non-toxic<sup>4-5</sup>. The aim of this study is preparation of a light cured, so – in dentistry – an in situ practically used hydrogel system. This nanoparticles created system provides possibilities allow the tailoring of the properties such as the mechanical, swelling, and related to these the release properties.

### EXPERIMENTAL METHODS

The molecular characterizations of the modified PGAs (PGA-MNP) were accomplished by Proton Nuclear Magnetic Resonance Spectroscopy (<sup>1</sup>H NMR), and dynamic light scattering measurement (DLS) was used for the determination of hydrodynamic diameter of nanoparticles (NPs).

The NPs created hydrogels (PGA nanogel) were imaged using scanning electron microscope (SEM), and the mechanical parameters were investigated by compression tests on 2mm height, 5mm diameter cylindrical samples. The swelling experiments were carried out by immersion of hydrogels in saline-solution. The release properties were study by high-pressure liquid chromatograph (HPLC).

The biocompatibility of the PGA-nanogels was proved by Alamar Blue assays. The viability, the morphology, and the proliferation tendencies were followed by fluorescent and confocal laser scanning microscopy. Saos-2 cells were used in all of these experiments. The statistical analyses were performed by using SPSS version 17.0.

### RESULTS AND DISCUSSION

The NMR results proved that the crosslinking- and the methacrylating-reactions were successful. The resulted 10% reactive group is allowed the fast photopolymerization reaction. DLS measurements verified the nanosize ranges of the particles, average diameter was around 80 nm. The SEM micrographs of the PGA nanogels confirmed the DLS results, because the different nanoscale objects clearly visible also on broken surfaces. (Figure 1)

Figure 1 The size distribution of NPs according to the DLS measurements and b) SEM image of PGA nanogel

Different reticulate structures could be found in the nanogels, where the dimensions are in the nanoscale. Rigid gel could be obtained in relatively short photopolymerization time -3 min- this is the main condition for the applicability. The mechanical testing shows that the Young's modulus of nanogel  $0.927 \pm 0.433$  MPa. The swelling properties of the gels are connected to the more compact nanostructure. This is around 110% in the case of PGA-nanogel, what is less than the non-nanoparticles created hydrogel. The HPLC results show a retentive effect for the release of the ampicillin from PGA-nanogel, what can give possibilities for the control. The Alamar blue assay cannot show significant different between the cell viability of the control and the nanogel samples in 3 days period. The microscopy techniques highlighted the presence of proliferating cells after 1 week.

### CONCLUSION

Exclusively PGA nanoparticles created, in situ useable hydrogel system was demonstrated in this study. This PGA-nanogel could be suitable candidate for direct application in dentistry. The release behaviour of the nanogel could ensure a certain control possibilities for antibiotic administration, and the biocompatibility of the system was verified with various ways.

### INTRODUCTION

Rosacea is a common and chronic disorder, characterized by flushing and persistent erythema in the central facial area<sup>1</sup>. New liposomal formulations as treatment for facial erythema of rosacea were synthesized and characterized. The *in vitro* release profile of brimonidine tartrate (BT) incorporated into two types of liposomes (MLV and LUV), dispersed in different polymeric gel matrices, was analyzed. The influence of the liposomes size and the matrices characteristics over the BT release kinetics was studied.

### EXPERIMENTAL METHODS

Liposomes were prepared by the thin film hydration method. Briefly, lipids (Phosphatidylcholine and Cholesterol) were dissolved in an appropriate volume of chloroform. The organic solvent was evaporated from the round bottom flask (250 mL) resulting in formation of a thin film on the walls of the flask. Then, the lipid film was hydrated with a solution of 6% (w/v) BT (prepared in phosphate buffer saline - PBS, pH 7.4), at 40°C. After vigorous shaking, a spontaneous formation of MLVs occurred. The dispersion was placed in a bath sonicator for 10 min at 45°C, in order to break the existing aggregates. Finally, the liposomal dispersions were incubated for 1–2 hours at a temperature above the lipid transition temperature (at 25°C) for annealing membranes structural defects. The separation of liposomes from non-encapsulated brimonidine tartrate was achieved by centrifugation. The amount of BT entrapped in the liposomes was determined by breaking them with Triton X-100. LUVs were prepared by extrusion method. A MLVs suspension was forced through a polycarbonate filter with 100 nm pore size, at 40°C, to yield liposomes having a diameter near the pore size of the filter used. Carbopol940, hydroxypropylcellulose and some poloxamers were used for gel matrix synthesis. For the preparation of new systems, in each gel matrix a certain volume of BT loaded liposomes suspension was added. The final concentration of drug in obtained formulations was 0.5% (w/w).

### RESULTS AND DISCUSSION

The mean diameter of the liposomes was determined by laser light diffractometry technique. The mean diameters measured for the vesicles used in this study were 901 nm for MLVs and 110 nm for LUVs.

The *in vitro* released amount of BT was analyzed using Franz diffusion cells. A cellulose membrane separated the donor compartment, containing the drugs loaded liposomes from the receptor compartment filled with collection medium (Phosphate buffer solution - PBS, pH 5.5, 37°C). At predetermined time points, the amount of the drug diffused across the membrane was monitored by using UV-VIS spectroscopy at specific wavelength. The BT release from different matrices has been retarded from several days to weeks after BT inclusion in LUVs and MLVs entrapped subsequently in matrices with variable composition.

The release kinetics curves shows that the composition of liposomes had no significant influence on liposomes stability.

The BT release from LUVs was slower than from MLVs. The LUV liposomes proved to be superior to MLV liposomes in terms of stability and the obtained results are consistent with other research in the field<sup>2</sup>.

The liposomes stability was greatly improved by inclusion in polymeric matrices.

*In vitro* cytotoxicity of liposomal formulations was determined on the human dermal fibroblasts cell line. Liposomal formulations were shown to be non-cytotoxic.

### CONCLUSION

Liposomes obtained in this study proved to be stable. *In vitro* tests have shown a prolonged release profile of brimonidine tartrate and therefore the liposomal formulations can be used as topical delivery systems for treatment of facial erythema of rosacea.

[ochiuzd@yahoo.com](mailto:ochiuzd@yahoo.com)

### INTRODUCTION

Periodontal diseases are one of the common microbial infections which involve 35% of adult population in the world, that affect the gums and bones supporting the teeth and can lead to tooth loss<sup>1,2</sup>. Controlled delivery of chemotherapeutic agents within periodontal pockets can improve clinical signs of periodontitis and can prevent systemic side effects<sup>2</sup>. Hydrogels have generated great interest as biomaterial vehicle for drug delivery because many of them present excellent biocompatibility with minimal inflammatory responses. Considering this previous information, the main purpose of this study was to obtain a new type of biocompatible hydrogels based on natural polymers (chitosan and pectin) which are designed to deliver the drug into periodontal pocket, and which could present an excellent alternative for treatment of periodontitis.

### EXPERIMENTAL METHODS

#### Materials

Chitosan MMW (degree of deacetylation 91 %) and Tetracycline were purchased from Sigma Aldrich. Pectin (citrus) type USP/100 was purchased from CPKelco. Cryopreserved primary human dermal fibroblasts (HDF) cells (CO135C), Dulbecco's Modified Eagle's Medium, Fetal Bovine Serum (FBS) were purchased from Life Technologies. Penicillin, streptomycin, trypsin, non-essentials amino acids has been acquired from Antisel.

The hydrogels were prepared by complex coacervation method. The reaction took place by ionic interactions between the positively charged amino group of chitosan and negatively charged carboxyl group of pectin and offers the possibility of rapid formations of the thin films. Certain amount of chitosan was added in a lactic acid solution (1wt%) under magnetic stirring. Pectin solution has been added dropwise in chitosan aqueous solution under continuous stirring. Glycerol was added as plasticizer. Tetracycline solution was introduced in formed polyelectrolyte complex. Finally, the hydrogels were turned in the polycarbonate rectangular templates. The films were obtained after evaporation of water in an oven at  $37 \pm 0.5$  °C for 24 h. In order to remove any possible unreacted products, the films were purified by repeated washings with distilled water and then dried at room temperature for 24 h. The prepared hydrogels were analyzed from different points of view:

- FT-IR for both polymers and the hydrogels;
- Scanning electron microscopy (SEM) was used for morphology characterization;

- The swelling degree of the hydrogels in slightly alkaline aqueous medium (pH=7.2) and in artificial saliva (pH=6.75) was studied by using the gravimetric method;

- The Tetracycline release from hydrogels were performed in solutions that mimicking the biological fluids using UV-VIS spectroscopy;

- Cell viability was determined and cell number was counted with a hemocytometer.

### RESULTS AND DISCUSSION

The FT-IR spectra confirmed the interpolymeric complex formation between amino groups of chitosan and carboxyl group of pectin. Hydrogel swelling degree was caused by water penetration through diffusion within the empty pores and in the networks of the hydrogels, causing the swelling of polymer membrane. The swelling degree in artificial saliva was lower than in phosphate buffer solution (pH = 7.2). Hydrogels presented a good Tetracycline including and release capacity. The cytotoxicity of these materials was investigated on human dermal fibroblasts. Cell viability in contact with hydrogels was approximately 93% which means that the material have non-cytotoxic behavior. A slight decrease of the cells number from experimental cell cultures may be caused by the local mechanical damage as a result of the hard consistency of the material.

### CONCLUSION

In the present study, has been prepared chitosan - pectin hydrogels able to be used in the treatment of periodontitis. Hydrogels allowed a good drug release capacity of Tetracycline and showed a good cell viability.

## The Quantification of Doxorubicin and Lipids in Liposomal Doxorubicin Formulation

Jan Procek<sup>1</sup>, Maciej Łukawski<sup>1</sup>, Magdalena Przybyło<sup>1</sup>, Marek Langner<sup>1</sup>

<sup>1</sup>Faculty of the Fundamental Problems of Technology, Wrocław University of Technology, Poland  
[jan.procek@pwr.edu.pl](mailto:jan.procek@pwr.edu.pl)

### INTRODUCTION

The development of methods for the determination of active pharmaceutical ingredients (API) concentration in a drug is the main element of the documentation required for its registration. In liposomal doxorubicin (brand name: Doxil (USA), Caelyx (EU))<sup>1</sup> both lipids and doxorubicin are considered as APIs. There are numerous approaches in literature for the determination of active ingredients in liposomal doxorubicin. However, there are serious inconsistencies regarding preparation of standards for the encapsulated doxorubicin. This results with lack of a reliable data as illustrated by the low efficiency of doxorubicin recovery<sup>2</sup>. The aim of presented studies is the development of consistent and reproducible procedure, would ensure the satisfactory accuracy and precision of the quantification of doxorubicin in liposome formulation.

### EXPERIMENTAL METHODS

An HPLC-ELSD method for lipid content determination were developed and validated according to ICH Q2(R1) guidelines. Quantitative analysis of doxorubicin in liposomal form was performed using HPLC equipped with UV and Fluorescence detectors using C18 column. The reference samples of doxorubicin with lipids were prepared in a mobile phase consisting of methanol, histidine buffer, ammonium sulphate, lipid mixture and sucrose.

### RESULTS AND DISCUSSION

Data presented in table 1. summarise the results of HPLC analysis of lipids and doxorubicin quantities in Caelyx. Regardless of the type of doxorubicin reference standard used a good accuracy and precision were obtained. However, the recovery of doxorubicin always exceeded required value of 5%. The obtained results shown that free and liposomal doxorubicin are not equivalent from the analytical point of view. Conditions during and after the encapsulation process are so

complex that simple references are not sufficient. The results of lipids analysis pass the quality criteria.

Table 1. The accuracy, precision and ratio of recovery rate for doxorubicin and lipid obtained using HPLC analysis for liposomal formulation of doxorubicin.

	Method accuracy [%]	Intra-vials precision [%]	Ratio of recovery [%]
MPEG-DSPE	99.8±0.2	98.5±2.5	102.5±2.8
Doxorubicin	99.9±0.5	100.3±0.5	115 to 150

### CONCLUSION

The complex drug formulation such as liposomal doxorubicin requires dedicated methodologies for the quantification of active ingredients. Presented studies present the methodology for the quantification of lipids and encapsulated doxorubicin. Developed methodology allows for the determination of all main components of liposomal doxorubicin with accuracy satisfying standards imposed by regulatory institutions.

## Lactic Acid Photocrosslinkable Adhesives to be Used as Transdermal Delivery Systems

João Santos<sup>1</sup>, Filipe Aguiar<sup>2</sup>, Fernando Cruz<sup>2</sup>, Cristina Baptista<sup>1</sup>.

<sup>1</sup>CIEPQPF-Department of Chemical Engineering, University of Coimbra, Portugal

### INTRODUCTION

Lactic acid (LA), a 100% renewable raw material, is currently used to produce poly(lactic acid), a biodegradable/biocompatible polymer, FDA approved, with outstanding advantages over other synthetic polymers. Its properties allow a wide range of biomedical applications, though its use as a bioadhesive has not been thoroughly studied. Bioadhesives are important tools in the treatment of injured organic tissues<sup>1</sup>. Advances in adhesive science rendered their design simpler, allowing a customized thickness that improves patient comfort and increases potential for producing transdermal drug delivery systems (TDDS) with these adhesives. These systems are non-invasive, may improve therapeutic efficacy compared to conventional routes of drug administration and are ranked as patient-friendly treatments<sup>2</sup>. The pharmaceutical industry already provides transdermal drug delivery systems for hormone therapies or muscular aches treatment, as examples. In TDDS systems, known as patches, the medicine may be entrapped in the adhesive or in a layer over the film. Knowing that photo-polymerization allows a good control of film properties and fast curing rates<sup>3</sup>, in this study the performance of photocrosslinkable lactic acid adhesives as drug delivery devices was assessed.

### EXPERIMENTAL METHODS

Following a three steps process, photocrosslinkable adhesives were produced from two different lactic acid solutions upon heating at high temperatures: L-lactic acid (80%) (LA80) and lactic acid (85-90%) (LA85-90). 1,4-Butanediol (99%) was used as a co-monomer; catalysts or toxic solvents were not added. The prepolymers based on LA80 were further purified by dialysis and lyophilized to remove the residual water as well as lactic acid impurities. All LA products with OH end groups were modified with an isocyanate functional monomer, Laromer® LR 9000. Weight ratios of these reagents were in the range of 60/40 to 30/70. A low toxicity solvent, diethyl ether (99%), was used in the synthesis. In the last step different weight percentages of Irgacure® 2959, a photoinitiating agent, were added to form well defined films after UV irradiations for 2-5min. ATR-FTIR monitoring was performed to confirm the success of chemical reactions. TGA technique, surface energy measurements, *in vitro* degradation in phosphate buffer solution (PBS), water uptake in PBS, *in vitro* biocompatibility, haemocompatibility, and antimicrobial properties were assessed to characterize the synthesized materials. Drug release tests, using a

commercial drug for muscular pain, are underway to assess drug release kinetics from the bioadhesives.

### RESULTS AND DISCUSSION

The obtained membranes were transparent and highly flexible, which are major advantages for the envisaged application. These membranes were then characterized to evaluate their potential for TDDS. The swelling percentage of materials was moderate (around 20%) which means that the membranes present good hydration ability while not compromising skin adhesion. Degradation studies for 6 to 12 weeks showed a slight hydrolytic instability with a maximum weight loss of 20-30%; however the mechanical performance and chemical resistance of the films were not greatly compromised. TGA results revealed materials resistance at high temperature (> 200°C), meaning that membranes might be sterilized. Surface energy of materials ( $\gamma_s \approx 27\text{mN/m}$ ) were lower than the ones reported in the literature for skin ( $\gamma_s \approx 38\text{-}56\text{mN/m}$ ) thus, according to thermodynamic requirements<sup>2</sup>, the adhesives will adhere effectively to skin. Haemocompatibility was assessed and adhesives showed a thrombogenic character of approximately 80% and a non-haemolytic nature after a pre-incubation in PBS medium. Biocompatibility was evaluated *in vitro*: films confirmed cell viability above 85% and antimicrobial properties against *E. coli* and *S. aureus* models.

### CONCLUSION

A very simple and easy method was developed to produce biocompatible lactic acid adhesives. This method can be easily scaled up to obtain new transdermal drug delivery systems (for short or long term uses) using UV photocrosslinked materials. Drug delivery studies are the main goal of our research at the moment, and this includes using lactic acid based polymers as well as its copolymers.

### INTRODUCTION

Bone regeneration has been investigated with different calcium phosphate materials (CaPs) incorporating biomolecules such as growth factors i.e bone morphogenetic proteins (BMPs) or drugs<sup>1</sup>. Despite their bone stimulating ability, incorporation of BMPs is questioned by the risk of serious side effects. Alternatively, several reports have indicated a therapeutic benefit of statins especially simvastatin known for neovascularization and bone formation and other benefits after incorporating with CaPs<sup>2</sup>.

In this study, an unexploited low molecular weight drug from the family of statins, Pitavastatin (PTV) in combination with CaPs has been studied with the aim of enhancing bone regeneration and vascularization. Also, the effects of PTV on physico-chemical properties of the scaffolds have been assessed.

### EXPERIMENTAL METHODS

Stability of PTV dissolved in water and phosphate buffer saline over 2 weeks at 37 °C and 4 °C, at different pH 6.5, 8 and 9.5 was measured using High performance liquid chromatography (HPLC).

Rat mesenchymal stem cells (rMSCs) and rat endothelial progenitor cells (rEPCs), were cultured in cell culture media containing PTV (1 and 0.1 µM) and the expression of some genes involved in bone regeneration (Osteocalcin, collagen type 1, BMP-2, Alkaline phosphatase, Beta actin etc.) and vascularization (VEGFA, VEGFR1, VEGFR2, eNOS etc.) was monitored by Real Time - Polymerase Chain Reaction (RT-PCR) for 72h.

Self-setting CaP foams were prepared by mechanical mixing of solid phase ( $\alpha$ - tricalcium phosphate with 2wt% hydroxyapatite) and liquid phase (10 µM PTV, 1% Tween, 10% Pluronic in MQ water) in a 0.65 L/P ratio at 1700rpm. Microstructure was assessed by optical and electronic microscopy, porosity by mercury intrusion porosimetry and He pycnometry and specific surface area by Nitrogen adsorption (BET method).

### RESULTS AND DISCUSSION

Stability studies showed PTV solutions were stable for 2 weeks in all the conditions except for 15% and 25% degradation at pH of 8 and 9.5, respectively. The presence of PTV in the cell culture enhanced the expression of genes involved in mineralization (Osteocalcin and Collagen type 1) and vascularization (VEGFA, VEGFRs), in a dose-dependent way over the course of 72h, with an overexpression for 0.1µM (Figure 1).

Characterization of the self-setting CaP foams loaded with PTV showed no differences in the microstructural or textural properties such as porosity (~78%) and interconnected porosity. This can be explained based on the low concentrations used, based on *in vitro* studies.

Figure 1. Gene expression of (a) Osteocalcin in rMSCs and (b) VEGFA in rEPCs in growth media with PTV (0, 0.1 and 1 µM),

### CONCLUSION

*In vitro* studies provided a new evidence of the potential of PTV to enhance bone regeneration and vascularization. Addition of PTV in the CaP foams did not interfere with the setting reaction and did not alter the microstructural and textural properties of the materials. This novel approach opens the path for further investigation of PTV-loaded CaP scaffolds as matrices for drug release experiments, which are presently in process.

[freetama@naver.com](mailto:freetama@naver.com)

### INTRODUCTION

Polymeric nanoparticles prepared using amphiphilic polymeric derivatives has shown significant promise as carrier for imaging and therapeutic agents<sup>1</sup>. Currently, the stability of polymeric nanoparticles has been improved by covalently crosslinking using small molecule crosslinker and controlled mineralization on shell of the polymeric nanoparticles<sup>2</sup>. However, the former method utilizes toxic small molecule crosslinkers and complex crosslinking chemistry, whereas the later method is highly laborious. In this study, a new crosslinking method using gold nanoparticles as crosslinkers will be developed.

### EXPERIMENTAL METHODS

Synthesis Tertiary amine contained amphiphilic block copolymers using a versatile macroinitiator via ring opening polymerization and atom transfer radical polymerization. DOX was loaded into triblock copolymers using the simple dialysis method in dark circumstances. For the optimization of gold-crosslinking system, various molar ratio of  $\text{HAuCl}_4 \cdot 3\text{H}_2\text{O}$  was treated in contrast to tertiary amine of DOX loaded nanocarriers solution. In brief, prepared 2 mg of DOX loaded nanocarriers dissolved 2 ml of distilled water in vial and added 95 nmol (0.1 molar ratio) to 2.85  $\mu\text{mol}$  (3.0 molar ratio) of  $\text{HAuCl}_4 \cdot 3\text{H}_2\text{O}$  solution. The mixture was stirred well at 40 °C for 12 h and resulting solution was centrifuged (15000 RPM, 30 minutes) to remove any residue. Then, lyophilize to obtain gold-crosslinked nanocarriers.

### RESULTS AND DISCUSSION

As prepared triblock copolymer, DOX-loaded nanocarriers and gold crosslinked nanocarriers have a hydrodynamic radius of  $195.4 \pm 0.7$ ,  $146.2 \pm 0.84$  and  $156.0 \pm 1.629$  with a zeta potential value of  $43.1 \pm 0.46$ ,  $24.9 \pm 0.29$  and  $40.2 \pm 0.4$ .

Gold crosslinked nanocarrier was confirmed using TEM imaging (Fig. 1) and UV-Vis spectrometer.

Fig.1. Images of gold crosslinked nanocarriers with various reaction conditions (a). and Transmission

electron microscopy (TEM) images of different feed ratio of  $\text{HAuCl}_4$ . 1:1 (b), 1:1.5 (c) and 1:3 (d)

In TEM image, we confirmed the reduction of  $\text{HAuCl}_4$  by tertiary amine inside nanocarriers.

One of the main advantages gold crosslinked nanocarriers is stability enhancement. The release of DOX from gold crosslinked nanocarriers was much slower than that from uncrosslinked nanocarriers (Fig. 2), which might be due to the crosslinked structure of gold crosslinked nanocarriers playing a role as the diffusion barrier.

Fig. 2. *In vitro* release behavior of DOX from DOX-loaded nanocarriers and gold crosslinked nanocarriers (a) and *In vitro* cytotoxicity (b)

### CONCLUSION

In this study, we developed gold crosslinked nanocarriers by Amine induced reduction. The gold crosslinking inside nanocarriers resulted in improved stability and allowed long circulation, sustained release of loaded drug, DOX. Overall results, gold crosslinked nanocarriers might have promising potential as a drug carrier system for DOX.

## Brushite/Alginate Microbeads for Sustained Drug Delivery

Alberto Lagazzo<sup>1</sup>, Laura Pastorino<sup>2</sup>, Noemi Frisina<sup>2</sup>, Fabrizio Barberis<sup>1</sup>, Marco Capurro<sup>1</sup>

<sup>1</sup>Department of Civil, Chemical and Environmental Engineering (DICCA), University of Genoa, Italy.

<sup>2</sup>Department of Informatics, Bioengineering, Robotics and Systems Engineering, University of Genoa, Italy.

[alberto.lagazzo@unige.it](mailto:alberto.lagazzo@unige.it)

### INTRODUCTION

Alginate is one of the most extensively studied polysaccharides and has shown great potential as drug and cell carrier<sup>1</sup>. Alginate beads can be prepared by extruding a solution of sodium alginate, containing bioactive compounds, as droplets, into a divalent crosslinking solution, such as  $\text{Ca}^{2+}$ . However, the use of alginate in drug delivery shows some drawback specifically for the release of low molecular weight molecules, since the release rate is very fast and can not be controlled or modulated<sup>2</sup>. In present work, we proposed the precipitation of brushite within alginate microdrops during alginate  $\text{CaCl}_2$  mediated crosslinking process using an encapsulation unit.

The association of microporous brushite and of biodegradable hydrogel like alginate leads to a composite material with improved mechanical properties and sustained release of encapsulated active molecules.

### EXPERIMENTAL METHODS

Composite microbeads were prepared using a commercially available air-driven droplet generator (Nisco encapsulation unit Var J30, Zurich, Switzerland). Alginate (low viscosity), 1% in ammonium phosphate monobasic, was sprayed into a  $\text{CaCl}_2$  (2% w/v) solution to gel under constant stirring using optimized instrumental parameters. A nozzle having a diameter 0.25 mm was used with a flow rate of the solution 0.2 ml/min, a pressure 100 mbar and the distance of the nozzle from the cross-linking solution was set 6 cm. A  $\text{CaCl}_2$  2% in distilled water was used as cross-linking. The composite microbeads were then washed in pure water using centrifugation at 1000 rpm for 2 minutes.

The morphology of the beads was characterized by scanning electron microscopy (SEM Hitachi 2500) and optical microscopy.

The rheological characteristics of the alginate solutions were determined using a rheometer Anton Paar MCR301, equipped with plate-cone geometry.

Mechanical properties of the microbeads (dynamic compression tests) were obtained with a homemade instrument<sup>3</sup>, consisting in a shaker, a force transducer and a laser to measure the displacement of the sample. The tests were run in the range 5-100Hz and at different pre-strains of the samples (particles).

A preliminary evaluation of the release properties of the composite microbeads was performed using model molecules, such as ibuprofen.

### RESULTS AND DISCUSSION

The alginate solution shows a rheological behaviour that can be considered Newtonian, without presence of yield stress. Morphological analysis from scanning electronic microscopy reveals particles of spherical shape with a diameter of  $50 \pm 10 \mu\text{m}$ . In comparison with the alginate microbeads produced without brushite, the surface appear more irregular and jagged, probably due to presence of brushite crystals that, trapped inside the alginate network, modify the structure of the particle and their external interface.

Mechanical tests show an increase until three times higher, of the particles stiffness, due to the brushite presence. This fact should be the cause of a more efficient behavior in the drug delivery application of these microbeads, as revealed in preliminary tests, where the composite microbeads had a more sustained release profile than alginate microbeads.

### CONCLUSION

Composite brushite-alginate microbeads showed improved mechanical properties as well as release profiles. Thus the composite material can be regarded as a promising for applications in sustained drug delivery applications.

## INTRODUCTION

High intensity focused ultrasound (HIFU), using cancer treatment for precise heating, is using as the source of focal heating for selective delivery of doxorubicin (DOX) with thermosensitive liposomes (TSLs). HIFU has been used for targeted drug release at tumour vasculature by mild hyperthermia immediately upon systemic administration of DOX bearing TSLs (DOX-TSLs). However, this single heating method (SHM) has limited on deep tissue penetration of DOX for high antitumor efficacy <sup>1,2</sup>. In an attempt to allow penetration of DOX at tumour deep tissue, the multiple heating method (MHM) has been developed. First, mild hyperthermia condition was applied by HIFU to increase vascular permeability of tumour. Second, the drug-loaded TSLs were systemically administered into the mice and selective accumulation in tumour site. Third, the mild hyperthermia was re-applied in tumour tissue to improvement drug bursting out of the cumulated TSLs. Herein, we report that the optimized timing of the hyperthermia treatment can significantly improve the antitumor efficacy.

## EXPERIMENTAL METHODS

DOX-TSLs were prepared using the ammonium sulfate gradient method as described previously [27]. The Cy5.5-labeled DOX-TSLs (Cy5.5-DOX-TSLs) were also prepared for imaging experiments, according to the procedure reported previously [28].

The HIFU parameters were optimized to maintain the temperature of tumour tissue at 42 °C (power = 20 W, frequency = 1.5 MHz, pulse repetition frequency = 15 Hz, duty cycle = 15%). Positions of about seven or eight HIFU focuses were preset on a tumour with 2.5 mm of an interval distance, and each of them was sequentially exposed by HIFU for 300 sec.

## RESULTS AND DISCUSSION

The temperature in tumour tissues where HIFU was focused reached 42 °C within 150 s, and rapidly decreased by 37 °C upon the termination of a HIFU exposure. As shown in Figure 1a for DOX-TSL with pre-heating by HIFU, the DOX amount in tumour tissues gradually increased and reached the maximum ( $9.89 \pm 1.92$  DOX  $\mu\text{g/g}$  tissue) at 6h post-injection. The beneficial effect of pre-heating on the TSL accumulation was proven by the comparison of DOX amounts in tumours at the optimal time point (Figure 1b). The *ex vivo* NIRF images of DOX in tumours were obtained. The MHM resulted in the higher DOX accumulation in tumour and significantly enhanced penetration depth compared to the other groups. It was noting that the highest anti-tumour efficacy was

observed from mice treated by MHM, which might be due to the effective delivery of DOX into the tumour tissue (Figure 2).

Figure 1. (a) DOX amounts in tumour tissue as a function of time after HIFU treatment. (b) The maximal amount of DOX in tumour tissue at the optimal time points.

Figure 2. Antitumor efficacy of DOX-TSLs.

## CONCLUSION

In this study, we developed a new approach to improve the antitumor efficacy of DOX-TSLs using HIFU. This was followed by a burst release of a large quantity of DOX out of the TSLs accumulated within tumour tissues, triggered by post-heating of HIFU. As a consequence, our new modality of the HIFU treatment for the use of TSLs could result in higher antitumor efficacy than IHA. This new approach could be adjusted and used for various cases of cancer treatment using TSLs.

### INTRODUCTION

Anticancer therapies based on liposomal drug delivery systems have the advantage of reducing toxicity to healthy tissues. Typically, release of encapsulated drugs from lipid-based carriers relies on either passive diffusion or the non-specific degradation of the lipid shell. Both mechanisms are slow and prevent cell cycle non-specific drugs such as doxorubicin (DOX) reaching effective local concentrations. In order to optimize time, location and amount of drug release, so much effort has been devoted to the development of liposomal systems capable of releasing drug in response to a specific stimulus. Examples of this are lysolipid-based thermosensitive liposomes (LTSL), which lipid membranes rapidly change structure and create pores at the gel-liquid crystal phase transition temperature ( $T_c$ ). LTSL formulation tuned for a  $T_c$  in the mild hyperthermia (HT) range of 40–42°C are very attractive carriers for chemotherapeutics as DOX, which antitumor effect is enhanced by mild HT. In this work, we incorporated DOX-loaded LTSL (DOX-LTSL) to *in situ* polymerizable fibrin hydrogels (lipogel) filled with plasmonic gold nanostructures that enable them to transduce photonic energy delivered by near-infrared (NIR) light into heat<sup>1</sup>. We tested the extent to which NIR-light of 808 nm, wavelength belonging to the “optical window” in biological tissue, can remotely control DOX release from plasmonic lipogels. Finally, we explored the therapeutic potential of this methodology in an *in vitro* model of human epithelial carcinoma.

### EXPERIMENTAL METHODS

Hollow gold nanoparticles (HGNPs) were synthesized via galvanic replacement of cobalt with gold as reported elsewhere<sup>1</sup>. DOX-LTSL with a  $T_c$  of 41.5°C were prepared as described elsewhere<sup>2</sup>. The plasmonic lipogels based in fibrin (fbn) were prepared after mixing 0.02 mg mL<sup>-1</sup> DOX-LTSL, 10 mg mL<sup>-1</sup> bovine fibrinogen, 0.01–0.05 mg mL<sup>-1</sup> HGNPs and 2 NIH units mL<sup>-1</sup> thrombin in a final volume of 1 mL of Dulbecco's Modified Eagle's Medium. Lipogels polymerized at 37°C in a CO<sub>2</sub> incubator for 1 h. The constructs were irradiated with a continuous wave NIR laser at 808 nm for 5–10 min at 33–44 mW mm<sup>-2</sup>, and then incubated at 37°C in a CO<sub>2</sub> incubator for 1–24 h. DOX release to the media was estimated by quantification of the emitted fluorescence at 590 nm, after excitation at 470 nm. Cell viability was evaluated by using the alamarBlue assay.

### RESULTS AND DISCUSSION

NIR-laser treatment of plasmonic lipogels led to a temperature increase in the construct, detected by IR thermography, which is dependent on the amount of HGNPs, the dose of photon energy delivered and the exposure time to NIR light. Temperature rises within constructs correlated with the increase in DOX concentration released to the culture medium, demonstrating the effective triggering of liposomal drug release. Close examination of irradiated plasmonic lipogels revealed the bleaching of 3-dimensional regions that faithfully matched the illuminated areas (Fig 1). This result indicates that the developed system can restrict drug release from NIR-targeted areas in the construct, also enabling temporal control of drug release. Finally, we found that NIR-controlled release of DOX from plasmonic lipogels effectively reduced the viability of HeLa cells cultures.

**Figure 1:** photographs of lipogels filled (a) or not (b) and (c) with HGNPs, 24 h after NIR irradiation at 44 mW mm<sup>-2</sup> for 7.5 min (a) or heat treatment at 42°C for 1 h in a thermostatically-controlled water bath (c). Scale bar= 5 mm. Dashed circle delimits area of NIR-laser influence.

### CONCLUSION

Photothermal treatment of thermosensitive plasmonic lipogels is a very attractive technology for remotely defining spatiotemporal patterns of chemotherapeutics bioavailability.

## Determination Of Liposomal Doxorubicin Concentration In Blood By Fluorescence Spectroscopy

Maciej Łukawski<sup>1</sup>, Magdalena Przybyło<sup>1</sup>, Marek Langner<sup>1</sup>.

<sup>1</sup>Faculty of the Fundamental Problems of Technology, Wrocław University of Technology, Poland  
[maciej.lukawski@pwr.edu.pl](mailto:maciej.lukawski@pwr.edu.pl)

### INTRODUCTION

After administration, the chemotherapeutic agents are transported to the tissues by the blood in different fractions: plasma water, plasma proteins or cells. This has to be taken into consideration while determining pharmacokinetics of the drug.<sup>1</sup> The key to correctly estimate levels of given drug in blood is to account for all the fractions.

Several methods for quantification of liposomal doxorubicin in biological fluids were reported up to this day. Most of them utilize HPLC with fluorescence detectors, with complex extraction procedures, involving organic solvents, prone to errors in the final estimation of concentration.

In the present investigation we discuss main concerns during development of the method for determination of liposomal doxorubicin concentration in blood samples, using fluorescence spectroscopy.

### EXPERIMENTAL METHODS

During this study, visible light range fluorescence spectroscopy was used to carry out the experiments. Human blood samples with varying hematocrit were prepared by dilution of initial sample with serum. Samples were incubated with free and liposomal doxorubicin, and divided for hemolysis or centrifugation. Complete hemolysis was obtained, according to standard procedures, with 0.5% w/w Triton X-100 solution, and diluted in Phosphate Buffered Saline to minimise inner filter effects.

### RESULTS AND DISCUSSION

There are strong interactions between doxorubicin and blood constituents, which result in underestimation of total drug concentration. Scale of this underestimation varies from patient to patient, and is dictated by composition of blood. After centrifugation of blood with different hematocrit value, there is clear correlation between amount of blood cells and fluorescence intensity, as shown in figure 1.

Figure 1. Fluorescence intensity of blood samples spiked with 20 µg/ml doxorubicin hydrochloride, varying in Ht. Doxorubicin fluorescence was measured in plasma, after centrifugation of blood cells.

In order to avoid consequences of interactions of drug with blood constituents, there is a possibility of hemolysis using agents such as Triton X-100. This procedure raises another major obstacle, namely release of strongly absorbing agents from blood cells, which obscure signals from the drug.

The possible solution to this problem is derivation of an equation, based on absorption spectra of hemolysed blood, to determine concentration of absorbing agents, and then correction of fluorescence intensity, to obtain final value of drug concentration.

### CONCLUSION

Measurement of the drug concentration in blood produces pharmacologically significant data about its distribution into blood cells.

Fluorescence measurements have the advantage of minimal required sample preparation, high sensitivity, and rapid collection of data. However in samples as complex as blood one has to account for multiple fluorescent and absorbing species. Carefully derived correction is crucial in development of such methods.

### INTRODUCTION

It is well known from the literature that natural clay mineral particles like as a smectite can be used in drug delivery systems. The structure of montmorillonite (MMT) is composed of silica tetrahedral sheets layered between alumina octahedral sheets. In the interlayer positions, positively charged ions are located, which can be relatively easily exchanged by other molecules/ions during the specific intercalation process. Because of the cation exchange capacity, large specific surface area and high adsorption ability - MMT is common ingredient of organic-inorganic hybrids materials. Typical drug particles (ibuprofen, vit. B, genatmicin) or biopolymers (polysaccharides i.e. alginate, chitosan) can be used as an organic compounds for modification of the MMT structure [1]. In such systems, addition of chitosan with gel-forming properties may preface intercalation process and facilitate the drug introduction. The aim of this study was to verify the effectiveness of methods for the preparation of nanocomposite Biofuroksym drug carriers based on chitosan (CS) and montmorillonite (MMT), and the evaluation of their properties.

### EXPERIMENTAL METHODS

Intercalation of Biofuroksym (Bf, Polphrama) into montmorillonite (MMT-K10, Sigma Aldrich) was made in three different ways using: (1) pure Bf, (2) Bf dissolved in diethylamine (DEA, Sigma-Aldrich) and (3) Bf dissolved in chitosan (CS, Sigma-Aldrich). Intercalation was carried out in the two-step process, in which initial hydration of MMT (24h/60°C) was followed by the proper intercalation (7days/60°C). The modified MMT powders were lyophilized, and then examined using scanning electron microscopy (SEM/EDS), X-ray diffraction (XRD) and Zeta potential method. All types of the MMT powders were used as fillers to produce the nanocomposite samples with a medium molecular weight chitosan matrix filled with 4% wt. of the clays. Finally, the water absorption tests were performed in the culture cells medium to determine stability *in vitro* of these materials.

### RESULTS AND DISCUSSION

Microstructural observation showed differences between pure clay and clays after intercalation process. Modified MMT particles have a smaller size and irregular shape. Additionally, same spherical macromolecules were present in the interlayer space of MMT. The EDS analysis confirmed the presence of Biofuroksym (sulphur energy peak). The change in the interlayer space of the modified MMT clays was also confirmed by the XRD measurement and typical diffraction peak at  $2\Theta=8.91$  which refers to the (001)

spacing was shifted to  $2\Theta=8.85$  after intercalation. All types of the clays modified with Biofuroksym showed characteristic reflection at about  $2\Theta=6.79$  (Fig. 1.).

Fig. 1. XRD patterns of MMT, MMT/Bf, MMT/DEA/Bf, MMT/CS/Bf.

Intercalation process influenced also the zeta potential of MMT particles: it increased for the clay modified with chitosan (polycation) and Biofuroksym, but it decreased when pure Biofuroksym or diethylenoamine with Biofuroksym were used as modifying compounds (Tab. 1). Results of zeta potential implies also a greater dispersion in water solution (chitosan solvent), since the decrease in the negative charges of MMT increases the spacing between the layers of clay.

Table 1. Zeta potential for the MMT-based systems

Type of MMT powder	Zeta potential [eV]
MMT	-31.2±1.56
MMT/DEA/Bf	-38.6±2.18
MMT/Bf	-42.0±1.89
MMT/CS/Bf	+37.4±2.54

### CONCLUSIONS

The obtained results, even if preliminary, may however indicate, that the skilful intercalation of drug into nanofiller and homogeneous distribution of the filler in the hydrogel matrix can provide a new solution in the field of drug delivery systems.

## Hydrolysis of Crosslinked Poly(ester anhydride) Networks in Different pH Conditions

Sanja Asikainen, Harri Korhonen and Jukka Seppälä

Research Group of Polymer Technology, School of Chemical Technology, Aalto University, Finland  
[sanja.asikainen@aalto.fi](mailto:sanja.asikainen@aalto.fi)

### INTRODUCTION

Poly(ester anhydrides) are promising materials especially for controlled drug release applications. They are surface eroding and they erode fast due to their hydrolytically labile anhydride bond. Crosslinkable poly(ester anhydrides) have been studied *in vitro* and *in vivo*, and no cytotoxicity and no or only mild inflammatory reactions in mice and rats were observed.<sup>1</sup> Since the degradation of polyanhydrides is known to be pH sensitive and they are more stable in acidic conditions<sup>2</sup>, possible application area for fast degrading poly(ester anhydrides) might be in oral drug delivery. The slow degradation of polymer matrix in acidic conditions would protect drug until it reaches the intestine.

The aim of this study was to investigate the effect of pH conditions on the hydrolysis of crosslinked poly(ester anhydride) networks. Different pH conditions simulate the pH conditions in the gastrointestinal tract.

### EXPERIMENTAL METHODS

#### Synthesis of precursors

The precursors were synthesized by a similar method to that used earlier<sup>3</sup>. In brief, the  $\epsilon$ -caprolactone based hydroxyl-terminated oligomers were synthesized in a batch reactor by using 10 mol-% pentaerythritol as a co-initiator and 0.02 mol-% Sn(II)octoate as an initiator. After polymerization, oligomers were functionalized with succinic anhydride to obtain acid-terminated oligomers. Crosslinkable precursors with labile anhydride bonds were obtained by allowing the acid-terminated oligomers to react with methacrylic anhydride. Reactions were monitored with nuclear magnetic resonance spectrometer (NMR).

#### Preparation of samples

Photoinitiator camphorquinone (1 wt-%) was mixed with the precursor until homogeneity was achieved. Teflon mould was used to obtain discs (2 mm thickness, 2 mm in diameter, 9 mg in weight). Crosslinking was carried out at room temperature by photoinitiation in visible light and post curing with blue light.

#### Molecular weight determination

The molecular weights of oligomer species were determined by room temperature size-exclusion chromatography (SEC). Chloroform was used as a solvent and eluent for polymers.

#### Gel content of crosslinked samples

Gel content was determined by immersing samples in dichloromethane for six hours. Samples were dried in vacuum overnight and weighted before ( $m_{t,0}$ ) and after ( $m_t$ ) immersion. Gel content (G) was calculated using the following equation:  $G = m_t/m_{t,0} \cdot 100\%$ .

### Hydrolysis experiment

Samples were weighted and immersed individually in 15 ml of phosphate buffer solution (pH 2.1, 6.8 and 7.4) at the temperature of 37 °C. The samples were mildly agitated at a rate of 90 strokes/min. The test specimens were removed from test tubes at different intervals and weighted after drying 24 h in vacuum at room temperature.

### RESULTS AND DISCUSSION

The molecular weights of different oligomer species as well as NMR confirmed the success of polymerization of the precursor. The gel content of the crosslinked samples was 92 %.

The mass loss of polymer samples is presented in Figure 1. Within 24 h, samples were totally eroded in pH 6.8 and 7.4, whereas in pH 2.1 the mass loss was only 6 % of initial weight. Degradation was the fastest in pH 7.4 and already small change in pH towards acidic conditions slowed the degradation down.

Figure 1. Mass loss of samples in different pH conditions.

### CONCLUSION

The degradation rate of poly(ester anhydride) samples is highly pH sensitive. Degradation rate is very slow at strongly acidic conditions and already a small drop in pH slows down the degradation.

[lruman@agh.edu.pl](mailto:lruman@agh.edu.pl)

### INTRODUCTION

Microbial infections are responsible for a significant part of failure rate of bone filling grafts and endosseous dental implants<sup>1</sup>. In the case of reconstructing large-size bone defects a three-dimensional scaffold is needed to support the healing. Therefore a design of scaffolds assuring both mechanical support, bone tissue ingrowth and a controlled antibiotics release seems very viable for an effective, long-term clinical outcome. Titanium dioxide (TiO<sub>2</sub>) has been reported as a plausible candidate as it is biocompatible and it has the ability to directly bond to bone tissue<sup>2</sup>.

The aim of this study was to: i) modify the surface of TiO<sub>2</sub> scaffolds with poly(L-lactide-co-glycolide) (PLGA) microparticles (MPs) loaded with gentamicin sulphate (Gent); ii) evaluate *in vitro* release profile of the drug and iii) assess the bactericidal activity of the proposed system.

### EXPERIMENTAL METHODS

TiO<sub>2</sub> scaffolds were manufactured by polymer sponge replication method and sintering<sup>2,3</sup>. PLGA MPs loaded with Gent were prepared by solid/oil/water method. Gent powder was emulsified in 1.67% (w/v) PLGA (PLGA, 85:15, Mn=80 kDa) solution in dichloromethane (10 mg of Gent per 100 mg of PLGA). The primary emulsion was then introduced into an aqueous solution of 4% polyvinyl alcohol and shear stress was applied (mechanical stirring 1000 rpm). Manufactured MPs were submitted to centrifugation, multistep washing procedure and freeze-drying. Defined amounts of MPs suspended in 0.2 or 0.02% solutions of sodium alginate (Alg) were introduced on the TiO<sub>2</sub> scaffolds by drop seeding and cross-linked with 50 mM CaCl<sub>2</sub>. Six batches of scaffolds were prepared with the use of 0.2 or 0.02% Alg and containing in total 0.5, 0.75 and 1 mg of Gent. *In vitro* release study was performed in PBS by diffusion through semipermeable membrane (Zellu TransRoth, MWCO 12 kDa) and spectrophotometric quantitative analysis of Gent by orthophthaldialdehyde method<sup>4</sup>. The samples were analysed for 3 months. Kirby-Bauer method (Agar diffusion test) was applied in order to determine antimicrobial activity against *S. aureus* and *S. epidermidis*.

### RESULTS AND DISCUSSION

TiO<sub>2</sub> scaffolds were highly porous (with total porosity of 90%) with oval interconnected pores of 400 µm in size, and their microstructure was very similar to that of natural cancellous bone. The average diameter of MPs was 4.2±2.9 µm with encapsulation efficiency of 42% and loading efficiency 5.0%. SEM pictures (Figure 1) show high effectiveness of suspending MPs in sodium alginate and drop seeding procedure. Higher concentration of Alg resulted in more homogenous

distribution of MPs within the scaffolds. Results of *in vitro* release study (Figure 2) show initial burst followed by slow, sustained release of Gent for all systems. The results showed that drug release profile can be easily adjusted by amount of MPs introduced in the system. Alg concentration did not influence drug release kinetics. Microbiological tests confirmed antibacterial activity of Gent released from the TiO<sub>2</sub> scaffolds.

Figure 1 SEM microphotographs of TiO<sub>2</sub> scaffold containing Gent loaded PLGA MPs immobilized with 0.02% Alg (mag. 350x and 1000x)

Figure 2 *In vitro* cumulative Gent release from different types of TiO<sub>2</sub> scaffolds

### CONCLUSION

The study showed that immobilization MPs loaded with Gent on TiO<sub>2</sub> scaffolds was successful; prolonged drug release was achieved and whole system exhibited antibacterial activity.

[borecka.alexandra@gmail.com](mailto:borecka.alexandra@gmail.com)

### INTRODUCTION

Implantable formulations with risperidone (RSP) are considered in the therapy of schizophrenia. One medical product is already available in the formulation of a long-acting injection includes microspheres composed of poly(D,L-lactide-co-glycolide) (D,L-PLGA) that must be applied every two weeks. In this medical product the main release of risperidone begins in the 3<sup>rd</sup> week, lasts from the 4<sup>th</sup> to 6<sup>th</sup> week and is accomplished within 7 weeks. This works aimed to develop delivery system which can be administered less frequently and risperidone will be released for a longer time. In this study the influence of degradation of D,L-PLGA 85:15 on RSP release and structural changes in matrices was determined.

### EXPERIMENTAL METHODS

The matrices containing RSP (10 wt-%) were obtained from D,L-PLGA 85:15 (100000 Da) by solution casting method. The D,L-PLGA was synthesized with the use of Zr(Acac)<sub>4</sub> as low toxic initiator of polymerization. Matrices with the diameter of 10 mm, thickness of 0.6273 mm ± 0.0196 (n=10) were incubated in PBS (pH 7.4) at 37°C under constant agitation. The release rate of RSP by HPLC, the composition of polymer and chain structure by NMR, thermal properties by DSC, morphology of matrices by AFM were determined.

### RESULTS AND DISCUSSION

The observations were conducted for 78 days. In this period 6163 µg ± 553 (n=10) of RSP was released, which was 91.7 % ± 0.17 of substance incorporated into matrix (Figure 1). The significant changes in release rate were observed, which resulted from degradation process. During the first 5 days 100 µg of RSP was released and the process proceeded evenly without burst effect. In the next 15 days, a gradual decrease of RSP release was noted and it turned into a phase of complete inhibition of the release in the 21<sup>th</sup> day. Resumption of release process was noted in the 41<sup>th</sup> day. This effect correlated with significant changes in copolymer. The increase of randomness was observed and decrease of the T<sub>g</sub> to 37 °C. This probably caused increase of copolymer chain mobility and improved water absorption into matrix and diffusion of drug molecules from matrix to the medium. As a result of those changes, regular and steady RSP release was observed from the day 43<sup>th</sup> to 78<sup>th</sup>.

During 78 days the NMR analysis revealed increase of content of lactidyl units from 85.0 % to 87.70% with adequate decrease of content of glycolidyl units from 15.0 to 12.3 (Table 1). An increase of average length of

lactidyl blocks from 8.99 to 9.50 was observed, whereas average length of glycolidyl blocks decreased from 1.69 to 1.30. The suppression of drug release was probably caused by increase of average length of lactidyl blocks, which may lead to crystallization and retain drug in matrix. The randomization ratio (R) increased from 0.41 to 0.60. The used copolymer had initially semi-blocky structure and became more random. The glass transition temperature (T<sub>g</sub>) of the native matrices was 54.0°C. A gradual decrease of T<sub>g</sub> to the 34.5 °C was noted. The morphologic observation revealed the changes in the surface of degraded matrices (Table 1). The native material characterized non-porous surface. However, degradation caused increase of heterogeneity of surface.

Figure 1. Fraction RSP released during the 78 days of degradation process.

Time [days]	$F_{LL}$ [%]	$F_{GG}$ [%]	$l_{LL}$	$l_{GG}$	R	$T_g$ [°C]
0	85.0	15.0	8.99	1.69	0.41	54.0
1	85.0	15.0	9.26	1.64	0.43	54.0
8	85.1	14.9	9.30	1.59	0.43	52.1
36	85.4	14.6	9.36	1.56	0.48	38.9
64	86.2	13.8	9.49	1.34	0.57	37.1
78	87.7	12.3	9.50	1.30	0.60	34.5

Table 1. The changes in structural and thermal properties during degradation.  $F_{LL}$  – mole fraction of lactidyl units;  $F_{GG}$  – mole fraction of glycolidyl units;  $l_{LL}$  - average length of lactidyl blocks;  $l_{GG}$  - average length of glycolidyl blocks; R – randomization ratio; T<sub>g</sub>- glass transition temperature.

### CONCLUSION

The degradation process significantly influences the release of RSP from D,L-PLGA matrices. Analysis of structural, thermal and morphological properties of matrices allow to develop a novel drug delivery system with for prolonged and tailored release of RSP.

## INTRODUCTION

Gene therapy holds great promise for treating many genetic disorders as well as cancer. Gene delivery, which introduces foreign DNA into host cells, is one of the steps necessary for gene therapy. Suitable vectors with good transfection efficiency and low cytotoxicity are essential for effective gene delivery. Since viral vectors cause safety concerns, non-viral vectors including cationic polymers are extensively investigated owing to their ease of preparation, manipulable structures, large DNA loading capability and absence of immune response<sup>1</sup>. Satisfactory transfection efficiency and good biocompatibility are two main challenges for developing successful, polymer-based vectors. Various strategies have been employed in the development of polymeric vectors for improving their ability of gene delivery at the cellular level. Among these polymers, poly(lactic-co-glycolic acid) (PLGA) is used to make biodegradable nanoparticles while poly(ethylenimine) (PEI) is applied to facilitate gene transfection but limited by its molecular weight-dependent cytotoxicity<sup>2</sup>. Poly(ethylene glycol) (PEG) modification of delivery vehicles is a proven strategy for providing shielding and ensuring long-circulation and can also serve as active sites for targeting ligand via covalent bonding. Folate is known for targeting most tumours and promotes transfection efficiency. Therefore, biodegradable copolymers with buffering capacity, hydrophilic modification and targeting ligand are promising for gene delivery with high efficiency. In this study, FOL-PEG-g-PEI-g-PLGA copolymers were synthesized and characterized as potential gene delivery vectors.

## EXPERIMENTAL METHODS

PLGA ( $M_w$ : 36kDa) with acid end group, PEI ( $M_w$ : 1.8kDa and 25kDa), PEG (COOH-PEG-NH<sub>2</sub>,  $M_w$ : 3kDa) and folic acid were used at particular molar ratios to synthesize designed copolymers through EDC/NHS amidation reaction. The chemical composition of copolymers was studied using FTIR and <sup>1</sup>H-NMR. Plasmid EGFP encoding enhanced green fluorescence protein was employed as a model gene for initial evaluation of copolymers. The morphology and structure of nanocomplexes were examined using SEM and TEM. Surface charge of freshly produced nanocomplexes was characterized using a Zetasizer. DNA condensation effect of copolymers was studied using agarose gel electrophoresis. HepG2 cells were used to evaluate the cytotoxicity of copolymers and assess their transfection efficiency.

## RESULTS AND DISCUSSION

The chemical composition of copolymers was confirmed by FTIR and <sup>1</sup>H-NMR, indicating successful synthesis of designed copolymers. SEM examination revealed that polyplexes were spherical in shape and

uniform in size (less than 200nm in diameter and with low polydispersity) (Fig. 1a). TEM results showed that a core-shell structure existed in polyplexes (Fig. 1b). Polyplexes exhibited slightly positive charge above certain N/P ratio (Fig. 2a). They were stable in aqueous solution with inappreciable aggregation for a week and could be freeze-dried and stored for further use with simple reconstitution. The surface charge of polyplexes exhibited a reversal to slightly positive with the increase in NP/pDNA ratio, indicating negatively charged DNA had been successfully encapsulated, which was also supported by the gel electrophoresis result (Fig. 2b). In the biological investigation, the amphiphilic FOL-PEG-g-PEI-g-PLGA copolymers exhibited low cytotoxicity and sufficient transfection efficiency.

Fig. 1. a: SEM image (left) of polyplexes, b: TEM image (right) of polyplexes

Fig. 2. a: zeta potential of polyplexes at 5:1 N/P ratio (left), b: agarose gel electrophoresis of polyplexes with different copolymers (right)

## CONCLUSION

Biodegradable FOL-PEG-g-PEI-g-PLGA copolymers with designed compositions and their polyplexes with uniform morphology, suitable particle size and designed structures were synthesized. Above certain N/P ratio, DNA was successfully encapsulated and condensed. Cytotoxicity of copolymers and transfection efficiency of polyplexes were evaluated, indicating the copolymers were promising for non-viral vectors for gene delivery.

## Assessment of Drug Incorporation and Release from a Novel Coronary Stent Coating

Craig Martin McKittrick<sup>1</sup>, Simon Dixon<sup>2</sup> and Christopher McCormick<sup>1</sup>

<sup>1</sup>Biomedical Engineering, University of Strathclyde, United Kingdom

<sup>2</sup>Biomer Technology Ltd, United Kingdom

[craig.m.mckittrick@strath.ac.uk](mailto:craig.m.mckittrick@strath.ac.uk)

### INTRODUCTION

Understanding drug elution kinetics from the surface of drug eluting stents (DES) is an important tool in the development of novel designs. It is useful for testing the reliability and reproducibility of coatings, for providing insight into mechanisms of drug release and for estimation of parameters for models describing drug uptake into tissues<sup>1</sup>. Here we describe the drug elution kinetics for varying polymer to drug ratio coatings of a novel acrylic-based polymer designed to promote re-endothelialisation<sup>2</sup>.

### EXPERIMENTAL METHODS

A polymer coating, BTL *accelerate*<sup>TM</sup> AT, proprietary to Biomer Technology Ltd, was applied to the surface of glass coverslips via a standard dip-coating method. Varying AT/rapamycin(R) coating concentration and ATR ratios were assessed for release of rapamycin over a period of 28 days (n=6). Coatings are described in **Table 1**. The coverslips were immersed in 1.5 ml of release medium, phosphate buffered saline:ethanol (90:10), and were transferred to fresh release medium at regular sampling points to maintain sink conditions. The end-point of the experiment was 28 days. To determine initial drug load separate coverslips (n=2) were immersed in 1.5 ml of methanol to rapidly dissolve the rapamycin from the polymer coating. The coverslips were transferred to fresh methanol every 24 hours for 7 days. The amount of rapamycin in release medium was determined by ultraviolet spectroscopy. Comparisons were drawn between all formulations tested using 2-way ANOVA with Bonferroni post-test. Significance was considered  $P < 0.05$ .

Sample	Bottom Coat	Top Coat	Drug Load ( $\mu$ g)
1	2% AT/R (50:50)	None	32
2	2% AT/R (50:50)	2% AT	19
3	2% AT/R (50:50)	2% AT/R (50:50)	39
4	8% AT/R (80:20)	None	66
5	8% AT/R (80:20)	8% AT	62
6	8% AT/R (80:20)	8% AT/R (80:20)	149

**Table 1:** Formulations of polymer/rapamycin used to coat glass coverslips used for drug release profile determination. AT=polymer, R=rapamycin.

### RESULTS AND DISCUSSION

There cumulative amount of drug released over the 28 day period between for all formulations is shown in **Figure 1** (1vs2  $p < 0.01$ , all others  $p < 0.001$  at 28 days). The release profiles generated here are similar to those of used clinically stents, such as the ENDEAVOR stent which releases the majority of its dose within 2 weeks<sup>3</sup>. **Figure 2** shows that coatings with a higher AT/R ratio eluted drug at a significantly slower rate than the lower ratio formulations and this was most apparent in the

initial 24 hours of the release period. This finding is in line with currently used stents such as the TAXUS stent, which was coated with high and low polymer/drug ratios to yield slow and medium release drug eluting stents, respectively<sup>4</sup>. The cumulative release of initial load data is shown in **figure 3**. The higher AT/R ratio formulations eluted a significantly lower percentage during the initial 24 hours. Again these profiles are comparable to clinically available stents such as the CYPHER DES which releases around 80% of drug load after 30 days<sup>3</sup>. Formulations with a higher AT/R ratio with a drug free top coat had eluted a significantly lower amount of initial drug load by the end of the 28 day release period.

**Figure 1:** Cumulative release of rapamycin. *Right panel 24 hour period.*

**Figure 2:** Cumulative percentage release of rapamycin. *Right panel 24 hour period.*

**Figure 3:** Cumulative percentage release of rapamycin initial load. *Right panel: focus on 24 hour period.*

### CONCLUSIONS

This study has demonstrated that rapamycin can be incorporated and released in clinically relevant concentrations, from a polymer designed to promote re-endothelialisation. Future in vivo studies will investigate the potential of this polymer/drug coating as an advanced stent coating.

## BMP-2 Release from Collagenous Particles

Didem Mumcuoglu<sup>1</sup>, Laura de Miguel<sup>1</sup>, Gerjo van Osch<sup>1</sup>

<sup>1</sup>Department of Orthopaedics, Erasmus University Medical Center, The Netherlands  
[z.mumcuoglu@erasmusmc.nl](mailto:z.mumcuoglu@erasmusmc.nl)

### INTRODUCTION

Development of appropriate delivery systems to regulate the release of growth factors is one of the key challenges in tissue engineering and regeneration studies<sup>1</sup>. Growth factors, especially BMPs, have a wide potential clinical application since they can mediate the bone regeneration process. In particular, BMP-2 has been used in the clinical practice delivered to the defect site adsorbed onto collagen sponges; however the high amounts of protein used have been associated to adverse effects observed<sup>2</sup>. Therefore, it is important to reduce the total dose of the protein and provide sustained delivery during the regeneration process of the bone. In this study, we produced collagenous microparticles and characterized the particles. BMP-2 was loaded to the particles the release of the protein from these particles was studied. The parameters that affect the release of the protein were studied.

### EXPERIMENTAL METHODS

Collagenous microparticles were produced by emulsification. For the release experiments particles were loaded with BMP-2 by incubating overnight with different concentrations of growth factor. Subsequently the release of BMP-2 was measured in time by rhBMP-2 ELISA development kit (Peprotech)

### RESULTS AND DISCUSSION

When BMP-2 was loaded to the microspheres and the release was measured by ELISA, a slow release of the protein has been observed in in vitro release study for

several weeks. Finally, the microspheres were degraded by collagenase thereby releasing the remaining protein fraction present in the microsphere. The release results indicate that these collagenous particles can be loaded with BMP-2 and they are suitable for the sustained delivery of these growth factors

### CONCLUSION

Collagenous particles loaded with BMP-2 demonstrated sustained release of the protein. Several factors were identified to be governing the release profile of BMP-2 from these collagenous microparticles.

## Functionalized Hydrophilic Nanogels for Endogenous Radiotherapy

Smriti Singh<sup>1</sup>, Natascha Drude<sup>1,2</sup>, Felix M. Mottaghy<sup>2</sup>, Agnieszka Morgenroth<sup>2</sup>, Martin Möller<sup>1</sup>

<sup>1</sup> DWI - Leibniz-Institute for Interactive Materials, Forckenbeckstrasse 50, D-52056 Aachen, Germany

<sup>2</sup>Department of Nuclear Medicine, RWTH Aachen University, Pauwelsstrasse 30, 52074 Aachen, Germany  
[singh@dwil.rwth-aachen.de](mailto:singh@dwil.rwth-aachen.de)

### INTRODUCTION

Most advancement in radiotherapy has been made in external beam treatments but it is still limited by the effects it induces in the surrounding healthy tissues and its limitations in patients with disseminated disease. Though endogenous radiotherapy allows a direct delivery of radiation to the tumor by means of radiolabelled antibodies, peptides, or isotopes of halogens that are organified (like radioiodine therapy of thyroid cancer), only few of these approaches are implemented in standard patient treatment since the biodistribution of these small molecules is not ideal and leads to relevant toxic doses in healthy tissue (critical organs are liver, kidneys and intestine). In order to overcome these limitations by increasing selective delivery of radiation to cancer manifestations, our approach focuses on the development of hydrophilic nanogel-carriers coupled with chelators for theranostic radioisotopes.

### EXPERIMENTAL METHODS

Nanogels were synthesized using star shaped PEG polymers with thiol functionalization; thiol chemistry was used for linking the maleimide functionalised chelator 1,4,7-triazacyclononane-1-glutaric acid-4,7-diacetic acid (NODAGA) to the polymer for radioisotope labelling, as well as for crosslinking the polymer in inverse miniemulsion to build up sub-micrometer sized nanogels.

### RESULTS AND DISCUSSION

A highly efficient and specific labelling with radioactive marker Gallium-68 was achieved in the nanogels with a radiochemical yield greater than 95% at room temperature. For in vitro studies the nanogels were additionally labelled with Alexa-Fluor 488. The studies demonstrated that the Alexa Fluor labelled nanogels were unrecognizable for monocytes. In vivo studies were performed by injection of <sup>68</sup>Ga-radiolabelled nanogels in the tail vein of male rats (n=10) and rodent  $\mu$ -PET imaging studies were done which indicated a long blood circulation of nanogels without visible accumulation in liver or spleen,

demonstrating that there was no uptake of the nanogels by the Mononuclear Phagocyte System (MPS).

### CONCLUSION

Such water swollen nano-carriers offer advantages, as their open structure barely interact with proteins and cells featuring long blood pool circulation, variability of the carrier and targeting function and responsive properties to environmental factors like enzymes, pH, ionic strength. Thus tumor targeting by the nanogels is supported by their stealth properties in combination with the enhanced permeability and retention effect (EPR effect) and is complemented by the incorporation of ligands of receptors overexpressed by tumor cells. Hence, first step in targeting results in the accumulation of the nanogels in tumor tissue by utilizing the EPR effect followed by the second step, which is targeting of tumor cells by addressing their specific surface property.

## Advanced Poly-( $\epsilon$ )-Lysine Dendrons as Functional Non Viral Macromolecules to Target Pancreatic $\beta$ Cells

Mariagemiliana Dessi<sup>1</sup>, Valeria Perugini, Gary Phillips and Matteo Santin

Brighton Centre for Regenerative Medicine, School of Pharmacy and Biomolecular Sciences, University of Brighton,  
UK

[M.Dessi2@brighton.ac.uk](mailto:M.Dessi2@brighton.ac.uk)

### INTRODUCTION

Type 1 diabetes mellitus is an autoimmune disorder characterized by the destruction of the insulin-producing  $\beta$  cells of pancreatic islets and high blood glucose levels. The disease results from a multitude of interactions between environmental exposures and different variant genes related to pancreatic  $\beta$  cell functions [1]. As a result, the transfection of  $\beta$  cells is providing great potential in gene therapy and diabetes therapies arena. To date, while the efficacy of viral gene vectors is indisputable, their unfavorable limitations in target-cell specificity, immunogenicity, toxicity and high costs of manufacturing, forced researchers to devise non-viral vectors [2]. In the current scenario, dendrons are emerging as challenging nano-vectors because of their unique properties such as: highly favorable branched structure, high loading ability, appropriate nanosize and targeting potentials. In order to evaluate the potency of dendrons as useful and safe non-viral vectors as therapeutics for gene delivery from bench to bedside, a full molecular design and characterization is needed. In this work, for the first time, hyperbranched dendrons have been specifically designed and characterized as *in vitro* model to predict the targeting of pancreatic cells. Cell studies were performed on MIN6 cell line that exhibit glucose-inducible insulin secretion similar to that of cultured normal mouse islet cells. They also have morphological characteristics comparable to of pancreatic  $\beta$  cells that make them a realistic model useful in the studies of the molecular mechanisms of pancreatic  $\beta$  cells.

### EXPERIMENTAL METHODS

Structurally well-defined dendrons were realized through a bottom up strategy based on a multistep sequence of coupling and deprotection reactions. The root of the dendron included an arginine moiety (R), onto which the three branching generations of lysine (G3K) were assembled. The complete molecule (RG3K) was characterised by HPLC, mass spectrometry (MS) and Fourier Transformed Infrared spectroscopy (FTIR). MIN6 cells were cultured at 37°C and 5% CO<sub>2</sub> in Dulbecco's Modified Eagle Medium (DMEM) at low glucose, with 10% (%) foetal calf serum. Cells were seeded in 24 well cell culture plates at a density of  $4.0 \times 10^4$  cells/cm<sup>2</sup> for 24 and 48 hours and mixed with increasing dendrons concentration (46, 85, 170 nmol/ml). Cell viability was assessed by Hoescht Propidium Iodide staining (HPI; Sigma, UK), while FITC labelled dendrons were used to investigate the cellular uptake.

### RESULTS AND DISCUSSION

Chemico-physical analysis confirmed the successful synthesis of hyperbranched molecules. The accurate mass measurements of MS confirmed that the actual

molecular weight matches the theoretical value (2097 m/z). The absorption bands of FTIR spectra reveal the characteristic elements present on the molecule backbone. Cell viability analysis reveals that after 24 hr in contact with dendrons, cells are viable as showed in Fig.1.

**Figure 1.** Confocal analysis of MIN6 cultured with a) 170 nmol/ml b) 85nmol/ml and c) 46 nmol/ml of RG3K dendrons and d) on tissue culture plate.

After 48hrs of exposure, cellular uptake of dendron can be detected and the FITC labeled dendron is distributed inside the nucleus (Fig.2).

**Figure 2.** Low RG3K concentration uptake in MIN6 cells.

### CONCLUSION

This work shows a systematic study on the design of characterization of novel dendron based non-viral vectors. The innovative platform presented herein shows that dendrons can be produced in mild condition with exquisite control of composition and architecture. Cells experiments on MIN6 cell line indicate that dendron based molecules are promising as an efficient targeting model for pancreatic  $\beta$  cells. The obtained results provide support for clinical translation of non-viral vectors for gene and drug delivery applications for type 1 diabetes.

## INTRODUCTION

Silica particles doped with magnetic nanoparticles and containing active substances (drugs) are seemed as an interesting materials for the biomedical applications<sup>1,2</sup>. Functionalized silica particles doped with nanoparticles of magnetic substances ( $\text{Fe}_2\text{O}_3$ ) have been obtained by the sol-gel method. To see the behavior and response of the obtained materials to external magnetic field special device was built to make a thermal induction measurements. Magnetic particles can respond to the action of alternating magnetic fields and induced thermal energy were measured in particles.

## EXPERIMENTAL METHODS

Silica particles doped with magnetic  $\text{Fe}_2\text{O}_3$  nanoparticles have been obtained by the sol-gel method. To measure the behavior and response of the obtained materials to external magnetic field special device was built (Fig.1). This device was supported on the induction of the eddy currents into conductors (silica particles with magnetic substances) by changing external magnetic field. Test stand consist on several (6 or 10) neodymium magnets, which are able to induce variable magnetic field with frequency up to 3 kHz. Induced thermal energy were measured in particles, closed into special gel capsules, by thermoelements which allow to make the temperature measurements during the experiment.

Fig. 1. Diagram of the measuring position: 1) capsules with materials, 2) handle of the capsules, 3) thermoelements, 4) neodymium magnets.

## RESULTS AND DISCUSSION

The size and morphology of silica magnetic particles were obtained using TEM (Fig. 2). Material presents the structure type core-shell and magnetic dopant are encapsulated within silica matrix, which isolates it from the environment. Simple silica particles are small, their diameter size is in the range 50-100 nm, but the presence of magnetic dopants cause that they stick

together and form bigger particles with diameter size about 250-350 nm.

Fig. 2. TEM micrograph of the  $\text{SiO}_2/\text{Fe}_2\text{O}_3$  particles.

Excitation of the magnetic silica particles with external AC magnetic field cause induction of the thermal energy. The observed highest growth in the temperature was over 4,5 K. The results of thermal energy induction in the prepared particles were shown in Figure 3. The red line represent thermocouple placed inside the gel capsule. This thermocouple was full surrounded with the silica particles. The second thermocouple (black line) was placed on the surface of the gel capsule.

Figure 3: Temperature change of magnetic particles measured with use of thermocouples a) for different frequencies of magnetic field changes, b) for maximum frequency of magnetic field changes.

## CONCLUSION

$\text{Fe}_2\text{O}_3$  nanoparticles encapsulated into amorphous  $\text{SiO}_2$  particles were prepared by the sol-gel method. Magnetization curves confirmed the presence of ferromagnetic behavior of this material. The application of the external AC magnetic field induce thermal energy in the particles. Generated heat was immediately released to the surroundings and growth in the temperature over 4,5 K was observed.

### INTRODUCTION

Age-related macular degeneration (AMD) is a major cause of blindness and is the leading cause of certified vision loss in the UK<sup>1</sup>. AMD affects the retina, the light sensing membrane at the back of the eye. In AMD the central part of the retina, the macula, degenerates causing the person to lose their central vision. AMD exists in two forms, wet and dry. Dry AMD is currently untreatable. Fortunately, the most severe form of AMD, wet AMD, is treatable by repeated injections of drugs into the back of the eye.

In wet AMD blood vessels grow from the choroid, the tissue behind the retina, into the retina. Blood vessel growth into the retina leads to swelling and bleeding, causing damage to the macula and scarring. Currently, the only method of delivering anti-VEGF drugs such as, ranibizumab or aflibercept to treat neovascularisation in AMD are by invasive intraocular injections. While the benefits of these drugs are necessary to prevent loss of vision in patients, a less invasive method of drug delivery using eye drops would prevent the associated risks of intraocular injections such as bleeding within the eye, tearing of the retinal tissues, cataracts and infection<sup>2</sup>.

In this study we present a novel cell-penetrating peptide construct (CPPC) delivery system which can allow the drugs currently used in the clinic to be delivered to the back of the eye using a topical administration of an eye drop instead of relying on invasive injections.

### EXPERIMENTAL METHODS

Peptides were synthesised using standard solid-phase peptide synthesis on a Liberty Blue peptide synthesiser. The peptides were analysed using mass spectrometry and purified using high-pressure liquid chromatography and used at a purity of >95 %. Peptide constructs were built around the drugs by vortexing for 10 seconds and incubating at room temperature. Drug delivery experiments were carried out ex-vivo in freshly enucleated porcine eyes. *In vivo* experiments were carried out in C57 mice. Mice had a three 100 µm laser burns to the choroid to model neo-vascularisation in AMD. The mice then received a single intravitreal injection of an anti-VEGF agent or cell penetrating peptide construct bound anti-VEGF drugs applied topically to the front of the eye twice daily for the duration of the experiment. Neovascularisation in the choroid was then measured using immunohistochemistry.

### RESULTS AND DISCUSSION

Ex vivo delivery into enucleated porcine eyes demonstrated that a single 60 µL drop could deliver 1.7

± 0.4 µg/mL of ranibizumab to the vitreous humour. Confocal images of immunohistochemistry on retinal wholemounts also showed the presence of ranibizumab in the retina. *In vivo* experiments showed that following laser burns to the choroid both intravitreal injection and cell-penetrating peptide construct bound anti-VEGF agents significantly reduced neovascularisation compared to controls with no significant differences between the two groups (Figure 1).

**Figure 1** Area of neovascularisation following injected and topical administration of current 'gold standard' drug. Each group shows average of 6 mice, error bars show standard error of the mean. \*p<0.05

### CONCLUSION

The pre-clinical *in vivo* data supports our hypothesis that cell-penetrating peptide constructs can be used to deliver drugs to the posterior segment of the eye via topical administration. This work has the potential to revolutionise the current treatment of diseases such as AMD, reducing the financial burden on the NHS and empowering patients.

### INTRODUCTION

Although small interfering RNAs (siRNAs) have surpassed expectations *in vitro* to alter gene expression, their transfer is still the major obstacle for the *in vivo* application of RNA interference (RNAi). One important aspect for their therapeutic employment is the immobilization on implants for local delivery, such as to reduce inflammatory processes like the adhesion molecule cascade accompanied by the expansion of coronary artery stents in patients with vascular stenosis. Therefore, delivery technologies could be established for the local application of RNAi<sup>1</sup>.

Poly(lactide-co-glycolide) (PLGA) already exists as biodegradable drug eluting polymer in Drug eluting stents<sup>2</sup> but not so far in connection with siRNA delivery. We want to show the ability of PLGA coatings to release siRNA, transfect endothelial cells and induce RNA interference. From our point of view PLGAs have the ability to achieve the requirements of a appropriate siRNA delivery system which can be used in many fields of implant technologies

### EXPERIMENTAL METHODS

Three different PLGAs (PLGA 1: Resomer® RG 752 H, acid terminated, PLGA 2: PLGA Mw 50,000-75,000, ester terminated, PLGA 3: Resomer® RG 756 S, ester terminated, Sigma-Aldrich®) were used for analysis.

The ph-value change in cell medium was analysed over four weeks.

Hemocompatibility tests with PLGA coated glass slides were carried out to determine the reaction with whole blood.

For biocompatibility tests EA.hy926 cells were cultured in PLGA conditioned medium. We also tested the immune response of EA.hy926, cultivated with PLGA-siRNA coated glass slides by quantitative real-time chain reaction (qRT-PCR).

Transfection efficiency was analysed with EA.hy926 cells which were incubated with PLGA mixed with fluorescent siRNA ((f)-siRNA) coated glass slides. For that, a layer of PLGA and Lipofectamine complexed with (f)-siRNA or scrambled siRNA (SCR) was air-dried onto glass slides.

To show the functionality of siRNA knockdown after transfection in EA.hy926 and hVEC<sup>3</sup> the knockdown of ICAM-1 was quantified by flow cytometry and qRT-PCR after incubation with PLGA-siICAM or PLGA-SCR coated glass slides.

### RESULTS AND DISCUSSION

No significant pH changes and no significant decrease in viability were measured after four weeks.

The hemocompatibility assay showed no significant changes of whole blood reactions compared to control without slides.

Release and transfection of (f)-siRNA could be detected for a period of four weeks, interestingly 5.22 % new cultured cells were still transfected after this period.

Significant ICAM-1 protein knockdown of 36,03% and mRNA knockdown of 47,1 % was measured.

PLGAs are biocompatible and hemocompatible materials for drug eluting systems which is also shown by Waugh<sup>2</sup> and Szymonowicz<sup>4</sup>.

We showed that it can be used to immobilise, release and transfect functional siRNA over a long period into cells to get a knockdown of specific proteins.

Especially Resomer® RG 752 H shows the highest knockdown of ICAM-1.

### CONCLUSION

The biocompatibility and hemocompatibility together with the transfection of siRNA into cells, when they are in contact with these PLGA layers, not inducing immune response etc., makes PLGA-siRNA coatings a feasible future therapeutic application for several diseases.

## INTRODUCTION

Despite the progress realized in the field of radiopharmaceuticals, there remains a need for effective delivery systems with prolonged circulation half-life and increased radionuclide loading capacity. Block copolymer micelles have shown to improve the payload delivery of therapeutic agents to tumours and hold great promise for passive uptake via EPR and specific uptake guided via targeting [1]. The aim of the present project is the development of molecular carriers suitable for theranostics through the modification of amphiphilic block copolymers. The synthesized polymers will enable both micelle formation as well as the incorporation of radionuclides.

## EXPERIMENTAL METHODS

In the present study, commercially available poloxamers (triblock copolymers of PEO-PPO-PEO, i.e. Pluronics) have been selected as starting materials to introduce amines [2] enabling the subsequent coupling of the chelating agent 2-(4-isothiocyanatobenzyl)-diethylenetriaminepentaacetic acid (p-SCN-Bn-DTPA) [3] (Fig. 1). The molecular carriers developed were analyzed using various techniques including NMR and IR spectroscopy for structure determination, GPC for molecular weight determination and dynamic light scattering (DLS) for micelle size evaluation. Polymers were labelled with generator produced PET nuclide Sc-44 [4]. Radiolabelling stability was tested in human serum media and in the presence of other metals (Ca<sup>2+</sup>, Fe<sup>3+</sup>, Mg<sup>2+</sup>) at 37°C for 4 h.

## RESULTS AND DISCUSSION

The IR and <sup>1</sup>H-NMR spectra indicate that the functionalization of polymers with primary amines was successful. Furthermore, SEC analysis performed excluded possible crosslinking of the polymer due to the reaction with ethylene diamine. Polymers were quantitatively labelled at room temperature within 15 min with Sc-44, showing high stability over time.

## CONCLUSION

Different Pluronics modified with primary amines serve as an excellent platform for further conjugation of various ligands, namely targeting vectors, contrast agents or chelating moieties to the polymer. Moreover, the method herein used to introduce chelating agents was successful. Therefore, we expect that the developed polymers can be used as safe and effective vehicles for theranostics.

### INTRODUCTION

Restoration of lost neuronal function after spinal cord injury (SCI) still remains a big challenge for current medicine. An important repair strategy is tissue reconstruction by bridging the SCI lesion with a supportive and stimulatory milieu that would enable axonal rewiring. Injectable extracellular matrix (ECM) derived hydrogels have been recently reported to have neurotrophic potential *in vitro*<sup>1</sup>. In this study, we evaluated the presumed neuroregenerative properties of ECM hydrogels *in vivo* in the acute model of SCI.

### EXPERIMENTAL METHODS

ECM hydrogels were prepared by decellularization of porcine spinal cord (SC) or porcine urinary bladder (UB) tissue<sup>1</sup>. *In vitro* cell growth on the surface of the hydrogels was characterized using a human umbilical cord-derived mesenchymal stem cell (hWJ-MSC) culture. Cell viability was determined after 1, 3, 7 and 14 days in culture using WST-1 reagent.

In an *in vivo* study, a hemisection was performed at the Th8 level, and hydrogels were acutely injected into the spinal cord defect and allowed to gelate *in situ* (n = 5 per group, per time point). The effects were evaluated via histological analysis and real-time qPCR at 2, 4 and 8 weeks.

### RESULTS AND DISCUSSION

Both ECM hydrogels showed comparable ability to support *in vitro* cell proliferation, which did not significantly differ from the control cell proliferation on tissue culture plastic. When injected into the spinal cord hemisection, both ECM hydrogels integrated into the host tissue and stimulated neovascularization and nervous tissue ingrowth into the lesion. No significant differences were found between SC-ECM and UB-ECM hydrogels with regards to ingrowth of neurofilaments and blood vessels in all observed time points. On the

other hand, massive infiltration of macrophages into the lesion and rapid hydrogel degradation did not prevent cyst formation, which progressively developed over 8 weeks. Gene expression analysis at 2 weeks post-SCI revealed significant down-regulation of genes related to immune response and inflammation in both hydrogel types, whereas this effect diminished at later time points. A combination of hWJ-MSC with SC-ECM did not further promote ingrowth of axons and blood vessels into the lesion, when compared with the SC-ECM hydrogel alone. Nevertheless, only a few transplanted cells were detected in the lesion after 4 weeks.

### CONCLUSION

Both ECM hydrogels modulated the innate immune response and provided the benefit of a stimulatory substrate for *in vivo* neural tissue regeneration. However, fast hydrogel degradation resulting in cyst formation might be a limiting factor for the use of ECM hydrogels in the treatment of acute SCI.

### INTRODUCTION

Advances surgical techniques for treating severe injuries of nerves of peripheral nervous system, when suturing of stumps is unfeasible, employ bridging. This may involve grafting of axon bundles harvested from a donor site, or application of guiding tubes. The primary function of the tubular prosthesis is to bridge a gap of discontinued nerve. Variety of formulations of biodegradable synthetic polymers offer wide range of mechanical properties and tunable degradation kinetics. Poly(trimethylene carbonate) (PTMC) is a suitable co-component to provide flexibility to poly(lactic acid) (PLA), the most utilized biodegradable synthetic polymer. Either copolymers and blends of these two components were proposed for manufacturing nerve guidance channels.[1, 2] Another strategy employs tubular structures with an internal scaffold to support mechanically regenerating nerve and be a reservoir of bioactive substances. A hydrogel matrix can be employed since its structure is characterized by random structures of interconnecting open pores. Permanent hydrogels natural polymers can be formed by chemical methods with crosslinking agents or utilizing ionizing radiation. Polysaccharides, despite general tendency for degradation, can be converted into permanent hydrogels when irradiated without additives under certain conditions. [3]

Carboxymethylchitosan (CMCS), a water-soluble biodegradable polysaccharide possesses advantageous physical, chemical and biological properties, such as low toxicity and sufficient biocompatibility to be applied as films, fibers and hydrogels in artificial bone material, drug delivery matrices or wound healing dressings.[4] Moreover, CMCS hydrogel can be synthesized by radiation methods to be applied for biomedical devices.

### EXPERIMENTAL METHODS

Carboxymethylchitosan (Kraeber GMBH & Co.) of the degree of deacetylation (DDA) 93.8% and degree of substitution (DS) 96% and viscosity-average molecular weight  $M_{\eta} = 32.5 \text{ kg mol}^{-1}$  was used. Method of tube manufacturing of poly(L-lactic acid), PLA and poly(trimethylene carbonate), PTMC was developed in our laboratory and is described elsewhere.[2] In vivo experiments on rats femoral nerve regeneration involved the hollow tubes, the tubes with CMCS hydrogel, and that including brain derives growth factor, and control group - ends suturing. Motor and sensor recovery of operated limbs, neuroma occurrence and histopathology of explanted nerves were evaluated.

### RESULTS AND DISCUSSION

Radiolysis of CMCS leads to degradation and crosslinking; the latter process predominates in concentrated solutions. Thus, irradiation of CMCS solutions of 10% and more results in formation of macroscopic hydrogel. This phenomenon was exploited for preparation of internal hydrogel matrix in nerve regeneration guides. 12% CMCS mixture with water, which formed a physical gel, was introduced into the lumen of the PTMC/PLA porous guide. Electron beam irradiation initiated crosslinking reactions to form CMCS hydrogel inside the tube, and the applied radiation dose of 25 kGy sterilized the device simultaneously. A schematic drawing of a guidance with hydrogel filling is shown along with its SEM picture in Figure 1. Biocompatibility of the produced tubes was confirmed in vitro.

Figure 1. A schematic drawing and SEM picture of the guidance with hydrogel filling, 1 – tube wall of PTMC/PLA and 2 – CMCS hydrogel matrix.

Application of the hollow tubes, these with hydrogel, and with hydrogel infiltrated with BDNF, in rat animal model effectively supports regeneration of discontinued femoral nerves as assessed through movement and sensitive functions recovery. It prevents neuroma formation, enhances the process of nervous tissue reconstruction and reduces scar tissue formation.

### CONCLUSIONS

Manufacturing and evaluation of the guides of PLA/PTMC biodegradable polymer blend with internal CMCS hydrogels scaffold is reported. In vivo experiments gave positive results and the variation between three types of tubes will be discussed.

### INTRODUCTION

Neural implants and stimulations are used to understand brain function and brain disorders cause by neural damage.

Alginate has a unique gelling ability which is widely leveraged in biomedical applications such as, encapsulating hydrogels for the delivery, or immobilisation of drugs, proteins or cells<sup>1,2</sup>. Conductive polymers (CPs) also play important roles in *in vivo* neural-electric platforms to increase neuron population. Poly(3,4 ethylenedioxythiophene): Poly(styrenesulfonate) (PEDOT:PSS); an aqueous solution with high conductivity and excellent cell adhesion is a popular option to employ as an organic electrochemical layer to influence and promote cell growth<sup>3</sup>.

This research aims to investigate the biocompatibility of alginate and PEDOT:PSS blended films and fibres with neurite outgrowth.

### EXPERIMENTAL METHODS

PEDOT:PSS was mixed with alginate and doped with 10 wt% of polyethylene glycol (PEG) to increase the conductivity. This solution was spun into fibres through  $\text{CaCl}_2$  (aq) (1 M), which were then subjected to heat treatment (150°C, 10 min). The properties were characterised by conductivity testing, tensile testing, and circuit stimulation.

Films were cast from high M alginate dissolved in PEDOT:PSS and other additives in different ratios. These were dried (RT, 12 h) before cross-linking with  $\text{CaCl}_2$  (aq) (50 mM) and the cell adhesion studied.

Samples were cut into small pieces and placed in 24 well plates, poly-L-lysine (PLL) was added to modify the implant surface and the wells seeded with foetal rat cortical neurons ( $10^6$  per well). The plates were observed at 7 and 14 days by live/dead cell assays under a fluorescent microscope.

### RESULTS AND DISCUSSION

Uniform fibres were continuously spun for several meters. PEG additive and heat treatment significantly increased the conductivity. However a reduction in mechanical properties was also observed in PEG mixed fibres, with a slight recovery following heat treatment. The circuit stimulations clearly showed the superior conductivity of blended fibres with added PEG and heat treatment which produced the highest light intensity (Fig 1).

Fig.1 The LED intensity of stimulate circuits from fibres 1) Alg-PED 2) Alg-PED-heated 3) Alg-PED-PEG and 4) Alg-PED-PEG heated.

Neurons were also studied on neat alginate films, as a control point for future research (Fig 2). Composite films and fibres will be aiming to improve this level of cell growth in ongoing experiments.

Fig.2 Fluorescent microscopy images of live (green) and dead (red) neurons growing on neat alginate films at day 7 and 14 respectively.

### CONCLUSION

Conductive alginate fibres were prepared containing PEDOT:PSS, addition of PEG and heat treatment affected their electrical conductivity and mechanical properties. Neuronal growth were observed on neat alginate films which demonstrates the ability of this materials for neurite outgrowth. These will contribute to improving the development of neural implants on composite films and fibres surface.

### INTRODUCTION

Traumatic spinal cord and brain injuries result in long-term neurological and functional disorders, as well as death<sup>1-3</sup>. Peripheral nerve injuries may affect sensory functions and motor capabilities<sup>1</sup>. Numerous tissue engineering strategies have been evaluated for reconstruction and regeneration of the nervous system<sup>1-2</sup>. The use of biodegradable polymer scaffolds can help in the restoration of the damaged spinal cord and peripheral nerves by connecting the transected stumps and supporting the growth of nerve cells. Electrospun nonwovens are promising scaffolds for neural tissue engineering that can help the artificial environment to mimic the native extracellular matrix<sup>1-3</sup>. Additionally, scaffolds can be augmented with cells or growth factors<sup>2</sup>. Olfactory ensheathing cells which have extraordinary neurotrophic properties have been chosen for *in vitro* evaluation of the scaffolds<sup>4-5</sup>.

### EXPERIMENTAL METHODS

Polyurethane/poly lactide (PU/PLDL) nonwovens were produced via solution electrospinning as potential matrices for olfactory ensheathing cell (OEC) growth. Influence of the composition and surface morphology on proliferation of OECs was investigated. The scaffolds were composed of PU and PLDL blended at three different w/w ratios, i.e., 8/2, 6/4 and 5/5. The morphology of electrospun PU/PLDL nonwovens were studied using scanning electron microscopy (SEM). Diameter of the fibers was evaluated with image analysis software based on SEM images. The hydrophilic nature of PU/PLDL nonwovens was determined by sessile drop water contact angle measurements. The *in vitro* bioassay of the materials comprised the characterization of morphology, and determination of metabolic activity of cultured OECs. Statistical differences were presented using the Student's ten-sample t-test.

### RESULTS AND DISCUSSION

SEM images of the PU/PLDL nonwovens show fibers of microscale diameter, creating 3D architecture. It was noticed that the introduction of different amounts of flexible PU and rigid PLDL in the polymer blend resulted with creation of networks with moderately different fibrous architectures. Random oriented PU/PLDL fibers showed diameters that ranged from 20 to 900 nm. Contact angles measured for nonwovens of different compositions are noticeably different. The

viability test revealed that none of investigated substrates showed cytotoxic effect on glial cells. OECs cultured on investigated scaffolds showed differences in metabolic activity, depending on the composition of the blend. OECs showed the presence of specific GFAP in all analysed scaffolds, as well as in the control. There is presently, a growing interest in the use of olfactory ensheathing cell transplantation<sup>4,5</sup>. Lesion in the spinal cord is followed by a sequence of primary and secondary damages, e.g. proliferation of overactive astrocytes and creation of impenetrable glial scar on the stumps. The OECs have the extraordinary ability to "open" sticky scar making it penetrable for regenerating axons. It has been shown that after transplantation into human patients, OECs can positively influence repair<sup>4</sup>. However, recent data suggests that a combination, such as a scaffold seeded with OECs might be more preferable in enhancing the level of regeneration across large lesions<sup>5</sup>. Consequently, the existing challenge for researchers is to develop a scaffold that is capable of stimulating OEC proliferation and the re-growth of host tissue. Results of *in vitro* culture of OEC confirmed the potential application of the PU/PLDL nonwovens as substrates for OEC delivery and neural tissue repair.

### CONCLUSION

Our study confirms usability of novel PU/PLDL fibrous scaffolds as substrates for enhancing OECs proliferation. The scaffolds enriched with these glial cells can be implanted directly into the spinal cord or into peripheral nerves to support nerve regeneration. We find electrospinning as a promising technique for fabrication of novel PU/PLDL nonwovens.

### INTRODUCTION

Injury to the spinal cord and brain have devastating consequences on motor, sensory and cognitive abilities<sup>1-3</sup>. A major difference between the central nervous system (CNS) and peripheral nervous system (PNS) is their regenerative capability. Peripheral nerve axons possess the ability to regenerate spontaneously in their natural environment, while CNS axons do not<sup>1-2</sup>. The difference results from different responses of the two systems to injury. Primary and secondary injuries are unique to the CNS<sup>1-2</sup>. Among other components, overactive astrocytes induce a physicochemical barrier to natural regeneration, a so-called glial scar<sup>1-2</sup>. Hindering glial scar formation after injury may be an attractive option for effective axon regrowth<sup>1</sup>. A unique population of cells, i.e. olfactory ensheathing cells (OECs) exhibit the capacity to migrate into the glial scar and promote axons regrowth, and remyelination<sup>4-5</sup>. Biomolecule/cell delivery systems have been extensively studied, and designed to stimulate endogenous repair mechanisms<sup>2-3</sup>. Biopolymers including collagen, hyaluronic acid or chitosan have been successfully used in the CNS repair, and have been found to promote axon regeneration as well as target inhibitory factors<sup>3</sup>. Hydrogels with mechanical properties comparable to these of the CNS (~2kPa) tissue can be used in place of soft nervous tissue<sup>1</sup>.

### EXPERIMENTAL METHODS

The aim of our research was to prepare and characterize alginate hydrogels in the context of neural tissue regeneration. We manipulated the conditions for external diffusion-based gelation of sodium alginate. To initiate gelation, sodium alginate sols were mixed with solutions of various concentrations of calcium chloride or calcium gluconate. Gelation rate was evaluated using rheometry methods. Microstructure of hydrogels after drying was observed using scanning electron microscopy (SEM). Viscoelastic behaviour of the ionically cross-linked alginate was verified using oscillatory shear test. Flow and viscosity curves were obtained. Rheological tests were performed at room temperature. *In vitro* tests were conducted using rat olfactory ensheathing cells isolated from the olfactory bulb. The morphology, viability and proliferation of the cells were evaluated.

### RESULTS AND DISCUSSION

Sodium alginate which is readily soluble in water can be transformed into gel by partial exchange of Na<sup>+</sup> ions for Ca<sup>2+</sup> ions. This process occurs with simultaneous crosslinking of the alginate chains, and thus rheomechanical properties of the hydrogel depend on the molar ratio of Na<sup>+</sup>/Ca<sup>2+</sup> ions. The gelation rate increases with the concentration of a parent solution of sodium alginate as well as with the concentration of Ca<sup>2+</sup> ions introduced into the parent solution. The macroscopic features of alginate hydrogels were from liquid for alginate containing small amount of Ca<sup>2+</sup> ions to dense and compact for calcium alginate gels. The SEM images showed porous structure of freeze dried gels. All aqueous sodium alginate sols exhibited shear thinning. Their viscosity increased with alginate concentration. Viscosity, complex modulus and loss angle were dependent on the concentration of parent sodium alginate sols, and the molar ratio of Na<sup>+</sup>/Ca<sup>2+</sup> ions. Varying sodium/calcium alginate compositions had significant differences in viscoelastic properties, some of them being comparable with biomechanical properties of CNS tissue. *In vitro* tests indicated that hydrogels are nontoxic, and support OECs proliferation. Injectable form of gels might be further investigated as materials for drug delivery to the CNS tissue or complementary materials to PNS tubes graft.

### CONCLUSION

The obtained results indicate that ionically cross-linked hydrogels offer a suitable viscoelastic properties and cytocompatibility, making them applicable as scaffolds for sensitive neural/glia cells cultivation and possible CNS repair. To obtain better mechanical strength, additional chemical covalent crosslinking is needed.

## Poly Glycerol Sebacate for Use as a Neuronal Biomaterial

Dharaminder Singh, John W. Haycock, Frederik Claeyssens

Department of Materials Science & Engineering, University of Sheffield, United Kingdom

[DSingh1@Sheffield.ac.uk](mailto:DSingh1@Sheffield.ac.uk)

### INTRODUCTION

There are three main clinical approaches to aid peripheral nerve regeneration. The first is to suture the proximal and distal stumps together, but providing effective regeneration is only effective over short distances. The second approach is to use an autograft to bridge the gap, whereby an autologous nerve is harvested from elsewhere in the body, however this may result in donor site morbidity and requires additional surgery. A third approach is to use a nerve guide conduit (NGC), which can be made from natural or synthetic materials, however these are currently limited to only short gap injuries. Poly glycerol sebacate (PGS) is a polyester with interesting properties such as biodegradability and an appropriate range of moduli for biomaterials and peripheral nerve tissue engineering<sup>1</sup>. Methacrylate moieties can be attached to the PGS to create a polymer that can be cured under UV light in the presence of a photoinitiator. The methacrylated polymer (PGSm) has yet to be explored as a biomaterial. It has the beneficial material properties of the widely used PGS, whilst avoiding some of the limitations such as time taken due to thermal curing and stability of reagents in the similarly acrylated versions of the polymer<sup>2</sup>.

**Figure 1** - the structural formula of PGSm and the synthesis process.

### EXPERIMENTAL METHODS

PGS was synthesised by a polycondensation reaction of glycerol and sebacic acid. Methacrylate moieties were added to the PGS to create, with the addition of a photoinitiator, a photocurable material (see Fig.1). The material was characterized by GPC, FTIR, NMR, DSC, rheology, nanoindentation, mechanical analysis and goniometry. The Young's modulus of the material was varied by controlling the level of methacrylation. PGSm of varying Young's moduli were assessed by initial in vitro studies using NG108-15 neuronal cells, cultured on flat disks of PGSm, with MTT viability, live/dead analysis and immunolabelling for  $\beta$ III-tubulin / counterlabelling nuclei (DAPI), plus confocal microscopy.

### RESULTS AND DISCUSSION

Viability and live/dead assay results showed that NG108-15 neuronal cells were able to grow on PGSm without any observed toxicity. Immunolabelling for  $\beta$ III-tubulin revealed PGSm to be a good substrate for neuronal cell adhesion, spreading and neurite formation. The varied substrate modulus was shown to affect the cell survival and morphology. Young's modulus results of the material were similar to that of the native tissue. Nanoindenting results show the materials substrate modulus can be well adapted.

**Figure 2** - confocal image of NG108 neuronal cells differentiating on flat PGSm disks. DNA is labelled using DAPI (blue) and neuronal specific microtubules are labelled with  $\beta$ III-tubulin (green).

### CONCLUSION

PGSm is a biomaterial with potentially beneficial properties for neural regeneration, particularly as the Young's modulus can be varied from near GPa modulus to low MPa modulus levels. Initial studies have shown that it is a good substrate for supporting neuronal cell growth and differentiation in vitro. PGSm may therefore be useful as an NGC as it can be structured by UV photostereolithography techniques. PGSm has also been adapted to create 3D porous nerve guidance conduits, as it is postulated that by using a material which better replicates native nerves, it may be possible to increase the efficacy of NGCs.

**INTRODUCTION**

Despite over 150 years of experience in modern surgical management of the peripheral nerve, repair of a nerve gap remains a problem and several methods have been applied by the microsurgeons in order to repair the nerve gaps, including tissue engineering technology<sup>1</sup>.

Several types of synthetic bioresorbable materials have been examined for use in the fabrication of scaffold (conduit) in neural tissue engineering<sup>2</sup> but there is still room for developing new biomaterials with suitable characteristics as well as techniques of scaffolds fabrication.

Important parameters such as surface properties, porosity, bioresorption rate and the interaction and/or communication with the external environment of the conduits have yet to be optimized. Chitosan is a biopolymer with a variety of attractive properties that present great potential for use in this area<sup>3</sup>.

Here we describe the results of an study that were undertaken to evaluate the feasibility of chitosan conduits for use as scaffolds for promoting peripheral nerve regeneration.

**EXPERIMENTAL METHODS**

A 2,5% (w/v) solution of chitosan (deacetylation degree 80%, purchased from Polymar®, Aracaju, SE, Brazil) in acetic acid 3% (w/v) was prepared by magnetic stirring. After solubilization and homogenization the chitosan solution was poured into a petri dish and submitted to solvent evaporation during 24 h at room temperature in a fume hood. The formed film was immersed in NaOH solution 1M for neutralization and subsequently rinsed in deionized water.

The water uptake of the chitosan film was calculated by the equation: water uptake (%) =  $100 \times (m_s - m_0) / m_s$ , where  $m_s$  was the mass of water swelled sample and  $m_0$  was the mass of dried sample.

The film was equilibrated in water overnight, quick frozen by immersion in liquid N<sub>2</sub> and subsequently freeze-dried using a Thermo scientific - LLI500 for at least 3 days. The dried film was cut to the desired dimensions and wrapped around a stainless steel mandrel ( $\phi=1,2$  mm or  $\neq$ ) to complete 1.5 revolutions. Chitosan solution was used to glue the end of the film. The schematic procedure is showed in figure 1.

After bonding the conduit was removed from the mold, washed, dried and stored in refrigerator, immersed in deionized water. The dimensions of the conduit were

measured with micrometer and caliper; morphological aspects of the chitosan film were photographed and observed in a scanning electron microscopy (JEOL, JSM-601 LA).

Figure 1 – Scheme of chitosan scaffold fabrication.

**RESULTS AND DISCUSSION**

The thickness of the chitosan film obtained changed from  $(92 \pm 1)$   $\mu\text{m}$  in dry state to  $(106 \pm 1)$   $\mu\text{m}$  after water swelling. The maximum water uptake of the chitosan film was  $(70 \pm 2)$  %.

Figures 2 shows the morphological aspects of the external and internal chitosan film surfaces and figure 3 shows the conduits obtained by the manufacturing technique employed in this work.

Figure 2 - SEM images of the (a) external and (b) internal surfaces of chitosan film.

Figure 3 – Chitosan conduits.

Tubes with different dimensions (diameter and length) could be easily obtained and the next step of the study involve the biological performance tests.

**CONCLUSION**

The obtained results clearly indicates that the technique used allow the fabrication of a conduit suitable to be used as a chitosan scaffold for effective peripheral nerve regeneration allowing to easily variation of the internal diameter, wall thickness and length of the conduit.

### INTRODUCTION

The aim of this work was to compare the influence of UV/EtOH, ethylene oxide and cold plasma sterilization on the surface properties of polyurethane/poly lactide (PU/PLA) blends, which were intended to support peripheral nerve regeneration.

### EXPERIMENTAL METHODS

Blends of polyurethane and polylactide with a weight ratio of 80/20 were fabricated. Polyurethane (PU) synthesized from hexamethylene diisocyanate and polycaprolactone, with isosorbital as a chain extender was purchased from GOY Bayer (Germany). Polylactide (PLA) consisting of 80% poly-L-lactide and 20% poly-DL-lactide was purchased from Purac (Netherlands). Water contact angle of the obtained PU/PLA films was measured using sessile drop method with Drop Shape Analysis System (DSA Mk2, Krüss, Germany). Surface roughness of the film was determined using a profilometer (Hommelwerke, Germany). Morphology of elaborated materials was evaluated using scanning electron microscopy (Nova Nano SEM 200, FEJ EUROPE Company, USA). X-ray photoelectron spectroscopic (XPS) studies were performed on PHI Versa Probe II Scanning XPS Microprobe. The materials were sterilized by low temperature hydrogen peroxide plasma (Sterrad 100S Johnson & Johnson), ethylene oxide (sterilizer Getinge), and by immersion in ethanol combined with ultraviolet radiation in a laminar chamber (Alpine).

### RESULTS AND DISCUSSION

Table 1 presents are surface atomic compositions of PU/PLA films before and after sterilization, obtained from XPS studies.

Method of sterilization	Atomic concentration [%]		
	C	O	N
before	62,5	31,2	1,8
after H <sub>2</sub> O <sub>2</sub>	67,6	29,9	1,8
after EtO	65,6	32,3	1,6
after EtOH/UV	67,4	29,1	2,1

Table 1

It can be seen that sterilization caused slight enrichment of the surface in carbon, while amounts of oxygen and nitrogen depended on the sterilization method. Significant changes, however, occurred in relative amounts of C-C, C-O, C=O and O-C=O groups on the surface. All sterilization methods caused oxidation of the surface resulting in the increase of C=O groups concentration. Sputtering the surface with Ar<sub>2500+</sub> proved that only the surface undergoes oxidation, and

the deeper atomic layers were not affected. Table 2 shows the results of wettability and roughness measurements of the 80/20 PU/PLA film before and after sterilization.

Method of sterilization	$\Theta$ [°]		Ra[ $\mu$ m]	
	Top	Bottom	Top	Bottom
before	83 $\pm$ 7	75 $\pm$ 5	7,3 $\pm$ 1,3	9,2 $\pm$ 0,2
after H <sub>2</sub> O <sub>2</sub>	79 $\pm$ 8	77 $\pm$ 10	6,7 $\pm$ 0,5	9,8 $\pm$ 0,7
after EtO	98 $\pm$ 6	82 $\pm$ 7	8,2 $\pm$ 0,7	12,2 $\pm$ 2,9
after EtOH/UV	78 $\pm$ 5	57 $\pm$ 6	7,2 $\pm$ 0,6	7,3 $\pm$ 0,5

Table 2

Only in case of sterilization with cold hydrogen peroxide plasma, the value of the contact angle of the top and bottom surfaces remained almost unchanged. In contrast, ethylene oxide sterilization caused that both surfaces became more hydrophobic i.e. the contact angle increased about 15% for the top surface and 8% for the bottom surface. Sterilization with ethanol and UV radiation changed the nature of the surface to more hydrophilic. Average roughness of the top surface is substantially lower than the bottom surface of the untreated blend as well as all the samples following sterilization. None of the used sterilization methods caused significant changes in the roughness of the top surfaces. All applied sterilization methods practically did not change the surface morphology except EtOH combined with UV

radiation which smoothed the surface. Figure 1 shows SEM images of cross-sections of PU/PLA films before sterilization (a), after H<sub>2</sub>O<sub>2</sub> (b), after EtO (c), and after EtOH/UV (d).

### CONCLUSION

The low temperature hydrogen peroxide plasma did not significantly change the surface of the tested blend. The sterilization with ethylene oxide caused an increase in hydrophobicity and surface roughness. A change in surface properties is most noticeable after treatment with EtOH combined with ultraviolet radiation.

[Hans.Leemhuis@matricel.de](mailto:Hans.Leemhuis@matricel.de)

### INTRODUCTION

A variety of bioengineered nerve guides bridging the peripheral nerve defect were used experimentally and to some extent also clinically, but the clinical outcome for the treatment of larger defects is still limited. In this study we present the development of a novel two component microstructured collagen-based nerve guide from design to its first human use in a clinical study.

### EXPERIMENTAL METHODS

The novel nerve guide consists of two structural elements: An inner guiding structure for axonal regeneration “Perimaix” and a hollow outer structure replacing the epineural tube “Epimaix”, that can be sutured to the nerve ends. Both structural elements are manufactured from highly purified porcine collagen. The highly orientated Perimaix structure containing continuous, longitudinally orientated and interconnected pores is generated by a unidirectional solidification method [1]. Subsequently, the scaffolds are freeze-dried, chemically cross-linked and sterilized. The term “Neuromaix” is used to characterize the combination of Perimaix and Epimaix to bridge a peripheral nerve defect. In pre-clinical animal studies, Perimaix scaffolds without any cells and Perimaix scaffolds seeded with Schwann cells were compared against autologous nerve transplantation by bridging experimentally created supercritical defects of the sciatic nerve (2 cm) in rats.

### RESULTS AND DISCUSSION

The observed functional regeneration in this animal model initiated the design process of the Neuromaix nerve guide for human use. All essential requirements for a first clinical study were achieved and the clinical study with Neuromaix was approved and started. In this study, the medial sural nerve of patients undergoing a diagnostic nerve biopsy ( $\geq 2$  cm) is bridged by implantation of the microstructured nerve guide Neuromaix.

### CONCLUSION

Neuromaix demonstrated an improved tissue regeneration, due to the scaffold architecture which directs the cell migration and extra cellular matrix formation along the regeneration axis. So far, only a very limited number of bioengineered nerve guides have been studied successfully in humans and the step from preclinical work to a clinical application is very challenging. The Neuromaix clinical study will demonstrate the regenerative potential of this novel nerve guide.

## INTRODUCTION

Shape memory polymers and their composites are capable of adopting temporary shapes and recovering to the permanent shape upon an external stimulus. In recent years, SMPs have received increasing interest due to some unique advantages over other shape memory materials because of lightweight, low cost, low density, good manufacturability, high shape deformability and good biodegradability [1-2].

Biodegradable polymer composites are an emerging family within the field of smart materials and hold exciting potential as responsive biomaterials [3]. We investigated shape-memory poly(glycerol sebacate urethane) (PGSU) / cellulose nanocrystal (CNC) composites to assess their suitability as tendon specific biomaterials.

## EXPERIMENTAL METHODS

PGS pre-polymer was synthesized through the polycondensation process of equimolar amounts of glycerol and sebacic acid and crosslinking step. After polymer processing, desired amounts of the DMF solution of PGSU pre-polymer (pre-PGSU) and the CNC dioxane suspension were weighed and mixed under sonication for 30 minutes. The mixture was then cast onto a glass petri-dish to evaporate the solvent and to further crosslink the pre-PGSU into PGSU.

## RESULTS AND DISCUSSION

The presence of CNCs improved the tensile strength of PGSU, for the PGSU-CNC nanocomposite due to the strong interfacial interactions between CNCs and PGSU determined by FTIR. In addition, formation of a strong percolation network of CNCs in the matrix leads to enhancement of elastic modulus.

The incorporation of CNCs into PGSU induced the PGSU-CNC nanocomposites with shape-memory effects. The shape recovery became stable after the first three wetting-stretching drying cycles, owing to the elimination of the sample processing history and alignment of CNCs.

Figure 1. Water-active shape-memory effect of pre-treated composite

*In vitro* degradation results showed the PGSU nanocomposite showed the weight loss in an enzymatic PBS condition, which is lower than that for neat PGSU.

## CONCLUSION

Mechanical properties and water-responsive shape-memory performance of PGSU-CNC nanocomposites were investigated, which are dependent on the content of CNCs.

This work provides an approach to the preparation of enzymatically degradable polymer nanocomposites with water-active shape-memory that have potential for tendon regeneration.

## Electrochemical Study of Uncemented Hip Endoprosthesis Cups

Wojciech Kajzer<sup>1</sup>, Anita Kajzer<sup>1</sup>, Ola Grzeszczuk<sup>1</sup>, Jacek Semenowicz<sup>2</sup>, Adam Mroczka<sup>2</sup>

<sup>1</sup> Department of Biomaterials and Medical Devices Engineering, Faculty of Biomedical Engineering, Silesian University of Technology, Poland

<sup>2</sup> Dr Janusz Daab Independent Public Regional Hospital of Trauma Surgery in Piekary Slaskie, Poland  
[Wojciech.Kajzer@polsl.pl](mailto:Wojciech.Kajzer@polsl.pl)

### INTRODUCTION

Due to the fact that hip endoprosthesis is a long-term implant it is important to have appropriate mechanical and tribological features, above all, to have appropriate biocompatibility which is directly connected with corrosion resistance of the implant<sup>1</sup>. Therefore, for the metal biomaterials and for implants produced from those materials, electrochemical tests are conducted in order to evaluate the influence of tissue environment and body fluids on the pitting corrosion resistance<sup>2,3,4</sup>. As is well known, products of corrosion can have a negative influence on human body and can result in metal toxicity.

### EXPERIMENTAL METHODS

In the research uncemented hip endoprosthesis cup, covered with hydroxyapatite were used: No. 1 - new and No. 2 - cup after 68 months of implantation produced from high nitrogen stainless steel Cr-Ni-Mo which chemical composition and mechanical features are compatible with recommended ISO 5832-9 standards. The research was carried out on internal (Int.) and external (Ext.) surfaces. The test of pitting corrosion resistance was carried out with the use of the VoltaLab® PGP 201 system. As a result of the tests on the basis of designated polarization curves, mean values and standard deviation (SD) of corrosion potential  $E_{corr}$ , breakdown potential  $E_b$ , repassivation potential  $E_{rp}$  and polarization resistance  $R_p$  were determined. In order to obtain additional information on physiochemical properties electrochemical impedance spectroscopy - EIS was conducted. Measurements were taken using AutoLab's PGSTAT 302N measurement system. On this basis numerical values of resistance  $R$  and capacity  $C$  of the analysed systems were determined. Impedance spectra of the tested system were presented in the form of Nyquist and Bode's diagrams. The obtained EIS spectra were interpreted after they had been adjusted according to the method of the smallest squares to the substitute electric system with error estimation 2%-6%. All electrochemical tests were carried out in Ringer's solution having a temperature  $T=37\pm1$  °C, pH = 6,9 $\pm$ 0,2.

### RESULTS AND DISCUSSION

The sample results of the corrosion test were presented in the table 1. The increase of the values of corrosion potential and polarization resistance for the cup after implantation was stated, which is a beneficial phenomenon. The EIS results prove the outcome of the potentiodynamic tests and demonstrate the presence of double oxide film of capacitive nature on the surface of the cups – fig. 1 and 2, protecting the implant from corrosion

Surface		E <sub>corr</sub> , mV	SD, mV	E <sub>b</sub> , mV	SD, mV	R <sub>p</sub> , kΩcm <sup>2</sup>	SD, kΩcm <sup>2</sup>
1	Int.	-120	±4	1230	±12	61	±10
	Ext.	-139	±53	1242	±18	23	±13
2	Int.	-24	±31	1172	±204	279	±30
	Ext.	-47	±29	1081	±108	75	±33

Table 1 Sample results of pitting corrosion resistance test

Fig. 1. Sample impedance spectra for cup No.2 int.: a) Nyquist graph, b) Bode's diagram, c) electric substitute schemes

The steel with increased content of nitrogen compatible with recommended ISO 5832-9 standards, from which the tested cups were made, has a better corrosion resistance than steel Cr-Ni-Mo compatible with ISO 5832-1 standards because characteristic for this type of steel hysteresis loop was lower on the polarization curves<sup>2,4</sup>.

### CONCLUSION

On the basis of conducted research, it can be stated that both, polished internal surface and external surface covered with hydroxyapatite, are efficient barrier protecting the implant from the influence of the body fluids and its usage does not lead to decrease of biocompatibility described by corrosion resistance and EIS in comparison with the initial state. What is more, it was observed that, despite the necessity to remove the cup caused by their loosening, no significant differences were recorded in the analysis of parameters proving their corrosion resistance and consequently, their biocompatibility.

## INTRODUCTION

Many biological processes depend on specific interactions between glycoproteins and lectins, including cell-cell communication, binding of toxins and pathogenic infection. Synthetic glycopolypeptides are a useful tool to investigate those processes, since they can mimic properties of glycoproteins (e.g. form secondary structures) and are relatively easy of access compared to natural glycoproteins. Glycopolypeptides can be prepared by the polymerization of glycosylated monomers or by post-polymerization glycosylation in organic solvents.<sup>1,2</sup> These methods are often restricted to monosaccharides but in most biological interactions more complex sugars are involved. A recent publication demonstrates a way with mild reaction conditions using aqueous amide coupling.<sup>3</sup> Using this approach disaccharides (e.g. maltobiose, cellobiose) were coupled to a poly-( $\alpha$ ,L-glutamic acid) scaffold and compared with the corresponding monosaccharides.

## EXPERIMENTAL METHODS

Poly( $\alpha$ ,L-glutamic acid)-precursors (PGA) were obtained by acidic hydrolysis of poly-( $\gamma$ -benzyl-L-glutamate). 1-Deoxy-1-amino saccharides were synthesized by KOCHETKOV-amination and coupled to the PGA scaffold via aqueous amide coupling with 4-(4,6-dimethoxy-1,3,5-triazin-2-yl)-4-methylmorpholinium chloride (DMT-MM).<sup>3</sup>

Secondary structures were determined via CD spectroscopy at ambient temperature.

Biological activity was tested via isothermal titration calorimetry measurements (ITC) as well as via quantitative precipitation assays with concanavalin A. The amount of precipitated ConA per glycopolypeptide was determined via UV-Vis spectroscopy.

## RESULTS AND DISCUSSION

**Scheme:** Amide-coupling of maltosylamine to PGA-Na

The sugar density on the PGA scaffold is adjustable via the amount of DMT-MM used. For maltobiose (MB) and glucose (Glu) DS up to 80 %, and for cellobiose (CB) DS up to 74 % are possible.

CD-spectroscopy revealed that the PGA scaffold shows a pH-dependent helix-coil transition close to pH 5 with a maximum helicity of 80 % at pH 3.

The glycosylated PGAs also show helix-coil transitions up to a sugar density of 64 % (MB). However, the transition point shifts with increasing amount of sugar to more acidic pH values along with a decrease in helicity. For high sugar densities no helix-coil transition could be observed. PGA-CB and PGA-Glu have a slightly higher helicity compared to PGA-MB for all tested sugar densities.

Quantitative precipitation assays were performed with PGA-MB and ConA (Figure). Both glycopolypeptides interact with the lectin and precipitate ConA.

**Figure:** Quantitative Precipitation assay of PGA-MB DS 0.64

The number of ConA molecules precipitated per polymer is 3 (DS = 64 %) and 3.4 (DS = 80 %), respectively. An increase in sugar density leads to a small increase in the amount of precipitated lectin per polymer chain. PGA-MB (80 % DS) was used for ITC-measurements obtaining an equilibrium binding constant of 36 nM. This indicates affinity enhancement due to glycoside clustering.

## CONCLUSION

Well-defined, pH-responsive glycopolypeptides were prepared by post-polymerization glycosylation of poly( $\alpha$ ,L-glutamic acid) with 1-deoxy-1-amino sugars using the amide coupling agent DMT-MM in aqueous media. The glycopolypeptides showed pH-dependent helix-coil transition up to sugar densities of 64 % (CB), 62 % (Glu) and 55 % (MB), respectively. Precipitation of the lectin ConA as well as ITC measurements demonstrates biological activity.

## INTRODUCTION

Shape memory alloys NiTi type are becoming increasingly used in medicine due to their unique properties, such as shape memory and superelasticity. However, their high nickel content and corrosion in given circumstances [1] raises the need for surface modification in order to reduce the phenomenon of metallosis and enhance biocompatibility dedicated to particular applications. Significantly, various methods of surface engineering, which could improve a resistance for degradation and increase biocompatibility, carried out in temperature over 300°C destroy the alloy specific features [2]. Thus, low-temperature plasma oxynitriding process, similarly as nitriding [3] should offers unique possibilities to keep NiTi alloy complex properties. Preliminary studies indicated that it significantly improves the corrosion resistance of NiTi alloy [4]. Therefore, the aim of this work is to investigate the biological properties of the oxynitrided layers produced on the NiTi shape memory alloy in terms of use for bone implants.

## EXPERIMENTAL METHODS

NiTi shape memory alloy (50.8% Ni) was investigated. The glow discharge oxynitriding process was conducted at a temperature of 290°C in two stages: 30 min. of the nitriding and 15 min. of the oxidizing. Time of oxidizing was set on basis of the results of corrosion resistance investigations in Ringer solution [4]. The surface topography before and after the process was determined by SEM and AFM microscopic observation and optical profilometer use. Biocompatibility was assessed in terms of the adhesion and proliferation of osteoblast from cell line Normal Human Osteoblasts cultured on the surface of the tested samples for 2 hours (adhesion), and 24, 48 hours and 6 days (proliferation) at 37°C and tested under SEM.

## RESULTS AND DISCUSSION

The produced TiO<sub>2</sub> + TiN surface layer on NiTi alloy have increased surface roughness in comparison to NiTi alloy in initial state (Fig. 1). This was followed by a significant increase in the number of adhered osteoblasts on samples with a oxynitrided layer after 2 hours of incubation, as well as by increased cell proliferation in subsequent stages of culture (Figure 2). Osteoblasts on oxinitrided surface layers were multiform with numerous filopodia, that allowed them come into contact with each other.

The positive osteoblasts response to oxinitrided surface layer should also be considered in relation to the increased NiTi alloy corrosion resistance, which has an impact on the reduction of the metallosis effects which is

the migration of toxic nickel ions into the biological environment [4].

Fig.1. AFM image of the surface of NiTi alloy before (a) and after (b) oxynitriding process; area 1x1 μm.

Fig. 2. Adhesion (a) and proliferation of osteoblasts (b) on NiTi alloy in the initial state and with a layer of TiO<sub>2</sub> + TiN

Our findings are consistent with known effect of the surface topography on absorption of the proteins determining both platelets adhesion and proliferation of osteoblasts [5].

## CONCLUSION

Oxynitriding under glow discharge process conducted in the temperature of 290°C enhances the biocompatibility of NiTi alloy by improving the corrosion resistance and increasing surface roughness. Therefore, this method provides the possibility of application of NiTi alloy as material for bone implants.

[swipada@hotmail.com](mailto:swipada@hotmail.com)

### INTRODUCTION

Thiolated polymers have been interested for drug delivery due to the higher mucoadhesion by the forming disulfide bonds with mucus<sup>1</sup>. The various thiolated polymers were developed and used for drug delivery<sup>2</sup>. However, there is a lack of reports that indicate the application of thiolated chitosan (CS-SH) as a nanomaterial for mucoadhesive drug delivery. Thus, this study focused on the preparation and evaluation of CS-SH nanofiber mats.

### EXPERIMENTAL METHODS

#### Synthesis of CS-SH

The CS-SH was synthesised following the previous study<sup>3</sup>. Briefly, the cysteine were activated by 150 mM EDAC and then added into chitosan (CS, MW 110 kDa, DD 0.85, Sigma-Aldrich Chemical Company, USA) solution. After stirring for 6 h, the CS-SH was isolated by dialysing and lyophilised. The amount of thiol groups on the CS-SH was determined with Ellman's reagent.

#### Preparation of electrospun nanofiber mats

CS (2% w/v) or CS-SH (2-5% w/v) was dissolved with EDTA solution at the weight ratio of CS: EDTA (2:1). The CS or CS-SH solution was mixed with 10% w/v PVA solution at weight ratios of 30:70. The solution's viscosity and conductivity were measured before preparing the nanofiber mats via the electrospinning process.

#### Morphology characterization

The morphology of nanofiber mats were examined using SEM (Camscan Mx2000, England). The diameter of nanofiber mats was determined using image analysis software (JMicroVision V.1.2.7, Switzerland).

#### Mucoadhesive study

The mucoadhesive force of the CS-SH and CS nanofiber mats onto porcine buccal mucosa was carried out by a texture analyser (TA.XT plus, UK). The nanofiber mat was attached to the mucoadhesive probe. The probe with mat was put in contact with the buccal mucosa with 3 g of force for 1 min, and the mat was then withdrawn. The force required to separate the nanofiber mats from the tissue was recorded.

### RESULTS AND DISCUSSION

The CS-SH which contained  $469.75 \pm 2.82$   $\mu\text{mol}$  thiol groups/g of polymer was successfully prepared the nanofiber mats. Fig.1 (b-e) displays the morphology and diameter of CS-SH nanofiber mats. The increased concentration of CS-SH caused the increase diameter and the appearance of beads due to the increase of viscosity and conductivity of solution.

**Figure 1** SEM images and diameter of (a) 2% CS, (b) 2%, (c) 3%, (d) 4% and (e) 5% CS-SH nanofiber mats.

The mucoadhesion force of CS-SH nanofiber mats slightly increased when the concentration of CS-SH of electrospinning solution was increased (Fig.2a). This was due to the higher thiol groups to form disulphide bonds with the cysteine rich of the mucus glycoprotein. However, there were no significant differences between the concentrations of CS-SH on the mucoadhesion force. This indicated that the use of 2% CS-SH should be sufficient to improve mucoadhesion. Also, morphology of 2% CS-SH mats was smooth without the bead formation. Thus, the 2% CS-SH was the optimal concentration for nanofiber mats. Compared to 2% CS nanofiber mat, the mucoadhesive force of CS-SH mats was two times higher than CS mats (Fig. 2b).

**Figure 2** Mucoadhesive forces of (a) the various concentrations of CS-SH nanofiber mats and (b) 2% CS and CS-SH nanofiber mats.

### CONCLUSION

CS-SH was successfully prepared the nanofiber mats with a smaller diameter and good mucoadhesion. Thus, CS-SH has the potential to be a material of nanofiber mats for mucoadhesive drug delivery.

## Zwitterionic Polyampholyte as a Novel Inhibitor of Lysozyme Aggregation

Robin Rajan, Kazuaki Matsumura

School of Materials Science, Japan Advanced Institute of Science and Technology, Japan  
[robinrajan2004@gmail.com](mailto:robinrajan2004@gmail.com)

### INTRODUCTION

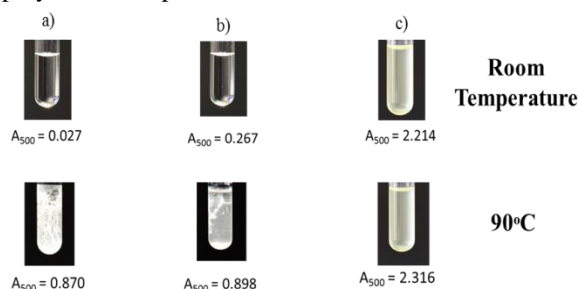

Protein instability in the form of protein aggregation is one of the major deterrents in the further growth of biopharmaceutics. It leads to an array of harmful effects including cellular effects like mitochondrial dysfunction, cell death, etc. and also trigger dreadful neurodegenerative diseases such as Alzheimer's Parkinson's, Prion's, Amyotrophic lateral sclerosis (ALS), etc.<sup>1</sup> Over the years, large number of organic compounds and protein engineering techniques has been employed for thermal inhibition of lysozyme aggregation with relatively good success but very high efficiencies have not been achieved yet. Polymers, especially synthetic polymers, have not been employed for such work with high efficiencies. In this report, we have developed a facile synthesis of a polyampholyte for thermal aggregation inhibition of chicken egg white lysozyme, with very high efficiency.

### EXPERIMENTAL METHODS

Poly-sulfobetaine (poly-SPB) was synthesized via reversible addition fragmentation chain transfer (RAFT) polymerization.<sup>2</sup> Polymer kinetics and control of its living nature was studied by using <sup>1</sup>H-NMR and infrared spectroscopy. Protein aggregation was observed visually, and quantitatively it was estimated using Thioflavin T. Aggregation was also observed by circular dichroism spectroscopy. The residual enzymatic activity of lysozyme was examined using gram positive cells, micrococcus lysodeikticus. Conformational states of lysozymes were also evaluated after heating by employing <sup>1</sup>H-NMR.

### RESULTS AND DISCUSSION

Lysozyme when heated in the absence of any additive displayed aggregation with 10-15 minutes whereas in the presence of poly-SPB, no aggregation was observed even after heating for an extended period of time (Fig. 1). Its efficiency was higher than its corresponding monomer also, due to more efficient interaction of polymers with proteins.

**Figure 1** Photographs of lysozyme in PBS at room temperature (top) and 90°C (bottom); a) without any additive; b) with 10% SPB; c) with poly-SPB. Numbers below indicate the absorbance value at 500nm.

Interaction between the lysozyme and the polymer was found to be electrostatic as revealed by zeta-potential measurements. Transmission electron microscopy images revealed the formation of amyloid fibrils on heating, which was then quantitatively analysed by employing Thioflavin T. The results demonstrated that poly-SPB effectively inhibits the formation of amyloid fibrils and its efficiency was found to be higher than some of the commercially available reagents also. Lysozymes retained very high enzymatic activity when heated in the presence of Poly-SPB. The study of the conformational states of lysozymes revealed that poly-SPB stabilizes the partial higher order structure of lysozyme during heating as all the amino acid residues present in the secondary structure were retained (Fig. 2), which in turn leads to the solubility of lysozyme at such elevated temperature.

**Figure 2** <sup>1</sup>H NMR spectra of a mixture of lysozyme mixed with poly-SPB at room temperature and after heating.

### CONCLUSION

Zwitterionic polyampholytes can be employed as efficient inhibitors of thermal aggregation of lysozyme. This is the first report where a zwitterionic polyampholyte has been employed for protein aggregation inhibition. Poly-SPB stabilizes lysozymes and preserves its higher order structure. Also, the solubility of lysozyme in the presence of poly-SPB was retained even at higher temperature which led to inhibition of lysozyme aggregation. Amyloid fibril formation was also suppressed.

## pH Dependence of Disruption of Liposomal Membranes by Artificial Lytic Peptide

Ayumi Kashiwada, Masaki Mizuno, Iori Yamane, Jun-ichi Hashimoto

Department of Applied Molecular Chemistry, Graduate School of Industrial Technology, Nihon University, Japan  
[kashiwada.ayumi@nihon-u.ac.jp](mailto:kashiwada.ayumi@nihon-u.ac.jp)

### INTRODUCTION

Lytic peptides have capability to disrupt lipid membranes. For example, melittin has a cationic C-terminal segment and a hydrophobic helical segment, and the cationic segment interacts with membranes and the hydrophobic helical segment disturbs the order of the membrane components to disrupt the membrane structure.<sup>1</sup> This bi-functional lytic activity of melittin has attracted a good deal of attention in constructing novel antibiotics. On the other hand, many scientists have been interested to design melittin-like artificial lytic peptides, because lytic peptides that respond to acidic pH can be utilized in liposomal DDS, since acidification of endosomes triggers membrane lysis to release the drugs from liposomes.

In this study, we report the design, synthesis, and characterization of an artificial lytic peptide (LP) and the novel designed pH-selective lytic peptides. Then, we discuss the results of analyses of the lytic potential of the peptide to induce leakage of liposomal contents.

### EXPERIMENTAL METHODS

**Peptide Synthesis:** The peptides with a C-terminal carboxyamide were all prepared from Fmoc solid-phase synthesis by using Fmoc-NH-SAL resin.

**Preparation of Calcein-Loaded Liposome:** Dried films of EggPC were hydrated in a calcein solution for 1 h. Then, the lipid suspension underwent the freezing-thawing process and the extrusion through a 100-nm pore sized polycarbonate filter. Non-encapsulated calcein was removed through the size exclusion chromatography column charged with a Sephadex G-25.

**Liposome Leakage Assay:** EggPC liposomes (0.2 mM) were loaded with the high concentration (90 mM) of calcein. All samples were excited at 490 nm and the emission at 530 nm was monitored for 25 min. The first 5 min of each measurement was monitored before the addition of peptide to confirm the presence of a stable baseline (0% leakage). Two  $\mu$ M of peptide was added to the sample and the calcein leakage was monitored for 20 min. To calibrate the fluorescence scale, the fluorescence intensity of calcein leaked when Triton X-100 was added to the sample was regarded as 100%.

### RESULTS AND DISCUSSION

The amino acid sequence of a typical membrane-lytic peptide (LP) is shown in Figure 1. LP has 26 amino acid residues composed of a hydrophobic helical segment (membrane interactive Leu-Ala repetitive sequence<sup>2</sup>) and a hydrophilic segment. We also designed acidic pH-selective lytic peptides (Figure 1). Our concept is to design pH-selective peptides with a hydrophobic helical segment of LP. We have replaced leucine residues with glutamic acid. This substitution is expected to cause a structural change from a

hydrophilic random coil at neutral pH to a hydrophobic  $\alpha$ -helix in an acidic pH range. This structural change would have a crucial effect on the lytic activity.

Figure 1 Amino acid sequence of artificial membrane lytic peptides used in this study.

The results of the leakage assay for characterizing pH-dependent membrane-lytic activity of designed peptides are shown in Figure 2. Acidic pH-selective membrane lysis was observed upon addition LPE3-1 to liposomes.

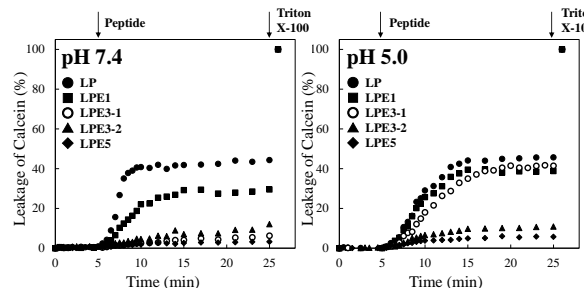

Figure 2 Kinetics of peptide induced calcein leakage.

These results indicate that replacement of three glutamic acids endows the hydrophobic segment with a suitable pH-sensitivity. Moreover, it also seems to be important to place three glutamic acids in the center of the hydrophobic segment. Thus, we consider LPE3-1 an ideal lytic peptide and a promising drug release tool for the liposomal DDS vehicle.

### CONCLUSION

We have succeeded to design and to synthesize weakly acidic pH-selective membrane-lytic peptides. Especially, LPE3-1 with a hydrophobic segment in which three leucine residues are replaced by glutamic acid ones exhibits a weakly acidic pH-controlled membrane-lytic activity. The present approach may pave the way to gain a deeper understanding of peptide-lipid interactions and their role in cell biological and pathological processes, with the potential of yielding new strategies for therapeutic applications.

[patrick.booms@kgu.de](mailto:patrick.booms@kgu.de)

### INTRODUCTION

The aim of the present study was the analysis of the *in vivo* (inflammatory) tissue response to a biphasic 3D-printed scaffold, combining two layers, i.e., a pure PLA component and a PLA/G5 component, with special focus on implant bed vascularization induced by multinucleated giant cells, with special focus on the bioactive glass component. Scaffolds of PLA and PLA/G5 alone were used as respective control materials. A further aim of this study was the evaluation of this model, which could assist reduction in the number of experimental animals required – in accordance with the principle of the 3Rs (Replacement, Reduction and Refinement).

### EXPERIMENTAL METHODS

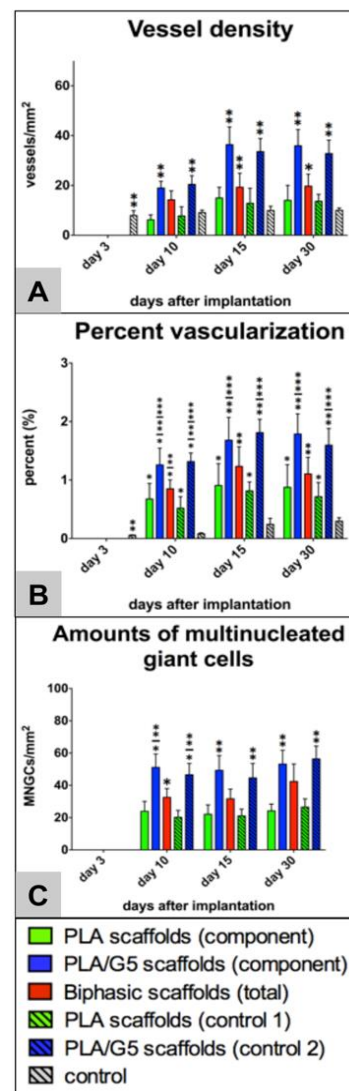

For this study an established subcutaneous implantation model was used in 60 female 6-8 week-old CD-1 mice<sup>1-3</sup>. Established histological and histomorphometrical methods were applied<sup>1-3</sup>.

### RESULTS AND DISCUSSION

In addition to the pure PLA control, and the separate PLA/G5 test samples, biphasic scaffolds PLA-PLA/G5 were included. The tissue reaction to the PLA component included low numbers of multinucleated giant cells and minimal vascularization of its implant beds (Fig. 1), which suggest a mild severity of a material-related foreign body response. In contrast, the addition of G5 particles (PLA/G5) induced a tissue reaction with the involvement of higher numbers of multinucleated giant cells and also a markedly higher implant bed vascularization (Fig. 1). Furthermore, these results were substantiated in the biphasic scaffolds, as only the PLA/G5 segment showed the increased multinucleated giant cell infiltration and the correspondingly higher vascularization response.

### CONCLUSION

Bioactive glass (G5) induced an increase in the number of multinucleated giant cells and subsequently higher vascularization of the implant bed. Further studies are required to establish the influence of potential additional components, e.g. therapeutic ions on multinucleated giant cell-induced vascularization. Furthermore, the use of such biphasic scaffold represents a suitable platform to study the influence of G5 particles on the induction of multinucleated giant cells in the implant bed and subsequent vascularization. Moreover, this model could help reduce the number of experimental animals required.

**Fig. 1** Shows the results of the histomorphometrical analyses.

## INTRODUCTION

Quantum dots are broadly used for industry and health application because of their excellent features [1, 2]. A wide range of chemical and physical methods has been used to synthesise quantum dots. However, different kind of chemical pollutants have been left to the environment. Biosynthesis of nanomaterial is determined as eco-friendly technology to reduce the toxicity of materials and amount of used chemicals. In recent years, studies focused on this topic have accelerated [3-5]. Researchers have obtained the QDs by using plant extract extracts as a source of reductants [6]. It is known that plants generate Cd-S complex to reduce the toxicity of Cd [7]. From this point of view, in this study CdS QDs (Cadmium Sulphide Quantum Dots) was obtained by the aquatic plant extract (*Mentha aquatica* L.) when reacted with a mixture of CdCl<sub>2</sub> and Na<sub>2</sub>SO<sub>3</sub>.

**Keywords:** Biosynthesis; CdS quantum dots; *Mentha aquatica*; bactericidal activity; XRD

## EXPERIMENTAL METHODS

### Synthesis of CdS QDs

In our study, CdS QDs was obtained using the method of Prasad and Jha [5]. Briefly, dried leaves (5 g) were surface cleaned with distilled water, boiled in distilled water for 20 min and filtered through Whatman No.1 filter paper. 5 ml leaf extract was added into 50 ml cadmium chloride (2 mM) solution. Sodium sulfide (50 ml, 2 mM) dissolved in deionized water was added drop wise into the solution of cadmium chloride under magnetic stirring. The mixture was mixed at 200 rpm, 30 °C for 12 h in dark condition.

### Characterization

Obtained QDs were characterized by UV-visible spectroscopy, scanning electron microscopy (SEM), X-ray diffraction (XRD), dynamic light scattering (DLS), transmission electron microscopy (TEM) and Fourier Transform Infra-Red spectroscopy (FTIR).

### Antimicrobial activity

The agar diffusion method was used for the determination of antimicrobial activities of the Cd QD's. *Escherichia coli* O157 was selected as test organism. 250 µl of *E. coli* was added into a flask containing 25 mL sterile Mueller–Hinton agar at 45 °C and poured into Petri dishes. In the agar, four equidistant holes were made and loaded with 25 µg/mL (50 µl) of the solution. Petri dish was incubated at 37 °C for 18-24 h. At the end of the period, petri dish was examined for zones of growth inhibition, and the

diameters of these zones were measured in millimeters.

## RESULTS AND DISCUSSION

UV-visible spectrum of the aqueous medium peaked between 320-360 nm corresponding to the absorbance of CdS (Fig. 1). XRD results confirmed the formation of CdS. Dynamic light scattering results showed size of CdS quantum dots are in the range of 32-52 nm (Fig 2). Zeta potential of CdS was found to be -12.9 mV (Fig. 3), so it indicates the moderate stability and dispersion. Besides, CdS QDs showed excellent bactericidal activity against pathogenic bacteria *E. coli*.

## CONCLUSION

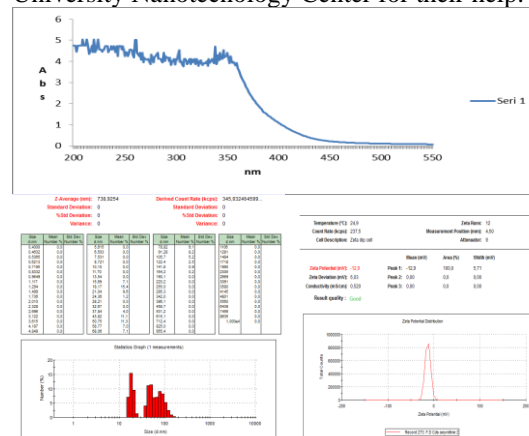

The herbal based fabrication provides an economical, green chemistry approach for production of CdS quantum dots.

## Design of Multilayer Collagen-based Systems for *in situ* Drug and/or Cell Release

Diogo F.L. Rodrigues, Teresa Russo, Ugo D'Amora, Olimpia Oliviero, Antonio Gloria, Roberto De Santis, Luigi Ambrosio

Institute of Polymers, Composites and Biomaterials, National Research Council of Italy, V. le J.F. Kennedy - Pad. 20, Mostra d'Oltremare, 80125 Naples, Italy  
[diogo.lopesrodrigues@gmail.com](mailto:diogo.lopesrodrigues@gmail.com)

### INTRODUCTION

Over the past years, hydrogel-based materials such as patches or injectable devices for *in situ* drug or cell release have been widely studied. In the treatment of cardiovascular disease (CVD)<sup>1</sup>, a natural mimic hydrogel construct should play an important role as a reservoir system to deliver multiple biomolecules to targeted ischemic sites. The aim of the present study was to propose a preliminary approach in the design of a multilayer hydrogel based on collagen/collagen–gelatin nanoparticles (GNPs)/collagen-low molecular weight hyaluronic acid (LMWHA). The viscoelastic properties, as well as the morphological/biological features of the developed systems were preliminary assessed.

### EXPERIMENTAL METHODS

Three-layer systems were suitably developed through the integration of a conventional method and an electrospray-based technique. Each system consisted of a lower collagen layer, an upper collagen or collagen-LMWHA layer, and a middle GNP-loaded collagen layer.

Schematic representation of the multilayer collagen-based system

Small amplitude oscillatory shear tests were performed on all the developed systems and the linear viscoelastic behaviour was investigated. All of the tests were carried out at a temperature of 37°C, using a rheometer (Gemini, Bohlin Instruments). The viscosity as a function of the shear rate was evaluated through steady state shear measurements at a temperature of 37°C in a wide range of shear rate (0.01 – 100 s<sup>-1</sup>). Scanning Electron Microscopy (SEM) was performed to assess the morphological features of GNPs and collagen-based networks with a great attention on the middle layer. MTT assay and further SEM analyses were also carried out on cell-laden constructs.

### RESULTS AND DISCUSSION

Results from small amplitude shear tests highlighted that the values of both dynamic moduli generally increased with frequency, and G' values were always higher than G'' ones in the frequency range investigated. A shear thinning behaviour was evidenced for all the proposed systems, as the viscosity decreased with increasing the shear rate. MTT assay provided interesting results in terms of MSC viability/proliferation. SEM analysis showed the influence of GNPs on the structural/morphological features of the collagen-based network (i.e., fibrils diameter) and the effect of collagen-LMWHA layer on cell adhesion and spreading.

### CONCLUSION

A preliminary approach in the design of patches and injectable multilayer hydrogels was proposed. The possibility to tailor the structural/morphological features and the rheological properties of the multilayer hydrogels was also highlighted. In particular, regarding the upper layer the presence of LMWHA acted as a “reinforcement”, as well as in the case of structures loaded with a specific amount of GNPs. Furthermore, the presence of collagen-LMWHA layer influenced cell adhesion and spreading.

## INTRODUCTION

The standard method to produce bioactive glass is by melting a mixture of oxides, carbonates and phosphates and then quenching the molten liquid to form in most cases glass frit. Next the frit is milled to obtain powder or granules. The second way for fabricate bioglasses is the sol-gel chemical method which is based on chemical reaction: hydrolysis and polycondensations occurs in solution. These processes can be provided in the different medium: alcohol or water with different reaction catalyst and raw materials, and can affects the properties of obtained materials. In comparison to the melting sol-gel route allowed to obtain higher purity and homogeneity, and different textural parameters [1-2,4]. The present work investigated the effect of synthesis methods on the structure and properties of alkali-free bioglass. With the our best knowledge there are no in literature comparison of melted and gel-derived bioglasses with the same chemical composition, except bioactive glass 45S5, which has been studied extensively [2-3].

## EXPERIMENTAL METHODS

Alkali free glasses from the  $\text{CaO-SiO}_2\text{-P}_2\text{O}_5$  system with chemical composition  $40\text{SiO}_2$ ,  $6\text{P}_2\text{O}_5$ ,  $54\text{CaO}$  (mol%) were obtained by 1). traditional melting using chemically pure  $\text{SiO}_2$ ,  $\text{P}_2\text{O}_5$  and  $\text{CaCO}_3$  in platinum crucible at  $1500^\circ\text{C}$  – marked as A2M; 2) sol-gel method in alcohol-based solution using TEOS, TEP and  $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  – marked as A2; 3) sol-gel method in aqueous solution with the same raw materials marked as A2W. The obtained gels were converted to ceramic materials by multistage heat treatment up to  $800^\circ\text{C}$ . All materials were characterized by DTA analyses, Fourier transform infrared spectroscopy FTIR and X-ray diffraction XRD as well as density, porosity and BET surface area. The resulting materials were also subjected to the bioactivity evaluation in vitro conditions using acellular simulated body fluid (SBF).

## RESULTS AND DISCUSSION

FTIR spectra of melt-derived glass (A2M) shows bands characteristic of the vibrations associated to the silicate network at  $480$ ,  $760$ ,  $935$ ,  $1020\text{ cm}^{-1}$  derived from Si-O-Si bending mode, Si-O-Si stretching mode of bridging oxygen atoms between tetrahedrons, Si-O-Si stretching of non-bridging oxygen atoms Si-O-Si stretching of bridging oxygen atoms within the tetrahedron respectively. There is also occur band at  $566\text{ cm}^{-1}$  assigned to P-O bond in the  $\text{PO}_4^{3-}$  groups in amorphous calcium phosphate structures. For gel-derived glasses (A2, A2W) there are visible bands associated with silicate network structure, but the band at  $760\text{ cm}^{-1}$  is vanished, the band located at  $930\text{ cm}^{-1}$  became more intense and the maximum of the band connected with Si-O-Si vibration in  $[\text{SiO}_4]$  is shifted to

higher wavenumbers, which can suggest the formation of Si-O-P bonds. The bands in the range  $1420\text{-}1480\text{ cm}^{-1}$  indicate the presence of  $\text{CO}_3^{2-}$  groups.

According to X-ray diffractograms gel-derived glasses exhibit beginning of crystallization hydroxyapatite and calcium silicate phases while the A2M is amorphous.

As it is shown in the table the density and surface area of the samples are different, the higher density have gel glasses due to presence of crystalline phases.

Materials	Density [ $\text{g/cm}^3$ ]	BET surface area [ $\text{m}^2/\text{g}$ ]
A2M	$2,785 \pm 0,005$	$0,265 \pm 0,007$
A2	$2,924 \pm 0,006$	$38,36 \pm 0,09$
A2W	$2,939 \pm 0,007$	$59,21 \pm 0,09$

The higher surface area results from the specificity of sol-gel process. To the bioactivity SBF test melted glass was used as a polished glass plate, while the gel-derived glasses were pressed to the pellets form. After 7 day's immersion time the surface of samples were analyzed. The surface of all glasses are fully covered with calcium phosphate layer, but the its morphology are different. The A2M surface is covered by uniform, smooth coating while the layer on gel-derived glasses exhibit cauliflower - like microstructure.

Fig. 1. Microstructure of the coating of bioactive glasses formed after immersion in SBF.

## SUMMARY

Our study demonstrate that the structure of melted glass was more polymerized then gel-derived ones. Additionally gel glasses show beginning of crystallization during heat treatment. Morphology of apatite layer formed after incubation in SBF depends on material form as well as synthesis method.

### INTRODUCTION

Hydrogels are commonly used in medicine, pharmacy, and tissue engineering. Due to their specific features, they are generally used for production of innovative bandaging materials. The aim of this work was evaluation of the impact of the modification of the hydrogel matrix with xanthan gum on the properties and structure of polymeric superabsorbents [1-5].

### EXPERIMENTAL METHODS

The research work included synthesis of hydrogels with different contents of xanthan gum. The scope of the research included measuring their ability to swell in distilled water and other physiological solutions. Incubation studies were also performed on synthesized samples. The biological activity of the hydrogels and their structure were analysed; the latter was performed using FTIR spectroscopy.

### RESULTS AND DISCUSSION

Acrylic-chitosan matrices of hydrogels with different amount of xanthan gum were synthesized and subjected to investigation of sorptive capabilities. The results showed that the synthesized hydrogels can swell both in distilled water and a solution of physiological salt. Due to the above, they can be used as bandage materials, allowing to absorb the effusion from the wound and keep it wet to accelerate the process of healing. Additionally, incubative studies of the synthesized samples in the distilled water, Ringer solution and artificial saliva, were also carried out. The pH value of the examined solutions did not vary significantly across hydrogel samples with different content of the xanthan gum. Moreover, no sudden changes of pH were observed, which confirms the compatibility of the obtained materials with a particular environment. Biological activity of hydrogels was also determined and the results of the studies confirmed this property in all samples. In order to explore this property further, studies on the cell lines will have to be carried out. Analysis of the polymer matrix structure of the synthesized hydrogels, before and after the incubation,

was also carried out using Fourier transform infrared spectroscopy (FT-IR).

### CONCLUSION

Incubation studies and tests of biological activity confirmed that the resulting hydrogels are active, and thus may have an impact on human tissue. With respect to this, they may be used for the production of dressings, which allow gas exchange between the wound and the environment, remove exudate with toxic compounds and provide protection of newly formed tissue. In a nutshell, wound dressings made of hydrogels could accelerate the regeneration of human tissue. This is suggested by the results of this preliminary analysis and hopefully will be confirmed by further investigations of the biological activity of the obtained hydrogels using cell lines.

## Study of Hydrogels Containing Magnetic Nanoparticles

Bożena Tylińczak<sup>1</sup>, Katarzyna Z. Gaca<sup>1</sup>, Katarzyna Bialik-Was<sup>1</sup>, Dagmara Malina<sup>2</sup>, Agnieszka Sobczak-Kupiec<sup>2</sup>

<sup>1</sup> Department of Chemistry and Technology of Polymers, Cracow University of Technology, Poland

<sup>2</sup> Institute of Inorganic Chemistry and Technology, Cracow University of Technology, Poland

[btyliszczak@chemia.pk.edu.pl](mailto:btyliszczak@chemia.pk.edu.pl)

### INTRODUCTION

Modified hydrogels have a variety of applications, including biomedical ones: they may be used for the controlled release of drugs, or for tissue engineering. Additives incorporated into the polymer structure, i.e. magnetic nanoparticles not only affect the final functionality of the material, but also can modify its properties and structure still at the synthesis stage [1-4].

### EXPERIMENTAL METHODS

The scope of the study included synthesis of acrylic hydrogels modified with magnetic nanoparticles, as well as structural analyses of the obtained hydrogel materials by means of infrared spectroscopy (FT-IR), evaluation of the surface morphology by scanning electron microscopy (SEM), research on the sorption capacity of the solutions: SBF, Ringer, Tyrode, water, 0.9% NaCl and 0.9% CaCl<sub>2</sub>, as well as degradation tests in water and simulated body fluids.

### RESULTS AND DISCUSSION

The influence of the chain length of crosslinking agents on the properties of the obtained materials was estimated. Furthermore, the study involved developing a method for obtaining hydrogel matrices containing nano-Fe<sub>2</sub>O<sub>3</sub> through photopolymerization. The absorption capacity of the obtained acrylic hydrogels was determined. Basing on the results, it was concluded that the length of the PEGDA crosslinker influences the materials' absorbency. It was also observed that the presence of nano-Fe<sub>2</sub>O<sub>3</sub> does not cause the significant decrease of swelling. The scope of the study included also the incubation studies in distilled water and simulated body fluid, which helped to determine how the hydrogel material with a given amount of magnetic nanoparticles behaves in plasma. Moreover, the structural analysis of the obtained hydrogel materials was conducted by means of infrared spectroscopy (FT-IR), which allowed to confirm the presence of the functional groups typical for this kind of material. The analysis of FT-IR spectra for the samples which had undergone incubation allowed to observe that the degradation of the obtained hydrogels containing nano-Fe<sub>2</sub>O<sub>3</sub> occurs most rapidly in the environment of Ringer's solution.

### CONCLUSION

Incubation studies in simulated body fluids and distilled water showed a change in the pH over 32 days. Modification of the polymer matrix with nano-Fe<sub>2</sub>O<sub>3</sub> significantly affects the reduction of the pH (7.5-5.0) for SBF fluid in which hydrogels crosslinked with PEGDA with  $M = 575$  and  $700$  [g / mol] were immersed. Hydrogels having greater amounts of magnetic nanoparticles yielded a pH similar to the body's natural pH (approx. 7.0). In case of Ringer's solution and distilled water, the results of the incubation test results were comparable. There was no sudden change in the pH which may adversely affect the release of the active ingredient. The addition of nano-Fe<sub>2</sub>O<sub>3</sub> is a good solution in case of biomedical applications of the received hydrogel matrices, as it influences the pH of the environment.

## INTRODUCTION

In this work, we have applied a novel reaction pathway based on mixed anhydrides for the synthesis of grafted-HA with photoreactive groups for cross-linking<sup>1</sup>. The method was used for the chemical modification of HA and demonstrated to be robust, cheap and easily upscalable.

## EXPERIMENTAL METHODS

Substituted benzoyl chlorides (BC) (**2**) were used to activate  $\alpha,\beta$ , unsaturated and aliphatic acids (**1**) yielding a mixed anhydride as intermediate (**3**). The *in situ* activation was successfully performed in a biphasic phase of water: organic solvent and uses a tertiary amine (**Figure 1a**). The mixed anhydride (**3**) reacts in the next step with the primary hydroxyl of HA (**Figure 2**). Using this reaction pathway HA can be esterified with several linkers of different reactivity which control the cross-linking rate (**Figure 1b**).

**Figure 1a.** Activation of linkers by Substituted-BC **1b**. Linkers studied in this work.

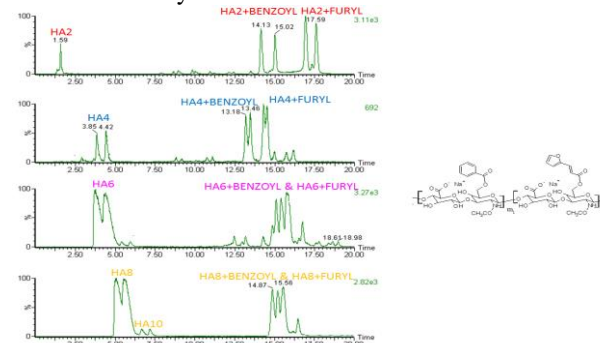

**Figure 2.** Reaction of mixed anhydride and HA

## RESULTS AND DISCUSSION

The activation of linkers (**5-11**) as depicted on Figure 2 was carried out by using 2,4,6 trichlorobenzoyl chloride (TBC), which in combination with DMAP produce acylation of primary  $-OH$  groups in HA and negligible attachment of the aromatic moiety. Benzoyl chloride (BC) a commercially available chloride is very useful from the point of view of industrial upscale due to its commercial availability and good price. Oppositely, TBC is expensive and difficult to obtain. The reaction was studied with benzoyl chloride (BC) and other activators. The reactivity of BC was found to be two times higher as compared to TBC. BC is able to produce acylation of HA even in absence of the toxic organocatalyst DMAP. In order to study the electronic effect of the substituents onto the aromatic ring some other activators were evaluated such as 4-methoxybenzoyl chloride (MBC) or 4-nitrobenzoyl chloride (NBC). The mixed anhydride (**3**) presents two

electrophilic atoms that may participate in the reaction. It is important to evaluate the reactivity of the aromatic moiety and possible grafting onto the polymeric backbone and evaluate its possible cytotoxicity. If TBC is used the nucleophilic attack have occurred exclusively on the carboxylic moiety corresponding to alkylic-carboxylic acid. Thus, the regioselectivity is controlled by steric hindrance of the chloro-substituents on the aromatic ring. Different linkers containing  $\alpha,\beta$  unsaturated bonds were tested during this development. The reaction was effective for the linkers **5,6,7,9** and **10**. On the opposite, linkers **8** and **11** characterized by the presence of a nucleophilic nitrogen atom were non-attached to the HA-backbone probably due to *N*-acylation of the linker. By a combination of steric and electronic properties, it was possible to perfectly tailor the degree of substitution (DS) and eliminate some toxic components onto the reaction feed.

In order to evaluate the feasibility of the benzoyl chloride catalysed reaction, the modified polysaccharide was enzymatically degraded and the fragments separated by chromatographic techniques (**Figure 3**). The possible cytotoxicity of active fragments (oligosaccharides) was analysed. Surprisingly, these oligosaccharides were found to increase the cell growth and were non-cytotoxic.

**Figure 3.** Characterization of fragments of linker **5** and benzoylation

## CONCLUSIONS

Different photo cross-linkable groups were attached to HA by mixed anhydride method. This method was found to be highly reproducible (up to 50g scale). Mixed anhydrides methodology is able to modify HA in a DS up to 45%. Additionally, the cyto-compatibility of the biomaterial was not affected after the chemical modification as demonstrated by the active fragments (degradation products). Thus, these materials have potential applications in biomedical field.

### INTRODUCTION

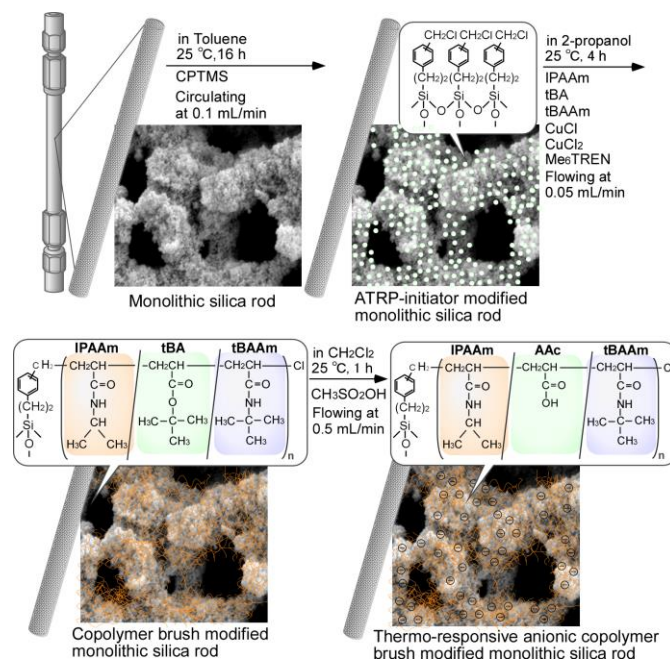

Temperature-responsive chromatography using poly(*N*-isopropylacrylamide) (PIPAAm) grafted silica beads is highly useful to control function and properties of the stationary phase for high performance liquid chromatography (HPLC) simply by changing column temperature<sup>1</sup>. In the present study, thermo-responsive anionic copolymer brushes were grafted porous monolithic silica support as an effective thermo-responsive chromatography matrices for basic biomolecules separation. Characterization of the prepared monolithic silica column was performed by observation of catechol amine and angiotensin peptides elution profiles.

### EXPERIMENTAL METHODS

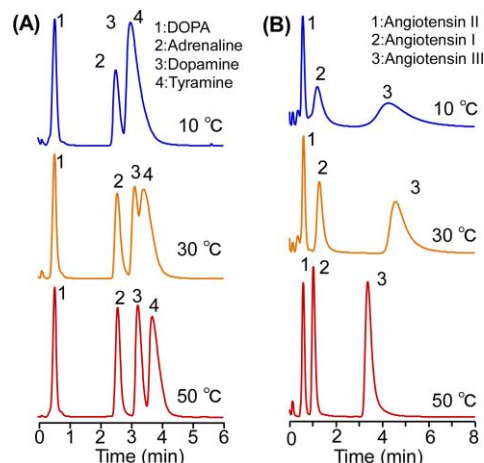

((Chloromethyl)phenylethyl)trimethoxysilane (CPTMS), ATRP-initiator, was modified on monolithic silica surfaces by flowing a toluene solution containing ATRP-initiator into monolithic silica columns. IPAAm, *tert*-butylacrylate (tBA), and *tert*-butylacrylamide (tBAAm) were grafted onto monolithic-silica-rod surfaces through surface-initiated ATRP using CuCl/CuCl<sub>2</sub>/Me<sub>6</sub>TREN as an ATRP catalytic system and 2-propanol as a reaction solution at 25 °C for 4 h (Fig.1). Then, the deprotection of *tert*-butyl group was performed with methanesulfonic acid solution in dichloromethane into the columns. The prepared thermoresponsive anionic copolymer brush modified monolithic silica rod column was connected to an HPLC system and the elution behaviour of catecholamine derivatives and angiotensin peptides were observed at various temperatures.

### RESULTS AND DISCUSSION

CHN elemental analysis and GPC measurement revealed that grafted amount and grafted density of anionic copolymer on monolithic silica were 3.33 mg/m<sup>2</sup> and 0.169 chains/nm<sup>2</sup>, respectively. These indicated that large amount of anionic copolymer was grafted on monolithic silica surface through surface-initiated ATRP. Fig.2 shows temperature dependent elution profiles of catecholamine derivatives and angiotensin peptides. High resolution separation was performed at elevated temperature, because these basic analytes interacted with copolymer brush through electrostatic and hydrophobic interaction at high temperature. Additionally, copolymer modified monolithic silica exhibits remarkable short analysis time, because of the reduced diffusion pathlength of monolithic supporting materials.

**Fig.1** Scheme of thermoresponsive anionic copolymer brush modified porous silica rod as thermoresponsive ion exchange chromatography matrices

**Fig.2** Elution Profile of catechol amine and angiotensin

### CONCLUSION

Thermoresponsive anionic copolymer brush on porous monolithic silica can effectively separate basic biomolecules. Therefore, the copolymer brush modified monolithic silica would be useful as a temperature responsive chromatographic materials.

## INTRODUCTION

Biodegradable polymers with shape memory effect present exciting possibility for development of less invasive smart medical devices. The thermoresponsive effect could allow not only to reduce the size of a medical device before implantation to a human body, but also to modulate release rate of biologically active molecules in drug delivery systems. Such materials could be utilized, for example, to fabricate drug or growth factor-eluting stents. However, the release of active molecules from polymeric delivery systems might depend on many intrinsic properties of the used polymers.

The goal of the present study was to investigate release kinetics of proteins from two novel thermoresponsive block copolymers composed of caprolactone (CL) and L-lactide (LA) and to correlate them with their thermal properties, crystallinity and wettability.

## EXPERIMENTAL METHODS

The polymers were composed of blocks of CL and LA with varying lengths (5CL-10LLA, 10CL-10LLA). To study release of growth factors, we decided to use Bovine Serum Albumin (BSA) as a model protein. BSA was incorporated into the polymers at concentration of 5 wt/wt% using water in oil emulsion technique<sup>1</sup>. Thermal properties of the polymers were characterized using Differential Scanning Calorimetry (DSC) and wettability using sessile drop technique. The release study was performed in Phosphate Buffered Saline (PBS) at 37 °C for a period of 12 days. Concentration of BSA in the supernatant was measured using micro-BCA assay according to manual supplied with the kit.

## RESULTS AND DISCUSSION

Figure 1. DSC curves of neat polymer 10CL-10LL (dashed line) and its blend with BSA (solid line).

Neat 5CL-10LL did not show a distinct melting endotherm in the CL-block range. Presence of BSA

increased crystallinity of the PCL fraction in blend 10CL-10LL\_BSA, which can be seen as a strong endothermic peak with minimum around 44°C (Figure 1). In case of 5CL-10LL\_BSA, the melting peak was much smaller and its minimum was present around 46°C.

BSA release curves are presented in Figure 2. The profiles were similar during first 24 hours of the experiment and we did not observe any burst release during that time. The release profiles started varying after 24 hours of incubation in PBS. In case of 10CL-10LL\_BSA, the release of BSA occurred in a very slow fashion, whereas 5CL-10LL\_BSA blend released the model protein at a faster rate of approximately 1% of initial load per day during first week of the experiment. This difference could arise due to lower crystallinity of the 5CL-10LL\_BSA blend and its higher hydrophilicity, both having an enhancing effect on water uptake and polymer degradation.

Figure 2. Profiles of BSA release from the 10CL-10LL\_BSA and 5CL-10LL\_BSA blends.

## CONCLUSION

Presence of the biologically active molecule can induce changes in the crystallinity of a material and shift the transition point of a shape memory material. We conclude, that crystallinity had bigger effect on the elution of BSA than the transition temperature. Current work focuses on investigation of BSA and growth factor release from thermoresponsive polymers with different compositions and their effect on biological response of MSC and HUVEC.

### INTRODUCTION

A tissue-adhesive hydrogel has been explored for medical devices such as a hemostat, adhesion barrier, wound dressing or drug release device. A film or sponge which forms an adhesive hydrogel absorbing blood or body fluid on the wet bio-tissue is useful as a hemostatic device or adhesion barrier, and some were already commercialized. Most of them are made of animal proteins such as gelatin (collagen) or fibrinogen, and risk of viral infection, bovine spongiform encephalopathy, or immunogenicity is not completely eliminated. Natural polysaccharides and their derivatives have also been utilized. However, the adhesion strength is not high, and the efficacy is limited because of their low flexibility in a dry state, and wound healing retardation properties.

We focused on a hydrogen bonding polymer complex consisting of poly(acrylic acid) (PAA), which has been known as a tissue-adhesive polymer, with poly(vinylpyrrolidone) (PVP). They are both highly safe synthetic polymers approved as pharmaceutical excipients. However, when aqueous PAA- and PVP-solutions are mixed, an insoluble precipitate soon forms. Resulting rigid gel does not swell, nor dissolve in water.

Recently, we found that solid PAA film would form a highly swollen gel by being immersed in a PVP solution. The swollen PAA/PVP complex gel was dried up to a transparent film, which could be swollen again in water to form a soft hydrogel. When it is put on a wet bio-tissue, it forms a gel absorbing body fluid, and strongly stick to it. In this study, complex-formation behavior of PAA film in PVP solution, and characteristic of the water-swallowable PAA/PVP complex was investigated. Clinical application of the tissue-adhesive hydrogel to a hemostatic agent for dental surgery was also examined.

### EXPERIMENTAL METHODS

#### Swelling behaviour of PAA film in PVP solution:

PAA solution in ethanol was poured onto a glass plate, and dried up to a film. The film on the glass was then immersed in an aqueous PVP solution to form a swollen complex gel, and changes in weight and transparency of the complex were measured.

#### Preparation of PAA/PVP complex film and sponge:

PAA solution was dried up to a clear film. PVP aqueous solution was then poured upon the PAA film to afford a swollen complex gel, which was followed by heated-air drying, or freeze-drying to give a transparent film or soft spongy sheet, respectively.

#### Swelling behaviour of PAA/PVP complex in water:

PAA/PVP complex was immersed in a buffer of pH 5 or 7, and change in weight was measured.

#### Clinical study:

Clinical study was carried out on the patients who underwent tooth extraction. PAA/PVP sponge was placed into the bleeding socket soon after the extraction, and hemostatic effect and recovery condition was observed.

### RESULTS AND DISCUSSION

#### Complex-formation behavior:

PAA film formed on a glass plate kept swelling for more than 10 hours in an aqueous PVP solution to a soft sticky hydrogel. Meanwhile, no precipitate nor clouding was observed. Swollen PAA/PVP complex hydrogel was then dried up to a transparent film. The swelling behaviour of the complex film in a buffer of pH 5 or 7 was investigated. The weight of PAA/PVP complex film in the buffer at pH 7 kept increasing for the first 100 min, and then slowly decreased. On the other hand, the film immersed in the buffer of pH 5 continued increasing in weight for more than 6 hours. Decrease in the weight in the neutral buffer would be attributed to a neutralization of the carboxyl groups of PAA, causing the dissociation of the complex to an original water-soluble polymers.

#### Clinical study:

In order to prepare the PAA/PVP complex which can be swollen rapidly, spongy PAA/PVP complex was prepared by freeze-drying the swollen hydrogel. Clinical study of the PAA/PVP complex sponge to control the bleeding after tooth extraction was performed on the patients taking anticoagulant medicine such as Bayaspirin or warfarin. The PAA/PVP sponge placed into the bleeding socket absorbed the blood, and immediately swelled to a hydrogel. It adhered to a bleeding site, and arrested the hemorrhage effectively, even in the anticoagulated patients.

### CONCLUSION

Water-swallowable PAA/PVP complex could be obtained under certain particular conditions. Excellent efficacy of the PAA/PVP complex sponge as a hemostatic device was confirmed in the clinical studies, and no adverse side effect was as yet observed.

## An Engineered Double Network Based Composite Hydrogel for a Synthetic OOKP Skirt

### INTRODUCTION

In the most severe cases of corneal and ocular disease or damage, osteo-odonto-keratoprosthesis (OOKP) surgery, a specific medical procedure also known as 'tooth in eye' surgery, can be employed in order to restore the patient's vision. The whole surgery procedure involves the removal of an autologous canine tooth and adjacent bone, which is used to support a polymethylmethacrylate (PMMA) optical cylinder, subsequently implanted beneath the oculi muscle and sutured onto the cornea.<sup>1</sup> OOKP uses a biological skirt in the form of the patient's own tooth root and alveolar bone to support a PMMA optical cylinder for the prosthesis, which makes the clinical use of OOKP very demanding and expensive. Various bioactive materials and bioinert materials such as silicone, Teflon, Dacron, poly-HEMA hydrogels and titanium,<sup>2, 3</sup> have been developed for OOKP skirt substitution. However, the majority of the devices have not proven to be ideal OOKP skirt materials because they lack suitable mechanical strength, cell adhesion and cell survival. The aim of this study was to investigate a synthetic skirt material using agarose and PEGDA interpenetrating network (IPN) hydrogel for the keratoprosthesis to replace the bone-dentine composite, which is used in the OOKP.

### EXPERIMENTAL METHODS

The primary approach taken is to use interpenetrating networks (IPNs) of agarose and poly(ethylene glycol) diacrylate (PEGDA) to provide mechanical strength while supplementing the network with hydroxyapatite (HA) coated poly(lactic-co-glycolic acid) (PLGA) microspheres in order to mimic bone micro-environment and improved cellular response. In a related approach, agarose is used as a first network to encapsulate keratocytes/3T3 fibroblasts and PEGDA is used as a crosslinker with varying molecular weights (2000 and 6000 Da) and concentrations (10, 20, and 40 wt%) to create a mechanically strong IPN hydrogel in a single synthesis step.

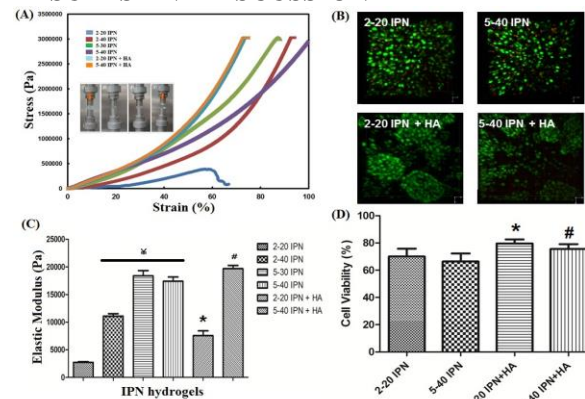

**Fig.1.** Schematic showing the formation of IPNs containing keratocytes and HA coated microspheres.

IPNs are created by encapsulating keratocytes/3T3 fibroblasts and HA coated microspheres in thermally gelling agarose, followed by soaking in a solution of PEGDA which is subsequently UV photopolymerized to form a copolymer network which interpenetrates the agarose constructs (Fig. 1). Crosslinked acellular IPN gels are made in a similar fashion but by

photopolymerizing a solution of PEGDA soaked in agarose disk without keratocytes.

### RESULTS AND DISCUSSION

**Fig.2.** Mechanical performance and cellular behaviour of 3T3 fibroblasts encapsulated in IPN hydrogels..

The elastic moduli for IPNs with the same agarose concentration were generally greater when the 6000 molecular weight PEG-DA was used, with this difference being more pronounced with increasing PEG-DA concentration. An increased concentration of either agarose or PEG-DA led to an increase in elastic modulus (Fig. 2A and 2C). However, IPNs containing 6000 molecular weight PEG-DA and 5% agarose incorporated with HA coated microspheres (5-40IPN+HA) had a higher elastic modulus than the IPN containing 2% agarose with 40% PEGDA (2-40%IPN) and 5% agarose with 40% PEGDA (5-40%IPN).

In the absence of HA coated microspheres, cell viability drops to 65% at 1 week post-encapsulation in culture. However, by incorporating HA coated microspheres within the IPN, this low viability was rescued to 78% at 1 week post-encapsulation (Fig. 2B and 2D).

### CONCLUSION

We successfully designed and synthesized a promising new class of engineered IPN hydrogel materials with a unique combination of high mechanical strength and cyto-compatibility. Tunable mechanical strength and enhanced cell viability with HA rich micro-environment are the desirable attributes of this hybrid material system, especially when used as a potential skirt material in OOKP.

## INTRODUCTION

The main goal of ongoing studies in the field of biomedicine is the attainment of biomaterials that resemble as much as possible naturally occurring mechanisms and systems<sup>1</sup>. The rate of biodegradation of the employed materials is one of the major issues. We have recently designed and synthesized an elastin-like recombinamer, cleavable by enzymes involved in tissue turnover and other mechanisms of the ECM<sup>2,3</sup>. The material is chemically functionalizable for the attainment of covalently cross-linked hydrogels, whose biodegradability is naturally controlled. The overall structure contains another recombinamer, carrying an RGD cell attachment sequence.

## EXPERIMENTAL METHODS

The iterative-recursive recombinant method<sup>4</sup> has been employed for the synthesis of the gene sequence of the enzymatically cleavable recombinamer, which has been inserted in an expression plasmid. The two recombinamers of the system have been produced in *E.coli* and purified through inverse transition cycling<sup>5</sup>. After dialysis and lyophilization, the final products have been characterized by NMR, DSC, FT-IR, MALDI-TOF and HPLC. The products have been chemically functionalized at the lysine residues of the amino acid sequences by adding an azide and an activated alkyne group. A catalyst-free click chemistry reaction for the hydrogel cross-linking has been performed in an aqueous ambient at r.t.<sup>6</sup> Rheological studies have been conducted at different recombinamer concentrations. *In vitro* proteolytic hydrolysis by matrix metalloproteinases of the degradable recombinamer in solution and in the hydrogel at a concentration of 50mg/mL has been performed. Cytocompatibility, cell adhesion and proliferation in human fibroblasts HFF1 has also been evaluated.

## RESULTS AND DISCUSSION

A stimuli responsive ELR, was synthesized, produced, purified and chemically modified. The characterization of the recombinamer confirmed the expected composition. Hydrogels have been prepared through click chemistry. Rheological results gave a storage modulus value up to 4kPa at 37°C, at different recombinamer concentrations.

Therefore, an increase in concentration shows an augmentation of the mechanical properties of the scaffold.

*In vitro* enzymatic cleavage of the recombinamer in solution proved the expected fragmentation of the polypeptide chain, and also the

hydrogel degradation with enzymes has been observed in time. *In vitro* tests with human fibroblasts confirmed cytocompatibility, as well as cell adhesion and proliferation.

## CONCLUSION

The natural provenance of the material suggests high cytocompatibility, which has also been proven for the mild catalyst-free reaction applied for the hydrogel crosslinking. The novel structure confers degradability to the scaffold it composes, by enzymes which are secreted by the cells that are aimed to colonize it. Rheological results suggest that the scaffold mechanical properties can be adjusted to different applications, as the storage modulus varies with recombinamer concentration. Further characterization of the constructed scaffold, including *in vivo* studies, is necessary in the future.

Figure 1. Scheme of the scaffold degradation by proteolytic enzymes, which brings to cell colonization and formation of new extracellular matrix

## INTRODUCTION

Hydroxyapatite ( $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$ , HA) is a member of the “apatite” compound family and constitutes the inorganic part of the bone which can be described as a kind of composite material composed of organic, i.e. collagen, and inorganic components<sup>1</sup>. It is an important issue to be able to produce HA powders in large amounts with controlled chemical composition and microstructure properties so that wet chemical precipitation technique is an ideal and simple way for this aim<sup>2-4</sup>. However, different apatite compounds can be obtained depending on the process parameters such as the dropping rate of the acid solution into the alkaline solution, reaction temperature, etc. and in this study, some of them were evaluated.

## EXPERIMENTAL METHODS

HA powders were obtained by the wet chemical precipitation technique by considering different process parameters such as the reaction temperature,  $\text{NH}_4\text{OH}$  addition, dropping rate of the acid solution, etc.<sup>5-7</sup> Calcium hydroxide ( $\text{Ca}(\text{OH})_2$ ) was used as the calcium source precursor while orthophosphoric acid ( $\text{H}_3\text{PO}_4$ ) as the phosphorus source precursor. The samples prepared were grouped in Table 1 and Table 2 depending on the order of precursor addition. Table 1 includes the samples that were produced by adding the phosphorus source to the calcium source and Table 2 contains the samples synthesized by calcium source addition to the phosphorus source. For every sample similar experimental sequence was followed which is composed of the stated steps respectively<sup>5,6</sup>: preparing 100 ml of 0,5M  $\text{Ca}(\text{OH})_2$  and 100 ml of 0,3M  $\text{H}_3(\text{PO}_4)$  solutions and reaction of these precursor solutions by applying continuous stirring, aging of the final solution and precipitation at room temperature, filtrating and washing the precipitation with distilled water, drying the precipitation at 110 °C for 2h and eventually heat treating the precipitation at 900 °C for 1h with 10 °C/min heating speed by using a high temperature laboratory furnace.

**Table 1.** Process parameters of the samples obtained by adding the phosphorus source to the calcium source.

Sample	Process Parameters
WCP-1	room temperature, without $\text{NH}_4\text{OH}$ addition, 4h stirring
WCP-2	room temperature, without $\text{NH}_4\text{OH}$ addition, rapid acid dropping rate
WCP-3	50-60 °C, with $\text{NH}_4\text{OH}$ addition, rapid acid dropping rate
WCP-4	50-60 °C, without $\text{NH}_4\text{OH}$ addition, rapid acid dropping rate

**Table 2.** Process parameters of the samples obtained by adding the calcium source to the phosphorus source.

Sample	Process Parameters
WCP-5	room temperature, without $\text{NH}_4\text{OH}$ addition, 3h stirring
WCP-6	60-70 °C, with $\text{NH}_4\text{OH}$ addition, 6h stirring
WCP-7	60-70 °C, without $\text{NH}_4\text{OH}$ addition, 6h stirring
WCP-8	room temperature, without $\text{NH}_4\text{OH}$ addition, 6h stirring

## RESULTS AND DISCUSSION

Crystal phases (Table 3) were determined by utilizing the X-Ray Diffraction (XRD) analysis.

**Table 3.** XRD results of the WCP-(1-8) samples.

Sample	XRD Results	Sample	XRD Results
WCP-1	HA	WCP-5	HA
WCP-2	HA	WCP-6	HA Whitlockite
WCP-3	HA	WCP-7	HA Whitlockite
WCP-4	HA Ca-deficient HA	WCP-8	HA Whitlockite

## CONCLUSION

Applying different process parameters resulted in the production of  $\text{Ca}_5(\text{PO}_4)_3(\text{OH})$  (HA, syn., PDF#09-0432) for the all experiments. However,  $\text{Ca}_3(\text{PO}_4)_2$  (Whitlockite, syn., PDF#09-0169) and  $\text{Ca}_9\text{HPO}_4(\text{PO}_4)_5\text{OH}$  (Ca-deficient HA, PDF#46-0905) phases were also detected for some of the cases during synthesis.

## INTRODUCTION

Polyurethane (PU) with good long-term cell and blood compatibility is highly desirable in cardiovascular applications. Most PUs currently in use were developed in early-late 1980's, however, they were not designed specifically to serve as scaffolds for vascular tissue engineering<sup>1</sup>. We have recently developed a new family of segmented polyurethanes (SPUs) possessing enhanced tunable mechanical properties<sup>2</sup> that undergoes biodegradation. In this study we report preliminary findings on degradability of SPUs in physiological condition and the cell compatibility of these surfaces to human endothelial cells.

## EXPERIMENTAL METHODS

Analytical Techniques: Differential Scanning Calorimetry (DSC) was used to determine the glass transition temperature ( $T_g$ ) of dry polymer films. Atomic Force Microscopy (AFM) was carried out on cryo fractured polymer samples to visualize phase segregation. Static water contact angle (CA) measurements were made on spun-cast polymer films at room temperature. Degradation studies were carried out polymer films in phosphate-buffered saline supplemented with sodium azide at 37 °C. The surfaces of the films were visually inspected and then imaged using scanning electron microscopy (SEM). The cellular compatibility of SPU films was assessed using human umbilical vein endothelial cells (HUVECs) and the viability was determined using MTT metabolic assay. Morphology of the cells were visualized using fluorescence microscopy after staining with FITC-Phalloidin for F-actin and DAPI nuclear stain.

## RESULTS AND DISCUSSION

SPU containing a 1:1 ratio of hydrophobic blocks and poly(L-lactic acid) (PLLA) showed a high CA of 110 ° in comparison to a CA of 83 ° for PLLA. So the high CA of 1:1 SPU could be attributed to the segregation of the hydrophobic segments to the surface due to their low surface energy. Degradation studies showed a gradual weight loss of polymer blocks without any cracks and breakage over a period of 6 months (**Figure 1**). SEM analysis revealed erosion on the surface of the polymer films with an intact bulk (**Figure 1, inset**). SPU 1:1 with 50% degradable PLLA component showed less weight loss than SPU 1:1.5 and SPU 1:2 which have 60 and 66 % PLLA in their composition respectively. This verified our design criteria that introduction of flexible hydrophobic segments could be used to both retard and control the degradation in the SPUs.

**Figure 1.** Retention of mass in SPUs as a function of time. Inset: SEMs of PSU 1:1 in two magnifications showing surface erosion.

To ascertain the suitability of these SPUs for cardiovascular applications, viability of HUVECs on SPU films of varying degradation behavior was undertaken and compared to

PLLA (Figure 2A). In general, HUVEC viability was comparable to PLLA a polymer approved by the FDA for many implantable applications. Also, qualitatively

**Figure 2:** HUVEC viability on SPUs (A), and morphology (B). PLLA were used as controls for this study.

the HUVECs showed greater spreading on SPUs in comparison to PLLA (Figure 2B)

## CONCLUSION

SPUs investigated in this study exhibit tunable degradation rates in physiological conditions and show good compatibility towards HUVECs. These properties in addition to the tunability of mechanical properties<sup>2</sup> make this family of SPUs a good material class for cardiovascular applications. In ongoing studies the blood biocompatibility and fibrin adsorption of these SPUs is being assessed.

## INTRODUCTION

Recently, active interaction control with biomolecules and cells using stimuli-responsive surfaces attracts great attention in biomedical field. In general, stimuli-responsive surfaces use hydrophilic/hydrophobic property change to regulate the interaction with bio-analytes<sup>1</sup>. On the other hand, moderately hydrophobic surfaces show high cell adhesiveness, while the strongly hydrophobic surfaces greatly reduce their cellular interaction<sup>2</sup>. We considered that the enhancement of surface hydrophobicity can be used as one of the triggers to reduce bio-related interaction. Herein, we designed a smart fluoropolymer-coated surface with showing a reversible surface hydrophobicity change derived from the photoisomerization of polymer-introducing spiropyrans moieties by light switch. Moreover, cell adhesion on photo-responsive surface was also investigated to demonstrate the possibility of reversible cell adhesion/detachment control.

Figure 1. Schematic representation of photo-responsive fluoropolymer coated surface for cell adhesion control via light irradiation.

## EXPERIMENTAL METHODS

Poly(heptafluorobutyl methacrylate-*co*-spiropyrans methacrylate) [poly(F7MA-*co*-SpMA), monomer ratio of F7MA/SpMA: 87/13, molecular weight: 44000] was synthesized and spin-coated (1wt% polymer solution) on hydrophobic glass surface (Figure 1). The surface was characterized by ATR/FT-IR and ellipsometry. We determined surface water-wettability change after irradiating either ultraviolet (UV, 352 nm) or visible (Vis, 530 nm) light by static contact angle measurement of water droplet method. Bovine endothelial cells (BECs) were cultured on UV light-treated surface, and then the difference in cell adhesiveness was investigated between before and after visible light irradiation. In

addition, confluent cultured cells were treated by Vis-light irradiation for harvesting as a cell monolayer.

## RESULTS AND DISCUSSION

The amount of polymer and polymer layer thickness on the surfaces were 6.08  $\mu\text{g}/\text{cm}^2$  and 36.3 nm, respectively. Contact angle study showed a reversible surface wettability change via UV/Vis-light irradiation due to the photoisomerization of spiropyrans units between hydrophilic merocyanine (ME) and hydrophobic spiropyran (SP) forms (contact angles after irradiating UV- and Vis-light were of 78° and 88°, respectively).

BECs significantly adhered on the moderately hydrophobic surface with ME-forms, compared to the strongly hydrophobic surface with SP-forms. In addition, adhering cells on the moderately hydrophobic surface spontaneously detached after Vis-light irradiation probably due to the decrease in surface-cell affinity (Figure 2). Moreover, confluent cultured cells were able to be harvested as a single cell monolayer (cell sheet) with maintaining cell-cell junctions and extracellular matrix proteins via the Vis-light irradiation. These results indicate that the light-induced moderately/strongly hydrophobic surface change can be used to control cell adhesion behavior.

Figure 2. Phase-contrast microscopic pictures of cells on poly(F7MA-*co*-SpMA) coated surface after irradiating (A) UV- and (B) Vis-light.

## CONCLUSION

Smart surface with showing moderately/strongly hydrophobic switchable surface was designed by physical coating of spiropyran-pendant fluoropolymer. Vis-light-induced hydrophobic enhancement allowed adhering cells to detach from the surfaces. This smart surfaces would be promising tools for cell manipulation and separation in biomedical applications.

# The Effect of the Vesicle Diameter on the Bending Rigidity of POPC and DOPC Lipid Bilayers

Dominik Drabik<sup>1</sup>, Magdalena Przybyło<sup>1</sup>, Marek Langner<sup>1</sup>

<sup>1</sup>Department of Biomedical Engineering, Wrocław University of Technology, Wrocław, Poland

[Dominik.drabik@pwr.edu.pl](mailto:Dominik.drabik@pwr.edu.pl)

## INTRODUCTION

Lipid bilayer, a constitutive component of any biological membrane, serves as a scaffold for many biochemical processes such as energy transfer. To understand these processes it is necessary to quantitate the lipid bilayer physical properties including its dynamics and mechanics. The elasticity of the lipid bilayer is believed to play important role in cell functioning by affecting the membrane trafficking within the cell volume whereas its dynamics influences a range of processes in different time scales. The membrane bending is quantitated by coefficient defined by W. Helfrich<sup>1</sup> model. The bending rigidity coefficient can be measured by quantitation thermal fluctuations of the lipid bilayer model.

## EXPERIMENTAL METHODS

The thermal fluctuations of the lipid bilayer can be used for the determination of the bending coefficient. In the methods the thermal fluctuations are quantitated based on a series of microscopic images of lipid membrane model ("flicker noise spectroscopy"). 1200 images of fluorescently labelled liposomes equatorial cross-sections are collected using fluorescence confocal microscopy (Zeiss LSM 510 Meta with 40x water immerse objective). Images were acquired at a rate of 7 frames per second. The acquired microscopic images are numerically analyzed according to well established methodologies; average-based method<sup>2</sup> or the statistical method<sup>3</sup>.

## RESULTS AND DISCUSSION

In presented studies the bending rigidity of lipid bilayers formed from DOPC or POPC lipids were measured. The typical image of fluorescently labelled liposome is presented on Figure 1. To identify contour of vesicle the self-written C++ software with OpenCV library was used. Obtained images were used to identify and quantitate thermal fluctuations, which have been next fitted to mechanical model. All calculations have been carried out with MATLAB software.

At least 8 vesicles were measured and analyzed to confirm possible correlation. The correlation of bending rigidity coefficient with liposome diameter was better than  $R^2=0,80$ . The correlation between bending rigidity of DOPC and POPC membranes and diameters of vesicles is presented on Figure 2 and Figure 3, respectively.

Figure 1. The typical image of DOPC vesicle cross-section.

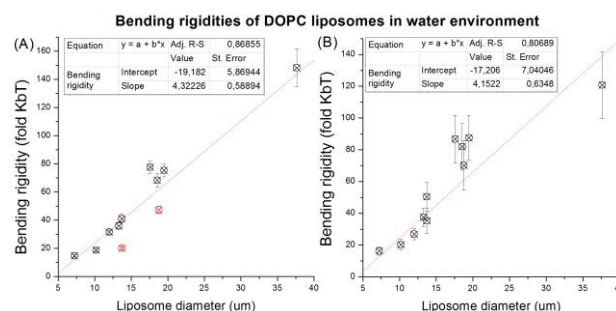

Figure 2. The dependence of the bending rigidity of DOPC membrane in water on vesicle diameter. Panel A and Panel B present data obtained when vesicle contour was analyzed using average-based method and statistical method, respectively.

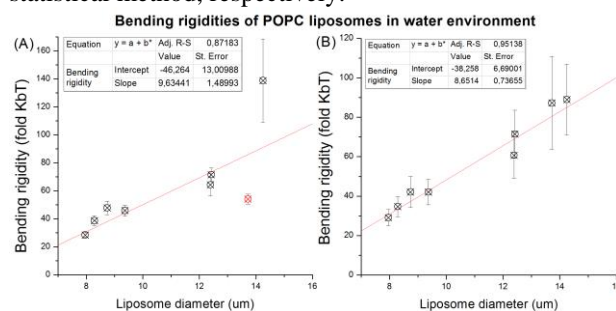

Figure 3. The dependence of the bending rigidity of POPC membrane in water on vesicle diameter. Panel A and Panel B present data obtained when vesicle contour was analyzed using average-based method and statistical method, respectively.

## CONCLUSION

Presented results show, for the first time, that the bending rigidity coefficient determined with the "flickering noise technique" depends on size of lipid vesicles. The effect is significant; the value of the bending rigidity coefficient rises by almost an order of magnitude when vesicle diameters differ only by factor of two.

## INTRODUCTION

Recently, numerous efforts to develop an ideal scaffold mimicking a native extracellular matrix (ECM) have been conducted using a variety of materials and techniques. In particular, hydrogel has been designed to provide a specific site or three-dimensional space for cells to regenerate damaged tissue. However, some hydrogels have exhibited different microenvironments without fibrous architectures similar to a collagen presented by ECM, and the structural discrepancy might hinder the development of artificial tissues or organs. In this report, we developed fibrous particles (FP), which can act as collagen fibrils in the ECM, and investigated the influence of FP on the encapsulated hMSC behavior in the hydrogel.

## EXPERIMENTAL METHODS

A PLLA sheet was fabricated through electrospinning, which was fragmented into the FP by aminolysis under shear stress.<sup>1</sup> For the functionalization, acrylic acid was grafted onto the FP under gamma-ray exposure,<sup>2</sup> and subsequently RGD peptide was conjugated through the induced carboxyl groups by EDC chemistry. RGD-FP and hMSC were mixed in the alginate solution, which was cross-linked by Ca<sup>2+</sup> ions. The cellular responses in the hydrogel were investigated with metabolic activity measurement, immunofluorescent staining, and an ALP assay for osteogenic differentiation.

## RESULTS AND DISCUSSION

The mean length of FP was  $28.9 \pm 6.6 \mu\text{m}$ , and  $177.2 \pm 18.9 \text{ nmol/mg}$  of the RGD peptide was conjugated. The RGD-FP was homogeneously distributed in the hydrogel. Gelation behaviors and mechanical property of the hydrogel were affected by the RGD-FP incorporation. Gelation time was delayed in a RGD-FP concentration dependent manner, and storage or loss modulus was significantly increased due to the loaded RGD-FP. The RGD-FP loaded hydrogel improved the viability of the cells for 14 days, in which the metabolic activity of the cells was approximately 1.5-times higher than those in other hydrogels. Consistent results for cell viability were identified with Live/Dead staining. In hydrogel, the cells could bind to the RGD-FP, and presented spatial spreading morphology in 3D. Furthermore, those bindings facilitated osteogenic

differentiation and mineralization under constant differentiation induction.

Fig. 1. RGD-FP loaded hydrogel and cell spreading in 3D

## CONCLUSION

Our hybrid hydrogel containing RGD-FP concomitantly presents structural and biochemical cues for regulating cell behaviors. In a 3D hydrogel, the cells successfully bound to the particles, and displayed spatial spreading morphology. The bindings could improve the viability and differentiation of the cells. Therefore, our strategy to append the fibrous particles in the hydrogel can be a novel tool to improve the cell survival in 3D.

## INTRODUCTION

The multifunctional polymers that integrate shape-memory capability and biodegradability present enormous opportunities for the design of next generation, resorbable less invasive smart medical implants, tissue scaffolds and medical devices [1,2].

Shape memory polymers (SMPs) with thermo-responsive memory effect could utilize the difference between the ambient temperature and the temperature of the human body, as the stimulus that activate shape changing. The intrinsic mechanism for shape memory behaviour in thermal responsive SMPs is the reversible freezing and activation of polymeric chain motion in the switching segments below and above the transition temperature ( $T_{trans}$ ), respectively. The transition temperature ( $T_{trans}$ ) is either a glass transition temperature ( $T_g$ ), or a melting temperature ( $T_m$ ). The previous data [3] indicate that sharp transitions with narrow range of transition temperature and fully shape recovery exhibit SMPs with crystalline switching segments and fully cross-linked network. However, it should be noted that in case covalently cross-linked polymers limited number of processing methods could be utilized for fabrication of three-dimensional porous scaffolds.

Therefore, in order to intensify the transfer of research results to medical practice additional research in terms of technology optimization is required. The aim of the presented research is to develop thermoplastic biodegradable polymers with thermo-responsive shape memory effect in a narrow temperature range close to the physiological range.

## EXPERIMENTAL METHODS

Poly(lactide) (PLA) and polycaprolactone (PCL) were blended in solvent with different weight ratios. Polyurethanes based on caprolactone (CL) and lactide (LA) oligomers were synthesized in one-shot process using 1,6-hexamethylene diisocyanate (HMDI) as a coupling agent and dibutyltin dilaurate as the catalyst. Chemical structure of the materials were analysed by FTIR spectroscopy. Transition temperature – melting temperature ( $T_m$ ) and crystallinity were analysed by differential scanning calorimetry (DSC). The storage modulus of samples and shape memory effect were determined using a dynamic mechanical analyser (DMA). The shape recovery ratio  $R_r$  and the fixity ratio  $R_f$  were calculated based on DMA measurement. *In vitro* biocompatibility test with L929 cell line were also performed.

## RESULTS AND DISCUSSION

A series of biodegradable PCL/PLA blends and LA/CL-based urethanes with various compositions were obtained. The DSC results revealed that transition temperature can be more effectively modulated at urethane systems than at blends (Fig.1). Additionally, quantitative assessment of the shape memory performance through strain-controlled shape memory cycles verified that blends exhibited shape-fixing ratio in the range of 76-96% and shape recovery ratio from 50 to 100% whereas LA/CL-urethanes demonstrated  $R_f$  and  $R_r$  in the range of 79-99 % and 83-100%, respectively.

Fig. 1 DSC thermograms of PCL/PLA blends and PCL/PLA –based urethanes

These results indicate that the transition temperature ( $T_{trans}$ ) of the CL/LA-urethanes can be tailored for shape restoration when inserted in the human body without external heat source.

## CONCLUSION

A series of thermoplastic LA/CL-urethane materials with shape-memory properties based on biodegradable switching segments were designed. This kind of materials may have great potential as self-fitting tissue scaffolds and implants.

### INTRODUCTION

Nowadays science and technology have deep involvement in the development of embedded systems for health to achieve the wireless monitoring of different physiological parameters. Nevertheless, a natural response of the immunity system to the implantation of such devices within the human body is the fibrosis phenomenon consisting in an abnormal proliferation of the surrounding cells in order to isolate the electronic device considered as an unnatural intrusion. Currently, the compensation of fibrosis phenomenon represents a veritable challenge for future embedded system. Fibrosis can damage the embedded system by surrounding this one, making it suboptimal or non-functional. We investigate here the possibility of directly monitoring the fibrosis proliferation in the surroundings area of the implant in order to control and regulate its functioning.

### EXPERIMENTAL METHODS

The study of fibrosis induced by an implanted medical device can be studied by the impedance measurement of the interface between the cells and the electrode of the device<sup>1</sup>. More precisely, a comparative study of electrical and biological parameters collected along the time will allow identifying an electrical marker of fibrosis development, used for establishing a systematic monitoring method. Main principle of bioimpedance measurement is to submit the living tissue to a small AC electrical current (less than 20 $\mu$ A) and to extract from the response the changes in magnitude and phase shift so that to obtain a complex impedance diagram. Scan of a wide frequency range is of primary benefits for a more interesting characterization of the usual electrical cell model of fig. 1.

Fig. 1. Left: Frequency flow through cell membrane. Right: Example of Impedance Diagram obtained with the designed measurement circuits (in vitro conditions)

Taking into account the specificities of electrical model of figure 1, and the constraints imposed by a wireless embedded monitoring of impedance changes, we propose an adapted architecture based on the most recent technology and in accordance with a use in a culture chamber for instance. The embedded system for wireless impedance measurement is composed of a Mbed NXP LPC 1768 microcontroller, a AD5933 impedance converter chip<sup>2</sup>, a Xbee wireless

communication module and finally a Sensor/Electrode module.

In order to acquire impedance from the biological material, the AD5933 device excites the medium, with a frequency ranging from 10 Hz to 100 kHz, and gets the response. For each frequency step, the chip samples the response. After the frequency sweep is complete, a DFT is processed internally and returns the real and imaginary parts of the measured impedance for each frequency. These real and imaginary data are then transferred to an external PC Controller via the Xbee protocol. Cortex M0 processor allows to parametrize and drive all the devices and master the whole acquisition / transmission sequence.

### RESULTS AND DISCUSSION

The measuring system was experienced for different resistors. The results are summarized in Table 1.

Tab. 1 Measured resistances for system validation

Rtest ( $\Omega$ )	Real (Hexa)	Imaginary (Hexa)	Admittance magnitude (w/o SF)	Calculated Resistance
560	CEB2	ECB2	13555	716
1000	E36F	EFA3	8428	1152
4700	F8DF	FC37	2066	4700
10000	FBF3	004D	1034	9392

A non-zero value for the imaginary components was expected since the AD5933 operates with known intrinsic phase drift. For a resistor of 560  $\Omega$ , the difference between the resistor under test and the calculated one is large. Actually, the AD5933 datasheet defines its operating range from 1 k $\Omega$  to 1 M $\Omega$  [2]. For the three other values, the maximal relative error is of 15.2% when the mean one is about 7.1%.

### CONCLUSION

As a proof of feasibility, we demonstrate on simple use case that the proposed architecture makes possible an automatic, accurate and secure transmission of impedance data. This is the first step for an in vitro systematic use of the device in the context of an in-vitro monitoring of cell proliferation (see figure 2 for illustration of first results), tentatively related to the fibrosis phenomenon, but also, at a longer term for the designed of a complete in-vivo system to be used in real-leaving condition.

### INTRODUCTION

Chitin and chitosan are widely used in cosmetics, biotechnology and biomedicine. They are commonly used in preparation of hydrogel dressings, as they belong to a group of substances which accelerate the wound healing process. Great interest in these polysaccharides is primarily due to their properties, which include: biocompatibility, biodegradability, bacteriostatic properties, non-toxicity, good adsorption, very good mechanical strength and bioadhesion [1-4]. Chitosan which is derived from bees' exoskeletons is called Beetosan®.

### EXPERIMENTAL METHODS

The aim was to obtain Beetosan® - chitosan from exoskeletons (armours) of bees. Typically extraction of chitin from armour of the bees is carried out in the following manner: dead bees are crushed, then proteins and calcium carbide are removed chemically. Enzymatic deacetylation of chitin is an interesting alternative to the chemical process. Thin and soft bees' armours are well suited for the mild conditions of the process, which generates significantly less waste than conventional chemical process. Enzymatic modification also allows to carry out the process under controlled conditions, which would enable the production of Beetosan with a predetermined degree of acetylation.

### RESULTS AND DISCUSSION

Proteins were successfully removed using a weak solution of sodium hydroxide (1-10%) at a high temperature (85-110 °C). Liners were then chopped and deprived of calcium carbide, which was carried out by treatment with a weak solution of hydrochloric acid (1-10%) at room temperature. Physicochemical properties of the chitin naturally depend on the parameters of the extraction. The most influential parameters are: temperature, concentrations of used chemicals, the time of their operation and the concentration and size of armours. The basic parameters which characterize chitin are the degree of polymerization, deacetylation and purity. When chitin is soluble in weak acids, then we can speak of chitosan, which is formed when chitin is reacted with a strong solution of sodium hydroxide (NaOH) (> 40%) at a high temperature (90-120 °C). Such a "violent" reaction on chitin is its deacetylation, resulting in the removal of acetyl groups (-CH<sub>3</sub>) from

the amine groups (-NH<sub>2</sub>), forming a soluble product - chitosan. It is believed that at least 65% of acetyl groups should be removed from any chitin polymer to obtain a soluble product. The degree of deacetylation is dependent on the reaction time, temperature and concentration of NaOH

### CONCLUSION

The problem which is aimed to be solved within the project, is utilization of dead bees. Once every few years every beekeeper must replace the bee hives, and thus get rid of the old degenerate units. As a result, such an exchange produces waste in the form of dead bees which have to be disposed of. Often these wastes are incinerated in an uncontrolled manner or ground and served as food for farmed fish. Preparation of chitosan from bees' exoskeletons (armours) solves the utilization problem of these dead insects while giving high quality product for biomedical applications, especially wound dressings.

### INTRODUCTION

Hydrogels prepared from chitosan due to their high biocompatibility and biodegradability are increasingly often used in many areas of medicine and pharmacy. These materials can absorb and retain up to thousand times more water than their dry weight, which is why they are mainly used as wound dressings. The aim of this study was to obtain chitosan-based hydrogels and then to modify them with *salvia officinalis* extracts [1-5].

### EXPERIMENTAL METHODS

The scope of the research included measuring the swelling ability of the obtained hydrogels in various liquids: distilled water, sodium chloride and magnesium dichloride. Moreover, incubation studies were conducted in a number of solutions, such as distilled water, sodium chloride, Ringer's and Tyrode fluids. The biological activity was investigated with the addition of a solution of potassium chromate. Additionally, the structure of the samples was investigated by means of identification of several characteristic functional groups. This study was performed using Fourier transform infrared spectroscopy (FTIR).

### RESULTS AND DISCUSSION

In the initial stage of the research hydrogels containing different amounts of chitosan were synthesized using a UV lamp. Then samples were subjected to a swelling test in distilled water and 0,9 % solution sodium chloride and magnesium dichloride, which showed that the greatest sorptive capacity is exhibited in distilled water. The obtained hydrogels were also subjected to incubation tests in distilled water, 0,9 % NaCl solution, Ringer's solution and Tyrode fluid for a period of two weeks. In each of the solutions with an increase of pH value was observed. High biological activity was revealed by a very fast decolorization of a KMnO<sub>4</sub> solution. Finally the hydrogels were analysed using Fourier transform infrared spectroscopy (ATR-FTIR). For this purpose, the samples were placed on a diamond

and the measurement was possible due to incidence of the light beam on the inner surface of the hydrogels. This analysis allowed a detailed description of the spectrum, which contained characteristic vibrations of functional groups of the polymers.

### CONCLUSION

Basing on the incubation and biological activity studies, it can be stated that all obtained hydrogels containing different amount of chitosan exhibit high activity. This is due to the use of organic compounds such as chitosan and *salvia officinalis* as substrates. These materials are very promising and may be used in the treatment of diabetic wounds and burns.

## INTRODUCTION

The light-responsive polymers are a group of polymers whose structure and/or properties change in response to the absorbed light<sup>1</sup>. These properties include chemical reactivity, conductivity, refractivity, photochromism, etc. A special group of photoresponsive polymers are polymeric photosensitizers which do not change upon light absorption but may induce chemical reactions in other molecules present in their surroundings. Most of light-responsive polymers are of industrial and technological interest, while their biomedical uses are still infrequent. Here, we describe the applications of light-responsive polymers for the preparation of functional biomedical materials.

## RESULTS AND DISCUSSION

We have applied light-responsive polymers to obtain three different types of materials.

### 1. Molecularly photoimprinted hybrid polymer-silicagel materials for the selective adsorption of adenine compounds of biomedical interest.

We obtained a series of thymine-containing synthetic polymers to form LbL ultrathin multilayers on silicagel microspheres. Thymine forms dimers when excited with UV light, so irradiation of the multilayers with UV light results in the multilayer photocrosslinking. Thymine binds to adenine, a complementary nucleobase, via hydrogen bonds so the latter is adsorbed on the surface coated with a thymine-containing multilayer.

**Figure 1. A scheme showing the principle of the preparation of ATP-photoimprinted microspheres.**

Therefore, adenine or compounds containing adenine functionalities could be photoimprinted in the polymeric multilayer by adsorption of adenine followed by UV irradiation (see Figure 1). Photoimprinting resulted in increased selectivity of adsorption of adenine<sup>2</sup>, adenosine<sup>3</sup> and ATP<sup>4</sup> vs other nucleobases, nucleosides and nucleotides, respectively. These materials are of interest as adsorbents of adenine compounds which are biochemical markers of some pathologies, e.g. cancer. Importantly, the same principle can be applied to obtain adsorbents for compounds of other nucleobases.

### 2. Photocrosslinkable cell culture supports for culturing human mesenchymal stem cells (hMSCs).

We have prepared cell culture supports in the form of ultrathin LbL multilayers obtained from anionic

polysaccharides such as pectin,  $\iota$ -carrageenan, heparin, hyaluronic acid and chondroitin sulfate and photoactive cationic diazo-resin. Irradiation of the supports resulted in the photocrosslinking of the multilayers and their increased resistance against solvents. The supports obtained using pectin were found to induce osteogenic response in human mesenchymal stem cells<sup>5</sup>, while those obtained from  $\iota$ -carrageenan significantly accelerated the growth of hMSCs<sup>6</sup>.

### 3. Insulin-functionalized osteoinductive cell culture supports

Insulin could be photoimmobilized on the surface of the LbL multilayer cell culture support obtained from pectin and diazo-resin<sup>7</sup>. This was achieved by UV irradiation of the support immersed in the insulin solution resulting in the reaction of diazo-resin with insulin (Figure 2). It was found that the effect of immobilized insulin on the proliferation of cultured hMSCs and its osteoinductivity differs significantly from those of dissolved insulin. Moreover, osteogenic activities of insulin and rhBMP-2 protein were found to be additive.

**Figure 2. Fabrication of insulin-functionalized cell culture supports.**

## CONCLUSION

The light-responsive polymers are very attractive for preparation of smart functional biomedical materials.

# Hyaluronic Acid Modified as $\alpha,\beta$ -Unsaturated Aldehyde - Biopolymer Suitable for Tissue Engineering and Drug Delivery

Radovan Buffa<sup>1</sup>, Ivana Basarabová<sup>1</sup>, Petra Šedová<sup>1</sup>, Martina Dvořáková<sup>1</sup>, Lucie Wolfová<sup>1</sup>, Vladimír Velebný<sup>1</sup>.

<sup>1</sup>Department of Chemical Modification, Contipro Biotech, Czech Republic

[buffa@contipro.cz](mailto:buffa@contipro.cz)

## INTRODUCTION

Hyaluronic acid modified with an aldehyde group has been extensively used for various medical and tissue engineering applications<sup>1</sup>. The main advantage of aldehyde moieties is their ability to react with a wide range of amino compounds at physiological conditions. This presentation describes an application of a unique HA-aldehyde derivative  $\alpha,\beta$ -unsaturated-6(GlcNAc)-oxo HA ( $\Delta$ HA-CHO) for preparation of cross-linked materials.

## EXPERIMENTAL METHODS

$\Delta$ HA-CHO and deacetylated HA were prepared from the native HA according to previously described procedures<sup>1</sup>. Hydrogel samples were prepared by mixing and a thorough homogenization of both components (solution of HA derivative in PBS and solution of linker in PBS). The samples were always left to mature for 240 minutes at room temperature, thereafter a homogenous transparent gel is formed. All samples were of the same proportions and were measured at constant laboratory conditions (temperature, pressure, humidity).

## RESULTS AND DISCUSSION

Crosslinking of  $\Delta$ HA-CHO is based on the condensation reaction of amino and aldehyde groups. Reaction is reversible and pH dependent (Scheme1). Several parameters have been investigated in order to prepare hydrogels with suitable mechanical properties. The most important are follows: structure of the linker, the ratio (molar amount of amino groups / molar amount of aldehyde groups) and concentration of polymer in solution have been studied in details.

Scheme1. Crosslinking of  $\Delta$ HA-CHO

Scheme2. Crosslinking of HA-CHO

Materials prepared from  $\Delta$ HA-CHO and HA-CHO (Scheme2) showed significantly different mechanical properties (Table 1) and *in vivo* stability.

Nr.	Compressive Young's modulus (kPa)	Compressive stress at Break (kPa)	Modulus of Toughness (J/m <sup>3</sup> )	Storage modulus (Pa)	Shear loss angle $\delta$ (°)
1	0.844	382.06	29690	160	2.36
2	0.482	309.29	19488	55	10.3

Table1.

Material Nr1. - 3% solution of  $\Delta$ HA-CHO in PBS and 3% solution of deacetylated hyaluronan in PBS)

Material Nr2. - 3% solution of HA-CHO in PBS and 3% solution of deacetylated hyaluronan in PBS)

Results demonstrate the advantageousness of the use of the  $\Delta$ HA-CHO compared to the saturated HA-CHO with regard to the preparation of more rigid and more tenacious (better crosslinked) materials suitable for tissue engineering.

Another possible application of  $\Delta$ HA-CHO is pH-responsible attachment of biologically active amines e. g. doxorubicin (Scheme2).

Scheme 2. pH-dependent attachment of doxorubicin on  $\Delta$ HA-CHO

Detailed NMR study showed that equilibrium is shifted in the area of pH values, that is very promising for potential *in vivo* applications.

## CONCLUSION

Several parameters of crosslinking reaction were successfully tested and their influence on the final mechanical properties and *in vivo* stability has been investigated. Results showed that prepared cross-linked hydrogels are fully biocompatible so  $\Delta$ HA-CHO has great potential for applications in tissue engineering, drug delivery and regenerative medicine<sup>1</sup>.

## INTRODUCTION

It is well known that the differentiation of mesenchymal stromal cells (MSCs) can be controlled by adapting the mechanical properties of the matrix in which the cells reside<sup>1</sup>. For this purpose, we have developed a photocrosslinkable hydrogel platform consisting of gelatin methacrylamide (GelMA) and poly(ethylene glycol) dimethacrylate (PEGDMA).

In this study, the concentration of GelMA remained constant at 5% w/v in order to have a constant availability of bioactive sites for cell attachment. The concentration of PEGDMA was varied between 0% and 15% w/v, resulting in a range of hydrogel stiffness.

## EXPERIMENTAL METHODS

### HYDROGEL PREPARATION

PEGDMA and lyophilized GelMA were mixed into DPBS with 0.5% (w/v) 2-hydroxy-1(4-(hydroxyethoxy)phenyl)-2-methyl-1-propanone (Irgacure 2959; CIBA Chemicals) at 80°C until completely dissolved. Five percent (w/v) GelMA was mixed with 0%, 2.5%, 5%, 7.5%, 10%, or 15% (w/v) PEGDA. Prepolymer was pipetted between two glass slides separated by a 600µm spacer and exposed to 6.9mW/cm<sup>2</sup> UV light (360–480 nm) for 30 s.

### HYDROGEL ANALYSIS

Hydrogels were swollen in DPBS for 1 hour, after which a 6mm Ø biopsy punch was used to generate samples with a reproducible shape and size. For pore size analysis, samples were freeze dried, coated with a thin gold layer, and analyzed using a scanning electron microscope. Average pore size was determined using image-J. Mechanical properties were determined using an Instron mechanical tester. The compressive modulus was recorded at a compression of 10%

## RESULTS AND DISCUSSION

The addition of low amounts of PEGDMA resulted in a decrease of hydrogel compressive modulus (see fig1) and an increase in the hydrogel pore size (see fig2). Further increasing the amount of added PEGDMA resulted in an increase of the compressive modulus and a decrease in the hydrogel pore size.

**Fig1** Box-and-whisker plot showing the compressive modulus of hydrogels with different amounts of PEGDMA (n=10 from two separate experiments).

**Fig2** Average pore size of dehydrated hydrogels with different amounts of PEGDMA (n=4, average value and standard deviation shown).

## CONCLUSION

We have developed and analyzed a hydrogel system which allows us to make hydrogels with mechanical properties ranging from the sub-1 kPa to the 100 kPa range. This range is hypothesized to be adequate to direct the differentiation of MSC towards different tissue types, including osteogenic and neural cells<sup>2</sup>. Future studies will explore the differentiation of MSCs in these hydrogels.

# Toxic Chemical Crosslinker-free Chitosan Cryosponge for Cartilage Tissue Engineering

Takayuki Takei, Hiroki Yoshitomi, Kohei Fukumoto, Yoshihiro Ozuno, Masahiro Yoshida

Department of Chemical Engineering, Graduate School of Science and Engineering, Kagoshima University, Japan  
[takei@cen.kagoshima-u.ac.jp](mailto:takei@cen.kagoshima-u.ac.jp)

## INTRODUCTION

Principal function of articular cartilage is to reduce friction between bones and allow load distribution in articulation. Because the tissue is devoid of blood vessels, its self-repairing capacity is extremely limited. Development of tissue engineering has enabled us to regenerate damaged cartilage using porous scaffolds. To date, many natural and synthetic polymers have been utilized as scaffold materials.

Chitosan is an aminopolysaccharide present in fungal cell walls and exoskeletons of arthropods such as insects and crabs. The biocompatible and biodegradable natural polymer has been widely utilized as a scaffold material for cartilage regeneration because it has a similar structure to glucosaminoglycans that is a main component of cartilage. However, conventional chitosan porous scaffolds are prepared using toxic chemicals (chemical crosslinkers, polymerization initiators and salts). We previously developed a novel chitosan sponge containing no additives<sup>1,2</sup>. The sponge is formed only by freeze-thawing an aqueous solution with dissolved chitosan-gluconic acid conjugate (CG). We showed that the CG cryosponge (CG-sponge) accelerated wound healing<sup>1,2</sup>.

In this study, we applied the CG-sponge to cartilage tissue engineering. Proliferation of articular chondrocytes and their production of glucosaminoglycan in the CG-sponges were compared with those in CG cryosponges crosslinked by glutaraldehyde (CG/G-sponge).

## EXPERIMENTAL METHODS

CG was prepared according to our previous report<sup>1</sup>. The number of incorporated gluconic acid per 100 glucosamine units of chitosan were 12. CG was first dissolved in HCl solution (pH 4.0). The pH of the polymer solution was adjusted to 7.0 by adding a NaOH solution. The final concentration of CG was 2% (w/v). A 0.2 ml aliquot of the solution was poured into a vial and frozen at -30°C. After 12 h, it was stood at room temperature for 2 h for thawing. CG/G-sponge were prepared by freeze-thawing of a CG aqueous solution containing 0.5% glutaraldehyde. The CG- and CG/G-sponges were immersed 70% (w/v) ethanol solution for 2 h for sterilization and rinsed with culture media for removal of ethanol and unreacted glutaraldehyde. Bovine articular chondrocytes suspended in culture media (0.15 ml) were seeded in the sponges ( $4.4 \times 10^5$  cells/sponge). After 3 and 7 days of cultivation at 37°C, amounts of glucosaminoglycan and DNA in the sponges were determined.

Data are presented as mean  $\pm$  standard deviation. Statistical differences between two groups were analyzed using the two-tailed Student's unpaired *t*-test.

## RESULTS AND DISCUSSION

CG-sponges had porous structure as shown in Figure 1 (a). Pore size of the sponge was  $136 \pm 46 \mu\text{m}$ . Much difference was not observed between pore size of the CG- and CG/G-sponges. We confirmed that the CG-sponges were barely degraded in culture media for more than 7 days although they were not chemically crosslinked (data not shown). Bovine articular chondrocytes proliferated faster in CG-sponges than in CG/G-sponges (Figure 1 (b)). Furthermore, production rate of glucosaminoglycan by the chondrocytes was higher in CG-sponges than in CG/G-sponges (Figure 1 (c)). These results show that importance of use of toxic chemical crosslinker-free chitosan scaffold for cartilage tissue engineering.

Figure 1. (a) Scanning electron microscope image of CG-sponge. (b, c) DNA (b) and glucosaminoglycan contents (c) of CG-sponges (closed bars) and CG/G-sponges (open bars).

## CONCLUSION

Proliferation rate of chondrocytes and production rate of glucosaminoglycan were higher in CG-sponges than in CG/G-sponges. These results show that the toxic chemical crosslinker-free CG cryosponges possess a great potential as a scaffold for cartilage tissue engineering.

## INTRODUCTION

The development of innovative systems optimized for the controlled release of bioactive species represents a true challenge in biomaterial science. Biomaterials systems dealing with the release of molecules (such as drugs, growth factors, enzymes...) include several mechanisms, as burst effect, kinetic of release, and kinetic of degradation, which may be tuned to regulate the biologic effects. Self-assembled systems represent interesting way to control the release of active molecules like growth factors<sup>1</sup>. The reversible interactions implied in the self-assembled systems can be used in a first time for the retention of the molecules, and in a second time for their delivery. The liberation can be tune by specific physicochemical conditions (pH, temperature, ionic strength). Using self-assembled technique, we propose in this study the development of a core-shell innovative system of respectively albumin (+ the active specie) and chitosan. The release is controlled by enzymatic degradation of the chitosan capping layer using  $\alpha$ -amylase loaded into the particles. The release is activated and modulated at physiological temperature condition.

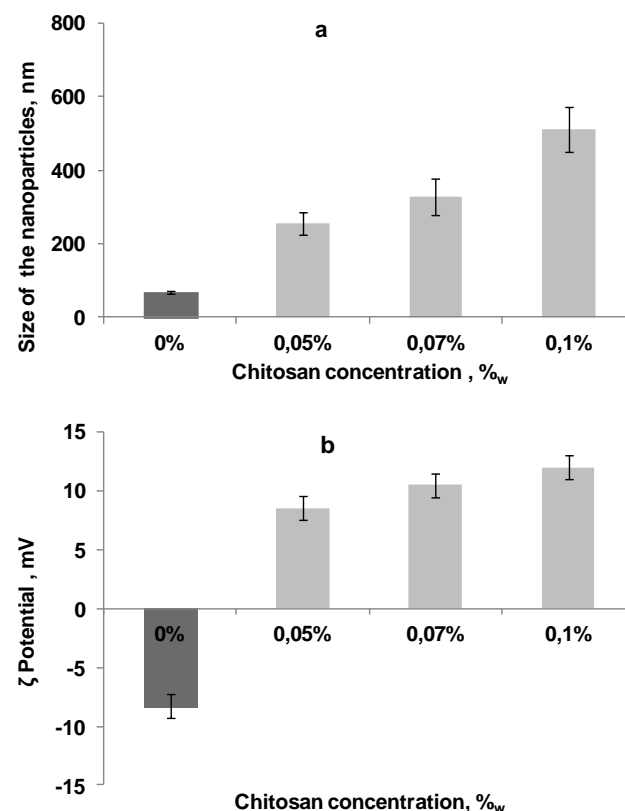

## EXPERIMENTAL METHODS

Core-shell nanoparticles are prepared by desolvation technique<sup>2</sup> using method previously described by Li<sup>3</sup>. Briefly, the nanoparticles are obtained by electrostatic interaction between negatively charged core-protein and positively charged shell-glucosamine. Core-protein is constituted by Bovine Serum Albumin (BSA, 1%<sub>w</sub>) and  $\alpha$ -amylase (pH9) by desolvation step with dropwise pure ethanol (BSA nanoparticles). The influence of the pH for the BSA solution on the size and zeta ( $\zeta$ ) potential of the nanoparticles are investigated at pH3, 5, 7 and 9. Finally, the complete core-shell nanoparticles are obtained adding BSA nanoparticles suspension in chitosan solution in excess (0.1%<sub>w</sub> in 1%<sub>v</sub> acetic acid, pH5.5). The thickness of the shell, constituted by chitosan coating, is evaluated in function of the chitosan concentration at 0.05, 0.07 and 0.1%<sub>w</sub>. Yield and protein/chitosan ratios are evaluated and the protein release is studied at 10, 19 and 37°C in PBS medium.

## RESULTS AND DISCUSSION

Whatever the pH of the BSA solution, the size of the BSA core is constant. However, the size of the global nanoparticles with chitosan decreases with the pH. Comparatively, the  $\zeta$  potential of the nanoparticles decreases with the pH probably due to chitosan adsorption decreasing on the BSA nanoparticles. Consequently, the protein/chitosan ratios increase with the pH. Oppositely, the size of the nanoparticles increases with the chitosan concentrations (Figure 1. a) The Figure 1. b. confirms the protein/chitosan ratios decreasing with chitosan concentrations. The increase

of the  $\zeta$  potential is proportional to the quantity of chitosan present around the particles.

**Figure 1.** Influence of the chitosan concentration (shell) on the size (a) and the  $\zeta$  potential of the nanoparticles (core-shell) (b). The 0%<sub>w</sub> chitosan concentration represents BSA nanoparticles (core) before chitosan adsorption.

Kinetic studies of the release of the protein loaded within the core shows that without  $\alpha$ -amylase very few deliveries is evident compared to those with the enzyme. We also demonstrate the ability to optimized and control the release from the nanoparticles with the temperature. 37°C appears as ideal to promote the delivery.

## CONCLUSION

In the next step we propose to use our innovative system to confine specific bioactive species (as growth factor) within the BSA core. The relative small size of these confined systems and their versatility, due to the nature of the different molecules used for their preparation, open the door to multiple applications as in hydrogels or thin films-based biomaterials.

[Emilia.wiehec@liu.se](mailto:Emilia.wiehec@liu.se)

Various studies have revealed phenotypic similarity between the induced-pluripotent stem cells (iPS) and cancer stem cells (CSCs). Both iPS and CSCs are fast proliferating cells with high propensity to form tumors, suggesting that molecular mechanisms of cell cycle regulation may be similar. In this work we compare the restriction (R) point-governed regulation of the cell cycle progression in different cellular systems (iPS, cancer, CSCs and normal cells) based on the expression profile of PFKFB3 and PFK1.

Our study reveals that cancer- and iPS when cultured under hypoxic conditions alter expressions of PFKFB3

and PFK1 so that the expression levels of both molecules resemble that found in CSCs. Moreover, we also observed cell type-related differences in response to PFKFB3 inhibition. Present study provides a new insight into the molecular mechanism of cell cycle regulation in various types of cells, especially CSCs and cancer cells. Possibility to distinguish CSCs from cancer- and iPS by PFKFB3 and PFK1 expression improves the chance for clinical application of stem cell-based therapies, for more precise detection of cancer stem cells.

### INTRODUCTION

Nano-sized extracellular vesicles (EVs) released by various cell types participate in physiological and pathological processes and have potential applications in diagnostics or therapeutics<sup>1</sup>. EVs originate from their donor cells either by shedding from the plasma membrane or as exosomes through secretion from late endosomal compartments<sup>2</sup>. Such cell-derived membranous vesicles contain bioactive molecules and can be detected in cell culture-conditioned medium where they may function as vehicles for intercellular communication. Although EVs from several stem cell (SC) populations including e.g. murine mesenchymal SCs<sup>3</sup>, embryonic SCs<sup>4</sup> and endothelial progenitor cells<sup>5</sup> have been already studied, the phenotypical and biological characteristics of EVs derived from murine induced pluripotent stem cells (iPSCs) has not been investigated yet. Thus, in this study, we characterized the morphology, size and molecular composition of murine EVs from iPSCs.

### EXPERIMENTAL METHODS

EVs were collected by differential centrifugation of conditioned media harvested from the serum-free and feeder-free culture of murine iPSCs obtained in our laboratory *via* genetic reprogramming. Atomic force microscopy (AFM) in liquid environment and dynamic light scattering (DLS) were used to reveal the morphology and size of EVs. Western blot and high-sensitivity flow cytometry analyses for EV markers were performed to confirm the presence of EVs in the samples. The level of transcripts related to pluripotency, angio- and cardiomyogenesis (e.g. Oct4, Nanog, Gata4) in iPSC-derived EVs and their parental cells was compared by real-time RT-PCR method. High-throughput approaches such as mass spectrometry-based proteomics and microRNA (miRNA) profiling are being currently used to further evaluate the molecular composition of miPSC-EVs.

### RESULTS AND DISCUSSION

AFM and DLS analyses showed that miPSC-EV samples contain homogenous spherical vesicles with the vast majority <100 nm in size. We established that miPS-EVs are rich in mRNAs, miRNAs and proteins carried by their donor cells. We also evaluated the

expression of selected exosomal markers in iPSC-EVs, including CD9, CD63 and CD81. Our preliminary data demonstrated that EVs derived from miPSCs may represent natural nanocarriers of genetic material to target cells.

### CONCLUSION

This study brings novel insights on EVs released by pluripotent stem cells and provides a reference for further studies of unmodified or engineered EVs and their synthetic mimics as potential therapeutic tools for tissue regeneration. Moreover, we optimized harvesting of EVs from serum-free and feeder-free cultures of murine iPSCs that may be further used for studying their potential regenerative capacity in murine models of ischemic tissue injury including limb ischemia and acute myocardial infarction that is currently ongoing. Thus, EVs derived from pluripotent SCs may be promising as highly bioactive, acellular carriers in a wide variety of biomedical applications including tissue regeneration.

\*correspondence: [ewa.zuba-surma@uj.edu.pl](mailto:ewa.zuba-surma@uj.edu.pl), presenting author: [malgorzata.sekula@uj.edu.pl](mailto:malgorzata.sekula@uj.edu.pl)

### INTRODUCTION

Regenerative medicine, combining biomaterials and stem cells is an innovative field in biomedical sciences. As stem cells are unique cell type possessing the ability to self-renewal and differentiation toward different types of specialized cells, their utilization is one of the greatest hopes of contemporary medicine. Together with biomaterials support, they are promising tools which can stimulate repair of injured tissue, directly by differentiation, or more likely due to paracrine effects and remodeling of extracellular environment. Recently, there has been great focus on mesenchymal stem cells (MSC) utilization in medical applications, resulted from their low immunogenicity that makes them suitable for transplantation with low risk of the rejection. Importantly, MSC can be easily isolated from various tissues including umbilical cord Wharton's jelly (UC), cord blood (CB), bone marrow or adipose tissue. However, it was shown, that UC-MSCs occurred to have significant advantages, as their collection is noninvasive and obtained cells display improved proliferative capacity and wider differentiation potential, comparing to non-neonatal sources. Nevertheless, there are still several limitations of stem cell utilization, like effectiveness of their directed differentiation or engraftment.

### EXPERIMENTAL METHODS

To challenge these expectations we develop innovative concept of stem cell utilization in association with biocompatible composites. In this study, we used graphene-oxide (GO) scaffolds for stem cell-related applications. Graphene is two dimensional (2D) single layer of carbon atoms which have been investigated in a broad range of scientific areas e.g. biosensing, prevention of bacterial infections, photothermal therapy, drug delivery, electrical cell stimulation or skeletal tissue engineering. Importantly, bio-functionalization of graphene sheets improves their biocompatibility, solubility and selectivity.

In current study we examined an influence of graphene-based substrate on UC-MSC physiology. GO was prepared from graphite according to the Marcano method. We tested different flake size, thickness and type of solvent (aqueous or alcohol) to determine the most effective graphene suspension for stem cell growth and differentiation. To investigate the effect of

graphene-based substrate on the behavior of UC-MSC, we analyzed morphology, proliferation capacity and migratory activity of cells cultured on GO scaffolds. Next, we employed flow cytometry to evaluate cells viability and apoptosis. Furthermore, we analyzed spontaneous and cardiomyocyte-directed differentiation of UC-MSC seeded on graphene-based substrate.

### RESULTS AND DISCUSSION

Our data revealed that GO is non-toxic culture substrate for UC-MSC. GO had no influence on UC-MSC proliferation potential. Moreover, we did not observe GO cytotoxicity, the number of apoptotic cells, measured after 48 h or 96 h of culture, was similar to control cells. Microscopic analysis of cells demonstrated, that GO can stimulate elongation of UC-MSC in a flake size-dependent manner. We observed that thicker and larger layers of GO flakes promoted elongated morphology of cells. On the other hand, GO-modified substrate had no significant influence on the UC-MSC migration, comparing to cells cultured in standard conditions. However, analysis of cells trajectories revealed, that GO flakes dissolved in ethanol slightly increased the speed of cell movement. We hypothesized, that this phenomenon may be associated with more uniform and smooth coating layer of GO flakes. Furthermore, our preliminary findings indicate that graphene derivatives stimulate UC-MSC differentiation toward cardiomyocytes. After 10 days of UC-MSC culture in cardiac medium, we observed changes of cell morphology toward more elongated cells. Importantly, real-time PCR analysis revealed, that there was higher upregulation of cardiomyocyte differentiation markers GATA-4 and VE-cadherin on mRNA level, comparing to cells without GO.

### CONCLUSION

Further studies are required to analyze the impact of combining stem cells and graphene-based nanomaterials in cardiomyocyte differentiation. However, we believe that they could provide a promising tools for tissue engineering in medical applications.

## INTRODUCTION

Cell scaffolds are important techniques for regenerative medicine to reproduce biological tissues, and have been actively studied in the world. Meanwhile, the application of nano carbon materials with nanostructure to the scaffolds remains to be unknown, and it has been a significant subject to clarify the effects of particularly the nm scale structure on cellular behaviors. Our group reported that flat graphene sheet attached on scaffold substrate promoted the proliferation of mouse myoblast cell (C2C12). In this study, the effects of graphene sheet on the proliferation and shape change of human mesenchymal stem cells were investigated.

## EXPERIMENTAL METHODS

Three kinds of scaffold substrates (Gr01, Gr02 and Gr03) were obtained by transferring graphene sheets deposited on copper foils by a large-area surface wave plasma (SWP) CVD<sup>1</sup> and microwave plasma CVD<sup>2</sup>, on PDMS (polydimethylsiloxane) flat plates. Oxygen plasma was irradiated on Gr01, Gr02 and Gr03 to obtain Gr01O<sub>2</sub>, Gr02O<sub>2</sub> and Gr03O<sub>2</sub>, respectively. Mesenchymal stem cells (hMSC: Lonza, PT-2501) were cultured on the substrates with MSCGM medium (Lonza, PT-3001) for 3 days, and observed the nuclei and F-actins stained by phalloidin and DAPI, respectively. The surfaces of the substrates were observed using confocal laser microscope (CLM) and evaluated with Raman spectroscopy. In addition, contact angle was measured for the surfaces.

## RESULTS AND DISCUSSION

Raman results showed that a few up to 10 layers of graphene were attached on the fabricated substrate surfaces. The CLM observation results indicated that three kinds of substrates had the different surface structures. Gr03 and Gr03O<sub>2</sub> were confirmed to have flat surfaces, indicating that graphene sheets were almost uniformly attached all over the surfaces. As for Gr01 and Gr01O<sub>2</sub>, the graphene sheets with a number of cracks on the surfaces were overspread. The graphene sheets of Gr02 and Gr02O<sub>2</sub> were exfoliated in fragments from the surface and curled to be in fibrous form. It was found that the oxygen plasma irradiated substrates showed lower contact angles, about 80 °, than non-irradiated ones, about 120 °.

As shown in Fig. 1, using the observation images of the nuclei and F-actins obtained by a fluorescence microscope, (a) the number of cells on the substrates and (b) the average area of one cell were calculated. The cells on Gr02 increased up to 1.3 times compared to the PDMS flat plates without graphene. More, it was

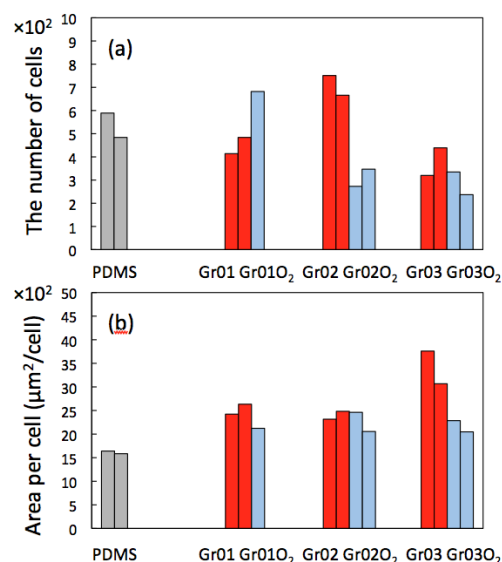

Fig. 1 Cell number and area obtained from the cell nuclei and F-actins stained images

found that the cells on the graphene-attached substrates had larger areas than the PDMS, and in particular the cells of Gr03 were about 2 times bigger than ones of PDMS. These results implied that the existence of graphene had the ability to promote the cell proliferation and enlargement, and the surface microstructure of attached graphene sheets affected cellular adhesion, division and stretching.

## CONCLUSION

The PDMS substrates transferred the graphene sheets prepared by the CVD methods were used as the scaffolds for human mesenchymal stem cells. The cells on PDMS substrates with graphene in fibrous form on the surfaces increased more compared to the flat PDMS. Moreover, the cells on the overspread flat graphene-attached PDMS substrates stretched and grew more than the PDMS.

# Very Small Embryonic-Like Stem Cells are Activated by Acute Tissue Injury In Vivo and Participate in Regeneration of Ischemic Tissue

Anna Labedz-Maslowska<sup>1</sup>, Elzbieta Kamycka<sup>1</sup>, Tomasz Brzozowski<sup>2</sup>, Mariusz Z. Ratajczak<sup>3</sup>, Zbigniew Madeja<sup>1</sup>, and Ewa K. Zuba-Surma<sup>1</sup>

<sup>3</sup>Stem Cell Biology Institute, University of Louisville, Louisville, KY, USA

Very small embryonic-like stem cells (VSELs) were identified as rare quiescent population of nonhematopoietic cells in adult murine and human tissues including bone marrow (BM). During tissue injury, BM-derived VSELs are mobilized into peripheral blood (PB). Moreover, these primitive stem cells can participate in heart repair after injection into infarcted myocardium by enhancing tissue perfusion and angiogenesis.

In this study, we examined if acute tissue injury may stimulate both proliferation of quiescent VSELs in BM and their mobilization into PB *in vivo*. We also investigated genetic status of VSELs following tissue injury including expression of genes controlling their proliferation. The other goal was to evaluate regenerative potential of VSELs injected into ischemic tissues in murine model of limb ischemia (LI) *in vivo*.

Thus, C57BL/6 mice underwent LI by permanent proximal femoral artery occlusion. Mice were administrated with BrdU and scarified at 2, 7, 14 and 28 days following LI. The presence of proliferating (BrdU<sup>+</sup>): VSELs (Sca-1<sup>+</sup>/Lin<sup>-</sup>/CD45<sup>-</sup>), endothelial progenitor cells (EPCs; Flk-1<sup>+</sup>/Sca-1<sup>+</sup>/Lin<sup>-</sup>/CD45<sup>-dim</sup>) and hematopoietic stem/progenitor cells (HSPCs; Sca-1<sup>+</sup>/Lin<sup>-</sup>/CD45<sup>+</sup>) in PB and BM was evaluated by flow

cytometry and ImageStream system. The expression of genes related to the presence of VSELs and EPCs was examined by real-time PCR. Moreover, we examined the change in secretion of angiogenesis-related proteins in plasma. Then, GFP VSELs sorted from ischemic and non-ischemic mice were injected into site of injured tissue in WT mice at 2d following LI. At 2, 7, 14 and 28days post transplantation, blood flow were measured by Laser Doppler System. Paraffin-embedded ischemic tissue sections were analyzed for GFP VSELs presence and formation of new blood vessels.

We found that the number of proliferating VSELs and EPCs was significantly increased in BM tissue and circulating in PB of ischemic mice at 7d post injury. Elevated number of BrdU<sup>+</sup> VSELs was accompanied with change in expression of genes guiding their proliferation. Moreover, changes in secretion of selected angiogenesis- related proteins may stimulate activation and proliferation of VSELs. Importantly, VSELs injected into ischemic tissues enhance the improvement in tissue perfusion and blood flow recovery by formation of new blood vessels. The data indicates vast impact of acute injury on activation of VSELs proliferation *in vivo* and possibility of their application for tissue regeneration.

## Human Adipose Stem Cells on Ti-6Al-4V Alloy with Various Surface Modifications

### INTRODUCTION

Adipose-derived stem cells (ASCs) are of great importance for regenerative medicine, including bone tissue engineering, thanks to their abundance in the body and less invasive methods of their isolation [1]. Liposuction is widely used method for obtaining ASCs, and the way in which it's done can affect the number, viability, growth and differentiation of the isolated cells. Nowadays, studies on the interaction of stem cells with artificial materials are very important for construction of tissue replacements, because these cells have a higher growth potential than conventionally used differentiated cells. In addition, stem cells are able to differentiate in many cell types and to produce growth factors by a paracrine manner, which stimulate the tissue regeneration [2].

### EXPERIMENTAL METHODS

In the first part of our study, we compared the properties of ASCs obtained from a patient (43 years old woman) by liposuction under lower and higher negative pressure, i.e. -200 mmHg and -700 mmHg, respectively. For each pressure, 10 ml of lipoaspirate was taken, and the ASCs were isolated by a method described earlier [3]. Briefly, the lipoaspirate was repeatedly rinsed in the phosphate-buffered saline, digested by 0.1 % collagenase type I (1 h and 37 °C), centrifuged, filtered through a cell filter (Cell Strainer, 100 µm, BD Falcon, USA) and seeded into polystyrene culture flasks (25 cm<sup>2</sup>, TPP, Switzerland) in the amount of 0.16 ml of the original lipoaspirate per cm<sup>2</sup>.

In the second part of our study, we focused on the adhesion and growth of ASCs (obtained from the patient in the first experiment) on Ti-6Al-4V alloy, currently used for the bone implants in clinical practice. The alloy samples were modified by different surface treatments, namely grit blasting and tarnishing (sample A), grinding to the roughness of  $R_a = 0.2$  µm (sample B) and grinding to the roughness of  $R_a = 0.08$  µm, followed by grit blasting and polishing (sample C). All these modifications were performed on samples with  $R_a = 0.28$  (control sample K). ASCs were seeded on the samples in the 2<sup>nd</sup> passage (~5700 cells per cm<sup>2</sup>).

### RESULTS AND DISCUSSION

In the first experiment we found that the higher negative pressure during liposuction was more suitable for obtaining of ASCs because of a higher number of the isolated cells and their faster proliferation. Five days after seeding, the ASCs obtained under high pressure reached a population density of ~63 000 cells/cm<sup>2</sup>, while in the cells obtained under low pressure, it was only ~40 000 cells/cm<sup>2</sup>. The differences in the cell

growth also persisted in passaged cells and after freezing and thawing of cells.

In the second experiment, we found that on day 1 after seeding, the spreading area was the largest in ASCs on A and K samples (1060-1310 µm<sup>2</sup>), and the smallest on B samples (730-820 µm<sup>2</sup>). However, on day 3, the cells on B samples reached the highest population density, which could be explained by an appropriate wettability and polarity of B samples. Nevertheless, on day 7, the cell numbers of A, B and C samples evened out and were significantly higher than on K samples. At the same time, the population densities of cells obtained under high pressure reached significantly higher population densities. These cells were mainly spindle-shaped, while the cells isolated under low pressure were mostly polygonal (**Fig. 1**). Experiments on the osteogenic differentiation of ASCs, measured by concentrations of collagen I, alkaline phosphatase and osteocalcin, are in progress.

**Fig. 1.** Human adipose-derived stem cells obtained by liposuction under low (L) and high (H) pressure in 7-day-old cultures on Ti-6Al-4V samples modified with grit blasting and tarnishing (group A). Stained with Hoechst 33258 (cell nuclei) and Texas Red C<sub>2</sub>-Maleimide (cell membrane and cytoplasm). Olympus IX 51 microscope, DP 70 digital camera, bar=200 µm.

### CONCLUSION

The adipose-derived stem cells obtained by high pressure liposuction were isolated in a larger quantity, grew faster. All tested surface modifications of Ti-6Al-4V samples enhanced the colonization of the alloy with the stem cells.

### INTRODUCTION

Human dental pulp cells (DPCs) are present in the cell population isolated from dental pulp tissues<sup>1</sup>. We reported that viral introduction of four transcription factors (*OCT3/4*, *SOX2*, *KLF4*, and *c-MYC*) can reprogram DPCs into induced pluripotent stem (iPS) cells, which closely resemble embryonic stem cells<sup>2</sup>. However, establishing quality-controlled iPS cell lines from a large number of individual patients is not easy and validation of them requires considerable time and cost.

Human leukocyte antigen (HLA) plays an important role in rejection of tissues and cells transplanted from allogenic donors. In recent days, tissue transplantation is conducted without complete matching of HLA because of shortage of the donors. Instead of matching HLA types, immunosuppressants are frequently used to prevent immune reaction both host to graft and graft to host directions; however, when the immune system function is suppressed, there is an increased susceptibility to infectious diseases and cancers.

To solve this problem, usage of HLA haplotype-homo (HHH) donors has been considered in iPS cell therapy<sup>3</sup>. HHH donors have a couple of identical HLA gene sets, resulting in presentation of HLA molecules half in the variation. Therefore, iPS cells derived from HHH donors are expected to be successfully transplanted to many patients with less possibility of rejection. However, it is not easy to obtain sufficient number of HHH donors to cover major part of Japanese population because of their rarity.

In this study, we tried to generate iPS cells, phenotypically similar to HHH cells, by directly modulating HLA loci of non-HHH cells with Zinc Finger Nucleases (ZFNs).

### EXPERIMENTAL METHODS

We designed 4 pair of ZFNs targeting exon2 or 3 of HLA-A02:01 gene by aid of SIGMA. Expression plasmids were introduced into DP144 cells with HLA type of HLA-A\*02, 33;B\*44, -;DRB1\*13, -. Cells were stained with an anti HLA-A02 specific monoclonal antibody, and subjected to cell sorting. PCR primers

were designed to amplify exon2 and 3 of HLA-A gene. iPS cells were generated by introducing 4 Yamanaka's factor using Sendai virus vector system.

### RESULTS AND DISCUSSION

After introduction of each pair of ZFNs, 1% to 5% cells became immunologically negative for HLA-A02. After expanding these cells, genomic DNA was prepared and HLA-A locus was sequenced. Among 63 sequences of HLA-A02, 17 (27%) contained in-del mutations. On the other hand no such mutations were found in 12 HLA-A33 sequences.

Then, we introduced Yamanaka's factors into HLA-A02 negative cells and established several iPS cell clones. One of the clones showed mutated HLA-A locus showing a mosaic structure of HLA-A02 and A33.

These results indicate that HLA locus can be modulated by subtype specific ZFNs. Targeted cells enriched using subtype specific antibodies could be subjected to derivation of iPS cells.

### CONCLUSION

Combination of HLA subtype specific ZFNs and monoclonal antibodies can be used to generate genetically designed HHH-like cells.

### INTRODUCTION

In the new era of regenerative medicine, human mesenchymal stem cells (hMSC) have generated great interest mainly because of their multidifferentiation potential and immunomodulatory role<sup>1</sup>. MSCs can be derived from different tissues but bone marrow is the most common although containing a relatively low frequency of hMSC, decreasing with the donor age<sup>2</sup>.

For cellular therapies, high cell numbers are required thus cells must be expanded *ex vivo*. Most of the current protocols make use of fetal bovine serum (FBS) as nutrient-rich supplement. However, several regulatory guidelines encourage novel xeno-free alternatives to define safer and standardized protocols for hMSC expansion. A new pharmaceutical-grade Cell Culture Supplement medium (SCC), derived from industrial human plasma pools, was recently described as a potential candidate for xeno-free supplementation of hMSC expansion media<sup>3</sup>. The behaviour of attachment-dependent cells, such as hMSC, is mediated not only by soluble factors present in the medium, but also by cell adhesive components that adsorb to the culture surface<sup>4</sup>. This work aims to evaluate the effect of different soluble and adsorbed bioactive factors in hMSC growth under xeno-free conditions in SCC supplemented medium.

### EXPERIMENTAL METHODS

BM-derived hMSC (Lonza) were plated at (3000 cells/cm<sup>2</sup>) in 24 well tissue culture polystyrene (TCPS) plates and cultured in media supplemented with 10% v/v SCC (Grifols) or 10% FBS (Hyclone). To analyse the effect of exogenously added adsorbed factors, plates were pre-coated with different xeno-free coatings before culture. To assess the effect of soluble factors, medium was supplemented with different human recombinant growth factors, alone or in combination. At days 1, 3, 7, 10 and 14 cell metabolic activity was assayed by Resazurin assay, while cells morphology was monitored through phase contrast optical microscopy. Finally, the maintenance of cells undifferentiated state was checked by Oil Red (adipogenesis), Alcian Blue (chondrogenesis) and ALP (osteogenic) staining.

### RESULTS AND DISCUSSION

While xeno-free coatings improve initial cell adhesion and preserve cell morphology, do not significantly

improve cell growth comparing to the animal-derived serum supplemented medium. The addition of human recombinant growth factors alone to the medium also did not show any improvement, but when used simultaneously these growth factors led to a substantial increase in metabolic activity levels, suggesting a synergistic role. This effect was further improved with the use of xeno-free coating. Also, cells maintained an undifferentiated state along 14 days in culture, implying the possibility to expand hMSC in animal – free condition for a safer use in regenerative medicine therapies.

A and B: hMSC morphology and ALP staining after 14 days culture on xeno free coating, FBS containing medium (animal-derived condition). C and D: hMSC morphology and ALP staining after 14 days culture on xeno free coating, SCC + GF containing medium (xeno-free condition). On xeno-free conditions hMSC appear well spread and keep undifferentiated state.

### CONCLUSION

SCC can be a potential candidate for cell culture supplement in xeno-free hMSC expansion.

## INTRODUCTION

Hard tissues are natural composites of inorganic (hydroxyapatite; HAP), and organic (collagen) components. The interlocking between the collagen nanofibers and the HAP nanocrystals growing on them provides the well known unique mechanical stability of hard tissues<sup>1</sup>. In case of partial fractures; bone or dental cements are often used. A widely used polymer; polymethyl-methacrylate (PMMA), has been long applied in this regard<sup>2</sup>. However, this polymer is classified as a bioinert material that can be accepted by the human body without having a positive interaction; bioactivity, with the surrounding tissues. Therefore, attempts have been done to introduce more bioactive bone/dental cements to replace PMMA.

Gypsum has been always considered a bioresorbable material and has wide scope of biomedical applications. In fact, gypsum is one of the first known biomaterials to be introduced to augment broken hard tissues<sup>3</sup>. However, gypsum as a calcium sulfate is characterized by its fast resorption after implantation, which may lead to limited stability of the cement after use. In addition, its chemical composition is different from that of the mineral components in hard tissues; HAP. Due to these concerns, a bioactive calcium silicate; known as wollastonite, has been considered to be added to gypsum to improve its bioactivity. Wollastonite is relatively more stable than gypsum in the body and is known to bond to the surrounding bone tissue through the formation of bone apatite-like layers on its surfaces after implantation<sup>4</sup>.

## EXPERIMENTAL METHODS

The current study investigates the formation of a composite of gypsum and wollastonite at weight percentages of 1, 5, and 10%. Three types of wollastonites; varying in their degree of crystallinity were used in the study. Powder mixtures of a gypsum precursor; Plaster of Paris (POP) and wollastonite were well blended prior to reactions with water. The effect of using as-received wollastonite fibers or those treated in acidic media on the setting reactions, phase composition, morphology, mechanical properties and the preliminary *in vitro* performance of the produced composites were studied. Phase composition and morphology were investigated by XRD, FT-IR, TGA, and SEM techniques. Both tensile and compressive strengths of the composites were measured. Preliminary *in vitro* performance tests were carried out in simulated body fluids and were followed by studying the variations of concentrations of certain ions in the solutions and morphology of the SBF-treated

composites after soaking for up to 14 days in these solutions.

## RESULTS AND DISCUSSION

Results showed an overall enhancement in the bioactivity of the composites as a result of the addition of wollastonites; both as-received and acid-treated. A slight decrease in the mechanical properties of the composites was observed with the addition of wollastonite fibers. Phase composition of the composites indicated no interference of wollastonite with the formation of gypsum. The advantages of the currently studied composites are, therefore, the enhancement of the bioactivity and the ability to control the biodegradation of the composite by controlling the proportion of POP in the original powder mixture of the reactants.

## CONCLUSION

Gypsum composites containing various types of wollastonite fibers were investigated for their mechanical and preliminary *in vitro* performance. Despite the fact that no significant improvement of the mechanical properties of the formed composites was observed, a pronounced improvement of the bioactivity of the composites was shown. Deposition of Hap from SBF media was observed on the prepared composites, indicating their potential for application as bone and dental cements with improved bioactivity.

### INTRODUCTION

The progress of medical therapies, which rely on the transplantation of microencapsulated cells has been widely investigated and has shown high potential to enter the clinics as treatment option for various types of diseases<sup>1</sup>.

However due to inflammatory response of the organism, one of the major challenges of cell encapsulation remains long term cell viability *in vivo*. Formation of fibrosis around the capsules prevents efficient diffusion of nutrients and results in cell asphyxiation<sup>2</sup>.

However, studies demonstrated that regular injection of anti-inflammatory drugs increases long term viability<sup>3</sup> but also lead to a loss of interest for using encapsulated cells as it requires constant medical intervention.

In order to improve the long term cell viability while avoiding recurrent medical interventions, the goal of this project is to produce modified PEG-grafted alginate hydrogels<sup>4</sup> conjugated to small anti-inflammatory molecules (fibroblast activation protein  $\alpha$  (FAP- $\alpha$ ) inhibitor). These molecules could interact with the surrounding of the capsule and limit formation of fibrosis in order to improve long term cell viability.

### EXPERIMENTAL METHODS

A convergent synthetic pathway was developed to produce Gly-Pro derivatives as inhibitors of FAP- $\alpha$  for further conjugation to alginate based hydrogels. A maleimide moiety was envisaged as anchoring group to thiol containing hydrogels.

Characterisation of synthetic intermediates and final products was done *via* nuclear magnetic resonance on a Bruker-ARX-400 spectrometer (400 MHz) (<sup>1</sup>H & <sup>13</sup>C). Precise mass (*m/z*) were obtained on a Nermag R-10-10C spectrometer. Infrared analysis were performed on a JASCO FT/IR 4100 spectrometer.

### RESULTS AND DISCUSSION

Coupling of building blocks **1** and **2** afforded the core of the inhibitor of FAP- $\alpha$ , which was further derivatized with a maleimide containing linker.

Fig 1: Synthetic strategy

Using the reactivity of maleimide moiety, the modified FAP- $\alpha$  inhibitor (**5**) was then linked to a thiol group available on PEG-grafted alginate derivatives (fig 2).

Fig 2: Functionalization of alg-based hydrogels

The effect of the modification of alg-based microspheres with anti-inflammatory molecules will be evaluated *in vitro* and in mice models.

### CONCLUSION

The improvement of biocompatibility and long term cell functionality remains a crucial challenge to further develop microencapsulated cells as therapy products. The modification of encapsulating hydrogels with anti-inflammatory agents, either covalently linked or co-encapsulated, might result in important benefit for the patient by reducing medical intervention. The functionalization strategy reported here can be applied to a large range of other active molecules presenting anti-inflammatory activities.

[anita.kajzer@polsl.pl](mailto:anita.kajzer@polsl.pl)

### INTRODUCTION

The surface layer of the biomaterial used in implants is constantly exposed to the activity of biological environment. The interaction between the surface layer of the product and the body is determined by many factors such as wettability and surface energy (SEP). Testing wettability and surface energy (SEP) gives us opportunity to predict the level of interaction between the material and the body. The high value of surface energy correlates with good protein adsorption and as a consequence, cells adhesion. In case of the low value of SEP we experience opposite effect<sup>1,2</sup>. Therefore, in order to predict those effects, the influence of biomaterial surface modifications on wettability as well as surface energy were analyzed. In addition, the same evaluation was conducted for the surface of the bone tissue.

### EXPERIMENTAL METHODS

In order to test wettability and surface energy, steel CrNiMo, titanium alloy Ti6Al4V, polyurethane, fresh and dry beef bones were selected. The surface of the steel and titanium alloy were grinded with 120 and 800 abrasive paper. Next, they were polished and passivated. In addition, the surface of the steel was covered with carbon layer and sol-gel. To determine the wettability of the surface on the selected samples we analyzed contact angles and surface energy (SEP) with the Owens-Wendt method. Contact angle measurements were performed using two liquids: distilled water and diiodomethane. Measurement of liquid drops and diiodomethane deposited onto surfaces of the specimens was made at room temperature on a test bench consisting of a SURFTENS UNIVERSAL manual goniometer manufactured by OEG and computer with Surftens 4.5 software for the analysis of the recorded drops' image. 5 drops of distilled water and diiodomethane were applied onto the surface of each sample, each with a capacity of 1.5  $\mu$ l. The measurement began 20 seconds after the application of the drops. The duration of a single measurement was 60 seconds with a sampling rate of 1 Hz. Next, the measured values of wetting angles were presented as mean values with a standard deviation

### RESULTS AND DISCUSSION

The results of the research are presented on the Fig. 1. It was stated that the surface of the steel CrNiMo sample covered with sol-gel presented values of contact angle and surface energy comparable to fresh beef bone. The increase of the surface wettability for substrate made of steel CrNiMo was observed for a sample with sol-gel layer. In case of titanium alloy Ti6Al4V substrate, the

highest value of wettability was observed on the surface grained with 800 abrasive paper, whereas the lowest value – on the polished surface. Among all the analysed samples the highest value of contact angle was observed on the surface of polyurethane, which proves its hydrophilic properties.

Fig. 1. Surface energy (SEP) and contact angles of selected materials

For various purposes, various properties of surface layer are desired. Thus, for log-term implants (eg. endoprosthesis) it is required to create opportunity for the best possible osteosynthesis, which helps to stabilize endoprosthesis properly in the bone. With such property correlates good surface wettability and therefore, hydrophilicity and higher value of surface energy. On the other hand, in case of dialysis devices or elements of artificial heart valves it is required they don't integrate with tissues or body fluids. Therefore, materials of low wettability and consequently, lower surface energy are required<sup>1,3,4</sup>.

### CONCLUSION

On the basis of carried research and obtained results it can be stated that surface layer modification has a significant influence on wettability and the value of surface energy.

## INTRODUCTION

The aim of this study is to combine the chemotactic activities of the trace elements copper and zinc with inorganic surface modification already successful in bone applications. In this combination chemotactic signals from released Cu ions are intended to provoke enhanced vascularization (demonstrated *in vivo* for amounts in the ng scale<sup>1</sup>) while released Zn ions recruit circulating bone forming cells to the site of surgery. Calcium phosphate phases (CPP) which are widely used in the field of bone surgery are utilized as a carrier for the selected trace elements in order to i) provide osteoconductive surfaces and ii) to allow fine tuning of immobilized amounts and release kinetics of the deposited trace elements.

## EXPERIMENTAL METHODS

Depositions of brushite were performed by using electrolytes composed of 83.5 mM  $\text{Ca}(\text{NO}_3)_2$  and 50 mM  $\text{NH}_4\text{H}_2\text{PO}_4$  (pH 4.0) with or without additional  $\text{Cu}(\text{NO}_3)_2$  or  $\text{Zn}(\text{NO}_3)_2$  in different concentrations. Electrochemically assisted depositions (ECAD) were carried out at 30°C applying a current density of  $-0.5 \text{ mA/cm}^2$  for 40 min. Sandblasted and additionally acid etched c.p.Ti discs were used as substrates.

The obtained coatings were characterized by i) scanning electron microscopy (SEM) with a DSM 982 Gemini combined with energy dispersive X-ray spectroscopy (EDX), ii) chemical analysis of calcium, phosphate, and zinc content in the layers following their dissolution in 0.1 N nitric acid with photometric assays and of copper content with atomic absorption spectroscopy.

## RESULTS AND DISCUSSION

Zinc and copper ions were added to the electrolytes in the range from 0.05 mM to 0.3 mM. Depending on the concentration this resulted in  $1.5 \pm 0.9 - 7.8 \pm 0.5 \text{ } \mu\text{g/cm}^2$  deposited Zn or  $5.9 \pm 0.7 - 31.7 \pm 2.9 \text{ } \mu\text{g/cm}^2$  Cu, respectively. The corresponding amounts of brushite were  $3150 \pm 200 \text{ } \mu\text{g/cm}^2$  irrespective of the added trace metal concentration.

Depositions of CPP in presence of Cu or Zn resulted in separate phases of brushite plates and Cu and Zn species, respectively (Fig. 1). EDX-mapping revealed isolated spots of copper structures within the brushite layers (Fig. 1a). This was in contrast to co-depositions under conditions which result in hydroxyapatite (HAp) layers, where the copper is homogeneously distributed throughout the HAp mineral coating<sup>2</sup>. The occurrence of dendritic structures in case of Cu indicates the partial reduction to Cu(I) and the subsequent formation of  $\text{Cu}_2\text{O}$  crystals. Further reduction to elemental copper is unlikely under the applied electrochemical conditions.

Fig. 1 SEM images of co-deposited trace element species within brushite layers on top of titanium surfaces: a) for 0.3 mM Cu, b) Cu mapping for 0.3 mM Cu, c) for 0.05 mM Zn and d) for 0.3 mM Zn in the respective electrolytes.

For the lowest applied concentration of added Zn (0.05 mM) Zn containing species homogeneously decorated the brushite plates. Increasing the concentration of zinc resulted in increased amounts of Zn in the deposited layers as well as changes in the morphology of the brushite plates (Fig. 1d).

## CONCLUSION

It was shown that copper and zinc can be co-deposited together with calcium phosphates onto metallic implant materials by means of electrochemically assisted deposition with only minor changes in general structure and amount of the deposited calcium phosphate. The relative amount of copper (or zinc) to calcium is tunable in a wide range. Current investigations focus on quantification of ion release in serum protein containing solutions and on improving retention of the trace metals within the coatings by other included components like chitosan.

The pro-angiogenic stimulation of human umbilical vein endothelial cells (HUVECs) by released copper ions is currently being studied with 2D and 3D angiogenic assays. For the chemotactic action of zinc the migration of human mesenchymal stromal cells (hMSC) will be analyzed.

## Surface Properties of Chitosan Mixtures with Hyaluronic Acid and Collagen as Materials Designed for Biomedical Applications

Alina Sionkowska<sup>1</sup>, Katarzyna Lewandowska<sup>1</sup>, Sylwia Grabska<sup>1</sup>

<sup>1</sup>Department of Chemistry of Biomaterials and Cosmetics, Faculty of Chemistry, Nicolaus Copernicus University in Toruń, Poland  
[as@chem.umk.pl](mailto:as@chem.umk.pl)

### INTRODUCTION

Manufacturing of new functional and structural materials from natural renewable and degradable materials has attracted much attention. Natural polysaccharides are the right candidates due to their unique structures and properties<sup>1-3</sup>.

In this paper, mixtures composed of chitosan (Ch) with hyaluronic acid (HA) and collagen (Coll) at different component ratio have been prepared as material designed for different applications e.g. biomedical applications.

The purpose of the present work was the preparation and evaluation of the physico-chemical properties of chitosan mixture with hyaluronic acid and collagen, using the tapping-mode atomic force microscopy and by means of contact angle measurements.

### EXPERIMENTAL METHODS

Hyaluronic acid (HA) is a commercial polymer from Aldrich Company with a viscosity average molecular weight of  $1.8 \times 10^6$ . Chitosan (Ch) sample has a degree of deacetylation of 78% with a viscosity average molecular weight of  $0.59 \times 10^6$ . Collagen (Coll) was extracted in our laboratory from rat tail tendon. Chitosan and HA mixture was prepared by mixing of two solutions in 50/50 weight ratio. Collagen was added in the ratio 10% based on the mixture.

The measurements of contact angles ( $\Theta$ ) by the sessile drop method were performed at the room temperature using the DSA10 goniometer of Krüss GmbH (Germany), equipped with software for the drop shape analysis. The droplets of probe liquid (high purity, volume of  $3 \mu\text{l}$ ) were deposited on studied surface by a microsyringe. Each value of contact angle is an average of 10 measurements.

AFM imaging in the tapping mode and ambient conditions was done using a multimode scanning probe microscope with a Nanoscope IIIa controller (Digital Instruments Santa Barbara, CA). Surface images, using scan widths ranging from  $1 \mu\text{m}$  to  $10 \mu\text{m}$ , with a scan rate of 1.97 Hz were acquired at fixed resolution ( $512 \times 512$  data points). The AFM images were obtained for different sample places and the most typical areas are presented.

### RESULTS AND DISCUSSION

The surface properties of chitosan mixtures films were observed using atomic force microscopy. The examples of AFM images of chitosan, Ch/HA and Ch/HA/Coll mixtures are shown in Figure 1. The AFM images show difference in surface properties films for the homopolymers and their mixtures.

Fig. 1. AFM images of the surface of chitosan film and films made of chitosan mixtures: a) Ch, b) Ch/HA, c) Ch/HA/Coll.

Table 1

Values of contact angles (deg) for Ch and its mixtures

Sample	contact angle (°) G	contact angle (°) D
Ch	$65.7 \pm 0.8$	$55.7 \pm 0.7$
Ch/HA	$67.9 \pm 0.8$	$57.7 \pm 0.6$
Ch/HA/Coll	$55.4 \pm 1.5$	$66.7 \pm 1.2$

As it can be observed (Table 1), the surfaces of chitosan film and its mixtures were rather hydrophobic. The lowest value of glycerol contact angles is found for Ch/HA/Coll mixture, which suggests that this surface is the most hydrophilic.

The obtained results suggested that there was existence of the strong interactions between polymeric components.

### CONCLUSION

The study of mixtures by AFM showed a completely different morphology when compared with pure components. This may indicate a strong interaction between the polymeric components. Moreover, it was found that the surfaces of pure components and their blends had similar values of contact angles. The exception is the Ch/HA/Coll mixture. Summarizing, the structure and surface properties of investigated mixtures depend on the mixture composition and on the used solvent.

## Alendronate Self assembling Monolayers. A Bioactive Bonding Agent on Titanium Surfaces

Luis Rojo<sup>1</sup>, Borzo Gharibi<sup>1</sup>, Sanjukta Deb<sup>1</sup>

<sup>1</sup> Division of Tissue Engineering & Biophotonics King's College London Dental Institute. United Kingdom.  
[luis.rojo\\_del\\_olmo@kcl.ac.uk](mailto:luis.rojo_del_olmo@kcl.ac.uk)

### INTRODUCTION

Ti6Al4V alloy is commonly used for manufacture of dental and orthopaedic implants because their biocompatibility, corrosion resistance, low modulus and good fatigue strengths, among other desirable properties. However different approaches have been investigated such as air blasting, acid etching, sol-gel and chemical treatments in order to obtain titanium implants grafted with extracellular matrix compounds with enhanced biological and chemical surface properties.

Bisphosphonates are a well-known class of osseointegrative drugs used in osteoporosis therapy with the ability to form self-assembled monolayers (SAMs) on titanium surfaces<sup>1</sup>. However, conventional methodologies for preparing these SAMs need the use of organic solvents that impede the widespread use of these materials as medical devices. This study presents an investigation of modification of Ti6Al4V alloy by chemisorption of alendronate SAMs from aqueous solutions with the capability to induce differentiation of human mesenchymal stem cells (hMSC) into bone cell phenotypes and promoting *in vitro* bone formation.

### EXPERIMENTAL METHODS

Alendronate SAMs formation onto alkali etched Ti6Al4V discs were carried out by solvent casting surface from alendronate aqueous solution and evaporation followed by gently washing with DI water and isopropanol. Control and treated discs were studied by contact angle measurements and surface free energy was calculated. SEM microscopy accompanied by energy dispersive X-ray analysis (EDX) (Hitachi S3500N) was used to obtain high resolution imaging and composition. Surface chemistry was further determined by RAMAN spectroscopy (Renishaw) and X-ray photoelectron spectroscopy (XPS, Kratos). Cell viability and osseointegrative capacity of alendronate SAMs were studied *in vitro* by assessing the expression of differentiation markers by hMSC cultured onto the treated discs.

### RESULTS AND DISCUSSION

Alendronate SAMs on Ti6Al4V have been effectively prepared from aqueous solution. Modified surfaces showed higher wettability than the native titanium alloy, with a regular surface topography and tailored surface chemistry. XPS analysis revealed that an effective Ti-O-P mode of bonding is created between the metal oxide surface and the phosphate residue of alendronate leading to the formation of homogenous drug distribution along the surface. hMSC cultured onto treated Ti6Al4V surfaces showed similar cell attachment capacity and proliferation rate than those observed for non-treated surfaces. However significant differences were found in the expression of skeletal markers ALP, osteopontin, RUNx2 and BMP compared to controls showing a clear differentiation of hMSC into skeletal cell phenotypes.

### CONCLUSION

Alendronate SAM formation from aqueous solution onto Ti6Al4V surfaces constitutes a simple approach to anchor bisphosphonates on titanium medical implants with enhanced osseointegration capacity. In addition the presence of free amino pendant groups of the alendronate SAM allows further surface modification permitting to act as bonding agent of further bioactive molecules such as hyaluronic acid, collagen and other surrounding extracellular matrix compounds.

## INTRODUCTION

Around the foreign body in a blood vessel, neointima is formed. To prevent this process metallic materials which are placed in the blood vessel, are usually modified. The new, smart coatings have the ability to both extend the life of structures and to provide additional functionalities to coated systems<sup>1</sup>. The paper describes the innovative, nano-composite, Cr/CrN+[Cr/ a-C:H implanted by metallic nanocrystals] coatings development which connects tribological protection together with increased biocompatibility in comparison with metallic substrates.

## EXPERIMENTAL METHODS

Thin films were fabricated by a hybrid Pulsed Laser Deposition technique<sup>2</sup>. Three types of coatings were investigated (Table 1).

Number	Description
1	Cr/CrN+[DLC (8 bilayer)]
2	Cr/CrN+[Cr-DLC/DLC (32 bilayer)]
3	Cr/CrN+[Cr-DLC/DLC (8 bilayer)]

The coatings were subjected under the analysis in the biomechanical system optimized to test the direct contact with a human whole blood<sup>3</sup>. The study considered physiological conditions, mainly related to the temperature and humidity and the frequency of cyclic deformation of the artificial vessel into which the tested sample was introduced (Fig. 1).

Fig. 1. Scheme of the bio-mimetic biological test.

The test was performed using electrodynamic tensile machine MTS Acumen equipped with bio- chamber. Blood above the investigated surface was examined by flow cytometry. Attached blood cells were examined by confocal laser scanning microscopy (CLSM) using Zeiss Exciter 5 instrument. Complex microstructure characterization of investigated coatings was performed by means of transmission electron microscopy techniques (TEM) using TECNAI G<sup>2</sup> F20 (200kV) FEG microscope.

## RESULTS AND DISCUSSION

The microstructure characterization was performed at the cross- section (Fig. 1).

Fig. 2. Microstructure characterization of investigated coatings performed by TEM technique.

The applied coating showed slight improvement of the haemocompatibility compared to pure titanium (Fig. 3).

Fig. 3. Haemocompatibility test results

The coating number 3 showed an immune response similar in nature to the coagulation cascade, which may indicate that the coating from the haemocompatible point of view exhibits properties intermediate between 1 and 2.

## CONCLUSION

- Investigated coatings were built of two parts, the inner Cr/CrN and the outer part (DLC)
- The bio- mimetic, biological investigation showed slight improvement of the haemocompatibility in the coated titanium substrate to pure titanium

**Silicon-enriched bioactive coatings were successfully produced on modified titanium substrates using hydrothermal method. The coatings were investigated for their chemical and phase composition, morphology, adhesion, thermal stability and bioactivity *in vitro*.**

### INTRODUCTION

In order to promote osseointegration at the implant-tissue interface, hydroxyapatite (HAp) has been used to coat the femoral stem of hip prosthesis. Among different deposition techniques, hydrothermal method was found to produce highly crystalline and uniform HAp coatings on titanium, dealing with complex shapes typical for orthopedic implants<sup>1</sup>. At the level of synthesis it is possible to introduce silicon, as it was found that bone mineralization requires the smallest amount of this element<sup>2</sup>. Silicon was also found to promote collagen type I synthesis and osteoblast differentiation<sup>3</sup>. It was shown to play an essential role in metabolic processes involving normal bone and cartilage formation<sup>4</sup>. In the following study the novel silicon-enriched bioactive coatings were synthesized and investigated for their potential to enhance biocompatibility of titanium implants.

### EXPERIMENTAL METHODS

The hydrothermal synthesis was performed on titanium plates of 10x10 mm previously undergone chemical and thermal treatment. The deposition process was carried out in an autoclave from stock solution containing: calcium salt hydrate, diammonium phosphate, calcium chelating agent and soluble source of silicon. Accordingly to expected wt% substitution of silicon in the HAp lattice, three kinds of samples were prepared with 0,2wt%, 0,8wt% and 1,5wt% of silicon. After the synthesis samples were left to dry and subsequently heated at 700°C, 850°C and 1000°C for adhesion improvement and thermal stability evaluation. The morphology and structure of as prepared specimens were characterized using XRD, SEM, EDX, FTIR and Raman techniques. Changes in surface morphology were examined after incubation in SBF and PBS solutions.

### RESULTS AND DISCUSSION

High crystallinity of HAp coating for implantation applications is desirable since low crystallinity accelerates the speed of dissolution of the HAp films in the living body, causing the disappearance of coatings that bond to bone tissue at an early stage after implantation. The XRD and spectroscopic analysis confirmed the existence of well crystallized HAp in the prepared specimens. The microstructure of synthesized

coatings, showed as an example on SEM image in Fig.1, demonstrates an interesting combination of HAp crystals and micro- and nano-sized spherical particles, likely of amorphous silica, deposited simultaneously during the hydrothermal process. As HAp is itself recognized to be an osteoconductive material, recent studies done on nanoparticle form of silica showed that it mediates potent anti-osteoclastogenic activities on monocytes and stimulates osteoblast differentiation<sup>5</sup>. XRD calculations on changes in the values of lattice parameters of HAp with increasing silicon content imply that the silicon has also replaced phosphorous in the crystal lattice of HAp. It has been reported that silicon-substituted HAp has enhanced bioactivity *in vitro*<sup>6</sup> rather than its pure form.

Fig. 1. SEM image and EDX spectrum of silicon-enriched coating with 0,8wt% of silicon in the HAp lattice.

### CONCLUSION

Hydrothermal synthesis followed by a thermal treatment resulted in crack-free, dense and durable silicon-enriched films. Biological activity was observed for each sample. The as-prepared coatings are promising for applications in the area of bioactive surface modification for titanium based implants. The technique should be extended to metal substrates of varying shapes, such as mesh, porous, or tubular geometry.

### INTRODUCTION

The rising demand for enhanced and stable adhesion between rigid, metallic implants and host tissue requires improvement of surface properties of these biomedical devices<sup>1</sup>. The composite sol-gel bioactive glass/chitosan coatings have been utilized for this particular purpose. Bioactive glasses are materials which quickly react with physiological fluids, forming hydroxyapatite layers on the surface and connect strongly with hard and soft tissues through cellular activity<sup>2</sup>. Chitosan is a natural cationic polysaccharide, which due to its adequate properties such as biocompatibility, biodegradability and antimicrobial properties has found its use in many biomedical applications<sup>3</sup>. One of the most efficient technique used for deposition of the composite coatings is electrophoretic deposition (EPD). This is due to its simplicity, versatility, low cost and high coating uniformity. The aim of this study was surface modification of Ti13Zr13Nb alloy by electrophoretic deposition of bioactive glass/chitosan coatings as well as characterization of microstructure of coated alloy.

### EXPERIMENTAL METHODS

Near- $\beta$  Ti13Zr13Nb titanium alloy was used as substrate material for coatings deposition. The coatings were deposited by EPD. Dilute solution of sol-gel bioactive glass (1.5 g/l) and chitosan (2 g/l) in a mixture of distilled water and 0.5 vol. % acetic acid and 50 vol. % ethanol was prepared by magnetic stirring at room temperature for 72 hours. The EPD was carried out in a two-electrode cell, under constant voltage conditions in the range of 8-30 V. Deposition time was varied in the range of 1-5 minutes and the distance between electrodes in the EPD cells was 10 mm. A titanium alloy, bioactive glass and coating microstructure were investigated by scanning- and transmission electron microscopy (SEM, TEM).

### RESULTS AND DISCUSSION

Ti13Zr13Nb alloy microstructure was mainly composed of  $\alpha'$  (hexagonal close-packed; hcp) laths in  $\beta$  (body-centered cubic; bcc) grains. Sporadically, a fine  $\alpha''$  laths (orthorhombic, Cmc<sub>2</sub>m space group) also could be observed. It was found during EPD that both, the chitosan molecules and bioglass particles were positively charged in the deposit used. The most homogeneous and continuous coatings were deposited using solution of bioactive glass (2 g/l) and chitosan (2 g/l) in a mixture of distilled water and 0.5 vol. % of acetic acid as well as 50 vol. % of ethanol at the voltage of 10 V during 4 minutes. The coating microstructure consisted of bioglass particles (diameter up to 4.5  $\mu$ m) homogeneously embedded in the chitosan matrix. The

chemical composition of sol-gel bioglass was 54 mol % CaO, 40 mol % SiO<sub>2</sub> and 6 mol% P<sub>2</sub>O<sub>5</sub><sup>4</sup>. SEM-EDS microanalyses confirmed the presence of Ca, Si, P and oxygen in the coating.

Fig. 1. Microstructure of as-deposited bioactive glass/chitosan coating on near- $\beta$  Ti13Zr13Nb alloy, SEM plan-view, secondary electron image

Due to micrometric particles size the surface topography of the coating exhibited high surface development.

### SUMMARY

The composite, sol-gel bioactive glass/chitosan coating has been successfully deposited by EPD technique on the near- $\beta$  Ti13Zr13Nb alloy. The coating was homogeneous and was composed of bioglass particles embedded in chitosan matrix. Further, optimization of EPD parameters as well as detailed investigation of microstructure and properties of the coated alloy are in progress.

### INTRODUCTION

An effective technique of deposition of the porous composite coatings for biomedical applications is electrophoretic deposition (EPD). EPD is based on the movement of the colloidal particles in a suspension under the influence of an electric field and the deposition of particles on the oppositely charged electrode<sup>1</sup>.

PEEK is a polymer which exhibits good mechanical properties, including low coefficient of friction and non-toxicity<sup>2</sup>. Bioactive glass particles are added to PEEK, because they facilitate the knitting of bone tissue. Therefore, this coating is advantageous in medical application. The aims of the present work were:

- to produce microporous, good quality sol-gel bioactive glass/PEEK 704 coating on near- $\beta$  Ti13Zr13Nb alloy by EPD,
- to characterise the microstructure and selected properties of coated alloy.

### EXPERIMENTAL METHODS

A near- $\beta$  Ti13Zr13Nb alloy was used as a substrate material. A calcium-rich glass with a composition (in mol %) of 54 CaO, 40 SiO<sub>2</sub>, 6 P<sub>2</sub>O<sub>5</sub> produced by a sol-gel method was applied as a bioactive coatings component<sup>3</sup>. Bioactive glass/PEEK 704 coating was deposited on titanium alloy by EPD. The EPD was performed at a constant voltage in a range of 30-80 V. Deposition time was 2 minutes. The distance between electrodes was 5 mm. The coated specimen was heat treated at temperature of 355 °C during 20 minutes.

The microstructure of the coating components and the coatings was investigated by scanning electron microscopy (SEM) and X-ray diffractometry (XRD). The coatings adhesion to the alloy was investigated by means of micro-scratch test method. The corrosion resistance of uncoated and coated alloy was studied in the Ringer's solution at 37 °C. Measurements were performed for pH equal 7.4 and in deaerated solutions using electrochemical techniques.

### RESULTS AND DISCUSSION

The microstructure of the sol-gel glass used for EPD was characterised by XRD and SEM. XRD analysis revealed the presence of Ca<sub>5</sub>(PO<sub>4</sub>)<sub>3</sub>(OH) (hexagonal primitive; hp) and CaSiO<sub>3</sub> (triclinic primitive; tp) phases. The particles size evaluated from SEM images was up to 40  $\mu$ m. During EPD, both the glass and the PEEK particles in suspension were positively charged and they moved towards the cathode under the applied electric field. The best quality, homogeneous coatings were achieved for suspension containing PEEK, bioactive glass and citric acid in ethanol at 50 V during 2 minutes. SEM investigation revealed that the coating

was highly porous with pores diameter up to 35  $\mu$ m (Fig. 1). The coating had an uniform thickness approx. of 35  $\mu$ m. SEM-EDS microanalyses confirmed the occurrence of glass particles containing Ca, Si, P and oxygen embedded in the PEEK matrix.

Fig. 1. Microstructure of the sol-gel glass/PEEK 704 coating on Ti13Zr13Nb titanium alloy. SEM plan-view

It was found that the coating exhibit sufficient (for non-tribological applications) adhesion to the titanium alloy substrate. No cohesive cracks were observed during micro-scratch test. First adhesive cracks were observed after scratching with a load of 8 N.

Both uncoated- and coated alloys have good corrosion resistance in neutral Ringer's solution, however the coated alloy exhibits slightly better resistance to corrosion than uncoated one.

### SUMMARY

This work shows that EPD is very useful technique to deposit fairly uniform, well-adhered and microporous composite sol-gel glass/PEEK 704 coatings on near- $\beta$  titanium alloy.

The coated alloy exhibited a good corrosion resistance in Ringer's solution.

### INTRODUCTION

Titanium alloys due to their unique properties are widely used in medical application<sup>1</sup>. A near- $\beta$  Ti13Zr13Nb alloy is designed for bone implants. However, its use in applications involving friction and wear is limited due to the relatively low hardness and poor tribological properties. Therefore, it is important to improve tribological properties of this alloy by surface engineering. A very promising coating material for improvement of tribological properties of metallic materials is polyetheretherketone (PEEK). PEEK is a semicrystalline, thermoplastic polymer, which is popular in the biomedical application. It exhibits high strength, excellent tribological properties, high hardness and toughness<sup>2,3</sup>. A very prospective technique for deposition of PEEK coating on titanium alloys is electrophoretic deposition (EPD)<sup>1</sup>. The aim of this work was application of PEEK 704 coating on Ti13Zr13Nb alloy by EPD and investigation microstructure as well as tribological properties of the baseline and coated alloy.

### EXPERIMENTAL METHODS

A polymer PEEK 704 coating was electrophoretically deposited on the near- $\beta$  Ti13Zr13Nb titanium alloy substrate. Suspension of PEEK powder in ethanol was used for coatings deposition. The EPD was performed at a constant voltage in the range of 70-90 V and deposition time equal to 60 s. The distance between the cathode and counter electrode was 10 mm. Post deposition heat treatment was performed at temperature of 355 °C for 30 minutes.

A microstructure of the alloy and the coating was characterized by scanning- and transmission electron microscopy (SEM, TEM). The adhesion of the coating to the titanium alloy was investigated by means of micro-scratch test method.

Hardness and Young's modulus were measured by instrumented indentation tests using a Vickers indenter. The friction and wear properties of the baseline and coated alloy were evaluated using a ball-on-disk apparatus at unlubricated contact. Alumina balls of 6 mm in diameter were used as the counter body.

### RESULTS AND DISCUSSION

Microstructure of the substrate material consisted of  $\alpha'$  laths (hexagonal close-packed; hcp) in  $\beta$  grains (body-centered cubic; bcc). Sporadically, a fine  $\alpha''$  laths (orthorhombic, Cmc<sub>2</sub>m space group) was also identified by selected area electron diffraction. The grain size of  $\beta$  ranged from 20  $\mu$ m to 60  $\mu$ m. During EPD the PEEK particles were negatively charged in the suspension. The best deposition conditions for PEEK coatings on

titanium alloy were obtained applying a constant voltage of 92 V and the deposition time of 60 seconds. SEM investigation revealed that the as-deposited and subsequently annealed PEEK coating was homogeneous. The coating thickness was about 70  $\mu$ m. It was found during micro-scratch test that PEEK 704 coating after annealing exhibited very good adhesion to the substrate material. The critical load was equal about 25 N. Hardness and Young's modulus of the alloy were measured as  $3 \pm 0.2$  GPa and  $89 \pm 2$  GPa, respectively. The coating hardness was measured as  $0.26 \pm 0.03$  GPa, while Young's modulus as  $4.7 \pm 0.3$  GPa. The coating essentially improved the frictional wear resistance of the titanium alloy (Fig. 1). Coated alloy exhibited much better wear resistance than that of the uncoated one.

Fig. 1. Frictional wear resistance of the PEEK 704 coating on Ti13Zr13Nb alloy compared with the wear of uncoated alloy

### SUMMARY

Homogeneous polymer PEEK 704 coating was successfully deposited on Ti13Zr13Nb alloy by EPD. It was found that the coating exhibited very good adhesion to the titanium alloy substrate and essentially improved the alloy wear resistance.

### INTRODUCTION

Titanium and its alloys are extensively used as suitable dental and orthopaedic implants in biomedical engineering<sup>1</sup>. Ti13Zr13Nb alloy exhibits low Young's modulus (below 100 GPa), good corrosion resistance and sufficient biocompatibility<sup>2</sup>. In order to further improve bone cell adhesion to the surfaces of the titanium alloy implant, the biodegradable polymers coating might be applied. Among different methods exploited for such coatings, electrophoretic deposition (EPD) is especially attractive. This is due to its ability to deposit uniform polymer coatings with controlled properties on complex-shaped and porous microstructure<sup>3</sup>. Chitosan is one of the most promising natural biopolymer, which due to its biocompatibility, biodegradability and non-toxicity has found significant interest in biomedical applications<sup>4</sup>. The aim of this work was detailed investigation of electrophoresis parameters for deposition of uniform, good quality chitosan coating on near- $\beta$  Ti13Zr13Nb alloy.

### EXPERIMENTAL METHODS

Near- $\beta$  Ti13Zr13Nb alloy was used as a substrate material for EPD of chitosan coatings. Dilute solution of chitosan (0.5 g/l) in a mixture of distilled water and 1 vol. % acetic acid as well as 9 dilute solutions of different concentrations of chitosan (0.5 g/l, 1 g/l, 2 g/l) in a mixture of distilled water, 50 vol. % ethanol and different vol. % of acetic acid (0.5%, 1% and 2%) were prepared by magnetic stirring at room temperature for 24-72 hours and later used for EPD. The EPD was carried out under constant voltage conditions in the range of 8-30 V. Deposition time was varied in the range of 1-5 minutes. The distance between electrodes in the EPD cells was 10 mm. Zeta potential of the solutions was measured by Zetasizer Nano ZS90 of Malvern Instruments Ltd. The coatings quality was evaluated by visual inspection and scanning electron microscopy (SEM) observations.

### RESULTS AND DISCUSSION

Electrophoretic mobility of suspended molecules in solution is one of the main driving forces of EPD and significantly affects the uniformity of as-deposited coatings. In our work the greatest value of electrophoretic mobility was achieved for solution of chitosan (2 g/l) in a mixture of distilled water and 0.5 vol. % of acetic acid and 50 vol. % of ethanol (Fig. 1). During EPD a voltage and deposition time were determined in order to obtain homogeneous coatings. The most homogeneous and continuous coatings were deposited at the constant voltage of 10 V and deposition time 4 minutes. It was also investigated, that addition of ethanol to chitosan suspension reduces H<sub>2</sub> bubbles formation and thus gas evolution during EPD, which

resulted in more homogenous chitosan coatings. Similar effect on the H<sub>2</sub> bubbles formation had an electrophoretic voltage value during EPD. If the voltage was higher than 10 V the H<sub>2</sub> bubbles formation was very intensive. On the other hand if the voltage value was lower than 10 V the coating was only partially deposited on the substrate surface.

Fig. 1. Electrophoretic mobility of different colloidal solutions used for EPD

### CONCLUSION

The adequate solution composition and EPD parameters were selected for EPD of good quality chitosan coatings on Ti13Zr13Nb alloy. It was established that the uniformity of the as-deposited chitosan coating is highly dependent on solution composition, EPD voltage and time. Further, microstructure and properties characterization of the coated alloy as well as biocompatibility analysis are in progress.

## INTRODUCTION

Commercially pure titanium (cp-Ti) and titanium alloys are widely used in various types of implants in orthopaedic and dental fields, because they have the greatest biocompatibility with bone among the metallic biomaterials. Ti-Nb-Sn alloy (Ti-35mass%Nb-7.9mass%Sn alloy) is a novel  $\beta$ -type Ti alloy with a 40 GPa Young's modulus, which is similar to that of human cortical bone (30 GPa)<sup>[1]</sup>. It is known that the biocompatibility of Ti will change with the condition of the surface oxide (titania: TiO<sub>2</sub>) film of implant Ti alloy. Electron cyclotron resonance (ECR) plasma is high-active plasma, and high-quality crystalline films can be obtained at low temperature for short time. ECR plasma oxidation is effective surface modification of metal Ti for biocompatibilities, which became clearly in previous study<sup>[2]</sup>. Our previous studies indicated that implantation of octacalcium phosphate [ $\text{Ca}_8\text{H}_2(\text{PO}_4)_6 \cdot 5\text{H}_2\text{O}$ , OCP] was efficiently enhanced bone regeneration compared to HAp<sup>[3]</sup>. In the present study, TiO<sub>2</sub> films were deposited on Ti-Nb-Sn alloy by ECR plasma oxidation, and the effect of oxidation conditions on structure and precipitation behaviour of OCP were investigated.

## EXPERIMENTAL METHODS

ECR plasma apparatus was used for oxidation of Ti-Nb-Sn alloy surface ( $8\Phi \times 1.0 \text{ mm}^3$ ). A magnetic field ( $8.75 \times 10^{-2} \text{ T}$ ) was applied to the plasma chamber to satisfy the ECR condition. The oxygen gas pressure during ECR oxidation was set to 0.003-1.5 Pa and the oxidation time was set to 1.8 ks. The microwave power was 900 W. An infrared lamp was used for controlling the substrate temperature in the range from room temperature (RT) to 600 °C.

The structure and morphology of the films were characterized by X-ray diffraction analysis (XRD) and

optical and scanning electron microscopy (SEM). OCP was precipitated in phosphate-buffered solution on TiO<sub>2</sub> film deposited Ti substrate<sup>[3]</sup>. The calcification ability was estimated by weighing the substrate before and after the immersion.

## RESULTS AND DISCUSSION

Figure 1 shows XRD patterns of the substrates oxidized by ECR plasma at various temperatures and after calcification. Crystalline rutile-type TiO<sub>2</sub> films were obtained above 500 °C. The ECR plasma was effective to prepare crystallized TiO<sub>2</sub> films at low temperatures. Mixtures of OCP and dicalcium phosphate dihydrate (DCPD) peaks were observed after calcification.

Fig. 2 shows macroscopic images of calcium phosphate deposits formed on the Ti-Nb-Sn alloy substrate after ECR plasma oxidation at 400°C. Whole surface was covered by many flocculent precipitates of calcium phosphate. The amount of OCP and DCPD after calcification increased with increasing total pressure ( $P_T$ ) from  $3.3 \times 10^{-3}$  -  $1.5 \times 10^{-2}$  Pa, and showed the maximum at  $P_T = 1.5 \times 10^{-2}$  Pa.

Fig. 3 shows the effect of the oxidation temperature and time on calcium phosphate deposition onto the substrate surfaces. The amount of calcium phosphate deposition was maximized at 600°C, 60 min.

It was suggested that ECR plasma oxidation method is effective surface modification for the Ti-Nb-Sn alloy, because of their calcification ability.

### INTRODUCTION

A transparent and avascular cornea is essential for healthy vision. Due to the high failure rate of cadaveric-donor corneal-limbal transplants, a range of biomaterials have been explored as potential scaffolds for cultivated autologous limbal epithelial transplants. One material that demonstrates significant potential for this role is the silk protein fibroin. Membranes prepared from *Bombyx mori* silk fibroin demonstrate attractive properties of tensile strength, biodegradability, and transparency that make them an excellent candidate scaffold material for corneal-limbal epithelial cells. The ability of fibroin-based membranes to support the attachment and growth of human limbal epithelial (HLE) cells has been reported by our group<sup>1</sup>. The limbus contains a population of stem cells responsible for regenerating the corneal epithelium. While these findings represent a significant advance in the application of fibroin biomaterials, the performance of fibroin for generating corneal epithelial equivalents does not yet match that of amniotic membrane that is widely utilised for this purpose. Elsewhere, others have modified fibroin substrata with biological materials that mimic the native environment of the cells to be implanted<sup>2</sup>. Previous studies by our group demonstrated that coating of fibroin films with collagen IV significantly improved attachment and growth of human corneal endothelial cells<sup>3</sup>. It has also been reported that vitronectin coating of therapeutic contact lenses encourages corneal epithelial migration during wound healing<sup>4</sup>. In the current study, selected extracellular matrix (ECM) components were shown to promote changes in morphology, attachment and spreading of corneal/limbal epithelial cells cultured on fibroin films. Findings such as these offer the potential to assist those seeking to develop improved strategies to yield functional corneal constructs

### EXPERIMENTAL METHODS

**Corneal epithelial cell attachment:** Attachment of transformed human corneal epithelial (HCE-T; n=4) and primary HLE cells (n=5) seeded onto fibroin-coated films treated with selected ECM components (0.2, 1 and 5 µg/mL) was determined after 90 min. HLE phenotype was assessed by performing immunohistochemistry for p63. **Corneal epithelial cell morphology and confluency:** HCE-T (n=4) and primary HLE cells (n=3) were seeded onto fibroin films coated with selected ECM components (5 µg/mL). Cultures were then assessed for changes in cell morphology or confluency after 1 or 73 h, respectively.

### RESULTS AND DISCUSSION

Figure 1 shows HCE-T cell attachment to *Bombyx mori* fibroin films coated with selected ECM components. Statistical analysis by two way ANOVA revealed a significant (\* =  $P < 0.05$ ) increase in cell attachment in response to coating with collagen I, III or IV. Collagen III coating was also found to significantly increase rates of HLE cell attachment to fibroin for the majority of primary donors. Figure 2 shows changes in HCE-T cell confluency on ECM-treated *Bombyx mori* fibroin-coated films. It was demonstrated that significantly higher (\* =  $P < 0.05$ ) levels of confluency were achieved on fibroin films coated with collagen III or IV after 49 hours. Coating of fibroin with collagen I, III, IV or fibronectin also induced significant changes in cell morphology which were consistent with re-epithelialisation.

### CONCLUSION

Results indicate that coating of fibroin films with selected ECM components substantially improved specific cellular processes crucial for corneal re-epithelialisation. In particular, collagen-coating of fibroin was found to dramatically increase HCE-T cell attachment and confluency while also promoting changes in cell morphology. Increased attachment of primary HLE cells in response to coating of fibroin with collagen III was also observed, however, further optimisation is required to improve donor consistency.

### INTRODUCTION

Beta-type Ti-29Nb-13Ta-4.6Zr (TNTZ) was recently developed as a representative biomedical Ti alloy. As-solutionized TNTZ has a low elastic modulus less than 60 GPa close to that of cortical bone along with very low cytotoxicity and good bone biocompatibility. Solution treatment and aging (STA) is a typical heat treatment for improving the mechanical properties of beta-type Ti alloys. However, STA also drastically increases the elastic modulus. Therefore, this study investigated the effects of fine particle bombarding, which is one of shot peening processes, on the mechanical properties of TNTZ subjected to more severe thermomechanical treatment in order to maintain a relatively low elastic modulus. The bone contact characteristics of TNTZ samples subjected to surface modification and cancellous bone were also compared.

### EXPERIMENTAL METHODS

This study used cold-swaged TNTZ bars (working ratio: around 94%), which was designated as TNTZ<sub>SW</sub>. TNTZ<sub>SW</sub> was solutionized at 1063 K for 3.6 ks in a vacuum followed by water quenching (WQ); it was designated as TNTZ<sub>ST</sub>. Some samples of TNTZ<sub>SW</sub> were aged at 573 to 723 K in under aging conditions. Mechanical surface modification by a fine particle bombarding (FPB) machine was applied to some samples of TNTZ<sub>SW</sub>, TNTZ<sub>ST</sub> and aged TNTZ<sub>SW</sub>; these specimens were designated as TNTZ<sub>SW</sub>/FPB, TNTZ<sub>ST</sub>/FPB and aged TNTZ<sub>SW</sub>/FPB, respectively. Optical microscopy (OM), scanning electron microscopy (SEM), and X-ray diffraction (XRD) spectroscopy were carried out on each specimen to evaluate the microstructure. The Vickers hardness elastic modulus and the tensile and fatigue properties were investigated for each specimen to examine the mechanical properties. For the bone contact characteristics, some cylinder-type samples of TNTZ<sub>SW</sub>/FPB and TNTZ<sub>SW</sub> with mirror and as-machined surfaces were implanted into the femurs of Japanese white rabbits. All samples were extracted 12 weeks after implantation. The bone contacts were evaluated by image analysis.

### RESULTS AND DISCUSSION

Figure 1 shows Vickers hardness and Young's modulus profiles from very edge of samples of TNTZ<sub>SW</sub> and TNTZ<sub>SW</sub>/FPB to around 300  $\mu\text{m}$  in depth on TNTZ<sub>SW</sub>/FPB and TNTZ<sub>ST</sub>/FPB. The Vickers hardness of the very edges for TNTZ<sub>SW</sub>/FPB and TNTZ<sub>ST</sub>/FPB showed the highest value, which is Hv 270 and Hv 235, respectively), and it tends to decrease drastically as a

Fig. 1 Vickers hardness and Young's modulus profiles of TNTZ<sub>SW</sub>/FPB and TNTZ<sub>ST</sub>/FPB.

function of distance from the surface to a depth of around 20  $\mu\text{m}$ . The trend of change in Young's modulus is almost similar to that of Vickers hardness.

The fatigue strength of TNTZ<sub>SW</sub>/FPB increased, especially in the high cycle fatigue life region. The fatigue limit of TNTZ<sub>SW</sub>/FPB was around 400 MPa and around 100 MPa higher than that of TNTZ<sub>SW</sub>. The Vickers hardness near the surface of the TNTZ<sub>SW</sub>/m-SP specimen was around 200 Hv higher than that at the center of specimen, as noted above. As a result, the effect of residual compressive stress by FPB was marked in the high cycle fatigue life region.

In animal tests, TNTZ<sub>SW</sub>/FPB had the highest bone contact ratio among the three kinds of sample, although the bone formation ratios of the three were almost the same.

### CONCLUSIONS

- (1) The Vickers hardness of cold-swaged TNTZ subjected to fine particle bombarding was increased significantly within 20  $\mu\text{m}$  from the very edge of the specimen surface.
- (2) The fatigue strength of TNTZ<sub>SW</sub> subjected to fine particle bombarding increased in the high cycle fatigue life region only. The fatigue limit was around 400 MPa.
- (3) The bone contact ratio of TNTZ subjected to fine particle bombarding was better than that of TNTZ with the mirror surface.

## Evaluation of the Possibilities of Affecting the Interspike Structural-osteoconductive Potential of Additively Manufactured Prototypes of the Multispiked Connecting Scaffold for Hip Resurfacing Arthroplasty Endoprostheses

Ryszard Uklejewski<sup>1,2</sup>, Mariusz Winiński<sup>1,2</sup>, Piotr Rogala<sup>3</sup>, Adam Patalas<sup>2</sup>

[winiński@ukw.ukw.pl](mailto:winiński@ukw.ukw.pl)

### INTRODUCTION

In case of porous coated long-stem endoprostheses the porostructural-osteoconductive properties of their porous coatings outer layers can be described by the poroaccessibility parameters set<sup>1</sup> and determined using the methodology<sup>2</sup> worked out in our research team for quantitative evaluation of the structural-osteoconductive potential of porous coatings outer layers. To determine such potential in case of the multispiked connecting scaffold (MSC-Scaffold), which is the essential innovation in the fixation technique of the components of the resurfacing arthroplasty (RA) endoprostheses<sup>3-5</sup>, the analogous structural analysis of its interspike space – regarding to the expected requirements of its pro-osteoconduction functionality and its proper successive osteointegration with the periarticular trabecular bone tissue – can be performed. The major purpose of this work is the examination of the prototypes of the MSC-Scaffold manufactured in the Selective Laser Melting (SLM) technology and the evaluation of the possibilities to affect its interspike structural-osteoconductive potential.

### EXPERIMENTAL METHODS

The confocal scanning of the SLM manufactured MSC-Scaffold of the THRA endoprosthesis prototype<sup>5</sup> was performed, and followed by the essential structural examination of the MSC-Scaffold specimens representing the fragments of various variants of the MSC-Scaffold of both components of the THRA endoprosthesis prototype. These variants were designed to investigate the aspects of possible affecting their interspike structural-osteoconductive potential. In CAD models of the two designed series of the MSC-Scaffold fragments there was assumed the specific modification of geometrical properties of their spikes to impact the interspike structural-osteoconductive potential of the MSC-Scaffold by the change of the nominal height of the spikes (1<sup>st</sup> series) and, independently, by the change of spikes' shape (2<sup>nd</sup> series). The verification of the assumed in particular CAD models effect was examined in the corresponding SLM manufactured MSC-Scaffold variants.

### RESULTS AND DISCUSSION

The values of the effective height of the MSC-Scaffold's spikes in the SLM manufactured prototype of THRA endoprosthesis were significantly lower (by 48%±9% for the femoral component and by 51%±9% for the acetabular component) in relation to the

effective height of their geometrical equivalents in the corresponding CAD models. This significantly reduces, in case of the SLM manufactured prototypes, the expected interspike structural-osteoconductive potential of the MSC-Scaffold, assumed in their CAD models. The change the geometrical shape of the MSC-Scaffold's spikes without change of its nominal height applied in CAD models of the 2<sup>nd</sup> series of specimens can affect the interspike structural-osteoconductive potential of the SLM manufactured MSC-Scaffold by the circa 20% increase of the effective height of its spikes in relation to the initial variant.

### CONCLUSIONS

Being aware of the appearing technological limitations of the SLM technology, which is determined among others by the powder grain size distribution or the applied laser beam properties, the necessary modification in the CAD model design of the MSC-Scaffold, taking into account the adjustments of the technological limitations, have to be considered. The most favourable effect of the possible affecting the interspike structural-osteoconductive potential of the MSC-Scaffold can be obtained by the combined modification of its spikes design in the CAD model, which includes the extension of the spikes nominal height with the simultaneous modification of its geometrical shape in the CAD model. This allows achieving the effective height of the MSC-Scaffold's spikes in the SLM manufactured prototype at the same level as designed and expected from the CAD model of the original prototype.

### INTRODUCTION

Surface modification of biomedical materials is one of the most important objectives of research this time. Therefore, different surface modification strategies should be investigated. This study reports on application of radio-frequency (RF) magnetron sputtering to prepare thin CaP-based coatings on the surface of permanent (Ti, NiTi) or biodegradable (Mg-based) metallic substrates.

### EXPERIMENTAL METHODS

Pure hydroxyapatite (HA) and silicon-containing HA coatings with the content of silicon 0.5 and 1.72 mol were deposited by a conventional RF magnetron sputtering set-up operated in high vacuum conditions. Details on the coating deposition regimes can be found elsewhere [1,2]. Different thicknesses of the coatings up to 1500 nm were obtained. The physico-chemical properties of the biocomposites were studied by TEM, SEM, EDS, and XRD. Wettability, contact angle hysteresis, nanohardness and adhesion strength, corrosion resistance were also measured, together with biological *in vitro* tests. Cross-sections of the specimens were prepared by FIB to study the microstructure of the coatings by TEM.

### RESULTS AND DISCUSSION

The CaP coating homogeneously covered the entire surface of the substrates. In all cases, a single phase coating of HA was prepared. The coating deposition process resulted in a slight increase of the surface roughness and in nano-scale grains, generating an amorphous layer at the substrate/coating interface and inducing the growth of a columnar grain structure perpendicular to the substrate surface. A microstructural analysis of the film showed that the grain size and crystallinity increased with increasing deposition time. In the case of NiTi substrates, a significant decrease of the Ni release rate compare to the bare substrate was observed [2]. Nanoindentation tests demonstrated that all HA coatings had an increased surface hardness on both the micro- and nanoscale. The films significantly enhanced the wear resistance of this resorbable alloy. The nanostructured HA-based coatings were not cytotoxic, as proven by *in vitro* assays using primary dental pulp stem cells (DPS) and mouse fibroblast NCTC clone L929 cells. HA coatings with different thicknesses stimulated cells to attach, proliferate and form mineralized nodules on the surface better than uncoated substrates (Fig. 1). Potentiodynamic

polarization tests indicated that the corrosion current density ( $I_{corr}$ ) of the 1500-nm thick HA coated AZ31 magnesium alloy substrate was significantly lower ( $9.2 \cdot 10^{-7}$  A/cm<sup>2</sup>) compared with to the uncoated alloy substrate. Thus, the nanocrystalline HA coating can increase the corrosion resistance of AZ31 magnesium alloy ( $I_{corr}=1.3 \cdot 10^{-5}$  A/cm<sup>2</sup>), and such coated magnesium alloys have a good potential for biomedical applications.

Fig. 1. SEM images of the mineralized matrix synthesized by DPS cells cultured on a 440 nm thick CaP coating (left) and on uncoated titanium (right). The signs of mineralization are marked by arrows (left) [1].

### CONCLUSION

RF magnetron sputtering is a versatile technique to prepare nanostructured CaP-based coatings on the surface of biodegradable and permanent implants. The corrosion resistance of the magnesium-based alloys can be improved by RF magnetron sputter deposited nanocrystalline CaP coatings. The bias applied during the deposition of HA coating resulted in a decrease of the grain and crystallite size of the film having a positive effect on the mechanical properties of the biocomposites. The potentiodynamic polarization test demonstrated that a 1500-nm thick nanocrystalline HA coating significantly improved the corrosion resistance of the bare AZ31 magnesium alloy. HA coatings with different thicknesses stimulated cells to attach, proliferate and form mineralized nodules on the surface better than uncoated substrates.

## Electrochemical Immobilisation of Doxycycline on Titanium Surfaces

Sebastian Geissler, Hanna Tiainen, Håvard Haugen

Department of Biomaterials, Institute of Clinical Dentistry, University of Oslo, Norway  
[sebastian.geissler@odont.uio.no](mailto:sebastian.geissler@odont.uio.no)

### INTRODUCTION

Cathodic polarisation has been used to bind doxycycline to implant surfaces aiming at infection control and stimulation of bone formation<sup>1</sup>. It was hypothesised that the molecule binds covalently to a complex layer of hydrogen and oxygen created on the metal surface during the polarisation process. However, the exact binding mechanisms and their effect on short- and long-term availability of doxycycline still remain poorly understood.

### EXPERIMENTAL METHODS

The extent of adsorbed doxycycline on mirror-polished titanium coins that were cathodically polarised for 3 h with a current density of 1 mA/cm<sup>2</sup> in 2 M sodium acetate buffer at pH 3 was examined. Doxycycline hyclate was added to the buffer with a concentration of 1 mg/ml. After polarisation, the coins were thoroughly rinsed with deionised water and dried with nitrogen gas. Surface topography was analysed by AFM. Characterisation of the surface chemistry was done by XPS. Furthermore, the presence of doxycycline was evaluated using diffuse reflectance FTIR and fluorescence microscopy. Following this, the coins were immersed in DI water for 10 h and the analyses were repeated.

### RESULTS AND DISCUSSION

The doxycycline coated coins showed a significant increase in nano-roughness compared to the polished coins. Reduction of the substrate XPS signal and increase of the carbon and nitrogen signal confirmed the presence of an organic layer on the surface. Bands characteristic for doxycycline were seen in the infrared spectra. In addition, the build-up of a fluorescent film was observed. After immersion in DI water, the roughness had decreased and the morphology of the surface had changed significantly (Fig. 1). Increased substrate signals as well as decreased carbon and nitrogen signals were detected. The characteristic infrared bands were weakened and fluorescence had disappeared completely. This indicates that a fraction of the biomolecules is only weakly attached to the titanium surface.

### CONCLUSION

An adsorbed layer of doxycycline was found to be present after the polarisation process. This layer could be easily removed by immersion in water and thus only short-term effects of the antibiotic can be expected. The remaining lower substrate signal and increased carbon signal indicate that there still is organic material attached to the surface. The nature of this material, the

way it is bound to the surface and the potential release of it will be further explored.

Fig. 1: AFM images of the doxycycline coated surface before (top) and after immersion (bottom).

## INTRODUCTION

In a recent study by Johnson and Johnson, it has been observed and revealed that 40% of the artificial articular joints fail within five years of its implantation<sup>1</sup>. Failures of these orthopaedic implants are extensively credited towards the wear particles generated by the implant material itself. The wear debris generated within the prosthetic joints initiate a cascade of tissue responses, leading to osteolysis and results in the loosening of implants. Immense research efforts are contributed to improve the biocompatibility and longevity of the prosthetic joints by engineering the implant materials and its tribological properties. The present study is based on a markedly different view point to the problem; instead of developing a wear resistant material for implants, we aim to reduce the wear by administering lubricants to prosthetic joints. This approach would be synonymous to the work on lubricin<sup>2</sup> (a natural Mucin-like macromolecule secreted by the synovial membranes surrounding the joints, regulates the synovial homeostasis, eliminates any friction in the joints, protect the cartilage surfaces and also inhibits synovial cell overgrowth<sup>3</sup>) in the natural synovial joints. Our work is primarily on the recently developed polymeric lubricant additives that are water-soluble and claimed to improve anti-friction and anti-wear properties of a various engineering materials, including metal alloys, polymers, ceramics etc. We created injectable lubricant comprising of water-soluble polymers in aqueous solutions and are specifically targeted to lubricate and reduce the wear production from ultrahigh molecular weight polyethylene (UHMWPE) materials. As a proof of concept, first set of experiments were conducted to challenge the lubricating efficacy and/or mechanism in the model synovial fluids, serum. The in-vitro cytotoxicity tests of the screened lubricants are also analyzed and discussed.

## EXPERIMENTAL METHODS

Pin-on-disk tribometry was employed to assess the lubricating capabilities of injectable lubricants for the sliding contacts between UHMWPE and CoCrMo tribo-pair. Injectable lubricants were formulated by dissolving commercial amphiphilic triblock copolymers, PEO-PPO-PEO (Pluronics), especially "F127", "F108", "P105" and "F68" in aqueous solution (1 mM HEPES). For comparison, various biopolymers, including hyaluronic acid (HA), bovine submaxillary mucin (BSM), bovine serum albumin (BSA) and alginic acid (AA) were tested as lubricant additives. Influence of temperature, longevity, composition of model synovial fluid (serum) and aging of implants were also tested as control parameters. In-vitro cytotoxicity tests were attributed by analyzing the cell morphology and standard MTT assay on murine fibroblast (L929 fibroblasts) and murine osteoblast (MC3T3). Free

prostaglandin-E<sub>2</sub> (PGE<sub>2</sub>) on the cell are estimated by ELISA as a correlation of the immune response stimulated by bone lysis (*experiment in progress*)<sup>4</sup>.

## RESULTS AND DISCUSSION

All lubricants exhibited immediate reduction in the coefficient of friction (COF) upon injecting into serum while sliding between CoCrMo pin and UHMWPE disk as tribo-pair (Fig 1). This reduction was proportional to the concentration of lubricant additives. While the influence of temperature (22° C vs. 37° C) on the tribometry was insignificant, lubricant additives were equally effective on both aged and damaged UHMWPE and CoCrMo materials<sup>4</sup>. In model synovial fluid, 3.5 mg/ml hyaluronic acid was added along with serum to further emulate real synovial fluid. However, the efficacy on the reduction of friction coefficient was retarded. While the homo-polymeric lubricant additives were effective in reducing the friction forces (less extent when compared to amphiphilic copolymers), none of the biopolymers tested showed any lubrication<sup>4</sup>. In-vitro cytotoxicity, as observed from both cell morphology and MTT assay, showed that hydrophilic copolymers F127 and F108 are more favorable for the cell viability (Fig 2)<sup>4</sup>. Analysis of free PGE<sub>2</sub> on the cells as a correlation of immune response due to bone lysis would be discussed (*experiment in progress*)<sup>4</sup>.

**Fig 1:** Graph showing the effect of COF when F127 copolymer was injected (arrow) into the serum solution at 300 rotations<sup>4</sup>.

**Fig 2:** (A) and (B) are slides showing good morphology of viable L929 fibroblast cells after exposure to F127 and F108 copolymers respectively for seven days.

# pH Triggered Aggregation of Structurally Disordered Proline-Rich Polypeptide

Hanna Tiainen<sup>1</sup>, Sebastian Geißler<sup>1</sup>, Reidar Lund<sup>2</sup>, Håvard J. Haugen<sup>1</sup>

<sup>1</sup>Department of Biomaterials, University of Oslo, Norway

<sup>2</sup>Department of Chemistry, University of Oslo, Norway

[hanna.tiainen@odont.uio.no](mailto:hanna.tiainen@odont.uio.no)

## INTRODUCTION

Unfolded, structurally disordered, proline-rich regions of natural proteins such as collagen, amelogenin, and ameloblastin have recently been found to play an important role in biomineralisation.<sup>1</sup> Short synthetic peptides that mimic the disordered regions of such proteins may therefore be bound onto biomaterial surfaces to stimulate bone formation and regeneration in vivo. Since the function and bioactivity of these peptides is likely to be strongly linked to their lack of well-defined three-dimensional structure, it is important to understand the behaviour of such biomolecules when dissolved in aqueous media.

## EXPERIMENTAL METHODS

The structure of two dissolved synthetic proline-rich polypeptides (Table 1) that have previously shown potential in inducing bone mineralisation of both osteoblast-like cells and mesenchymal stem cells<sup>2</sup> were examined.

Table 1: Amino acid sequence of the two examined proline-rich polypeptides.

Peptide	Sequence
P2	PLV PSQ PLV PSQ PLV PSQ PQP PLP P
P5	PLV PSS PLV PCC PLV PCC PSP PLP P

These polypeptides were dissolved in either TRIS-buffered saline (pH 6-12) or sodium acetate buffer (pH 3-5.5) at 5 mg/ml concentration and their structure was analysed with small-angle X-ray scattering (bioSAXS; BM29 beamline, ESRF, Grenoble). In order to evaluate chain conformation and the size and shape of the peptide aggregates, both model-independent analysis (IFT, Guinier) and geometrical body modelling were performed. Circular dichroism spectroscopy (CD) was used to characterise the secondary structures of the polypeptides at three different pH: 5, 7.5, and 9.

## RESULTS AND DISCUSSION

While P2 maintained its disordered random coil -like structure throughout the tested pH range (pH 3-12), P5 formed aggregates at high pH (pH 8-12) as shown in Fig. 1. Radius of gyration nearly doubled and over tenfold increase in the calculated molecular weight was observed in this pH region, indicating that several polypeptide chains clustered together into nanoparticles whose scattering profile best fitted a geometrical scatter model for a triaxial ellipsoidal structure. However, no formation of specific secondary structures within these polypeptide aggregates was observed at pH 9.

Fig. 1: Kratky plots reveal the pH dependent assembly of P5 to elongated globular structures

The main difference between the two examined proline-rich polypeptides P2 and P5 is the presence of cysteine (C) in the amino acid sequence of P5. Cysteine being the only amino acid that contains a thiol group (-SH), the observed aggregation at high pH may be explained by the formation of disulphide bonds (-S-S-) which link several polypeptide chains together as the thiol groups of the cysteines become deprotonated with increasing pH ( $pK_{a_{thiol}} = 8.3$ ). Consequently, the disordered polypeptide chains assemble together forming elongated covalently bound clusters that were observed as the characteristic increase in the scatter intensity.

## CONCLUSION

Aggregation of the polypeptide chains was not observed within physiological pH range, and it is therefore not expected to influence the bioactivity of the molecule. However, such pH dependent change in peptide characteristic must be taken into account when choosing the appropriate processing conditions for binding the disordered peptides onto biomaterial surfaces.

# Stability of Oxygen Plasma Treatment of Parylene C Biomedical Coating

Monika Gołda-Cępa<sup>1</sup>, K. Engvall<sup>2</sup>, A. Kotarba<sup>1</sup>

<sup>1</sup>Faculty of Chemistry/Jagiellonian University, Krakow, Poland,

<sup>2</sup>Department of Chemical Engineering and Technology/KTH Royal Institute of Technology, Stockholm, Sweden.

[golda@chemia.uj.edu.pl](mailto:golda@chemia.uj.edu.pl)

The effect of oxygen plasma treatment of parylene C on its thermal stability and surface properties was evaluated using thermogravimetric analysis (TG/DTA) and contact angle measurement, respectively. The influence of oxygen plasma treatment depends strongly on operation parameters set ( $pO_2 = 0.2$  mbar,  $t=10$  min,  $P=50$  W). The bulk thermal stability of parylene C, remained unaffected even after overexposure to oxygen plasma. The hydrophilicity of the treated samples was constant only for the first hours after the plasma exposure.

## INTRODUCTION

Parylene C has previously been proven to be an excellent anticorrosive coating<sup>1</sup>. Continuous, dense, thin films on metallic substrates, produced by chemical vapour deposition (CVD), exhibit excellent mechanical properties and low permeability to water. For example, a 8  $\mu$ m layer creates an effective and protective barrier for heavy metal ion release, as well as implant surface corrosion in the body. Moreover, the parylene surface can be functionalized via oxygen plasma treatment, forming specific chemical surface groups<sup>2,3</sup>. The oxygen plasma technique offers the possibility of changing the chemical composition and properties of a surface, and thus the overall performance of the material. The oxygen-containing groups, formed on the surface ( $-C-OH$ ,  $-C=O$ ,  $-COOH$ ), changing the surface properties into hydrophilic, and at the same time provide with adsorption centres for drug molecules. However, oxygen plasma modification and insertion of oxygen into the polymer chain, beneficial for its biocompatibility, may influence the thermal stability of parylene C. This is a critical parameter, since steam sterilization procedure, carried out at  $T = 121^\circ C$ , and hence the polymer has to be stable well above this temperature.

## EXPERIMENTAL METHODS

Parylene C films were prepared by CVD technique (provided by ParaTech Coating Scandinavia AB). In order to modify the parylene C surface, the oxygen plasma treatment was carried out using a Diener electronic Femto plasma system. Thermogravimetric analysis (TG/DTA) were performed with the use of the TG/DTA Mettler-Toledo apparatus. The experiments were carried out in the temperature range  $30-600^\circ C$ , with a heating rate of  $6.5^\circ C/min$  and an Ar flow of  $50\text{ cm}^3/min$ .

## RESULTS AND DISCUSSION

Typical changes of  $T_{melt}$  (grey plot) and water contact angle (blue plot) evolution in time are shown in Fig. 1. The general trend in  $T_{melt}$ , as a function of plasma exposure time, can be observed for the unmodified and oxygen plasma modified samples (grey plot). The  $T_{melt}$

of oxygen plasma modified parylene C remain essentially stable until the plasma exposure time reaches 5 min. After longer exposure times to plasma,  $T_{melt}$  of the samples shifts to a higher temperature. After 30 min of oxygen plasma exposure, the  $T_{melt}$  is significantly higher:  $300.7^\circ C$ . These values are in line with the XRD results and indicate a clear substantial bulk changes in the polymer structure upon longer plasma treatment. However, the  $T_{melt}$  of oxygen plasma modified parylene C, is still at a significantly higher range of temperatures, compared to the steam sterilization temperature. The aging of plasma treatment was evaluated by water contact angle ( $\theta_w$ ) measurements. 24h after the treatment, a recovery of the hydrophobicity is observed. However, still after 21 days, the obtained contact  $\theta_w$  is approx.  $50^\circ$ , which implies a significantly more hydrophilic surface compared to the unmodified parylene C ( $\theta_w \approx 90^\circ$ ).

Fig. 1 The general trend in  $T_{melt}$  of parylene C as a function of plasma exposure time (grey) and the plasma treatment aging process presented by the means of  $\theta_w$  (blue)

## CONCLUSION

The influence of oxygen plasma treatment on the properties of parylene C depends strongly on the time of exposure to oxygen reactive species. Overexposure to oxygen plasma alters significantly the bulk properties of parylene C, shifting the melting point temperature. Although adverse bulk changes, the thermal stability of treated parylene C remains similar to the unmodified one. Therefore, the functionality in a biomedical application context will remain unaffected. Moreover, the water contact angle measurements imply that a biomedical application of oxygen plasma modified parylene C, should take place before 48h after the plasma exposure.

## INTRODUCTION

There has been enormous interest in the area of thermo-sensitive hydrogels for drug delivery<sup>1</sup>. It is noted that chitosan(CS) is biocompatible, biodegradable, antibacterial and low toxicity. Pluronic P407 is a typical commercial thermo-sensitive hydrogels, which has potential application in experimental medicine. But the drawback of P407 hydrogels are their weak mechanical strength and being easily eroded<sup>2</sup>. Thus, how to increase the mechanical strength and enhance the anti-erosion of the P407 hydrogel is important for biomedical applications of the bio-materials<sup>3</sup>. This paper reports modifications of thermo-sensitive carbon nanotubes hydrogel with soluble multi-walled carbon nanotubes (CNTs).

## EXPERIMENTAL METHODS

In this work, Poloxamer 407 and chitosan (degree of N-deacetylation (80~95%)) were purchased from Sinopharm Chemical Reagent CO., Ltd., China. CS solution (0.2 % w/v) used in this study was prepared by weighing the CS in a solution of acetic acid 0.5% (v/w). A pre-determined amount of MWNTs were dissolved in the poloxamer 407/chitosan hydrogel(PCH), which was chosen for optimum composing by measuring the gelation temperature of PCH. Statistical analysis of the data was performed via one-way analysis of variance (ANOVA) using origin software; a value of  $p < 0.05$  was considered significant ( $n = 3$ ).

## RESULTS AND DISCUSSION

### 3.1 Critical gelation temperature of PCH and PCCH

The gelation temperature of PCH and PCCH: (a) Critical gelation temperature of PCH with different content of P407; (b) Critical gelation temperature of PCCH with different content of MWNTs.

### 3.2 The interactions occurred between the P407 and CS during the preparation of PCH

### 3.3 In vitro drug release

The UV-vis absorption spectrum of 5-FU in water, (lower right of Fig a) the standard curve of 5-FU in water at 265 nm<sup>-1</sup>, (b) the release profile for the 5-FU from the 5-FU-PCH and 5-FU-PCCH

### 3.4 Cytotoxicity studies

Optical in vitro bioimaging of hepatoma cell line smmc 7721 cells incubated with 25 µg / mL PCCH-NPs (a) and MWNTs-NPs (b) for 24 h

## CONCLUSION

The thermo-sensitive carbon nanotubes hydrogel was found to significantly improve the solubility and biocompatibility of the MWNTs in aqueous media. The experimental results show that the MWNTs can improve the drug release life and delay the degradation of poloxamer407/chitosan. The thermo-sensitive poloxamer 407/chitosan-functionalized carbon nanotube hydrogels are promising materials for drug delivery and further investigation of MWNTs is under way for enabling the new material to function as a novel drug delivery platform.

**The present study is concerned on development of the technology for obtaining the nanotubular oxide layers on porous titanium alloy Ti13Nb13Zr followed by deposition of phosphate coating by electrochemical method.**

## INTRODUCTION

Titanium and its alloys are currently widely used for load-bearing implants, such as hip joint endoprosthesis. They possess a very good strength, high corrosion resistance, and they are biocompatible [1]. Despite the improvement of biomaterials and technologies for their production, about 15-25% of metal implants is degraded after 15 years of use [2,3]. Such negative behavior is associated with an inappropriate (too weak) bond of the bone and implant. There is a need for such modification, which will increase the biological activity on the interface implant - environment of tissues and body fluids [3].

## EXPERIMENTAL METHODS

Tests were carried on porous samples (Fig. 1) made of titanium alloy Ti-13Nb-13Zr. The samples were polished with grinding papers, No. 2500 as the last, and washed in an ultrasonic cleaner in three different reagents - acetone, 2-propanol and distilled water. The prepared samples were subjected to electrochemical oxidation in the 1M H<sub>3</sub>PO<sub>4</sub> + 0.3% wt. HF environment, during 30 min, at a voltage of 20 V.

Fig. 1. Surface top view (SEM) of porous sample made of titanium alloy Ti13Nb13Zr

## RESULTS AND DISCUSSION

The microscopic examinations of anodized specimen was performed with the SEM, JEOL JSM-7600F (EDS) at the University of Zielona Góra. The results are presented in Fig. 2 after anodizing process.

The obtained results are an evidence that this ternary and biphasic porous alloy can be successfully oxidized electrochemically to nanotubular structure. The length of nanotubes can be adjusted by mainly change in time. The drastic change in voltage may result in disappearance of nanotubular structure, change in

temperature – in an increase in porosity or decrease in crystallinity. The colonies of nanotubes may vary depending on the phase composition of the substrate but this effect seems relatively small.

Fig. 2. Surface top view (SEM) of nanotubular oxide layer formed in 1M H<sub>3</sub>PO<sub>4</sub> + 0.3% HF, and temperature 20°C for:30 min

## CONCLUSION

- Titanium alloy here studied is susceptible to produce nanotubular titanium oxide layer
- The presence of nanotubular oxide layers with internal diameter ranging from 20 to 100 nm is observed. The resulting nanotubes have dimensions able to facilitate an adhesion of hydroxyapatite and / or osteoblasts to the metallic implant
- Formation of nanotubes on the surface of two-phase alloy is a complex process, determined by the crystallisation of the acid solution in presence of fluorides

### INTRODUCTION

Atomic layer deposition (ALD), a technique which has widely used in semiconductor industry, can deposit high quality nanoscale films with a uniform thickness. Recently, some research groups develop a low temperature ALD technique which can be applied in low thermal resistance substrates such as polymers [1]. Thus, ALD technology is used in surface modification of medical grade polymer in this study.

### EXPERIMENTAL METHODS

Poly(vinyl chloride) (PVC, raw material of cannula in daily practice) was used as a substrate and ultrasonically cleaned with deionized water before study.  $\text{Al}(\text{CH}_3)_3$  was reacted with water vapour (thermal mode) or/and oxygen plasma (plasma mode) to form a thin  $\text{Al}_2\text{O}_3$  film on PVC substrates using a low-temperature ALD technique. Prepared  $\text{Al}_2\text{O}_3$ -coated PVA and un-treated PVA samples were characterized.

### RESULTS AND DISCUSSION

The surface morphology and water contact angle of thermal mode and plasma mode  $\text{Al}_2\text{O}_3$ -coated PVC samples were shown in Fig. 1 to Fig. 3. A highly uniform thin  $\text{Al}_2\text{O}_3$  layer was successfully grown on the PVC substrates by difference mode deposition, but the surface roughness is widely discrepancy with each other and raw PVC. That mean we can tune the biological response on PVC materials in difference application. It possible to form “wavy surface” or “non-uniform surface” when polymer substrate used ALD process, which is due to PVC has a porous surface that the interstitial space between individual molecules. Furthermore, the precursor was diffuse into the bulk of the polymer matrix, the reaction will occurred efficiently at or near the surface of the polymer plate and  $\text{Al}_2\text{O}_3$  clusters will be formed [2]. The hydrophobic surface, which improves protein absorption on the substrates.

Fig. 1: Surface morphology of  $\text{Al}_2\text{O}_3$ -coated PVC substrates with thermal mode and plasma mode deposition.

Fig. 2: Wettability of  $\text{Al}_2\text{O}_3$ -coated PVC substrates with thermal mode and plasma mode deposition.

Fig. 3: Contact angle of un-treated PVC and  $\text{Al}_2\text{O}_3$ -coated PVC substrates with thermal mode and plasma mode deposition.

### CONCLUSION

A highly uniform thin  $\text{Al}_2\text{O}_3$  layer was successfully grown on the PVC substrates. This surface modification approach makes PVC surface more hydrophobic or hydrophilic. Albumin films also prevent platelet adhesion, and may decrease the formation of thrombosis. This study reveals surface modification using ALD technology can improve the hemocompatibility of PVC. ALD technology may also be applied to modify other biomaterials.

## INTRODUCTION

Stainless steel (SS) 316L is often used for medical applications, e.g. for fabrication of stents or artificial valves. However, these life-saving devices have negative long-term influence on tissues of a patient. Adsorption of platelets and leukocytes leads to formation of blood clots and inflammation<sup>1</sup>. Also, steel releases toxic ions (e.g. Cr or Ni); in case of stents there is also a problem of restenosis<sup>2</sup>. Many approaches<sup>3</sup> has been undertaken to solve these problems, however none of them seems to be good enough. Coating the surface of steel with biocompatible layer is expected to minimize harmful effects by isolating it from blood components and other tissues and thus prolonging the lifetime of a steel device. In present paper we propose a novel method of SS coating which appears to give satisfactory results.

## EXPERIMENTAL METHODS

In this work we propose a method of electrochemical SS 316L surface coating with a) phospholipids from soy lecithin and b) polymers such as poly(glycol dimethacrylate) (PEGDMA). We use flat SS 316L discs (Ø14mm) because we consider it be a comfortable model of an SS object.

### SS 316L coating

We applied electrochemical method of coating. The aqueous solution contained a) phospholipids and b) PEGDMA as main component. DC power supply was used as a power source. Several physicochemical parameters vital for the process of coating, such as pH, time of coating, main compound concentration, current density, were altered.

### Analysis of coatings

The dependence of obtained coatings quality on altered process parameters was investigated. Coatings homogeneity was studied with the use of infrared spectroscopy (FTIR-ATR) and electron microscopy (SEM). Roughness of the layers ( $R_a$ ) was determined (optical profilometry).

## RESULTS AND DISCUSSION

Both phospholipid and PEGDMA coatings seem to be present on the whole surface of coated SS discs, which has been determined thanks to FTIR-ATR and SEM techniques. SEM indicated that thickness of coatings depends on process time and component concentration. First trials revealed that calculated  $R_a$  fits in the range assigned by other authors<sup>4</sup>. However, the roughness needs to be further minimized to decrease the risk of blood clotting. It has to be highlighted that there is no sufficient data available in existing body of literature to fully compare gained results with other authors' observations. Most suitable process parameters have

been selected, yet the research is still being conducted. Selected materials are going to be further studied to determine their influence on blood in static conditions (analysis of coagulation parameters) and cytotoxic properties (e.g. MTT in vitro test).

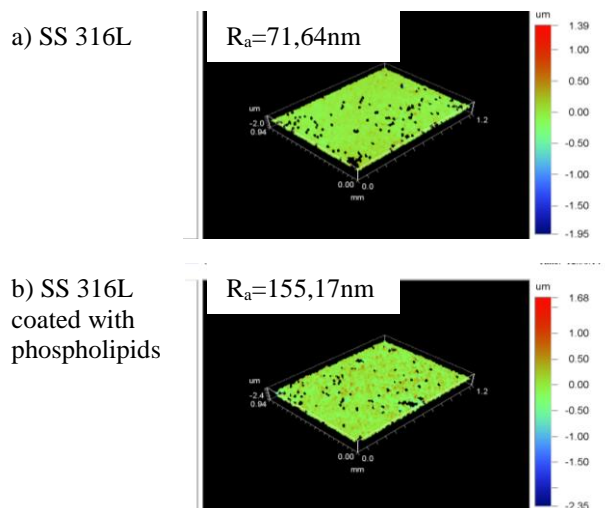

Fig. 1. An example of obtained profilometric 3d plots showing roughness of a) SS 316L and b) SS 316L coated with phospholipids. Calculated  $R_a$  given.

## CONCLUSION

It has been proven that it is possible to obtain a phospholipid or polymer coating on SS 316L surface through a not yet reported method utilizing electrochemical processes. The method is fast and cheap, hence it could be considered as an alternative for already proposed methods. It could possibly be applicable for objects of complex shape such as stents. The procedure is promising, thus we are still working on it.

## INTRODUCTION

Surface modification techniques are currently extensively applied in wide variety of biomaterials, i.e. ferrous and non-ferrous alloys, ceramics and polymers. The use of ferrous alloys in medical applications is still a concern due to their questionable corrosion and wear resistance. To extent their biocompatibility and maximize performance, diffusion layers and coatings are applied to the surface. Unfortunately, there is relatively little data concerning martensitic stainless steels and their surface modification in biomedical applications. As shown in previous studies, low-temperature plasma nitriding (LTN), successfully used in industry for over 30 years, can lead even to deterioration of corrosion resistance of AISI 440B martensitic stainless steel<sup>1</sup>.

The aim of the study was to evaluate the effect of TiN, DLC and LTN surface modification on biofunctional properties, i.e. corrosion resistance and wear, of AISI 440B martensitic stainless steel.

## EXPERIMENTAL METHODS

Material has been divided in following groups:

- I. reference I, heat treated in 250°C,
- II. reference II, heat treated in 500°C,
- III. LTN diffusion layer modified, 390°C, 50% H : 50% N,
- IV. DLC modified
- V. TiN modified.

Electrochemical corrosion studies were carried out in 0,9% NaCl<sub>aq</sub> using potentiostat-galvanostat (PGP-201, Radiometer). A conventional three-electrode system was used. Corrosion potential ( $E_{corr}$ ), corrosion current ( $i_{corr}$ ) (Tafel method) and pitting potential ( $E_p$ ) were determined. Open circuit potential ( $E_{ocp}$ ) was monitored for 2 hours of immersion.

Wear tests were performed on a disc-on-plate tribometer working in a reversing movement mode of a frequency of 1 Hz with given initial gap between working surfaces. 0,9% NaCl<sub>aq</sub> solution was used as lubricant.

The post-test samples pit and surface morphology were studied by scanning electron microscopy (SEM – S-3000N, Hitachi), confocal laser scanning microscopy (CLSM – LEXT OLS 4000, Olympus) and energy-dispersive X-ray analyser (EDX).

## RESULTS AND DISCUSSION

### Corrosion resistance

Both  $E_{ocp}$  observations and anodic polarization tests suggest that DLC layers have the most beneficial impact on corrosion resistance of AISI 440B amongst all applied layers. In comparison with reference, TiN and LTN treated material, DLC application results in significant shift of  $E_{ocp}$  and  $E_{corr}$  towards noble values,

as well as in two orders of magnitude lower  $i_{corr}$ . This may be due to low porosity and high density of DLC layers<sup>2</sup>. TiN layers did not affect significantly corrosion resistance of considered steel. As some authors claim, the titanium nitride layers are porous<sup>3,4</sup> and water-penetrable<sup>4,5</sup>. Due to that, they do not limit the aqueous solutions contact with metals.

The worst performance in corrosion tests amongst all modified samples exhibited the LTN modified ones. Not only  $E_{corr}$  and  $i_{corr}$  values were not far different from the reference ones, but also visible even with the unaided eye corrosion pits occurred. Due to that, LTN samples were not considered in wear tests.

### Wear resistance

Wear studies indicated that DLC layers are characterized by low friction coefficient value (average  $\mu = 0,03$ ), which remained stable during whole 2 h test. On the contrary, friction coefficient of TiN-modified samples rose each time until the end of the test, to reach even the redoubled value of DLC  $\mu$ . What is the most important, modified samples fulfilled its task as anti-wear layers. Unlike the reference material, DLC and TiN modified samples indicated no measurable wear. It should however be noted that there are noted cases of TiN spalling from martensitic stainless steels<sup>6</sup>.

## CONCLUSION

Experiments performed on reference and surface modified AISI 440B martensitic stainless steel show that the best biofunctional properties are exhibited by DLC-modified material. Deposition of DLC layer results in significant reduction of corrosion and wear rate. In the future it will be necessary to perform further analyses in martensitic stainless steels surface modification techniques.

### INTRODUCTION

Recent developments in bio-interface engineering have shown that inkjet printing is a promising method for surface modification as it allows for noncontact layer-by-layer accurate deposition of conductive particles on the surface, however it requires the careful preparation of stable in time inks of appropriate viscosity and suitable ability to drying after deposition<sup>1</sup>. The non-contact mode of the operation reduces cross-contamination between samples and that is why inkjet printing has become the technique of choice for the functionalization of biomaterials<sup>2</sup>. The current drop-on-demand (DOD) inkjet printing technology allows the generation of accurate patterns on various substances using a layer by layer deposition with ink droplets of a few picolitres. Inks can be composed of soluble or well dispersed and stable in time particles, including conductive polymers or biomolecules. In case of piezoelectric nozzles, the process can be done at room temperature which is beneficial for temperature-sensitive materials, so that the functionality of the immobilized substance can be maintained. The conductive polymers (e.g. polyaniline (PANI)) possesses many interesting properties that make them attractive materials for variety of applications. They have electrical properties similar to semiconductors and metals while their mechanical properties are similar to conventional polymers<sup>3</sup>. These materials have been considered for biomedical applications because of their physical, electrical, and biocompatibility characteristics<sup>4</sup>. Furthermore, conducting polymer structures can also be fabricated with inkjet printer. Combining electrospun, biodegradable scaffolds with conductive polymers would enable us to stimulate a multitude of cellular functions, including attachment, proliferation, migration, and differentiation through a modulation of electrical stimuli to the cell.

### EXPERIMENTAL METHODS

Conductive polymer (polyaniline) were deposited on the surface of various electrospun composite membranes (PCL, PLA, gelatin modified with hydroxyapatite, bioglass and osteogenon) using piezoelectric material printer DMP-2831. Determination of the electrical properties of materials was done basing on the electrochemical impedance spectroscopy measurements (EIS). The complex structure of the obtained scaffolds and their chemistry were characterized using SEM, FTIR, and WAXD. The scaffolds were also characterized in terms of their

porosity, mechanical properties and bioactivity, as well as by in-vitro cellular tests using NHOst cells.

### RESULTS AND DISCUSSION

In the current paper we have proposed a method to obtain a novel composite scaffolds for bone tissue engineering. Two techniques, namely electrospinning and inkjet printing processes, were used to fabricate bioactive scaffolds which provide an electrically conductive environment for cells.

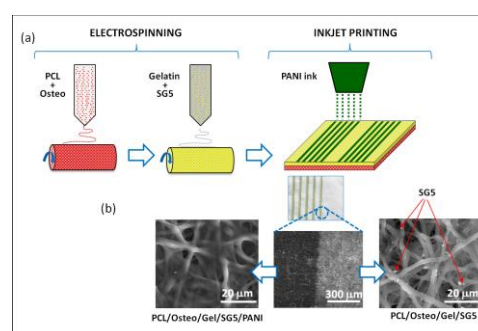

Fig. 1. (a) Scheme of the scaffold preparation process. (b) SEM images of the electrospun scaffold after inkjet printing<sup>5</sup>.

### CONCLUSION

Our research is initially aimed at fabricating scaffolds for improved cell-material interactions. Conductive PANI micropatterns were successfully inkjet printed on electrospun scaffolds. Presence of PANI did not affect apatite formation in SBF fluid. Cells proliferation was observed both on PANI modified and non-modified surface of scaffold.

## INTRODUCTION

Nowadays, the use of natural fibers to reinforce polymers in order to improve their properties is widespread. Biocomposite materials are increasingly used in various sectors such as automotive, medicine and manufacturing. There is a particular class of biocomposite materials wherein a biodegradable polymeric matrix is reinforced with natural fibers, and such materials are called green biocomposite materials and they represent a growing field in polymer science<sup>1</sup>.

Aliphatic polyesters such as poly(butylene succinate) (PBSu) have intriguing properties, including biodegradability and non-toxic hydrolysis products. One of the main problems with polymer-natural fiber composites is the low interfacial adhesion due to the hydrophilicity of the fibers and the hydrophobicity of most polyesters.

The primary method for enhancing the interaction between the fiber and the matrix is the surface modification of the fiber. The addition of binders on the fibers surface and/or compatibilizers in the polymeric matrix, leads to good compatibility between the cellulosic fibers and the nonpolar polymeric matrices<sup>2</sup>. In the present work citric acid was used to modify hemp fibers in order to increase the mechanical performance of PBSu/hemp composites.

## EXPERIMENTAL METHODS

Hemp fibers have been modified by 2 different ways: first by the use of NaOH and with a combination of NaOH treatment and citric acid addition. Thus, two series of PBSu composites have been prepared, with the two different modifications of the fibers. The fiber content was 20, 30 and 50wt%. The composites have been prepared by melt blending, using a twin screw co-rotating extruder, followed by their physicochemical characterization. Mechanical properties were studied by measuring the tensile and impact strength as well as their rate of biodegradation by enzymatic hydrolysis and degradation in soil. The dispersion and adhesion were studied with scanning electron microscopy (SEM). Interactions between the matrix and the fibers was also studied with FTIR spectroscopy.

## RESULTS AND DISCUSSION

Washing with NaOH removed the excess of waxes and hemi-cellulose from the surface of hemp fibers, and the remaining cellulose can react with citric acid in high temperature during melt mixing. The cellulosic hydroxyl groups combined with citric acid anhydride form an ester linkage and introduced carboxyl groups to the natural fiber, thus providing more polar groups available for the creation of hydrogen bonds with the polymer. The reaction of the modification is presented in Fig. 1.

Figure 1: Thermochemical reaction of hemp cellulose with citric acid

SEM micrographs of the modified fibers revealed a smoother and cleaner surface, due to the efficient removal of waxes and hemi-cellulose. Stronger OH peaks in the FTIR spectra suggest the exposure of cellulose that can induce stronger interactions with the polymeric matrix. XRD diffractograms reveal increased crystallinity in the modified fibers, consistent with the removal of amorphous components of the fibers during the modification. The composite materials with hemp fibers modified with citric acid exhibited improved mechanical properties and interfacial adhesion, due to the large number of hydroxyls and carboxyl groups on the fillers surface. The presence of hemp fibers caused great rates of biodegradability in the composite materials, as was revealed after enzymatic hydrolysis and soil burial for several days.

## CONCLUSION

The modification of hemp fibers led to more sites available for hydrogen bonding with PBSu polymeric matrix. Thus, stronger interactions are taking place enhancing the interfacial adhesion between the different materials. As the result these composites have improved mechanical properties compared with unmodified fibers.

### INTRODUCTION

Guidewires are used for proper insertion of catheters, endoscopes or stents during urological treatment<sup>1</sup>. They should feature high resistance to electrochemical corrosion in the environment of tissues and body fluids<sup>2,3</sup>. Guidewires after their production are subject to sterilisation aimed at getting rid of all microorganisms. The purpose of this study is to evaluate the impact of surface modification and sterilisation in ethylene oxide on electrochemical characteristics of wires made of stainless steel X10CrNi 18-8 used as urological guidewires.

### EXPERIMENTAL METHODS

Wires made of steel X10CrNi 18-8 after cold drawing were used for the tests. Wire surface was modified, in turn, by means of electrochemical polishing and chemical passivation. Resistance to electrochemical corrosion was evaluated on the ground of potentiodynamic tests with application of VoltaLab PGP201 system by Radiometer. EIS was performed with application of measurement system Auto Lab PGSTAT 302N equipped with FRA2 module. Tests were performed in the environment of artificial urine at the temperature of  $T = 37\text{ }^{\circ}\text{C}$ <sup>2,4,5</sup>.

### RESULTS AND DISCUSSION

Potentiodynamic tests results (mean measurement values of 5 measurements) are presented in Table 1.

Table 1. Potentiodynamic tests results

Type of surface	$E_{\text{corr}}$ , mV	$E_b$ , mV	$R_p$ , $\text{k}\Omega\text{ cm}^2$
Polished*	-84	+331	294

Passivated**	+84	+757	2600

\*wires prior to sterilisation

\*\*wires after sterilisation in ethylene oxide

Analysis of experimentally determined impedance spectra of corrosion systems was made with application of electric equivalent systems presented in Fig. 1. The best matching of model spectra to impedance spectra determined experimentally in the solution of artificial urine for wires prior to sterilisation was provided by a simple model of oxide layer (it consisted of a parallel CPE connected with the resistance of ion transition through phase boundary: electrode –  $R_{\text{ct}}$  solution and resistance at high frequencies, that may be attributed to the resistance of electrolyte  $R_s$ ). Whereas, for samples after sterilisation, the best matching of impedance spectra was obtained through application of electric equivalent system that consisted of two consecutive parallel systems of CPE connected with resistance of transition and resistance at high

frequencies –  $R_s$ . In addition,  $R_{\text{pore}}$  means resistance of electrolyte in the porous layer, and  $\text{CPE}_{\text{pore}}$  capacity of the surface zone of material with high degree of surface development (porous)<sup>6</sup>.

Fig. 1. Models of electric equivalent system for wires prior to sterilisation (a) and after sterilisation (b)

On the ground of obtained equivalent circuit diagrams, electrical values were determined; they are presented in Table 2. Results obtained in impedance tests confirmed favourable impact of sterilisation process in ethylene oxide. Increase of resistance of ion  $R_{\text{ct}}$  transition was observed, irrespective of the way of surface preparation, which is a favourable phenomenon and improves resistance of the material to electrochemical corrosion.

Table 2. Results of impedance tests

Type of surface	$R_{\text{pore}}$ , $\text{k}\Omega\text{ cm}^2$	$\text{CPE}_{\text{pore}}$		$R_s$ , $\text{k}\Omega\text{ cm}^2$	$\text{CPE}_{\text{dl}}$

\*wires prior to sterilisation

\*\*wires after sterilisation in ethylene oxide

### CONCLUSION

On the ground of performed corrosion tests it was proved that chemical passivation and sterilisation in ethylene oxide have favourable impact on corrosion resistance of wires made of stainless steel X10CrNi 18-8. Passive layer created on the surface of wire protects the alloy from impact of corrosion environment in a more efficient way and secures proper bio-tolerance of steel wires used in urology. Chemical passivation is surface modification treatment useful for creation of a barrier layer protecting steel from influence of artificial urine.

### INTRODUCTION

Hydrogels are a class of cross-linked polymers and due to their three-dimensional structure and hydrophilic nature, they can absorb large quantities of water. These materials have high physical, chemical and mechanical stability in the swollen state. Water absorbance of the hydrogels can range from ten up to a thousand percent of its own volume. Chitosan is a polymer containing a primary amine group and two free hydroxyl groups on each molecule of glucose. The purpose of the study was to obtain polymeric hydrogels based on chitosan with the addition of iron (II,III) oxide nanoparticles by means of photopolymerization, and then to investigate their properties.

### EXPERIMENTAL METHODS

Hydrogels with different amounts of a crosslinking agent - diacrylate poly(ethylene glycol) (PEGDA) - and photoinitiator were synthesized by direct ultraviolet (UV) photopolymerization. Subsequently, the following investigations were carried out: sorptive ability in distilled water and different solutions, incubation studies in water and simulated body fluids (Ringer's solution and SBF). Incubation studies were also performed on the synthesized samples. Biological activity and structure analysis were performed on the polymer matrix using FT-IR spectroscopy.

### RESULTS AND DISCUSSION

The research covered synthesis of the polymer matrix with addition of iron (II,III) oxide nanoparticles, physicochemical tests and in vitro incubation research. A decrease in water absorption was observed in samples with an increasing amount of added crosslinking agent. Moreover, the type of solution in which the sample was immersed, also influenced the results. The lowest absorption occurred in a solution of  $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ . Analysis of the polymer matrix structure of the synthesized hydrogels, before and after the incubation, was also carried out using Fourier transform infrared spectroscopy (FT-IR).

By using systems sensitive to magnetic fields, various treatments can be more effective, thus use of oxide iron (II,III) nanoparticles may assist a better and faster delivery of the drug into the tissue.

### CONCLUSION

Hydrogels containing nanoparticles of iron (II, III) oxide can be used in many medical applications. Use of materials containing such metal oxides may be useful, for example, in dressings applied to the affected part of the body and subjected to a magnetic field to enhance the therapeutical effect. Additionally the generated heat will act beneficially.

[110425241@ccalumni.meijo-u.ac.jp](mailto:110425241@ccalumni.meijo-u.ac.jp)

### INTRODUCTION

In recent years, a relatively low elastic modulus of around 30 GPa nearly equal to the bone has been demanded on the metallic biomaterial. However, in the case of the application with the spinal fixture, the metallic material needs a relatively high elastic modulus in order to suppress the spring back during deformation process. Therefore, the control of the elastic modulus by stress-induced transformation on newly developed biomedical  $\beta$ -type Ti-Cr system alloy has been proposed by preset authors. During the local plastic deformation, the elastic modulus rises locally by the precipitation of  $\omega$  phase.

Therefore, the change in the mechanical properties of Ti-Cr system alloy for the spinal fixture subjected to heat treatments and surface modification processing was investigated in this study.

### EXPERIMENTAL METHODS

Materials used in this study were hot forged Ti-12Cr ( $\phi$ : around 3.0 mm) and Ti-29Nb-13Ta-4.6Zr alloy ( $\phi$ : around 3.0 mm) bars. Ti-12Cr and Ti-29Nb-13Ta-4.6Zr (TNTZ) were solutionized at 1003 K and 1063 K for 3.6 ks in a vacuum followed by water quenching (WQ), respectively. Both solutionized alloys are designated as Ti-12Cr<sub>ST</sub> and TNTZ<sub>ST</sub>. Some Ti-12Cr<sub>ST</sub> were subjected to aging treatment (AT) at 573 K, 673 K and 723 K. Aged Ti-12Cr<sub>ST</sub> was classified by aging temperature (e.g. Ti-12Cr<sub>AT573K</sub>). Surface modification used by fine particle bombarding (FPB) was done on the specimen surface of Ti-12Cr<sub>ST</sub> at a pressure of 0.6 MPa for 0.3 to 0.6ks, which is designated as e.g. Ti-12Cr<sub>ST</sub>/FPB<sub>0.3ks</sub>.

For the evaluation of microstructures, the optical microscope (OM), and the X-ray diffraction (XRD) spectroscopy were carried out on each specimen. For the mechanical properties, Vickers hardness and tensile properties were investigated on each specimen.

### RESULTS AND DISCUSSION

Figure 1 shows the profiles of HV and elastic modulus ranging from very edge of the specimen surface to the center of cross-section of Ti-12Cr<sub>ST</sub>/FPB<sub>0.3ks</sub>. The change in HV and elastic modulus shows almost the same trend each other. Each HV (elastic modulus) of very edge of specimen surface and the center is 354 HV (104 GPa) and 354 HV (80 GPa), respectively. Therefore, HV and elastic modulus is increased by around 15 % and 30 % through FPB.

Figure 2 shows XRD profiles of Ti-12Cr<sub>ST</sub> and Ti-12Cr<sub>ST</sub>/FPB<sub>0.3ks</sub>. The XRD profile of Ti-12Cr<sub>ST</sub>/FPB<sub>0.3ks</sub> shows the stress-induced  $\omega$  phase.

From these results, an increase in HV and elastic

modulus near the specimen surface mainly is attributed to the precipitation of  $\omega$  phase and work hardening, which is enhanced by  $\omega$  phase through FPB.

Fig. 1 Vickers hardness and elastic modulus profiles of Ti-12Cr<sub>ST</sub>/FPB<sub>0.3ks</sub>

Fig. 2 XRD profiles of Ti-12Cr<sub>ST</sub> and Ti-12Cr<sub>ST</sub>/FPB<sub>0.3ks</sub>

### CONCLUSIONS

- 1) Precipitation of stress-induced  $\omega$  phase was confirmed on Ti-12Cr through FPB.
- 2) An increase in HV and elastic modulus near the specimen surface was attributed to the precipitation of  $\omega$  phase and work hardening, which was enhanced by  $\omega$  phase on Ti-12Cr through FPB.

## High Mechanical Functionalization of Biomedical Ti Alloys Subjected to Air Oxidation Processing

Yoshiki Tsujimura<sup>1</sup>, Toshikazu Akahori<sup>2</sup>, and Tomokazu Hattori<sup>2</sup>

<sup>1</sup>Graduate School of Science and Technology, Meijo University, Japan

<sup>2</sup>Faculty of Science and Technology, Meijo University, Japan

[110434044@calumni.meijo-u.ac.jp](mailto:110434044@calumni.meijo-u.ac.jp)

### INTRODUCTION

Recently, Ti alloys are getting great attention as metallic biomedical material,  $\beta$ -type Ti-29Nb-13Ta-4.6Zr alloy (TNTZ) with high biocompatibility and low elastic modulus similar to the cortical bone around 30 GPa has been developed in Japan.

Surface modification processing for metals is mainly applied for improvement in the wear resistance by the formation of hardened layer on the surface. Air oxidation processing (OX)<sup>1)</sup> is one of the simple methods for obtaining the hardened layer. In this study, the mechanical properties of TNTZ and  $\alpha+\beta$ -type Ti-6Al-4V (Ti64) as a comparison material subjected to OX under various conditions were investigated. In addition, the change in mechanical properties of TNTZ and Ti64 subjected to fine particle bombarding (FPB) were also done for improving those more.

### EXPERIMENTAL METHODS

Materials used in this study were TNTZ and Ti64 respectively. TNTZ was solutionized at 1063 K for 3.6 ks in a vacuum followed by water quenching (WQ), which is designed as TNTZ/ST. Ti64 was used in anneal condition. Some samples were conducted with OX at 873 K for 3.6 ks, 10.8 ks and 21.6 ks followed by air cooling (AC). Those are classified by the holding time (e.g. TNTZ/OX 3.6 ks). FPB with high speed steel particles less than 150 $\mu$ m in diameter was applied to some TNTZ/OX and Ti64/OX (e.g. TNTZ/OX 3.6 ks+FPB). Optical microscopy (OM) and X-ray diffraction (XRD) spectroscopy were carried out on each specimen to evaluate the microstructure. Vickers hardness, and tensile and fatigue properties were investigated for each specimen to evaluate the mechanical properties.

### RESULTS AND DISCUSSION

Figure 1 shows Vickers hardness profiles from very edge of specimen surface to subsurface in depth around 100  $\mu$ m of TNTZ/OX and TNTZ/OX+FPB. Vickers hardness near the specimen surface of TNTZ/OX is around 300 Hv higher than that of the subsurface near center of cross section. Vickers hardness increases remarkably with the holding time for OX. On the other hand, Vickers hardness of all TNTZ/OX+FPB increase by around 60 Hv as compared to that of TNTZ/OX. 0.2% proof stress and tensile strength of TNTZ/OX 3.6 ks was slightly higher than those of TNTZ/ST while the elongation showed a reverse trend. According to an increase in the holding time of OX, both 0.2% proof stress and tensile strength rose due to mainly solid solution hardening and formation of oxide layer. On the other hand, a decrease in elongation was due to easily

crack initiation in the oxide layer. 0.2% proof stress and tensile strength of TNTZ/OX+FPB were slightly higher than those of TNTZ/OX while the elongation was also slightly reduced. These trends of TNTZ were almost similar to Ti64. From these results, it needs to investigate the optimization of OX condition with relatively short holding time because of poor balance of tensile properties in OX condition with long holding time.

Fig. 1 Vickers hardness profiles of (a) TNTZ/OX and (b) TNTZ/OX+FPB.

### CONCLUSIONS

- 1) Vickers hardness near the specimen surface of TNTZ/OX 21.6 ks and TNTZ/OX 21.6 ks+FPB showed the maximum value (Hv 516 and 571).
- 2) 0.2% proof stress and tensile strength of TNTZ/OX and Ti64/OX was slightly increased with an increase in holding time of OX.

## INTRODUCTION

Newly developed  $\beta$ -type Ti-29Nb-13Ta-4.6Zr (TNTZ) is one of representative biomedical Ti alloys with high biocompatibility and a relatively low elastic modulus around 60 GPa close to that of cortical bone<sup>1)</sup>. However, TNTZ doesn't show the direct contact with the bone while biomedical ceramics such as hydroxyapatite (HAp) easily contacts with that. Therefore, the formation of bioactive layer on the surface of TNTZ and the change in mechanical properties of TNTZ by HAp fine particle bombarding were investigated in this study.

## EXPERIMENTAL METHODS

Materials used in this study were TNTZ subjected to a solution treatment (ST) at 1063 K for 3.6 ks in a vacuum followed by water quenching (WQ), which are designated as TNTZ<sub>ST</sub>. Some samples were subjected to aging treatment at 673 K for 1.2 ks after ST, which are designated as TNTZ<sub>AT673 K</sub>. Surface modification by HAp fine particle bombarding (HAp FPB) for 10 and 20s was conducted with all samples as mentioned above, which are designated as TNTZ<sub>ST</sub>/HAp and TNTZ<sub>AT</sub>/HAp, respectively. Annealed Ti-6Al-4V was used as a comparison material (Ti64<sub>annealed</sub>). Ti64<sub>annealed</sub> was also subjected to HAp FPB in the same condition for TNTZ, which is designated as Ti64/HAp. Optical microscopy (OM), scanning electron microscopy (SEM), and X-ray diffraction (XRD) spectroscopy were carried out on each specimen to evaluate the microstructure. Vickers hardness (HV) and fatigue tests were performed to examine the mechanical properties.

## RESULTS AND DISCUSSION

HV of TNTZ<sub>ST</sub>/HAp for 10 and 20s, TNTZ<sub>AT</sub>/HAp for 10 and 20s and Ti64/HAp for 10 and 20s increased slightly near the specimen surface as compared with that of TNTZ<sub>ST</sub>, TNTZ<sub>AT673 K</sub> and Ti64<sub>annealed</sub>. HV profile of TNTZ<sub>ST</sub>/HAp for 10s and TNTZ<sub>ST</sub>/HAp for 20s as representatively shown in Fig. 1 have a hardened region of HV from the specimen surface to around 100 $\mu$ m in depth. The increased value of HV on TNTZ<sub>ST</sub>/HAp is around 30 HV higher as compared to that of TNTZ<sub>ST</sub>. According to an increase in treatment time for FPB, the thickness of harden layer increases

slightly. Figure 2 shows S-N curves obtained from fatigue tests on TNTZ<sub>ST</sub> and TNTZ<sub>ST</sub>/HAp for 20s. The fatigue strength of TNTZ<sub>ST</sub>/HAp for 20s increases in the high cycle fatigue life region. The fatigue limit of TNTZ<sub>ST</sub>/HAp for 20s is around 300 MPa and around 60 MPa higher than that of TNTZ<sub>ST</sub>. HV near specimen surface on TNTZ<sub>ST</sub>/HAp for 20s was around 40 HV higher than that of center of specimen as mentioned above. As a result, it is considered that the effect of residual compressive stress by HAp FPB occurred in high cycle fatigue life region.

Fig.1 HV profiles of TNTZ<sub>ST</sub>, TNTZ<sub>ST</sub>/HAp for 10 and 20s

Fig.2 S-N curves of TNTZ<sub>ST</sub> and TNTZ<sub>ST</sub>/HAp for 20s

## CONCLUSION

- (1) HV of TNTZ<sub>ST</sub> subjected to HAp FPB showed the maximum value in very edge of specimen surface. In particular, HV near the specimen surface of TNTZ<sub>ST</sub>/HAp 20s increased by around 30HV as compared to that of TNTZ<sub>ST</sub>.
- (2) Fatigue strength of TNTZ<sub>ST</sub> subjected to HAp FPB increased in high cycle fatigue life region. The fatigue limit was around 300 MPa.

### INTRODUCTION

Liposomes are self-assembled vesicular lipidic bilayers surrounding aqueous compartments. As Drug Delivery Systems (DDS), they are able to circumvent cell barriers, allow the incorporation and protection of hydrophilic and lipophilic drugs, and facilitate their release for effective target delivery. Many efforts have been made to further enhance the properties of liposomes. Its surface modification by polymeric materials is a remarkable example<sup>1</sup>.

The key idea is to gather in the same amphiphilic polymeric entity two crucial attributes: caging capabilities (for liposome stabilization) and high degree of functionalization (for polymer structural response to pH and/or temperature stimuli)<sup>2</sup>. The development of new polymers to be used in polymer-liposome complexes (PLC) is crucial in these systems. In this regard, the tailored synthesis of macromolecules based on control/living radical polymerization (C/LRP) method is a suitable approach<sup>3</sup>. In particular, ATRP is very well established for different families of monomers<sup>4</sup>, and has several advantages over other methods, such as mild work conditions, fast kinetics, and very high tolerance to different functionalities<sup>4</sup>.

### EXPERIMENTAL METHODS

**Polymer synthesis:** In this work, cholesterol (CHO) was used to anchor the polymer into liposome. The synthesis started with the esterification of the OH-end group of CHO with bromocarboxylic acids, yielding an initiator structure<sup>5,6</sup>. CHO-Br initiator was later used for the ATRP of tert-butyl acrylate (tBA) with Cu(0) and Me<sub>6</sub>-TREN in dimethylsulfoxide (DMSO) at 25 °C. The tBA units of CHO-PtBA were then deprotected with trifluoroacetic acid (TFA) in CH<sub>2</sub>Cl<sub>2</sub> to form CHO-PAA (Scheme 1). ATRP method of synthesis is much simpler than other C/LRP methods and uses mild conditions of polymerization along with a rigorous control of the polymer properties (viz. molecular weight).

**Scheme 1:** Schematic illustration of the synthesis of CHO-PAA.

**PAA caged liposomes:** The liposome formulation DMPC:DMPG (50:5) was selected and CHO-PAA polymer was incorporated into the liposomal bilayer to obtain polymer-incorporated liposomes (PIL). Then, PILs were crosslinked using the COOH groups from PAA with a diamine in order to obtain polymer

liposomes complexes (PLCs). To assess the PCL efficacy to encapsulate an active drug, BSA was used to load the liposomes and several PLC parameters were evaluated. The cytotoxicity of PLC systems was determined for THP-1 cell line using the MTS assay.

### RESULTS AND DISCUSSION

The chemical structure of the obtained polymer was analysed by NMR and FTIR spectroscopies. Gel permeation chromatography (GPC) was used to determine the number-average molecular weight ( $M_n$ ) and dispersity ( $\bar{D} = M_w/M_n$ ). The good control over the polymer synthesis achieved by the ATRP method could be supported by the results ( $\bar{D} \approx 1$ ).

The results from calorimetric and zeta-potential studies demonstrated that cholesterol is inserted in the hydrophobic moiety of PIL (more negative surface charge and an enthalpy reduction in comparison to the formulation without polymer). The crosslinking of PAA in the PLC formulation was confirmed by FTIR and TEM studies. The same studies confirmed that the PLC parameters and membrane rigidity were not affected by the entrapment of BSA. Finally, none of the formulations tested revealed signs of *in vitro* toxicity after 24 h of incubation.

### CONCLUSION

These studies have established that PAA with a CHO end-group obtained by ATRP was successfully incorporated in a DMPC:DMPG liposomal membrane, which allowed to achieve PLC with high degrees of reticulation, non-toxic, and competent to incorporate active molecules.

[claus.moseke@fmz.uni-wuerzburg.de](mailto:claus.moseke@fmz.uni-wuerzburg.de)

Silver-doped Ti films were produced using a single magnetron sputtering source equipped with a titanium target with implemented silver modules under variation of bias voltage and substrate temperature. The Ti(Ag) films were characterized regarding their morphology, contact angle, phase composition, silver content and distribution as well as the elution of Ag<sup>+</sup> ions into cell culture medium.

## INTRODUCTION

Physical vapor deposition (PVD) is a common method to generate hard implant coatings, e.g. for abrasion-resistant or antimicrobial surface properties. The latter are realized in the binary system Ti-Ag by simultaneous vaporization using both magnetron sputtering and arc vaporization of single component targets. Here we simplified this process by developing modular Ti/Ag targets for an easy and precise variation of the silver content in magnetron-sputtered Ti(Ag) coatings.

## EXPERIMENTAL METHODS

Conventional disc-shaped titanium targets were modified with circular concentrated holes (5 mm in diameter) which were filled with silver nuggets by means of spot-welding. It was possible to change the silver fraction in the coating by either altering the number of holes filled with Ag or by varying the deposition parameters such as applied substrate bias (up to 200 V) and substrate temperature (up to 500 °C). X-ray diffraction (XRD) was used to examine the crystal structure of the generated films.

Figure 1: PVD setup with modular target.

The silver content of the coatings and the elution of silver into cell culture medium were quantified by inductively coupled mass spectrometry (ICP-MS). The morphology of the coating was investigated with scanning electron microscopy (SEM) and focused ion beam (FIB).

## RESULTS AND DISCUSSION

SEM pictures (Figure 2) showed that substrate heating during film deposition led to an even and dense surface layer, an effect that was even enforced by applying a negative substrate bias voltage. This was also reflected in decreased surface roughness. XRD confirmed the deposition of both Ti and Ag. ICP-MS showed a clear correlation between the applied sputtering parameters and the silver content of the coatings. Additional elution measurements using ICP-MS revealed that the elution kinetics of silver could be strongly influenced by variation of the sputter conditions.

Figure 2: SEM image of a FIB cut through a Ti(Ag) film deposited with 400 W sputtering power and a substrate temperature of 500 °C.

## CONCLUSION

Modular targets are easy to build, very flexible in their material configuration and were successfully used to deposit Ti(Ag) films. The properties of the films can be adjusted by variation of the coating parameters such as the applied bias voltage, sputtering power, and substrate temperature. In particular, the Ag content of the films and the amount of eluted silver could be influenced by coating parameters.

### INTRODUCTION

Controlling the interface between the implant and the surrounding tissue is of paramount importance to ensure the success of implantable devices. Adverse body reactions to the implant, such as fibrous encapsulation, can be avoided by accurately tuning the properties of the synthetic material surface. For this purpose, one approach, which is explored in this study, is to chemically functionalize the surface with bioactive molecules, capable of binding cell receptors and thereby influencing cell behaviour<sup>1</sup>. Specifically, the aim of our modification is to guide the response of human mesenchymal stem cells (hMSCs), enhancing adhesion, growth and differentiation into the osteoblastic lineage. Following a biomimetic approach, the two fibronectin sequences RGD and PHSRN have been chosen as bioactive moieties of our double-branched ligand (fig. 1). This recently synthesized peptidic platform<sup>2</sup> guarantees the co-presentation of the motifs, which are known to synergically bind integrin  $\alpha 5\beta 1$ <sup>3</sup>, a key receptor in osteogenesis<sup>4</sup>.

**Fig 2.** Schematic representation of the dual ligand for the co-presentation of RGD and PHSRN sequences.

### EXPERIMENTAL METHODS

The divalent platform was covalently immobilized on smooth mirror-like commercially pure Ti (grade 2) via silanization with 3-(aminopropyl)-triethoxysilane (APTES). The physicochemical properties of the surface were studied with contact angle measurement, white light interferometry, AFM and XPS.

The response of hMSCs was analyzed by means of immunofluorescence, proliferation and differentiation studies. These included evaluation of calcium deposits formation by Alizarin Red staining method, analysis of ALP expression via enzymatic-assay, and gene expression by RT-PCR.

One-way ANOVA with Tukey post-hoc analysis was used to detect significant differences.

### RESULTS AND DISCUSSION

The immobilization of the dual ligand significantly increased the adhesive capacity of the metallic surface: the number of cells attached and their projected area were significantly increased compared to the control (fig. 2). Proliferation of cells was efficiently supported

by the synthetic ligand at all time points. Analysis of calcium deposits, ALP activity and gene expression revealed that the branched ligand is able to support the differentiation into the osteoblastic lineage. This study provides further evidence that an accurate choice and controlled presentation of peptidic ligands is crucial to design bioactive coatings and significantly improve the biological performance of an implantable material.

**Fig 1.** Actin immunostaining of the uncoated (a), RGD-functionalized (b), and RGD/PHSRN dual ligand-functionalized (c) Ti disks. Bar 500  $\mu\text{m}$  in (a), 200  $\mu\text{m}$  in (b) and (c).

### CONCLUSION

The covalent immobilization method was proved efficient to stably anchor the peptidic ligand to the metallic surface. Stem cells attached and spread to a higher extent on the surfaces coated with the dual biomolecule, displaying a polygonal shape, which is associated to the differentiation into bone-forming cells. The analysis of gene expression, ALP activity and calcium deposits also confirmed that the simultaneous co-presentation of the RGD and PHSRN motifs is able to stimulate the differentiation of stem cells into osteoblasts. Hence, our functionalization strategy constitutes a promising and versatile approach to guide stem cells behaviour by tailoring surface anchored ligands.

## INTRODUCTION

When a backbone disease is treated with an operation, there is a method to fix the backbone with a medical appliance. Polyetheretherketone (PEEK) is popularly used for such an appliance. The advantage of PEEK is high strength and high biocompatibility. In addition, composites of PEEK and carbon are also expected as novel medical devices with enhanced mechanical properties. However, such PEEK-based materials cannot combine with bone tissue. Tight bone integration of PEEK medical devices is necessary for long-term stability *in vivo*.

It is reported that formation of bone-like apatite on artificial materials in body environment through chemical reaction with body fluid is essential requirement for exhibiting bone-bonding ability, i.e. bioactivity [1]. Although several techniques including sulfuric acid treatment [2] and incorporation of sol-gel-derived CaO-SiO<sub>2</sub> powders [3] have been attempted, such modification is not applied for the PEEK-carbon composites.

In the present study, we attempted various acid treatments and subsequent incorporation of Ca<sup>2+</sup> to provide with the apatite-forming ability on the composites. After the treatment, we evaluated their apatite formation ability *in vitro* by soaking the modified composites in simulated body fluid (SBF).

## EXPERIMENTAL METHODS

The PEEK-carbon composite disks with 10 mm in diameter and 1.2 mm in thickness were soaked in 5 mL of concentrated sulfuric acid (97 wt%) at 20°C for 1 min or 5 mL of concentrated acetic acid at 20°C for 24 h. After the treatment, they were soaked in 30 mL of 1 M-CaCl<sub>2</sub> solution at 36.5°C for 24 h and subsequently 30 mL of SBF at 36.5°C for 14 days.

Surface structural changes were characterized by scanning electron microscopic (SEM) observation attached with energy-dispersive X-ray (EDX) spectroscopy, Fourier-transform infrared spectroscopy (FT-IR) and contact angle measurement.

## RESULTS AND DISCUSSION

Sulfonic group was formed on the PEEK surfaces and morphology of the PEEK changed into porous structure after the sulfuric acid treatment. On the other hand, obvious change in chemical structure was not detected in FT-IR spectra after the acetic acid treatment, although contact angle decreased by the treatment. This means that top surface of the composite would become more hydrophilic by the treatment. Fig. 1 shows SEM photographs and EDX spectra of the surfaces of PEEK-

carbon composites treated with sulfuric and acetic acid, followed by CaCl<sub>2</sub> treatment and soaking in SBF for 14 d. Fine particles containing Ca and P were observed for the sulfuric acid treatment, but such particles were hardly observed for the acetic acid treatment.

The sulfonic groups formed on the PEEK-carbon composites would act site for the heterogeneous apatite nucleation. In addition, it was found that sulfonic groups were formed even on pure carbon plates after the sulfuric acid treatment. They would also contribute to the apatite formation.

### Sulfuric acid treatment

### Acetic acid treatment

**Fig. 1** SEM photographs and EDX spectra of the surfaces of PEEK-carbon composites treated with sulfuric and acetic acid, followed by CaCl<sub>2</sub> treatment and soaking in SBF for 14 d.

## CONCLUSION

It was found that chemical surface modification using sulfuric acid was effective for providing PEEK-carbon composites with apatite-forming ability. This type of treatment would be effective for development of PEEK-based biomaterials by immobilization of various biological molecules.

# Controlled Growth of Smooth Muscle Cells to Provide Biomaterial with Blood Vessel-like Properties

Aldona Mzyk<sup>1</sup>, Roman Major<sup>1</sup>, Jan Marczak<sup>2</sup>, Bogusław Major<sup>1</sup>

<sup>1</sup>Institute of Metallurgy and Materials Science, Polish Academy of Sciences, Poland

<sup>2</sup>Laser Technology Division/Institute of Optoelectronics, Military University of Technology, Poland  
[aldonamzyk@gmail.com](mailto:aldonamzyk@gmail.com)

## INTRODUCTION

Nowadays, the hemocompatibility improvement of blood contacting material is aimed at vessel wall structure reconstruction on its surface.<sup>1</sup> The most recent studies focus on cells interacting with flat scaffolds. However, in blood vessels smooth muscle cells are found covering a highly curved surface.<sup>2</sup> It raises a fundamental question how surface curvature may determine cells behavior. This study was aimed at showing the mechanism of smooth muscle cells adhesion, morphology and function control in response to surface patterning.

## EXPERIMENTAL METHODS

The substrate surface was covered with 500 nm a-C:H:Si coating by physical vapor deposition method. Then, the laser interference lithography technique was used to form channel-like patterns of 32  $\mu\text{m}$  diameter with the 25  $\mu\text{m}$  inter-channel distance. Patterns were prepared in two depth variants, as consist of 5  $\mu\text{m}$  and 15  $\mu\text{m}$  sections (Fig. 2A) or 30  $\mu\text{m}$  (Fig. 2B) on the entire length of channel. After patterns formation, the 24 bilayer poly-L-lysine/hyaluronic acid (PLL/HA) films were deposited. Changes in coating microstructure after patterning were investigated by the transmission electron microscopy (TEM), whereas surface topography and cells response was analyzed by the confocal laser microscopy (CLSM) technique.

## RESULTS AND DISCUSSION

The analysis of TEM images confirmed microstructure inhomogeneity in the area of patterns (Fig. 1). The deformation around pattern was smaller for deeper channels. Selected area electron diffraction (SAED) pattern revealed the change of the crystal size.

The relation between surface topography and smooth muscle cells preferences during migration and spreading on the a-C:H:S surface was found. On the flat surface the migration and settlement was not oriented similarly to other researchers observation.<sup>2</sup> It has been shown that channel depth of 5  $\mu\text{m}$  also did not promote oriented cells growth. Moreover, cells were able to growing on the all surface area, including channels' bottom. Contrary, cells alignment was observed on 15  $\mu\text{m}$  and 30  $\mu\text{m}$  pattern depth variants. Surface coverage by polyelectrolyte films had an beneficial influence on cellular behavior. It was found that PLL/HA films promoted intercellular connections formation between smooth muscle cells from the opposite sides of channel.

Fig.1. Microstructure and SAED patterns of unmodified (A) and modified (B) channel surface area.

Fig.2. Surface topography (A,C) and (B,D) smooth muscle cells growth on the patterned surface.

## CONCLUSION

Among investigated patterns, channels of deepness above 15  $\mu\text{m}$  and inter-channel distance of 25  $\mu\text{m}$  facilitate directed cells culture *in vitro* analogous to the orientation of blood vessel wall's smooth muscle cells. Modification of patterned surface by PLL/HA film enhanced intercellular connections formation across the channels.

## INTRODUCTION

Cr-based nitrides or oxynitrides with silicon addition were found to typically consist of crystalline CrN or CrON and amorphous SiN<sub>x</sub> phases<sup>1</sup>. It was also shown that CrNO presented better biocompatibility and corrosion resistance as compared with nitrides<sup>2</sup>.

For this work, three types of novel multilayers were prepared by cathodic arc technique in order to increase the mechanical properties of CoCr alloy used in biological applications.

## EXPERIMENTAL METHODS

CoCr alloy discs (25 mm diameter) were used as substrates for the multilayer coatings with different structures: Cr/CrSi/CrSiN/CrSiON; CrSi/CrSiN/CrSiON; CrSiN/CrSiON. An example of a multilayer system is shown in Fig. 1.

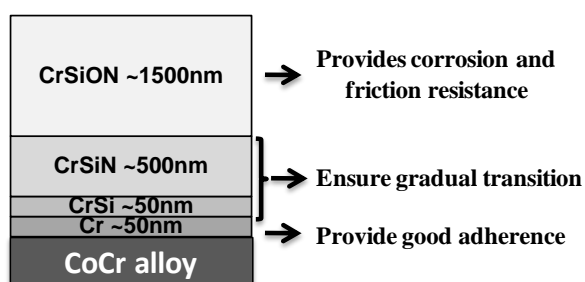

Fig. 1. Architecture of the multilayer coatings

The phase composition and crystallographic structure of the coatings were determined using X-ray diffraction. A comparison between the hardness and tribological properties (friction, wear) of the coatings was performed. Tribological tests were conducted using a ball-on-disc tribometer (3N load, 1500 m sliding distance). After the sliding tests, a surface profilometer was used to measure the wear tracks profiles in order to determine the worn out volume and thereafter the wear rate of the uncoated and coated CoCr samples. The surface morphology and elemental composition of the wear tracks were carried out by scanning electron microscope (equipped with an energy dispersive X-ray spectroscope).

## RESULTS AND DISCUSSION

XRD patterns revealed face-centered cubic (FCC) structures, with (200) preferred orientations. This orientation is indicative of the surface energy dominance.

All coatings exhibited similar hardness values (~14 GPa), higher than the CoCr substrate (~4 GPa).

The evolution of the friction coefficient ( $\mu$ ) as a function of sliding distance (Fig. 2) showed an improved friction behaviour for the samples with the adhesion layer. Cr/CrSi/CrSiN/CrSiON also exhibited the lowest wear rate after 1500m sliding distance under a constant normal load of 3N. SEM results showed that for the coatings which displayed lower friction coefficients as compared with the uncoated CoCr sample, more flat surfaces are formed at the contact area.

Fig. 2. Evolution of friction coefficient as a function of sliding distance

## CONCLUSION

The main conclusion is that the Cr-based multilayer coatings improved significantly the hardness and tribological characteristics of the CoCr alloy. Among the coatings, the Cr/CrSi/CrSiN/CrSiON system exhibited the highest hardness and the best friction and wear performance.

### INTRODUCTION

Magnetic resonance imaging technique plays a very important role in medical diagnostic<sup>1,2</sup>. In order to improve quality of this kind of research it is necessary to use contrast agents which have influence on protons relaxation times. This work describe synthesis and physicochemical properties of biocompatible magnetic nanoparticles (superparamagnetic iron oxide nanoparticles, in brief: SPIONs) which shorten  $T_1$  and  $T_2$  proton NMR relaxation times. The materials obtained exhibit an advantage over commonly used MRI contrast agents (shortening usually one type of relaxation time  $T_1$  or  $T_2$ ) which implies their name: dual modal MRI contrast agents.

### EXPERIMENTAL

Dual modal nanoparticle agents consisting of maghemite magnetic and protective coatings of ionic chitosan with gadolinium complex have been synthesized. Three types of preparation methods of those materials were proposed. They differ from each other in the way the gadolinium ions were introduced into the coating layer: SPION-Gd (ACh-GdDTPA) involves covalent and SPION-Gd (electrostatic) electrostatic Gd-complex attachment. The properties of materials obtained were investigated with several methods e.g.: nuclear magnetic resonance (NMR), X-ray fluorescence (XRF), transmission electron microscopy (TEM), vibrating sample magnetometry (VSM), FTIR spectroscopy and dynamic light scattering (DLS).

### RESULTS AND DISCUSSION

Physiochemical measurements allowed us to determine the following properties of SPIONs: DLS (hydrodynamic diameters: ca. 100 nm and Zeta potential), VSM (SPION-Gd (ACh-GdDTPA) exhibit superparamagnetic behaviour and a high saturation magnetisation) and XRF (confirmed gadolinium contents in the material synthesized). NMR studies show a linear dependence of  $1/T_1$  and  $1/T_2$  relaxation rates versus nanoparticle concentrations. This allowed us to derive the respective relaxivities:  $r_1$  and  $r_2$ . Their values obtained for SPION-Gd (ACh-GdDTPA) and SPION-Gd (electrostatic) are outstanding when compared to commercial contrast agents: FeREX<sup>TM</sup> and Ocean (table 1).

Sample name	$r_1$ (mM <sup>-1</sup> s <sup>-1</sup> )	$r_2$ (mM <sup>-1</sup> s <sup>-1</sup> )
SPION-Gd (ACh-GdDTPA)	36.0 ± 0.9	361.4 ± 4.3
SPION-Gd (electrostatic)	53.7 ± 1.1	375.5 ± 9.7
SPION-CCh	46.5 ± 2.8	282 ± 21
Ocean	23.5 ± 0.9	93.8 ± 1.9
FeREX <sup>TM</sup>	33.1 ± 1.3	160.1 ± 6.6

Table 1 show  $r_1$ ,  $r_2$  relaxivities values of all samples.

These results imply that dual modal MRI contrast agents synthesized and studied in this work exhibit better properties than single positive or negative agents.

### CONCLUSION

The dual modal agents obtained exhibit an outstanding relaxivity (high values of  $r_1$  and  $r_2$ ) and a very good long-term stability. Presence of gadolinium atoms in polymer layer influences magnetic properties of nanoparticles. The method of synthesis used in this work enables us to: change the type of (SPIONs) coating polymer and precisely control the distance between core and gadolinium complex. The nanoparticle materials presented can be considered as effective contrast agents for low-field MRI scanners.

### INTRODUCTION

Ti6Al4V alloy (Ti64) is the metallic biomaterial most widely used for the fabrication of orthopaedic implants. The interaction of the alloy with physiological fluids affects the stability of the passive outer layer that provides corrosion resistance. Technologies to produce outer layers resilient to chemical attack include thermal oxidation in air, which generates thick rutile layers on Ti64 surfaces<sup>1</sup>. However, the full component has to be subjected to treatment, which may cause thermal stability loss of the alloy microstructure.

Laser shock processing (LP) is a technology in which metallic surfaces are irradiated with short and intensive laser pulses. The net effect is the development of compressive residual stresses that improve fatigue strength<sup>2</sup>. Interestingly, LP is suitable for treating local areas of a component. For biomedical applications, LP cannot use sacrificial layers as they may lead to toxicity due to surface contamination. In the absence of ablative coatings, thermal rise at the surface during laser focusing is extremely high, which may oxidize the alloy surface. The changes that experience the Ti64 surface treated by means of LP without protective coating and the interactions of bone cells with the treated alloy, not addressed to date, were studied in this work.

### EXPERIMENTAL METHODS

Discs of Ti6Al4V ELI (extra low interstitial) alloy were irradiated with a Q-switched Nd-YAG laser working in fundamental harmonic at 1.6 J/pulse and producing pulses of 10 ns. Samples were irradiated at a density of 421 pulses cm<sup>-2</sup>. Samples polished to get a mirror-like finish were used as control. Surface characterization included scanning electron microscopy (SEM), X-ray diffraction, atomic force microscopy, X-ray photoelectron spectroscopy and time of flight secondary ion mass spectrometry analyses. Human mesenchymal stem cells (hMSC) and primary cultures of human osteoblasts (hOB) were used for cytocompatibility studies. Cell adhesion was examined by spectral confocal microscopy and SEM. For immunostaining, cells were stained with specific antibodies for paxillin, p-FAK Y397 and fibronectin. To visualize actin filaments, cells were stained with phalloidine-TRITC. p-FAK Y397 levels were quantified in protein extracts using a specific immunoassay kit. Cell viability was assessed using the alamarBlue assay. The degree of cell

layer maturation was investigated in cells cultured in osteogenic medium, by means of Alizarin Red staining and determination of alkaline phosphatase (ALP) activity.

### RESULTS AND DISCUSSION

Due to the temperature rise during LP, melting and ablation generate a waved surface with roughness values at the submicron scale that can be recognized by cells. A small percentage of metastable TiO was detected in the treated surface. In addition to Al-OH, not detectable in the untreated alloy, the outer surface layer of the treated alloy contains higher amounts of Ti<sub>2</sub>O<sub>3</sub>. The oxide layer and oxygen diffusion zone in the treated surface is several microns thick. Cells adopt a stretched morphology on the treated alloy and exhibit a great number of filopodia. Only some minor colocalization of paxillin and p-FAK Y397 with actin fibers are observed in the attachment sites. Morphometric analysis indicates that focal adhesion length decreases in cells cultured in the treated alloy. Intracellular p-FAK Y397 levels are lower than in cells incubated on the untreated alloy. Despite quality of adhesion is deeply affected in the LP-treated Ti64 surface, the rate of cell attachment is identical than in the untreated surface. Cell viability and organization of extracellular fibronectin matrix are also as in the untreated alloy. Moreover, the degree of cell mineralization and ALP activity in cells cultured in treated Ti64 are higher than in the untreated alloy.

### CONCLUSION

Ti64 surface thermally oxidized by means of LP allows the proliferation of hMSC and hOB, and enhances the osteoblastic maturation of hMSC as well as the lineage-specific activities of terminally differentiated hOB.

## Cell Adhesion to Plasma Treated and Fluorinated Collagen Surfaces

Ina Prade, Frauke Junghans, Michael Meyer

Collagen / Leather / Biopolymers, Forschungsinstitut für Leder und Kunststoffbahnen, Germany  
[ina.prade@filkfreiberg.de](mailto:ina.prade@filkfreiberg.de)

### INTRODUCTION

Cell adhesion to biomaterials, implant surfaces and tissue engineering scaffolds is essential for the formation of tissues *in vitro* and *in vivo*. Especially cell adhesion to extracellular matrix proteins like collagen influences cellular morphology, proliferation and differentiation<sup>1</sup>. In this study, collagen coatings and foils were functionalized with atmospheric plasma and gaseous fluorine, respectively, to investigate effects of a modified surface chemistry on cell adhesion.

### EXPERIMENTAL METHODS

Plasma activation was performed as a dielectric-barrier discharge (DBD) in the presence of the process gases air, nitrogen or argon. The fluorination took place in a reaction chamber, which was filled with a fluorine/nitrogen mixture (ratio 10 : 90) and air.

### RESULTS AND DISCUSSION

Cell cultivation on functionalized collagen surfaces revealed two effects. Oxo-fluorination and plasma treatment resulted in an increase in cellular adhesion and elevated cell density after three days of cultivation. Spreading area of the cells was remarkably increased especially for fluorinated collagen surfaces.

Contact angle measurements showed significant improvement of surface wettability and a decrease in

surface energy after plasma treatment. Fluorinated surfaces however revealed only weak changes, indicating that improved cell adhesion can not be explained with hydrophilic surface properties. Interestingly, X-ray photoelectron spectroscopy (XPS) analyses indicate changes in the elemental composition of treated collagen. Oxygen and nitrogen content was increased upon plasma treatment and fluor atoms were found in the surface of oxo-fluorinated samples.

The thermal stability of collagen was not affected as observed by differential scanning calorimetry (DSC).

Increased cellular adhesion to fluorinated surfaces is not affected by topography of the surface, because no differences could be observed with scanning electron microscopy (SEM).

Ongoing studies with chemical derivatisation of the treated collagen surface will further help to identify differences in chemical composition of the surface. So far the reason for the improved cellular adhesion is unknown and new surface sensitive methods are required to explain these observations.

### CONCLUSION

By now, the results demonstrate that it is possible to influence cell adhesion to collagen in a biocompatible way without the use of solvents. Plasma techniques and fluorination could thereby improve the properties of collagen and increase its applicability.

### INTRODUCTION

Hydroxyapatite (HAP) ceramics belong to a class of calcium phosphate-based materials, which have been widely used as coating on titanium medical implants in order to improve bone fixation and thus increasing the lifetime of the implant<sup>1-3</sup>. The aim of the study is to evaluate the influence of the substrate temperature on the characteristics of HAP coatings prepared by RF magnetron sputtering. It was reported that the HAP coatings with the best bioactivity properties could be obtained by controlling the morphology, surface roughness, and crystallinity of the coatings<sup>3</sup>.

### EXPERIMENTAL METHODS

As substrates, Si wafers (100) and Ti based alloy discs (10 mm diameter) were used. The coatings were prepared using a RF magnetron unit equipped with one cathode made of HAP (1 inch diameter, 99.9 % purity, Kurt Lesker Ltd). The deposition parameters were: the base pressure =  $1.3 \times 10^{-4}$  Pa, Ar working pressure =  $6.6 \times 10^{-1}$  Pa, target power fed = 50 W, substrate bias voltages = -60 V, substrate temperature = 400, 500, 600, 700, 800°C, deposition time = 360 min.

The element composition was carried out using a Scanning Electron Microscope coupled with Energy Dispersive Spectroscopy. Crystalline structure, phase composition and texture were determined by means of X-ray diffractometer (XRD). The surface morphologies were evaluated by Atomic Force Microscope (AFM), on  $10 \times 10 \mu\text{m}^2$  area. The corrosion behaviour of the coatings was evaluated in Fusayama artificial saliva solution at 37°C, according to the ASTM standard G 59 - 97 (reapproved 2003). Viability of MG63 cells was measured by the MTT (3-(4,5-dimethylthiazol-2-yl)-2,5 diphenyl tetrazolium bromide) assay. MG 63 human osteosarcoma cells were cultured in Dulbecco's modified Eagle's medium (DMEM) with 10% inactivated fetal bovine serum (FBS) supplemented with 1% penicillin, streptomycin and neomycin (Sigma). The  $25 \times 10^3$  cells/cm<sup>2</sup> were seeded and cultured for 3, 5 and 7 days on studied samples.

### RESULTS AND DISCUSSION

EDS analysis of the coatings reveals that all samples exhibited the Ca/P ratios in the range 1.67 – 1.81. The Ca/P ratios of the HAP prepared at 600 °C and at 700 °C are close to 1.67, which corresponds to a stoichiometric HAP. All the coatings exhibit a (002) texture, which is a common for the HAP coatings deposited by RF magnetron sputtering technique. The HAP prepared at 400 °C show two peaks: (002) and (202). The increase in temperature leads to the occurrence of new diffraction peaks (corresponding to planes (200), (222),

(213) and (004). The SEM analysis indicates that the morphology of the HAP coatings deposited at 400 and 500°C are very smooth with a few visible particles. For the HAP prepared at substrate temperatures ranged from 600 to 800°C, some spherical in-growths appear.

The roughness of the coatings increases with increasing substrate temperature. At low temperature, an enlarged boundary grains are observable. The increase of the substrate temperature leads to the decrease in corrosion current density, indicating an enhancement of the corrosion resistance. Regarding the polarization resistance, note that this increase with substrate temperature and all the coatings have much higher polarization resistance than the uncoated alloy. First of all, it can be seen that all the coatings improve the biocompatibility of the Ti based alloy, independent on the days of culture. Comparing the coatings, after 1 day, no significant changes in cell viability were observed. After 5 days, the cell viability of the coatings increased by increasing the substrate temperatures (Fig.1).

Fig. 1. Actin cytoskeletal organization and nuclear staining of the osteosarcoma cell growth on the investigated surfaces after 5 days (blue-nuclei; green - F-actin fibres)

### CONCLUSION

The results showed that all of the coatings exhibited uniformly growth and that the increasing substrate temperature induced an increase in the crystallinity of the prepared coatings. Corrosion performance of the coatings was improved with the increase of the substrate temperature from 400°C to 800°C. Furthermore, all of the coatings support the attachment and growth of the osteosarcoma cells with regard to the in vitro test findings.

### INTRODUCTION

The rapid cellular acceptance of the implant surface by the surrounding tissue is the crucial factor for the ingrowth in the bone. The aim is the fast and successful osseointegration by improved initial interactions of the titanium surface with bone regenerating osteoblasts. These interactions may be supported by additional bioactive coatings.

Gas-discharge plasma processes are successfully applied for the modification of titanium surfaces. Physico-chemical surface properties like roughness, cleanness, and also chemical coatings determine the cellular acceptance *in vitro* and *in vivo*. The cell adhesion via integrins but also additional adhesion mechanisms via hyaluronan play a key role in the very first encounter with the biomaterial. A new surface functionalization strategy was developed by stimulating the electrostatic immobilization [1,2]. The deposition of plasma polymerized allylamine (PPAAm) leads to the desired surface properties. Furthermore, the knowledge of long term stability, sterizability of such plasma polymer coatings is essential for the use of implants. Besides *in vitro* studies especially *in vivo* investigations show no inflammatory response and an enhanced surface adhesion capacity of these nitrogen containing plasma polymers.

### EXPERIMENTAL METHODS

**Implants and film preparation.** Polished discs and platelets (1-3 cm; 5x5x1cm) from chemically pure Ti-6Al-4V\_P were used as substrates. They were coated with 50–100 nm thin PPAAM films applying low-pressure microwave discharge plasma [1]. Film properties were analyzed by XPS, FT-IR (IRRAS), water contact angle, and surface energy, after film deposition,  $\gamma$ -sterilization and aging.

***In vitro* study.** Human osteoblasts (MG-63 cells) were cultured on the samples in serum-free DMEM [1]. Adhesion and cell cycle phases were calculated by flow cytometry. Spreading and actin cytoskeleton were visualized by confocal microscopy.

***In vivo* study.** The biocompatibility was studied after intramuscular implantation of untreated Ti6Al4V and PPAAM-coated platelets in male LEWIS rats. The inflammatory tissue response was analysed after 7, 14, and 56 days [3].

Custom-made implants were used for the determination of the bone-to-implant contact BIC by  $\mu$ CT [4].

### RESULTS AND DISCUSSION

Closed pinhole-free PPAAM films resistant to hydrolysis and delamination were detected. Advantageous medium hydrophilicity exists.

The density of primary amino groups is at about 2-3 %. It could be shown that not only primary amino groups but also other nitrogen-functional groups as e.g. acid amides or imides play a role for initial cell functions. PPAAM aging processes are not relevant for cell response during one year's storage. Gamma sterilization has no influence on film and also cell adhesion [5].

The positively charged surfaces improve impressively adhesion and spreading of MG-63 osteoblastic cells as initial cellular effect. The PPAAM film enables the cells to literally melt into the structure of the titanium alloy substrate.

No local inflammation processes could be observed.

Implants with PPAAM coating revealed a clear but not significant increase of the bone-to-implant contact BIC (58.5%) compared to uncoated titanium surfaces [4].

**Figure 1:** Morphology (SEM) of MG-63 cells (after 30 min) on a PPAAM surface stored for 360 d. (magnification 2000x, 45°, DSM 960A, Carl Zeiss; bar = 10 µm)

### CONCLUSION

Although the bioactivation of material surfaces with immobilized proteins and peptides is an established method, our results demonstrate that functionalization of Ti-6Al-4V\_P alone with positively charged nitrogen functional groups carrying plasma polymer films is sufficient enough to improve initial steps of the cellular contact to the material surface significantly.

It could be shown that also other N-functional groups as e.g. acid amides or imides seem to play an important role for initial cell functions as well.

*In vivo* results demonstrate that PPAAM films are biocompatible; local inflammatory reactions do not exist. An increase of BIC could be verified.

[tomasz.goryczka@us.edu.pl](mailto:tomasz.goryczka@us.edu.pl)

### INTRODUCTION

The NiTi shape memory alloy has been known from its medical applications<sup>1</sup>. However, relatively long time of its being in the human body environment can cause corrosion as well as migration of nickel ions. Nickel is known from its toxicity. In order to reserve unique shape memory properties of the NiTi alloys for medicine, the surface can be modified with layers, coatings or/and covers. Covering NiTi alloy with multi-layers leads to improvement of its functionality as a material for medical implants.

### EXPERIMENTAL METHODS

Rectangular samples (8mm x 5mm) of commercial NiTi shape memory alloy (49.4at%Ti and 50.6at.%Ni) was used as a matrix for multi-layers deposition. First, polished samples were subjected to oxidizing or nitriding/oxidizing. Next, a hydroxyapatite layer was deposited. Samples were sintered at temperature ranged from 400°C to 800°C and sintering time from 5 minutes to 2 hours. Finally, they were divided into two groups. One group was subjected for studies of the biodegradation in bacteria environment whereas second for fibroblast growing.

### RESULTS AND DISCUSSION

#### Structure of multi-layer deposited on NiTi

The microscopy observations shown that the structure, on the cross section of the layers, is in a nanoscale. Following steps in layer deposition, first the TiN and then the TiO<sub>2</sub> layer was formed on surface of the NiTi alloy. An average thickness of the layer was 26 nm and 32 nm for the TiN and the TiO<sub>2</sub> phase, respectively. Roughnesses of top of the surface varied in the range of several nanometers. On the top of the TiN/TiO<sub>2</sub> layer the hydroxyapatite was deposited with use of electrophoresis. The thickness of the HAp layer was about 2µm. Dependently on the HAp sintering temperature, the roughness of the top layer increased from 5nm to 170 nm.

#### Cytotoxicity of the deposited multi-layers

Experiments were done with use of normal human dermal fibroblasts (NHDF). The cells were growing in the culture medium DMEM/F12. The cell growth was determined from the number of cells, adhesion as well as their morphology after 24, 48, 72, 96 hours from the seeding. The surviving fraction was determined in reference to the control group of cells.

After 24 hours the oxidized surface show comparable degree of cell growth to the control group. Surface covered with sintered the HAp was covered by the fibroblast in lower density than control group. However,

they were growing in colonies and their morphology were not correctly developed. Extending time of cell growth up to 96 hours brought improvement of the fibroblast adhesion. Also, cell morphology got improved and higher number of the correctly developed cells was observed. The lowest proliferation of the cells and their low amount was observed for the surface sintered at 800°C. Surfaces sintered at temperatures between 500°C and 700°C revealed similar properties to the control group. However, number of the cells was lower than one observed on the oxidized surface.

#### Bacteria adhesion and composite biodegradation

Resistivity of the NiTi alloy covered with multi-layers against bacteria adhesion and biodegradation in bacterial environment was carried out with use of bacteria mixture consisted of: "Staphylococcus aureus", "Staphylococcus epidermidis", "Enterococcus faecalis", "Enterobacter cloacae" and "Pseudomonas aeruginosa". Samples were deeped in bacterial solution for 1, 3 and 6 months at 38°C. Covered NiTi without its sintering as well as after HAp sintered at temperature up to 600°C revealed good adhesion for bacteria, biofilm formation and pitting effect event for short time immersion. Increase of the sintering temperature above 700°C improved resistivity for bacteria adhesion as well as a biodegradation of the composite. Even for long time immersion (6 months) no effects of bacteria activity on sample surface was observed.

### CONCLUSION

Reassuming all received results it can be found, that the NiTi shape memory alloy after surface modification, done with deposited multi-layer, improves its properties as potential material for implant application. Multi-layers consisted of titanium nitride, titanium oxide as well as hydroxyapatite sintered at temperatures between 700°C - 800°C are beneficial for the fibroblast growing. Moreover, they can create effective barrier against bacteria adhesion.

[mihai.tarcolea@upb.ro](mailto:mihai.tarcolea@upb.ro)

### INTRODUCTION

Chromium nitride and oxynitride layers showed good corrosion resistance and biocompatibility properties<sup>1,2</sup>. For this reason, this type of coatings could be successfully applied in biomedical field, where the action of the corrosive body environment on the used biomaterials could be reduced.

In this study, CrSi-based oxynitrides with protective properties were developed by cathodic arc method. Since the obtained coatings are intended to be used as interlayers between ceramic and metallic components of dental restorations, their electrochemical behaviour in artificial saliva was analysed.

### EXPERIMENTAL METHODS

NiCr and CoCr dental alloy discs with 12 mm diameter were obtained by casting in an induction furnace. 150  $\mu\text{m}$  alumina particles were used for sandblasting of the experimental samples. CrSi-based oxynitrides were deposited on NiCr and CoCr discs using cathodic arc technique in an  $\text{N}_2/\text{N}_2 + \text{O}_2$  mixed reactive atmosphere. The obtained coatings have different grading structures and a total thickness of 2  $\mu\text{m}$ .

Protective properties of the coatings were analyzed by potentiodynamic polarization technique in artificial saliva at 37°C. Pt counter electrode, SCE reference electrode and a working electrode with 1  $\text{cm}^2$  exposed area were used. After the OCP was monitored during 60 min immersion time, the potentiodynamic curves were plotted from -1 V to 1.5V vs. SCE (0.166 mV/s scanning rate) and the main electrochemical parameters were determined ( $E_{\text{corr}}$  - corrosion potential,  $i_{\text{corr}}$  - corrosion current density,  $R_p$  - polarisation resistance).

The surface roughness before and after the electrochemical evaluation was measured using a stylus surface profilometer and the surface morphology was determined by a scanning electron microscope.

### RESULTS AND DISCUSSION

Before electrochemical tests, the Cr-based oxynitrides exhibited a surface roughness between 1.5 and 2  $\mu\text{m}$  as a function of substrate. SEM investigations showed that the obtained coatings have a compact surface without defects.

After 60 min immersion in artificial saliva all the tested coatings exhibited more electropositive potential values as compared with the substrates, indicating a higher corrosion resistance. Among them, the coatings deposited on NiCr alloy showed a higher tendency to form passive films after only ~ 60 s immersion.

The electrochemical parameters also demonstrated the protective behaviour of the CrSi-based oxynitride coatings. The type of the substrate used influenced the

corrosion resistance of the coatings. Thus, the use of NiCr as a substrate resulted in lower values of the  $E_{\text{corr}}$  and  $i_{\text{corr}}$ . The best electrochemical behaviour was exhibited by the CrSi/CrSiN/CrSiON coating, deposited both on NiCr and CoCr.

Fig. 1. Open circuit potential of CrSi-based oxynitride coatings deposited on NiCr alloy

Fig. 2. Potentiodynamic polarisation curves of CrSi-based oxynitride coatings deposited on NiCr alloy

### CONCLUSION

The experimental results showed that CrSi-based oxynitrides with different grading structures deposited on NiCr and CoCr dental alloys by cathodic arc technique improved the corrosion resistance of the substrates. Among them, the CrSi/CrSiN/CrSiON coating exhibited the most electropositive  $E_{\text{OC}}$  values, the lowest corrosion current density and the highest polarisation resistance, irrespective of the substrate type.

### INTRODUCTION

Study of dynamics of magnetic nanoparticles (MNPs) is an attractive field of research due to possible applications e.g. in medicine. The knowledge about motion, aggregation and aligning of MNPs is very important when considering bioimaging, drug delivery and magnetic hyperthermia. Presence of interparticle magnetic forces leads to formation of aggregates. They form chain-like structures when interacting with external magnetic field, and undergo displacement when the magnetic field is inhomogeneous.

### EXPERIMENTAL METHODS

Computer simulations of movements of magnetic nanoparticles were carried out at various magnetic field strength (0.0 – 0.4 T) and its gradient (0 - 100 MT/m) in fluids of different density and viscosity (water, glycerine, propanol, liquid epoxy resin) and their results have been verified experimentally. Simulations were taking into account the gravity, buoyancy, and magnetic forces and solving Newton equations for each particle. In the experiments suspensions of magnetic micro- and nanoparticles dispersed in liquid at zero and nonzero applied field have been obtained and observed with optical microscope and SEM/TEM. The images of obtained structures are used for generation of distributions of particles position, concentration and distances between them. The degree of structural anisotropy has been estimated for different samples using Mean Intercept Length and Line Fraction Deviation methods for both simulations and experiment data to compare the quality of final structures formed by magnetic particles. Temperature dependences of the AC susceptibility have been measured for the suspensions of magnetic nanoparticles at the range 4 K – 330 K, i.e. in the solidified and liquid states.

### RESULTS AND DISCUSSION

Computer simulations show an increase in particle dynamics with growing magnetic field. The resultant structures are characterized by longer chains and higher speed of particle displacement. An average spacing between the closest neighbour, which can serve as a measure of the number of aggregated particles, was calculated. It decreases with elapsing time and saturates at nonzero value, which means that there are still some grains not connected to chains. For higher field the

saturation value is an order of magnitude lower than for simulations performed without applied magnetic field.

In the system simulated at no external magnetic field chains combine into closed loops. Magnetic moments of particles form a closed structure due to magnetic interactions between grains. Average velocity of particle translational motion is limited by drag force caused by fluid viscosity. It is the highest in propanol and water but causes that particles collide at relatively high velocity and energy and aggregates are destroyed. In more dense and viscous glycerol and resin the structures formed are more stable – the energy of high speed particles after collision is dissipated by friction.

The results of AC magnetic susceptibility measurements for various frequencies of the alternating field have been analysed. From a step-like change of the real and imaginary susceptibility values the contributions related to Brownian motions have been derived and compared with the predictions obtained from simulations at zero constant magnetic field.

### CONCLUSION

A combined computational and experimental study of dynamics of magnetic nanoparticles reveals a complex character of their behaviour at zero and nonzero DC and AC magnetic fields. It includes occurrence of a pulse-like force of considerable magnitude that can be exerted on adjacent particles or e.g. biological cells. Possible applications of the results in medical therapy (ultrasound, AC magnetic field hyperthermia) and diagnostics (MRI) are discussed.

## INTRODUCTION

For several years, interest in nanomaterials, especially carbon nanomaterials, has been increasing in the fields of biology and medicine. Bearing in mind a number of the unusual properties of these materials such as their electrical and mechanical properties, as well as the possibility of modifying their surfaces using chemical and biological substances, gives those involved with them hope for nerve tissue regeneration and stimulation<sup>1,2</sup>. Nanomaterials deposited on the surface of different traditional materials such as metal may serve as a kind of protective coating on standard metal electrodes, such as those used in deep brain stimulation (DBS), to protect them from increased proliferation of glial cells and glial scar formation that affects the transfer of electrical impulses from the electrode to the tissue. In order to analyze the effects of nanomaterials on nerve cells, the physicochemical properties of these nanomaterials, the properties of coatings made from these materials on the surfaces of metallic substrates, and also the interaction at the interface of metal-carbon nanomaterials should be understood in detail. The physicochemical analysis is the first stage of research of carbon nanomaterials coatings for their potential application in nerve cells regeneration and stimulation.

## EXPERIMENTAL METHODS

Two types of multi walled carbon nanotubes (MWCNTs) differing in kind of chemical groups on their surface and one kind of graphene were selected to the experiments. One of the MWCNTs have carboxyl (-COOH) and one hydroxyl (-OH) groups. Nanomaterials were deposited by an electrophoretic deposition (EPD) method on titanium substrates, which was prepared in an appropriate way to ensure good adhesion of MWCNTs and hybride (combination MWCNTs and graphene) coatings. For this purpose titanium substrates were chemically etched in two types of solution; in 5% HF solution and in mixture of concentrated HF:HNO<sub>3</sub> acids. During EPD process two parameters were optimized such as deposition time and voltage value. Carbon nanomaterials coatings on titanium were subject to a detailed assessment: the integrity of the carbon coating's bonding to the substrate, the continuity and thickness of the coatings, their morphology, microstructure and structural properties. For these investigations several methods such as SEM, TEM, AFM, FTIR and Raman spectroscopy were used.

## RESULTS AND DISCUSSION

Our investigations demonstrated that thickness, homogeneity, integrity of carbon coatings to titanium

substrates strongly depend on duration of the EPD process and voltage value. Also types of chemically etched of titanium substrates have big impact for coating adhesion. The physicochemical properties such as wettability and surface energy, which are very important from the point of view of the cellular response, strongly depend on functional groups on MWCNTs surface. The presence of graphene in MWCNTs coatings influence their morphology, microstructure and structure properties Fig. 1.

Figures 1 presents SEM morphology of carbon nanomaterials coatings containing only MWCNTs (A) and MWCNTs with graphene (B) (hybrid coating). The presence of several percent of graphene in MWCNT-based coatings also improves their adhesion to the titanium substrates.

## CONCLUSION

An exists several parameters such as time deposition of carbon nanomaterials, presence of functional groups on MWCNTs surface, voltage value and presence of another type of nanocarbon such as graphene which have significant impact on carbon nanomaterials coatings deposited on titanium surface. By optimizing the EPD process conditions it is possible to obtained carbon nanomaterials coatings which could be used as a potential substrates for nerve cells stimulation and regeneration.

## INTRODUCTION

Stainless steel (SS) 316L has been applied in medicine for fabrication of implantable devices such like stents or artificial valves. The surface of steel induces dangerous biochemical events such like blood clotting<sup>1</sup> and thus superficial coating is demanded. Surface pre-treatment is an obligatory initial step of SS 316L surface modification since the surface naturally presents oxides layer that needs to be removed in order to provide proper adhesion between organic layer and metal<sup>2</sup>. In existing body of literature there are several methods of SS 316L pre-treatment reported. Nevertheless, we state that provided data are not sufficient and there are still many controversies among this subject. In present work we focused on comparing the usability of two different methods of oxides layer removal as the initial step of SS 316L surface coating.

## EXPERIMENTAL METHODS

In this work we applied two methods of SS 316L pre-treatment: a) electropolishing and b) mechanical polishing. We use flat SS 316L discs (ø14mm) as we consider it be a comfortable model of an SS object.

### *Electropolishing of SS 316L surface*

Electropolishing bath consisted of H<sub>3</sub>PO<sub>4</sub> (60% v/v), H<sub>2</sub>SO<sub>4</sub> (35% v/v) and triethanolamine (5% v/v). We studied the influence of time of the process, temperature and current density. Samples were then cleaned and dried.

### *Mechanical polishing of SS 316L surface*

Different methods were applied, such as grinding with abrasive paper of different gradation and polishing with a polish past. Samples were then cleaned and dried.

### *Analysis of coatings*

Obtained surfaces quality was investigated with the use of infrared spectroscopy (FTIR-ATR) and electron microscopy (SEM). Roughness of the layers (R<sub>a</sub>) was determined (optical profilometry).

## RESULTS AND DISCUSSION

### *Electropolishing of SS 316L surface*

Unlike the authors<sup>3</sup> who studied electropolishing process we found that this actual combination of process parameters does not lead to obtain smooth SS 316L surface. Current density, temperature and polishing time need to be carefully selected to avoid breaches and irregularities. For 55°C and 15 min we achieved the smoothest surface with no traces of oxides, nevertheless further studies revealed that such “mirror-like” surface precludes organic layer deposition in the next step of SS 316L surface modification, which was not clearly pointed out by other authors.

### *Mechanical polishing of SS 316L surface*

We found that this is the easiest and the fastest way to both remove the oxides and standardize all samples' surface. However, after the pre-treatment the surfaces presented relatively high roughness (e.g. R<sub>a</sub> = 173nm). High roughness value of the surface of a blood-contacting material needs to be avoided since it could increase the risk of thrombosis. Thus, further study concerning the effect on blood is demanded. So far, very few authors<sup>4</sup> have undertaken such detailed research and more data is still needed. Also, it has to be remembered that mechanical polishing cannot be applied for stents pre-treatment.

Fig. 1. The appearance of SS 316L surface: a) untreated, b) electrochemically polished, c) mechanically polished

## CONCLUSION

Although we present rather basic study, we believe that it would help to select a proper method of metallic surface pre-treatment since the majority of authors focus on the stage on coating and not on the stage of preparing the surface. So far, we state that mechanical polishing gives better results than electrochemical polishing. In case of stents, other method could be applicable, such like acidic etching.

## INTRODUCTION

Current cardiac electrodes limit the lifetime of pacemakers. Approximately one percent of the energy that is available in a battery of current cardiac pacemakers is used for the regular stimulation of cardiomyocytes. More than half of the stored energy is lost by leakage currents and at the interfaces between pacemaker and tissue – the electrodes that are implanted at the heart muscle.

FIGURE 1: To optimize the electrode-tissue interaction, interdisciplinary methods are employed. The approach includes Cybernetics, Nanotechnology and Tissue Engineering.

The implantation of an electrode induces the migration of immune cells from the vasculature to the electrode surface [1]. After an acute inflammation, macrophages stimulate cells from the connective tissue such as fibroblasts to migrate to the implant via chemokines. The macrophages and fibroblasts form a two-layered fibrous capsule that insulates the electrode from the body, and increases the electric resistance [2]. By controlling the foreign body reaction, the lifetime of the battery/ pacemaker could be extended.

## EXPERIMENTAL METHODS

The aim of the project is to realize seamless electronic-tissue interfaces for efficient electronic-tissue communication. Therefore, methods of Cybernetics, Nanotechnology and Tissue Engineering are employed (see Figure 1).

## RESULTS AND DISCUSSION

By generating nano- and microstructured electrode surfaces, the cell-material interaction is controlled to modulate immunological reactions. To analyze the cellular crosstalk that results in encapsulation of the implant, computational modelling is performed. Additionally, the distribution of the electric potential at a given nanostructured surface is investigated by simulations prior to experimental studies.

## CONCLUSION

Based on methods of tissue engineering, an in vitro model will be developed as a standardized test platform for the characterization of the generated electrodes. These test systems will fulfill the electrophysiological properties of myocardial tissue. Furthermore, the foreign body reaction will be included to study the integration of a nanostructured electrode.

### INTRODUCTION

Concerns regarding cytotoxic properties of vanadium and possible neurotoxicity of aluminium were raised years ago<sup>1</sup>, which led to the belief that a substitute for notoriously applied Ti-6Al-4V alloy needs to be devised. One of such candidate alloys for this purpose is Ti-13Nb-13Zr alloy, which not only exhibits higher corrosion resistance in physiological fluids compared to that of Ti-6Al-4V<sup>2</sup> but also has a notably lower elastic modulus<sup>3</sup>. The latter has a significant effect on stress shielding of the load bearing elements of orthopaedic implants.

Nevertheless, attempts to improve surface properties of this alloy are still made as they play a key role in the overall response of the host organism upon implantation<sup>4</sup>.

Plasma electrolytic oxidation (PEO) is an electrochemical technique of surface modification of valve metals (capable of growing insulating passive oxide layers). The metallic surfaces treated by PEO are porous and enriched with electrolyte species present in anodising baths<sup>5</sup>. By introducing bio-elements (such as Ca and P) into oxide layers bioactivity of the surface can be enhanced<sup>6</sup>.

This work is concerned with surface modification of Ti-13Nb-13Zr alloy by PEO process in Ca containing electrolytes.

### EXPERIMENTAL METHODS

Disc-shaped samples (diameter = 8 mm) of Ti-13Nb-13Zr alloy (BIMO metals) after electropolishing were subjected to anodising (Kikusui, 800H DC power supply) at constant current density in calcium formate and calcium lactate solutions with different concentration at voltages of 200 and 400 V.

The resulting coatings were characterised by a large gamut of experimental techniques: SEM/EDX (Hitachi S-3400N /Thermo Noran), AFM (NanoScope E, Digital Instruments), XRD (X-Pert Philips PW 3040/60), XPS (PHI 5700, Physical Electronics) and XRF (ZSX Primus, Rigaku). Bioactivity was assessed by the use of SBF soaking and biological studies using adult human bone marrow derived mesenchymal stem cells (hBMSC).

### RESULTS AND DISCUSSION

The results of SEM/EDX investigations have shown that surface morphology was highly influenced by the anodising voltage and electrolyte composition. Rougher

and more porous surfaces were obtained at higher concentrations of calcium salts and higher voltages. The incorporation of calcium into the oxide layer was the most significant in the case of 1 M Ca(HCOO)<sub>2</sub> electrolyte solution.

Rutile and anatase TiO<sub>2</sub> phases were identified in the oxide layers. Calcium was present in the form of calcium oxide and calcium carbonates as was determined by XPS. Additionally, it was found Ca was uniformly distributed within the oxide layers. The coating obtained from 0.1 M calcium lactate solution was additionally enriched with the salt in the unchanged form (Ca(C<sub>2</sub>H<sub>4</sub>OHCOO)<sub>2</sub>).

SBF soaking tests showed that no calcium phosphates were precipitated after 4 weeks. However some crystallites of CaO were observed. Their number increased slightly after each week of immersion.

hBMSC cultures has shown that the anodised surfaces are suitable for proliferation of the cells. The most notable seems to be the surface obtained after anodising in a 0.1 M calcium lactate solution as stem cells colonise the surface and form a 3-D structures. Moreover, Col 1 mRNA gene expression determined for this sample was approximately 20-fold higher compared to the electropolished Ti alloy sample.

### CONCLUSION

Authors proposed a method of surface modification of vanadium-free Ti-13Nb-13Zr alloy which consisted of electropolishing and plasma electrolytic oxidation of the alloy in calcium formate and calcium lactate solutions. The examinations have shown that the procedure has a positive effect on the overall bioactivity of Ti-13Nb-13Zr alloy.

## INTRODUCTION

Titanium and its alloys have been widely used for permanent orthopaedic implants; however, they are considered as bioinert, which means that fibrous layer is often formed on the implant-bone interface. For better integration of the implant that could accelerate healing and prolong lifespan of the implant, material surfaces can be modified in various ways. It has been shown that nanotopography influences cell adhesion and differentiation<sup>1</sup>. Anodic oxidation in appropriate electrolytes<sup>2</sup> is a method which can be used for scale-up nanopatterning of metallic materials. Specific parameters of the nanotubes and their influence on the cell growth have been extensively studied recently. Interestingly, various authors obtained contradictory results when performing *in vitro* tests with TiO<sub>2</sub> nanotubes (diameter 15 – 100 nm) using mesenchymal stem cells (MSCs)<sup>3,4</sup>.

Our aim was to perform *in vitro* tests with nanotubular surfaces on commercial titanium alloy and to study the influence of the nanostructure on the adhesion, growth and differentiation of human bone marrow-derived MSCs.

## EXPERIMENTAL METHODS

Cylindrical discs of Ti-6Al-4V alloy with nanotubes (50 nm and 100 nm in diameter) were used. Polished discs of the same alloy served as a control. Human bone marrow-derived MSCs were seeded onto the surfaces at a density of 5,000 cells·cm<sup>-2</sup>. After three days, cells were fixed, permeabilized and stained with DAPI, phalloidin-FITC and immunostained for vinculin (primary anti-vinculin antibody, secondary biotinylated antibody, TexasRed-streptavidin). Images were taken at 10x magnification using epifluorescence microscope Olympus BX51. Samples were subsequently processed for electron microscopy according to a standard protocol and analysed by FEI Quanta 200F ESEM.

## RESULTS AND DISCUSSION

Our previous experiments with Saos-2 cell line showed no differences in cell numbers on nanostructures compared to control (unpublished data). However, we observed decreased adhesion of human bone marrow derived MSCs after 3 days of growth on the surfaces. Also the cell shape area was smaller compared to control (Fig. 1, A, C, E). These observations suggest potential change in cell phenotype that may subsequently lead to reduction in fibrogenesis. We also detected less filopodia compared to control (Fig. 1 B, D, F), which could imply decreased cell motility.

Fig. 1 Human bone marrow derived MSCs on Ti-alloy samples (A, B – flat control, C, D – nanotubes 50 nm, E, F - nanotubes 100 nm in diameter) after 3 days of growth. Green – actin, red – vinculin, blue – nuclei. Scale bar equals to 100 µm.

## CONCLUSION

Surface nanotubular structures on Ti-alloy altered cell adhesion and morphology. Determination of markers of differentiation and stemness by immunofluorescence microscopy and also at mRNA level using qPCR will follow in order to uncover the cell responses to the surfaces.

## INTRODUCTION

The excellent bulk properties of poly(ethylene terephthalate) (PET) including mechanical strength and chemical resistance, propelled it as one of the few materials considered suitable for long-term cardiovascular applications. However, its poor surface properties negatively influence its biological performance (e.g. haemo- and biocompatibility) and represent the major drawback of pristine PET.

To date, a wide variety of surface modification strategies (physical and/or chemical) has been pursued to improve the surface properties of PET. Physical strategies generally result in low stability coatings or imply the use of toxic substance (e.g. glutaraldehyde) in order to increase their stability<sup>1</sup>. Chemical approaches provide a more stable coating. In the latter case, the outer layer is generally functionalized with alcohols, carboxylic acids, amines, etc., that are further used as anchoring points for the covalent coupling of proteins, anti-inflammatory agents (e.g. gamoxilicin, amikacin) or anti-coagulants (e.g. heparin). The main drawback is the need for complex procedures which demand time-consuming protocols under harsh chemical conditions and often compromise the mechanical properties of PET. Consequently, novel concepts are required in this field. In the present study, we propose the covalent immobilization of gelatin on PET *via* two different surface functionalization strategies: 1) the use of a perfluoro aromatic succinimide ester and 2) dopamine. A comparative study between thus-modified PET surfaces was initiated in an attempt to identify the most promising protocol. Gelatin has been selected due to its non-toxic nature, biodegradability, low price and cell-interactive properties<sup>2</sup>.

## EXPERIMENTAL METHODS

A two-step surface modification strategy was applied to PET. The surface of PET was functionalized with 4-azido-2,3,5,6-tetrafluorobenzoic acid, succinimidyl ester (AFB) by UV-C treatment (15 min, 254 nm) and gelatin type B (GelB, 5w%) was subsequently immobilized. In parallel, a dopamine-based coating procedure<sup>3</sup> was used to facilitate the GelB coating (5w%) to become immobilized.

An in depth study of the gelatin-modified PET surfaces was pursued. The surface morphology was assessed by atomic force microscopy (AFM) and scanning electron microscopy (SEM), the coating composition and homogeneity was verified by X-ray photoelectron spectroscopy (XPS) and static contact angle (SCA) measurements, while the coating stability was analyzed *via* radiolabelling experiments.

## RESULTS AND DISCUSSION

For both strategies, the appearance of a distinctive peak in the XPS spectra characteristic for N (10 to 12 at%) together with a sharp decrease in hydrophobicity ( $SCA_{PET} = 73^\circ C$ ,  $SCA_{PET-GelB} \sim 50^\circ C$ ) confirmed the successful immobilization of GelB on PET. Although no distinct differences were observed between the chemical compositions of the final gelatin coated surfaces *via* the two above-mentioned functionalization methods, AFM indicated the presence of different morphologies and roughness profiles (see Figure 1).

**Figure 1.** AFM profile images of gelatin modified PET immobilized *via* AFB strategy (A1), dopamine (B1) and pristine PET (C1); SEM images showing platelet adhesion on gelatin modified PET (A2, B2 and C2). The Z scale for AFM is 3600nm and the scale bars for the SEM images are 10  $\mu m$ , and.

A roughness value being a 7-fold lower was noticed for the AFB-based strategy compared with the dopamine methodology ( $R_{RMS, AFB} = 18 \text{ nm}$ ,  $R_{RMS, dopamine} = 132 \text{ nm}$  for a scan size  $10 \times 10 \mu m^2$ ). As expected, platelet activation slightly increased with surface roughness, but, overall, it was much lower than for pristine PET.

## CONCLUSION

The main aim of the present work was to compare two different surface modification strategies adequate to obtain a stable/durable protein coating on PET for cardiovascular applications. Both AFB and dopamine based approaches successfully facilitate the covalent immobilization of GelB, but strategy-specific surface morphologies were noticed. Preliminary platelet adhesion tests indicated a superior behavior of modified surfaces compared with pristine PET. Future perspectives include the transition of the surface modification strategies from 2D to 3D tubular structures which can be inserted into veins.

## INTRODUCTION

NiTi alloys are widely used for many purposes including medical and technical applications. Metabolic activity of sulphate-reducing bacteria (SRB) such as *Desulfovibrio desulfuricans* species may lead to corrosion of various metals<sup>1</sup>. It has been demonstrated that also titanium and its alloys may corrode in the presence of these bacteria strains<sup>2,3</sup>. In this study, the influence of the NiTi-alloy surface passivation on the biofilm formation by *D. desulfuricans* bacteria in the presence of artificial saliva or inflammatory saliva has been investigated.

## EXPERIMENTAL METHODS

The samples of NiTi were electropolished or passivated, then cleaned in ethanol in an ultrasonic bath, air dried, and sterilized at 180°C. The sterile samples were placed into tubes containing the artificial or inflammatory saliva and then were inoculated with bacteria *Desulfovibrio desulfuricans* (standard soil strain DSM and two wild intestinal strains). As control samples, the sterile systems without bacteria were used. The tubes were incubated at 30°C under anaerobic conditions. Biofilm formation was studied after 48 hours and after 7, 14, 28 days of samples' incubation, using following methods: assay of protein concentration in a medium, extraction of extracellular polymeric substances (EPS), and examination of bacterial biofilms using scanning electron microscope (SEM) analysis.

## RESULTS AND DISCUSSION

Table 1 presents examples of biofilms formed by DSM strain in artificial or inflammatory saliva on a surface of the NiTi electropolished or passivated samples.

Table 1. Growth of *D. desulfuricans* DSM strain on surface of the NiTi-alloy samples (electropolished or passivated), submerged in artificial or inflammatory saliva.

Diversity between intensity of biofilms formation by *D. desulfuricans* on the NiTi samples surface was due to the alloy surface state (electropolished or passivated) as well as to character of artificial saliva. Inflammatory state of saliva proved to be especially important factor promoting the bacteria growth on NiTi surface, also after its passivation.

## CONCLUSION

It has been demonstrated that *D. desulfuricans* can form biofilms in the presence of both artificial and inflammatory saliva on the NiTi alloy surface, even when it was passivated. However, inhibition of the biofilm growth on passivated surface of alloy was observed after 28 days, whereas the mature biofilm was formed during this time on the NiTi samples immersed in inflammatory saliva.

## INTRODUCTION

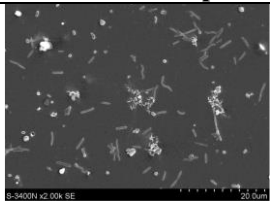

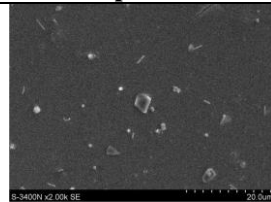

Titanium and its alloys possess exceptional corrosion resistance in various aggressive environments including mouth. For that reason, they are also used as orthodontic alloys<sup>1</sup>. For example, the nickel-titanium (NiTi) alloys are applied in the endodontic instruments in form of super-elastic wires for root canal treatment. Among many other, the sulphate-reducing bacteria (SRB) can be present in mouth, mainly in tooth plaque and cavities<sup>2</sup>. SRB such as *Desulfovibrio desulfuricans* species may be responsible for corrosion of many metals, including titanium and its alloys<sup>2-4</sup>. The aim of this study was to investigate the dynamics of *D. desulfuricans* growth on grinded surface of NiTi-alloy in solution of artificial saliva, also with the inflammatory state.

## EXPERIMENTAL METHODS

The NiTi samples were electropolished or grinded, then cleaned in ethanol in an ultrasonic bath, air dried, and sterilized at 180°C. The sterile samples were placed into tubes containing the artificial or inflammatory saliva and then were inoculated with bacteria *D. desulfuricans* (standard soil strain DSM and two wild intestinal strains: DV/A, DV/B). As control samples, the sterile systems without bacteria were used. The tubes were incubated at 30°C under anaerobic conditions. Biofilm formation was studied after 24 and 48 hours, and after 7, 14 and 28 days of samples' incubation, using following methods: assay of protein concentration in a medium, extraction of extracellular polymeric substances (EPS), and examination of bacterial biofilms using scanning electron microscope (SEM) analysis.

## RESULTS AND DISCUSSION

Table 1. Dynamics of growth of *D. desulfuricans* biofilm (DV/A strain) on surface of the NiTi-alloy samples (electropolished or grinded), submerged in artificial or inflammatory saliva.

Electropolished NiTi samples	
	
Saliva/inflammatory, 24h, SEM, 2000x	Saliva/artificial, 28d, SEM, 2000x

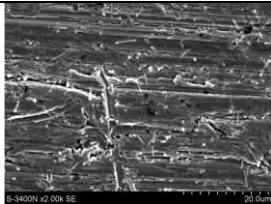

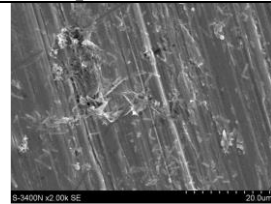

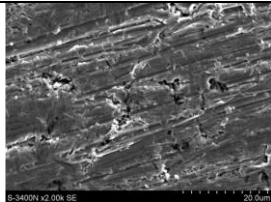

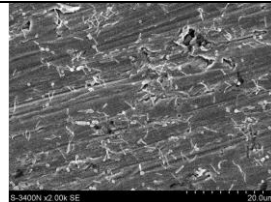

Grinded NiTi samples	
	
Saliva/inflammatory, 24h, SEM, 2000x	Saliva/inflammatory, 48h, SEM, 2000x
	
Saliva/inflammatory, 14d, SEM, 2000x	Saliva/artificial, 28d, SEM, 2000x

Table 1 presents examples of biofilms formed on the NiTi-alloy surfaces (electropolished or grinded) after incubation with *D. desulfuricans* strain DV/A, in the solutions of artificial or inflammatory saliva.

## CONCLUSION

It has been demonstrated that *D. desulfuricans* can form biofilms on the NiTi alloy surface in the presence of both artificial and inflammatory saliva. However, scratches present on the surface of grinded samples have stimulated the bacteria settlement on alloy surface, and thus induced the biofilm formation. The biofilm growth on the NiTi grinded samples was affected by both the surface roughness as well as the inflammatory state of saliva.

### INTRODUCTION

As an emerging biomaterial, PEDOT has proven to be electrically more stable than polypyrrole (PPy). However, in most biomedical related studies, PEDOT was electrochemically polymerized on metal electrodes, which is ideal for sensors but not suitable for tissue regeneration. Electrospun nanofibres made of PEDOT and poly(lactide-co-glycolide), polycaprolactone and chitosan have also been explored. Conductive mat made of electrospun nanofibres normally have pores too small for cell penetration, and also contain rather high percentage of the non-biodegradable conductive polymer because it is bulk rather than surface modification. This study was to present a new conductive nonwoven textile fabric made of biodegradable PLLA and a very thin layer of PEDOT, and to show that the resulting 3D material was electrically stable, easy for cell penetration and retained its textile structure and flexible properties. Such a conductive and largely biodegradable scaffold is easily prepared and would be useful in biomedical applications where a conductive, flexible and fibrous scaffold is needed.

### EXPERIMENTAL METHODS

A thermoplastic fibre grade PLLA resin was heated to 240 °C and melt spun through a spunbond machine. By cooling the web on the moving collector belt a continuous spunbond fabric containing microfibres was produced. The nonwoven PLLA fabric was thoroughly washed to eliminate all chemical residuals left from the manufacturing process. To synthesize the polymer, the PLLA fabric was first immersed in a series of concentrations of EDOT solution in methanol to absorb monomers. Then, FeCl<sub>3</sub> dissolved in deionized water was introduced dropwise onto the EDOT-adsorbed PLLA fabrics to trigger an oxidative polymerization. The polymerisation continued at room temperature for 24h. Finally, the PEDOT-coated PLLA fabrics were thoroughly washed in a solution of MeOH:H<sub>2</sub>O (50:50) to eliminate all residual FeCl<sub>3</sub> and FeCl<sub>2</sub>, and then dried, firstly at 37 °C in a hot air oven, and then in a vacuum oven overnight at room temperature. The surface morphology, surface chemistry and wettability, mechanical property, electrical conductivity and stability were analyzed. Cytotoxicity was tested using human skin fibroblasts. Preliminary experiment was performed to test the feasibility of stimulating cells by

using such conducting scaffold.

### RESULTS AND DISCUSSION

When monomer concentration increased from 0.10 to 0.25 mol/L, the surface resistivity of the fabric decreased dramatically from 49.4 KΩ/square to 0.4 KΩ/square. Further increases in EDOT concentration up to 1.0 mol/L did not significantly affect the surface resistivity. Therefore the optimal concentration in polymerization was found to be 0.25 mol/L. The PEDOT coated fabric appeared dark in color but with no significant change in surface morphology under both optical and scanning electron microscopes, meaning a very thin layer of PEDOT on the microfibers. X-ray photoelectron spectroscopy and water wettability measurements revealed a surface property mixed of PLLA and PEDOT. Thermal analysis showed that the polymerization process did not significantly affect the crystalline structures of the fibres but increased material phase separation. Electrical stability test demonstrated that the PEDOT coated fabric had superior stability than the PPy coated fabric. Cytotoxicity experiment showed that the PEDOT-coated fabric was not toxic to human skin fibroblasts, and supported cell growth as the non-coated fabric did. Finally, the ES activated fibroblasts showed slightly higher proliferation than the controls, showing that this new type of conductive fabric is suitable to mediate ES to cultured cells.

### CONCLUSION

A two-step surface polymerization process was successfully developed to prepare a new type of conductive scaffold based on biodegradable nonwoven web. The fabric web was rendered conductive with other properties not significantly affected. This conductive web can be used as scaffold for cell growth and to mediate ES to the cells.

## Electroless Deposition of Calcium-Phosphate Coatings on Ti6Al4V and Their Biological Response

Ena A. Aguilar-Reyes, Benito Jacinto-Díaz, Carlos A. León-Patiño

Instituto de Investigación en Metalurgia y Materiales, Universidad Michoacana de San Nicolás de Hidalgo, México  
[aareyes@umich.mx](mailto:aareyes@umich.mx)

### INTRODUCTION

Titanium implants have relatively low density, high strength and good processability. The surface of such implants exhibits bioactivity, which can be controlled through the titanium oxide layer that forms [1]. In the case of the metal structure with a fine-grained dispersed, the bioactivity can be increased simply through an intense plastic deformation [2]. The application of synthetic calcium phosphate is the most effective way for surface modification, as it provides an osseointegration of metal implant with bone tissue. Calcium phosphate is the main mineral component of bone tissue and the presence of several components of calcium phosphate in the coating provides the possibility to control the biochemical activity through changes to the composition of the phase [3]. This work is aimed at obtaining Ca-P coatings on Ti6Al4V substrates by an autocatalytic route in order to increase the osteoconductivity through biochemical and surface modification.

### EXPERIMENTAL METHODS

Rectangular substrates of dimensions of 10 mm x 10 mm x 1.6 mm were cut from an annealed plate of Ti6Al4V alloy (Titanium Industries, USA) of 1.6 mm in thickness. The samples were pre-treated in an alkali solution of NaOH 5 M for 24 h. Autocatalytic bath solutions of a 1.2 Ca/P molar ratio were prepared through the dissolution of appropriate amounts of  $\text{CaCl}_2$ ,  $\text{NaH}_2\text{PO}_2$ , and  $\text{C}_4\text{H}_4\text{Na}_2\text{O}_4 \cdot 6\text{H}_2\text{O}$  in distilled water. Electroless deposition experiments were carried out at different pH (5.5 and 6.0), temperatures (80 to 90°C) and times (60 and 180 min). After coating, the samples were characterized by FE-SEM, AFM, XRD, and IR spectroscopy.

### RESULTS AND DISCUSSION

The SEM micrographs in Figure 1 show the morphology of the Ca-P coating formed on the Ti6Al4V substrate after being immersed in the autocatalytic bath for a period of 480 minutes (8 hours) at pH 5.5 and at a 80 °C. As it can be seen, these deposits consist of small particles and the substrate is coated on most of its surface.

**Fig. 1.** SEM micrographs of Ca/P coatings on Ti6Al4V substrate obtained at 80°C, pH of 5.5 and 480 min of immersion time at 50x and 5000x, respectively.

Figure 2 shows the Ca/P coated surface after immersion in cell media for a period of 6 days. According to the results of cell culture, the obtained coatings showed no cytotoxicity and attachment of cells on the surface.

**Fig. 2.** SEM micrographs Ca/P coated-Ti6Al4V substrates after 6 days immersion in MC3T3-E1 preosteoblast subclone 4 cells media at 250x and 1000x, respectively.

### CONCLUSION

The obtained results indicated that it was possible the complete coating of the metallic surface (Ti6Al4V) with a Ca/P layer (100 µm in thickness) after 480 min of immersion in autocatalytic solutions. The morphology and microstructure of Ca/P coatings were directly affected by the different processing conditions such as pH, temperature and time.

Furthermore, calcium phosphate coatings were cytocompatible since adhesion of MC3T3-E1 preosteoblast subclone 4 cells was observed.

### INTRODUCTION

Bioresorbable polymers are the interesting class of materials used for medical devices such as implants and scaffolds<sup>1</sup>. Due to the chemical characteristic those materials does not cause any inflammation in the human body as degrade to non-toxic products<sup>2</sup>. The polymers like polylactide (PLA), polycaprolactone (PCL) poly(lactic-co-glycolic acid) (PLGA) and theirs copolymers are worldwide approved for clinical application and been the subject of many investigations<sup>2,3</sup>.

Despite the growing use of polylactide, there are still unsolved issues regarding the chemical and mechanical properties of the material due to manufacture process.

During the technological processes leading to a product substrate is subjected to a series of actions which could affect the chemical properties of thus changing the mechanical properties.

Shaping polymeric sheets with thickness under 400 microns mechanically can be problematic and not accurate. The use of laser to form the polymer could be the answer in order to obtain good accuracy especially in small objects.

Laser beam has an optical power concentrated to a small area with enough energy to cause the ablation of polymer and in the result cut it. When use under ablation threshold can modify the surface of material by partly degradation.

The aim of the study was to investigate the differences in mechanical properties by defining microhardness of the polylactide sheets exposed to laser light.

### EXPERIMENTAL METHODS

The polymer sheets having a thickness of 340 microns were extruded from commercial medical poly(L-lactide) (Evonic, RESOMER®). Mechanical properties were determined for modified chemical composition of polymer surface by KrF (248 nm) excimer laser. The samples were prepared by irradiation of 5 x 5 mm fragments with increasing number of pulses with same fluence.

Regarding the sheets thickness the method used to characterized specimens was Vickers hardness test method, conducted on microindenter CSM Micro Combi Tester.

During the indentation the force and depth of the penetration are measure, the microhardness HV is calculated as a ratio of the Fi to the lateral surface area of the impression left by the Vickers indenter.

### RESULTS AND DISCUSSION

Conducted studies show that the irradiation of poly(L-lactide) below ablation threshold by the KrF excimer changes the mechanical properties of the surface significant. With the increasing number of irritation pulses on unit of area the polymer become more degraded therefore the decrease of the structure integrity was observed.

Fig.1. Impression left by the Vickers indenter on non-irradiated PLLA, magnification 200x

### CONCLUSION

Application of the laser technique may be the solution for precise shaping of the thin polymer layers for usage as a medical devices. It should however be noticed that the cutting edges arising are affected by laser beam causing ablation. The hardness of used in experiment poly(L-lactide) changes for different laser beam parameters. Thus linking the mechanical properties with characteristic of the laser beam will be relevant for manufacturing process.

### INTRODUCTION

Silver was known for its antibacterial properties as long ago as in antiquity. The Greeks covered their plates and mugs with silver to prevent spread of diseases, they also put silver coins into jugs of water to prolong the duration of the liquid. Greek children were given silver spoons to suck to prevent them from getting ill. In the 90 of the 20<sup>th</sup> century scientists discovered that people with insufficient amount of silver in their bodies are frequently subjected to virus, bacteria and other illnesses. However too much silver introduced into the body may result in necrosis of the liver tissues [1].

### EXPERIMENTAL METHODS

The first research was conducted on specimens covered with nanosilver. The specimens were dipped into the bacteria liquids containing 5 most aggressive bacteria occurring in human body. It was shown by the microscope examinations performed 6 months later, the bacteria didn't form any biofilm. Only separated bacteria were attached to the surface.

The further experiments were followed on the metallic specimens (titanium and titanium alloys) deposited with hydroxyapatite coatings by an use of electrophoretic method, at different voltage and time. Afterwards the nanometals (nanosilver and nanocopper) were implemented into the hydroxyapatite coatings.

The future research is planned to be carried out on cytotoxicity and osteoblast adhesion to the biomaterials. The biological research will be performed in vivo on animals.

### CONCLUSION

To reduce unfavourable phenomena occurring after introducing an implant into human body various modifications of the surface are suggested. Such modifications may have significant impact on biocompatibility of metallic materials. The nanosilver and nanocopper layers are considered most biocompatible. Those layers prevent bacteria from forming the biofilm.

[anna.regiel@uj.edu.pl](mailto:anna.regiel@uj.edu.pl)

### INTRODUCTION

Due to the UVA and UVB light absorption semiconducting metal oxides nanoparticles (NPs), *e.g.* zinc oxide (ZnO) or titanium dioxide (TiO<sub>2</sub>), are the main components of sunscreen lotions<sup>1</sup>. Their main task is ultraviolet irradiation absorption, reflection and scattering. However, the most important concern in the use of oxides NPs as protective component of suntan lotions is Reactive Oxygen Species generation (ROS) and resulting toxicity. Several efforts are undertaken in order to minimize the photoactivity and thus cytotoxicity of ZnO/TiO<sub>2</sub> materials. Usually deactivation is achieved through their surface chemical modifications with polymers or addition of antioxidants<sup>2</sup>. Herein, we present nanocomposite materials with quenched photoactivity based on zinc and titanium oxide nanoparticles, surface-modified with chitosan (CS).

### EXPERIMENTAL METHODS

Two grades of commercially available ZnO-NPs and TiO<sub>2</sub>-NPs, varying in the average particle size, were utilized in our studies. Chitosan with medium average molecular weight was chosen for semiconductors modification (~1300 kDa). Chitosan modified ZnO/TiO<sub>2</sub>-NPs were prepared by ionic-gelation technique with sodium tripolyphosphate (TPP) as a cross-linking agent. Physicochemical characterization of the materials was conducted with application of several techniques. The average hydrodynamic diameter and zeta potential before and after surface modification were measured by Dynamic Light Scattering technique (DLS). Scanning Electron Microscopy (SEM) was used for materials morphology visualization. Chemical composition and sample purity was assessed *via* Energy Dispersive Spectroscopy (EDS). X-Ray diffraction measurements were performed to determine the crystalline pattern of ZnO/TiO<sub>2</sub>-NPs. The chitosan presence on NPs surface was confirmed by IR- spectra measurements. The UV light absorption ability was confirmed *via* collecting the reflectance spectra. In order to check the photocatalytic activity of the composites degradation processes of Azure B, bovine serum albumin and  $\alpha$ -terpinene was monitored. For all materials the photocurrents generation was measured. Moreover, the antibacterial activity against Gram-positive (*Staphylococcus aureus*) and Gram-negative bacteria (*Escherichia coli*) was evaluated by colony-forming capability test. The potential cytotoxicity of materials was tested by MTT assay on human keratinocyte cell line (HaCaT).

### RESULTS AND DISCUSSION

The polymer layer on the ZnO and TiO<sub>2</sub> grains aggregates was observed as round and smooth shapes on SEM micrographs. Also DLS measurements and IR spectra confirmed chitosan presence on NPs surface. Modification of semiconductor nanoparticles with chitosan did not block the UV light absorption ability of materials. A significant decrease in ZnO/TiO<sub>2</sub> photocatalytic activity after chitosan modification in connection with a considerable inhibition of photo-induced charge transfer processes make nanocomposites a perfect protective agent in biomedical field. What is more, chitosan modified materials were recognized as efficient antibacterial agents against both tested bacterial strains: *Staphylococcus aureus* *Escherichia coli*. Simultaneously, no cytotoxic effect towards HaCaT cell line was confirmed.

### CONCLUSION

Our studies focused on developing new nanocomposites with potential biomedical application based on zinc oxide and titanium dioxide NPs and biocompatible, antibacterial polymer-chitosan. The preserved UV light absorption ability and blanked photocatalytic activity towards selected substrates confirms materials photoprotective properties. Moreover, materials did not generate reactive oxygen species such as singlet oxygen. Furthermore, a complete photocurrents quenching for chitosan modified oxides was obtained, which confirms the lack of photoactivity. Presented materials resolve the problem of risks associated with semiconductor nanoparticles utilization as the active ingredient of sunscreen formulations.

## INTRODUCTION

Mg alloys are promising materials for orthopaedic biodegradable devices due to their biocompatibility, low density and a high mechanical strength, but corrosion rate of Mg and its alloys currently available is still too high. One of the methods to improve their initial corrosion resistance and cytocompatibility is polymer coatings<sup>1),2)</sup>. However, details of the relation between coating properties and their improvement remain unclear. In this study, the improvement of cytocompatibility and corrosion resistance of ZM21 alloy was conducted by spin-coating of different biodegradable polymers. The effect of polymer structures on their coating properties as well as their improvement of substrate corrosion resistance and cytocompatibility was investigated.

## EXPERIMENTAL METHODS

Cast ZM21 alloy (2.0 wt% Zn and 0.98 wt% Mn) was used in this study. Samples (10x5x1.5mm) were polished using SiC papers up to #600 in ethanol. Then, 2% (w/v) chloroform solution of poly(lactic-co-glycolic) acid [PLGA], poly-L-lactide (PLLA), poly(3-hydroxybutyrate) [PHB] or poly(3-hydroxybutyrate-co-3-hydroxyvalerate) [PHBV] was spin-coated on both sides of the samples. These samples are abbreviated as PLGA, PLLA, PHB, and PHBV, respectively. Static water contact angle (WCA) was measured at 2000 msec after the contact of a water droplet to the sample surface. Prior to cell culture, samples were sterilized with ethylene oxide gas (EOG).

For WST-1 assay, human osteosarcoma cell line (SaOS-2) was inoculated at a density of 4000 cells/ml in 27.5 ml of Dulbecco's Modified Eagle Minimum Essential Medium supplemented with 10% (v/v) fetal bovine serum, abbreviated as D-MEM+10%FBS, and was incubated under cell culture condition (37°C, 5% CO<sub>2</sub>) for 1, 4 and 7 days. For calcification and alkaline phosphatase (ALP) tests, SaOS-2 was inoculated at a density of 10 000 cells/ml in 27.5 ml of D-MEM+10% FBS and incubated under cell culture condition for 7 days. Then, culture medium was replaced into a "osteogenic medium", which was D-MEM+10%FBS supplemented with 0.5 mM  $\beta$ -glycerophosphate, 50  $\mu$ g/mL L-ascorbic acid and 1% (v/v) antibiotic solution [penicillin (5000IU/mL) and streptomycin (5000  $\mu$ g/mL)]. Then, samples were additionally incubated for 7 and 14 days with exchange of the osteogenic medium every 7 days. Degradation of the substrate during cell culture was examined by quantification of released Mg<sup>2+</sup> ions.

## RESULTS AND DISCUSSION

Polymer coating increased the hydrophobicity of the ZM21 substrate surface. PHB and PHBV, which have relatively hydrophobic moieties, showed relatively high WCA around 80° whereas PLGA and PLLA showed those around 74°. The WCA of ZM21 substrate was around 62°. The thickness of the coated layer is around 0.20, 0.28, and 0.18  $\mu$ m for PLLA, PHB, and PHBV, respectively, whereas that of PLGA was 0.12  $\mu$ m. This may be due to the much lower molecular weight of PLGA than those of other polymers.

PLLA, PHB and PHBV coatings successfully improved cell growth during 7 days of incubation and suppressed the Mg<sup>2+</sup> ion release, while PLGA has no significant impact on corrosion suppression. This is probably because of thinner coating of PLGA as described above, as well as its relatively high degradation ratio.

The samples coated with PLLA, PHB and PHBV have much larger calcified area than PLGA or ZM21 substrate after 2 weeks of incubation in the osteogenic medium. The results of ALP tests after 1 week of incubation in osteogenic medium agreed with this trend. After 2 weeks, however, ALP activities decreased for PLLA, PHB and PHBV, whereas they increased for ZM21 substrate and PLGA coated samples. This suggests that SaOS-2 on the former samples differentiated into the next phase of bone formation process. PLLA, PHB and PHBV encourage higher cell growth and faster functionality.

## CONCLUSION

The polymeric coatings modified the physicochemical properties of ZM21 alloy surface, which contributes to improve its biocompatibility. During cell culture, PLLA, PHB, PHBV coatings successfully reduced the Mg<sup>2+</sup> release, while PLGA had no impact on the corrosion suppression. This is probably due to the smaller molecular weight, thinner coating thickness and faster degradation of PLGA. The successful reduction of substrate corrosion by the three polymers contributed to improve cell growth and cell functionality. It is also found that higher cell growth in the early stage of incubation is important to support faster and higher cell functionality in the later stage.

## INTRODUCTION

Implantation, especially total hip replacement is a serious surgery to human body, for that reason there is a need to improve biocompatibility and osseointegration of material of which implants are made *e.g.* titanium alloys<sup>1</sup>. Diamond-like Carbon (DLC) coatings has been developed in order to improve parameters important from biological application point of view.

Noteworthy, such properties as modulus of elasticity and residual stress may cause unfavourable stress distribution at the substrate-coating interface. There is possibilities to reduce these disadvantages by intermediate layer deposition or by doping with silicon<sup>2</sup> and nitrogen<sup>3</sup> atoms with plasmochemical methods application.

In this work multilayer, nitrogen doped coatings based on carbon and silicon deposition by Microwave Plasma Assisted Chemical Vapour Deposition method were studied.

## EXPERIMENTAL METHODS

Samples of 3 mm thickness made from two titanium alloys: Grade2 (10mm dia.) and Ti6Al7Nb (14mm dia.) were mechanically polished to achieve mirror-like surfaces. Then surface modification in Plasma Assisted Chemical Vapour Deposition (PA CVD) vacuum system, equipped with microwave (2.45 GHz) antenna was performed. Two processes varying depending on the substrate pre-functionalization with plasma nitriding process were studied (Figure 1).

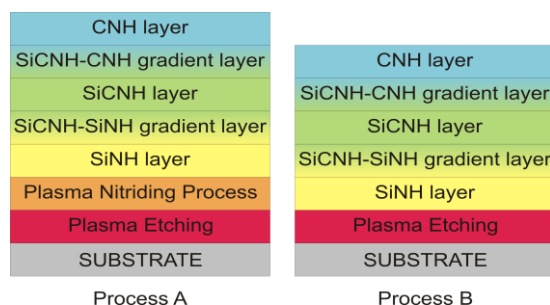

Figure 1. Scheme of the applied plasma processes.

Structure characterization (in various atomic scale) of the resulting coatings by SEM, AFM and spectroscopic methods (FT-IR, Raman) was carrying out. Hardness and modulus of elasticity were determined by nanoINDENTER® G200 (Agilent technologies, USA) with continuous stiffness measurement. Preliminary biological study *in vitro* was performed: (i) cytotoxicity towards human osteosarcoma MG-63 cell line was evaluated by MTT assay and (ii) level of Ti and Al ions

release in cell culture media was detected by ICP-MS technique.

## RESULTS AND DISCUSSION

MW PA CVD process application resulted in obtaining of coatings with relatively low hardness ( $3.2 \pm 0.4$  GPa) for Ti6Al7Nb sample after process B (Figure 2). While in case of process A, increase of surface hardness for Ti-Grade2 sample to value of  $3.7 \pm 0.4$  GPa was achieved.

Figure 2. Microstructure of Ti6Al7Nb sample after process B application.

Sample	Hardness GPa	
	Ti-Grade2	Ti6Al7Nb
Reference	$3.38 \pm 0.1$	$4.79 \pm 0.2$
After process A	$3.70 \pm 0.4$	$4.31 \pm 0.2$
After process B	$3.23 \pm 0.4$	$3.20 \pm 0.4$

Table 1. Hardness values for the obtained coatings.

The tendency to increase of hardness by plasma nitriding process application was observed (Table 1). The resulting values of hardness are probably connected with their non-dense and columnar structure, which is characteristic for MW PA CVD coating method application<sup>4</sup>.

## CONCLUSION

This investigation resulted in successful two novel deposition layers. Multi-layer deposition after only plasma etching without plasma nitriding process assures better osseointegration, biocompatibility, metal ions diffusion barrier (antimetabolism properties) and lower Young modulus. Nano-metric structure of the resulting coatings was correlated with hardness distribution obtained by nanoindentation method. Influence of plasma nitriding process on hardness parameters was observed.

### INTRODUCTION

One of the challenges in biomaterials research is the functionalization of implant surfaces to adjust their biocompatibility for specific applications. A relatively new approach is the use of topographic nanostructures for the regulation of cell adhesion. However, the solid-liquid interface between a biomaterial and the adjacent tissue is complex and cell adhesion is regulated by many factors such as the electrochemical double layer, protein adsorption and the interaction of cell-surface receptors with the adsorbed proteins<sup>1</sup>. As a consequence, nanostructured functionalizations are frequently developed by the “*trial and error*” method. For a more systematic tailoring of nanostructured functionalizations a detailed knowledge of the interplay between material properties, protein adsorption and cell adhesion is required. In the presented study, this interplay was examined in detail by analysing the influence of a periodically grooved nanostructure on the initial adhesion of L929 fibroblasts at different fibronectin concentrations.

### EXPERIMENTAL METHODS

Periodically grooved nanostructures with 90 nm groove and summit widths and groove depths of 120 nm were fabricated on silicon wafers using interference lithography (AMO GmbH, Aachen, Germany)<sup>2,3</sup>. The substrates were incubated with 0 µg/ml, 5 µg/ml and 25 µg/ml bovine fibronectin<sup>2,3</sup>. The local protein density and conformation was characterized using single-molecule force spectroscopy (SMFS)<sup>2</sup>. The interpretation of the experiments was supported by computer simulations in which numerical field calculation methods were combined with Brownian Dynamics and a simple mechanism for protein adsorption on topographic nanostructures was derived<sup>4</sup>. Moreover, the cell adhesion strength of L929 fibroblasts was observed by single-cell force spectroscopy (SCFS) and the results were correlated with the results from the protein adsorption<sup>3</sup>.

### RESULTS AND DISCUSSION

Cell adhesion to the nanostructure was compared with that to a similarly treated planar reference using single-cell force spectroscopy. The adhesion strength of L929 fibroblasts to the bare nanostructure (without fibronectin) was lower ( $79\% \pm 13\%$ ) than to the planar substrate, which we attribute to a reduced contact area<sup>3</sup>.

After pre-incubation with a low fibronectin concentration (5 µg/ml) the adhesion strengths to both surfaces (nanostructured and planar) increased, with adhesion strength on the nanostructure outweighing that of the planar substrate by  $133\% \pm 14\%$ <sup>3</sup>. At a high fibronectin concentration (25 µg/ml) the adhesion strengths further increased on both surfaces and showed wide variations<sup>3</sup>.

The comparison of the results from the SCFS and SMFS experiments suggest that the enhanced cell adhesion at the low fibronectin concentration (5 µg/ml) was caused by an increased amount of protein per surface area on the nanostructure as well as an associated higher rate of native proteins<sup>3</sup>. This interpretation is supported by the computer simulations that demonstrate that the interplay of van der Waals- and electrostatic forces lead to a locally increased protein concentration on a grooved nanostructure<sup>4</sup>.

### CONCLUSION

This study demonstrates that the adhesion strength of L929 fibroblasts can be influenced by a topographic nanostructure and that the exact effect of the nanostructure depends on the fibronectin concentration.

## The Effect of TiN and DLC Surface Modification on Wear of AISI 440B Martensitic Stainless Steel Surgical Drill Bits

Magdalena Łepicka, Małgorzata Grądzka-Dahlke

Department of Materials and Biomedical Engineering, Faculty of Mechanical Engineering, Białystok University of Technology, Poland  
[magdalena.lepicka@gmail.com](mailto:magdalena.lepicka@gmail.com)

### INTRODUCTION

Development in modern invasive surgery is highly dependent on surgical instruments performance, understood as long-term efficiency, arising i.e. from high resistance to wear and corrosion. Taking into consideration complexity, manufacturing costs and diversity of contemporary surgical instruments, it is an issue of great significance to provide reliable and durable medical devices<sup>1,2</sup>. In order to improve their ease of handling, resistance to wear and corrosion and stability in variable environmental conditions, surface modification techniques are applied. There are numerous reports considering research into improvement of surgical instruments' reliability and durability, especially drills, by the means of anti-wear layers deposition<sup>1,3,4</sup>.

Instruments designed to contact with bone tissue, e.g. saws, drills, chisels, are one of the most exposed to tribological wear medical devices. As early as after only few operational procedures their geometry changes, pre-sharpened edges round, sometimes even material chipping is noticeable<sup>5,6</sup>. As a consequence, it may cause problems with their handling, or even contribute to generating far too high temperatures during drilling, what results in bone necrosis<sup>7</sup>.

The aim of the study was to evaluate the effect of TiN and DLC surface modification on wear of AISI 440B martensitic stainless steel surgical drill bits.

### EXPERIMENTAL METHODS

Commercial surgical drill bits (AISI 440B stainless surgical steel) were chosen as research material. Cutting surgical instruments were divided in following groups (Figure 1):

- I. reference, heat treated in 250°C,
- II. DLC modified
- III. TiN modified.

Figure 1. Drill bits for field-testing

In order to evaluate effectiveness of modified and non-modified drill bits, study was carried out on cutting efforts when drilling porcine cortical bone. Tests were performed on a specially designed test stand, consisting of bench drill equipped with force sensor and force transducer, and a computer, on which friction torque changes during drilling were recorded. Femoral and

shin bones were picked up fresh from a local butchery and were prepared a few days after 10-months old piglets were sacrificed. 40 holes were made with each bit. Total cutting depth of each bit was approx.  $160 \times 10^{-6}$  m. After drilling, change of teeth geometry was measured on FALCON QC 3-axis non-contact video measuring machine.

### RESULTS AND DISCUSSION

No direct correlation between the number of drilled holes and drilling time or axial torque has been observed, as one would expect. This might be caused by heterogeneity of bone tissue. Uneven surface of the porcine bone could lead to the observed during experiment drill run-out. Performed studies were of comparative nature and in this respect obtained results can be considered reliable. Nevertheless, certain relationships and differences between the non-modified and modified drills were observed. The non-modified cutting tool was characterized by shorter cutting times and lower average friction forces during drilling. In comparison, the modified drills, especially the TiN one, was characterized by a significantly longer single-hole cutting time, higher frictional forces and additional heating of the tool. However, it had no significant effect on tool wear. The use of anti-wear layers has improved wear resistance of considered tools.

### CONCLUSION

Experimental procedure performed on reference and surface modified AISI 440B martensitic stainless steel drill bits shows that deposition of anti-wear layers improves wear resistance of surgical cutting tools. In the future it will be necessary to perform further analyses in surgical drill bits wear mechanisms.

## INTRODUCTION

Controlling material-tissue interaction with respect to tissue mechanics, physiological environment and biochemical signaling is likely to be beneficial to achieve guided reorganization of impaired tissue.

To fulfill these requirements we developed a toolbox of macromeres that can be cross-copolymerized into constructs with tunable hydrophilicity, swelling, biodegradability and mechanics. Copolymerization with monomethacrylated PEG (PEGMA) allowed for covalent surface modification with functional molecules.

In order to rationalize material development and surface design of 3D constructs, we processed the toolbox components into films as an analytical platform.

Film hydrophilicity and presentation of functional groups were assessed by static water contact angle and quantification of a covalently bound dye with a fluorescence plate reader. Cell adhesion onto films was determined where RGD-peptide modified films were employed as a proof of principle for functional film modification.

## EXPERIMENTAL METHODS

Films were cross-polymerized onto glass-disks bearing MA-silane layer using thermally controlled radical polymerization reactions with benzoylperoxide and 2-(4-dimethyl-aminophenyl)-ethanol as initiator/accelerator system. The films consisted of core molecules (T134, T170, T450) which are trivalent alcohols with different degrees of ethoxylation and thus molecular weights. These are flanked by lactic acid (LA) side chains of variable block length (LA2, LA4, LA6). This macromer platform can further be modified using PEGMAs and methoxyPEGMAs (mPEGMA). PEGMAs anchoring in the film surface, provided a free hydroxyl group to be modified by succinic anhydride and activated by dicyclohexyl-carbodiimide and N-hydroxy-succinimide. Density of functional groups present at the surface was determined by the immobilization of 5-((aminopentyl)thiouredyl)-fluorescein (Fcad). Hydrophilicity of films composed of pure macromeres and those containing 20% (m/m) PEG<sub>1000</sub>MA was systematically determined by measuring the static water contact angle. Saos-2 adhesion was characterized for the same compositions. A choice of materials was additionally functionalized with GRGDS peptide to check for positive effects on cell adhesion.

## RESULTS AND DISCUSSION

Static water contact angles of films consisting of pure macromers exhibited strong differences depending on the core molecule. T134 cores – without ethoxylation – were the most hydrophobic materials with contact

angles of approximately 60°. The degree of ethoxylation had the biggest impact on hydrophilicity as it led to a cut down of the contact angle to 35° for the most hydrophilic macromer 450LA2. By cross-copolymerization of the macromers with 20% PEG<sub>1000</sub>MA, the hydrophilicity of the films increased leading to contact angles in the range of 50°.

The usage of different anchoring groups (PEG<sub>526</sub>MA and PEG<sub>1000</sub>MA) gave the opportunity to tether adjustable amounts of Fcad in the range of up to 1 nmol/cm<sup>2</sup> onto films of the macromer T450LA2 when reaction batches consisted of 50% PEGMA.

Hydrophobic macromers, such as T134LA6, showed low analyte immobilization capacity which was limited to a range of pmol/cm<sup>2</sup> inspite of high PEG chain density. To improve their immobilization capacity, shorter mPEGMAs were cross-copolymerized with PEGMAs into the macromer films as mPEGs are known to foster brush-like structures on surfaces<sup>1</sup>. In order to limit the total amount of PEG in the films, detailed studies on mixing ratios of PEGMA and mPEGMA with T134LA6 and T450LA2 revealed that compositions with 20% of the PEGMA and 10% of the filler mPEGMA were sufficient to increase the immobilizing capacity by factor two to five depending on the macromer.

Adhesion experiments with Saos-2 cells showed just little differences in the number of attached cells between the macromers but a strong decrease in cell number for all formulations when 20% PEG<sub>1000</sub>MA were incorporated with the least cell numbers on films based on T450LA6. By functionalizing this material with GRGDS peptide, cell numbers exceeded those of all other formulation displaying the success of this surface functionalization concept.

## CONCLUSION

We engineered surfaces from a toolbox of biodegradable macromers that can be cross-copolymerized with PEGMA to functional films. The surface properties, namely hydrophilicity, immobilization capacity and cell adhesion were controlled by molecular weight of macromers and cross-copolymerization with PEGMAs. Relevant effects on cellular response were shown by immobilization of RGD peptides.

### INTRODUCTION

The improvement of the interface between bone and implant have been of particular interest in dental and orthopedic implant research. Titanium has been used in dentistry for more than five decades but there still ongoing research to improve the surface properties of the material in order to improve the molecular interactions, cellular response and thereby, osseointegration [1]. Tribocorrosion can be defined as a degradation phenomenon of material surfaces subjected to the combined action of mechanical loading and corrosion attack caused by the environment. Usually the dental implants undergo micro-movements under loading mastication when exposed to a biological aggressive environment, causing fretting corrosion [3]. TiO<sub>2</sub> nanotubes array give completely new types of interactions between implant surfaces and cells because the surface area is increased and the surface topography can be modified to resemble native bone tissue. The aim of this work was to evaluate the influence of the annealing treatment at different temperatures in the surface and tribocorrosion properties of TiO<sub>2</sub> nanotubes.

### EXPERIMENTAL METHODS

Samples with 30 x 20 x 1 mm were polished with SiC abrasive papers of #320, #600, #800, #1200 and colloidal silica. Then, they were cleaned ultrasonically in acetone, alcohol and rinsed in deionized water. The anodization was performed in a two-electrode configuration with Ti plate as working electrode and platinum foil as the counter electrode. The samples were anodized potentiostatically with 60 V, in an electrolyte containing calcium, phosphorous and fluoride ions. The TiO<sub>2</sub> nanotube layer morphology and crystalline phase were evaluated by scanning electron microscopy and X-ray diffraction measurements

respectively. The tribocorrosion evaluation was carried out using a linear reciprocating ball on flat tribometer with a three electrode electrochemical cell coupled to potentiostat.

### RESULTS AND DISCUSSION

The results show that the amount of rutile crystalline phase increases with annealing temperature improving the tribocorrosion resistance, producing though several cracks in the oxide layer due to elastic mismatch between the oxide layer and substrate.

### CONCLUSIONS

The tribocorrosion of TiO<sub>2</sub> nanotubes is influenced by the crystalline phase.

### INTRODUCTION

Gold nanoparticles (AuNPs) are taken notice of the uses of the hyperthermia for cancer cell in medical field<sup>1</sup>. The AuNPs should have the biocompatibility. We have decided to fabricate the AuNPs colloidal solution without several reagents, which have a possibility of low biocompatibility. In addition, we propose a hypothesis that if the biomolecule is not easy to adsorb on the AuNPs surface, the NPs have higher biocompatibility. In our previous study, we have revealed that the phosphatidylcholine (PC) molecule adsorbs on the Au material surface at hydrophilic group<sup>2</sup>. The PC molecule constitutes the biological membrane and has the hydrocarbon chain of the hydrophobic group. Y. Sato *et al.* have reported that the molecules with the hydrocarbon chain can possess the ordered state by the intermolecular force between hydrocarbon chains<sup>3</sup>. Thus, one of purposes in this study is to fabricate the AuNPs covered by phosphatidylcholine (PC). Subsequently, the other purpose is to reveal the adsorption reaction between L-cysteine and the AuNPs with/without the PC membrane because the L-cysteine has adsorbed rapidly on the AuNPs surface at thiol group (-SH)<sup>4</sup>.

### EXPERIMENTAL METHODS

The AuNPs colloidal solution was fabricated by the solution plasma method<sup>4</sup>. The solution plasma method used two materials only, which are gold rods and NaCl aqueous solution. The DPPC dissolved in milli-Q water. The DPPC aqueous solution was kept at 45 °C and was added into the AuNPs colloidal solution. The precipitate, which was the PC covered AuNPs, was produced and rinsed several times with the milli-Q water. The rinsed precipitate and the L-cysteine powder were mixed in aqueous solution. After promoting the adsorption reaction, the precipitate was rinsed with the milli-Q water again. This sample is described as Cysteine/DPPC/AuNPs. As the reference sample, the L-cysteine powder was added into the AuNPs aqueous solution and the occurred precipitate was rinsed with the milli-Q water. This sample is called as Cysteine/AuNPs. Infrared spectroscopy (IR) and S K-edge near-edge X-ray absorption fine structure (NEXAFS) measurements for those precipitates were carried out at the SR center BL-15 and AichiSR BL6N1 with He-path system, respectively.

### RESULTS AND DISCUSSION

Taking into account of the results of IR measurement,

not shown here, we suppose the DPPC molecules cover around the AuNPs surface with ordered state by the intermolecular force between the hydrocarbon chains of DPPC on NPs. Figure 1 shows the S K-edge NEXAFS spectra for Cysteine/AuNPs and Cysteine/DPPC/AuNPs under water environment. The peak intensity at 2470.0 eV corresponds the amount of atomic S on the AuNPs surface. The atomic S occurs by dissociating both S-H and S-C bonds of the L-cysteine adsorbed on AuNPs. Thus, we think that the L-cysteine molecule is not easy to adsorb on the AuNPs surface of DPPC/AuNPs compared to the non-covered AuNPs.

Figure 1. S K-edge NEXAFS spectra for Cysteine/AuNPs and Cysteine/DPPC/AuNPs.

### CONCLUSION

We have fabricated the AuNPs covered by DPPC membrane with ordered state. We think that the L-cysteine is not easy to adsorb on the AuNPs surface of DPPC/AuNPs compared to the non-covered AuNPs.

## INTRODUCTION

The use of titanium screws in implant therapy is highly predictable and successful. However, there are certain risk factors such as smoking, disease and periodontitis, which can predispose individuals to lower rates of success and to failure of the implant treatment<sup>1</sup>. In this context there is a great interest in finding new surface to promote bone formation and accelerate the osseointegration process. There is an increasing number of works that shows the beneficial effect of silicon containing biomaterials, such enhancing bioactivity and regulation of osteoblast proliferation and gene expression<sup>2</sup>. Moreover, their dissolution products have been proved to stimulate collagen type I synthesis and enhance osteoblast differentiation<sup>3</sup>. Furthermore, gelatine was selected because of its cell adhesion ability and osteoregenerative properties.

The aim of this work is to design new siloxane-gelatine coatings through the sol-gel process with tailored properties for titanium dental implants. For that, the effect and behaviour of different alkoxysilane precursors were evaluated in order to control the surface chemistry and the silicon release rate. This parameters and their influence on cell attachment and differentiation were studied.

## EXPERIMENTAL METHODS

**Synthesis:** Hybrids were prepared via sol-gel, using HCl 0.1M as catalyst, with methyltrimethoxysilane (MTMOS), 3-glycidypropyl trimethoxysilane (GPTMS) and tetraethoxysilane (TEOS). Different matrixes are called M:T and M:G:T. Hybrids synthesized with the incorporation of 0.9% by weight of gelatine are M:T\_0.9% and M:G:T\_0.9%. Titanium discs were coated with the different hybrids and a heat treatment of 80 °C for 2hours was applied.

**Chemical characterization:** <sup>29</sup>Si—NMR in liquid and solid states were used to follow the kinetics of the reaction and to study the cross-linking degree of the resulting materials, respectively. Since hydrophobicity/hydrophilicity has an important influence on protein and cell adhesion, coatings' contact angle measurements were performed.

**In vitro silicon release quantification:** The dissolution properties of films were determined by immersing them in PBS at 37 °C, and measuring the Si released at different time points using an inductively coupled plasma mass spectrometer (ICP-MS).

**Biological evaluation:** hMSC were seeded onto coated titanium surfaces. After 24 hr, the cell adhesion to these surfaces was quantified by a DNA quantification kit (PicoGreen assay kit). Finally, the osteogenic differentiation of hMSC on hybrids was evaluated at 7 and 14 days in the presence or absence of osteogenic induction. The relative gene expression of osteogenic markers (RunX2, ALP and BGLAP) was analyzed using quantitative polymerase chain reaction (qPCR).

## RESULTS AND DISCUSSION

Homogenous, transparent and crack-free coatings were obtained. <sup>29</sup>Si-NMR confirmed the siloxane network formation, as well as the presence of silanol groups in the surface, which are important in the bone formation process. The degradation rate was tailored with the incorporation of different silicon precursors and gelatine in the matrix, as was reflected by silicon quantification assay. The incorporation of the epoxy group through the addition of GPTMS resulted in a higher cell adhesion. Silicon released from the coatings promoted higher osteogenic differentiation of hMSC compared to titanium. This was proved by the earlier gene expression.

Figure 1. RunX2 and ALP gene expression after 14 days.

## CONCLUSION

The results of this study are encouraging for the use of siloxane-gelatine hybrids as bioresorbable and osteoinductive coatings for dental implants. Moreover they can have a potential application for patients with poor bone regenerative properties. Further investigation will be done to assess their behaviour *in vivo*.

## INTRODUCTION

One of the major problems in drug delivery to the brain is the difficulty of transporting therapeutic entities across the blood-brain barrier (BBB). Consequently, the treatment of many brain-associated disorders through conventional delivery strategies is of limited value.<sup>1</sup>

It has been suggested that nanoparticles of poly(alkyl cyanoacrylate) (PACA) with dextran may be capable of transporting actives across the BBB. Poly(butyl cyanoacrylate) nanoparticles coated with Polysorbate 80 are biodegradable carriers that have been demonstrated to facilitate the delivery of drugs and peptides across the BBB.<sup>2,3,4</sup>

This study is aimed towards the formulation of amphiphilic nanocarriers from alkyl cyanoacrylate and a functionalised dextran for improved therapeutic delivery to the brain. Work to date has involved the derivatisation of dextran with alkyl glycidyl ethers (alkyl glycerol has been shown to aid the transport of particles to the brain)<sup>5</sup> and their subsequent formulation with PACA nanoparticles

## EXPERIMENTAL METHODS

Functionalised dextran and poly (ethyl 2-cyanoacrylate) nanoparticles were prepared in two steps: grafting of the aliphatic chain of alkyl glycerol to dextran (and product characterisation using FTIR, which was followed by anionic polymerisation<sup>1</sup> with ethyl 2-cyanoacrylate

## RESULTS AND DISCUSSION

The successful synthesis of functionalised dextran was consistent with FTIR spectroscopy data: the grafting of alkyl glycerol chains resulted in the formation of a new secondary alcohol. The band at 1012 cm<sup>-1</sup> is assigned to the vibrational mode of C–O. In crystalline dextran, two absorption peaks at 851 and at 914 cm<sup>-1</sup> were observed, respectively assigned to (C–C) and (C–H) bending modes. It has been proposed that the absorption bands in the spectral range between 1200 and 1500 cm<sup>-1</sup> are mainly due to CH deformation vibrations and (COH) bending vibrations<sup>6</sup>. The bands at 2921 cm<sup>-1</sup> and at 3215 cm<sup>-1</sup> are respectively consistent with (C–H) and (O–H) stretching vibrations.

Fig. 1 FTIR spectrum of functionalised and non-functionalised dextran

## CONCLUSION

Anionic polymerisation of ethyl 2-cyanoacrylate with functionalised dextran and native dextran respectively, showed that polymerisation of ethyl 2-cyanoacrylate with functionalised dextran resulted in nanoparticles with lower polydispersity index and higher zeta potential when compared to non-functionalised dextran, which indicates that functionalization of dextran results in an improved nanoparticle formulation.

### INTRODUCTION

Titanium and its alloys are widely investigated for the development of biocompatible dental and orthopedic implants thanks to their good mechanical properties and their good resistance to corrosion due to the presence of a stable oxide layer<sup>1</sup>. With the aim of developing implantable devices, an accurate control of the surface device is needed since the surface structural properties modulate the bio-integration process. In particular, incorporation of calcium phosphates into the titanium oxide matrix can represent a viable strategy to promote osseointegration<sup>2</sup>. We investigated the growth of titanium oxide layers prepared by electrochemical anodization in order to correlate the growth conditions with the resulting surface layer structure and composition.

### EXPERIMENTAL METHODS

Mechanically polished titanium sheets were electrochemically oxidized by anodic spark deposition (ASD) in three electrolytes: sulphuric acid solution, phosphoric acid solution and in a solution containing both calcium (stabilized by complexation with EDTA) and phosphate ions<sup>3</sup>. Anodization voltages were varied in the range 100V – 250V. Oxidized samples were thoroughly rinsed with Milli-Q water and dried.

The morphology and chemical composition of the TiO<sub>2</sub> layers were analysed by Tapping Mode Atomic Force Microscopy (TM-AFM), Scanning Electron Microscopy (SEM) and X-Ray Photoemission Spectroscopy (XPS). Oxide layer thickness was evaluated by cross-section SEM and AFM analysis.

### RESULTS AND DISCUSSION

Titanium dioxide layers grown by ASD in all the three investigated electrolytes are characterized by a mesoporous structure. Fig 1 shows typical AFM images of TiO<sub>2</sub> layers grown in sulphuric acid at two different anodizing potentials.

Fig. 1. AFM images (5µm x 5µm) of TiO<sub>2</sub> surfaces prepared by ASD in a sulphuric acid electrolyte at (a) 150V, (b) 200V.

From the analysis of the profile of AFM images it turns out that increasing the anodization potential results in an increase of the pore diameter and depth, from a few hundreds nanometers to more than one micron, depending from the electrolyte.

The thickness of the oxide layer was evaluated by SEM and AFM sectional analysis. The data indicates a layer thickness ranging from 1 to 8 µm depending on the electrolyte and anodization potential.

The chemical analysis of the sample surfaces has been carried out by XPS measurements. Figure 2 shows the XPS survey spectra of titanium after anodization in the three electrolytes. Peaks corresponding to Ti, O and C are present in all the spectra. P peaks can be observed in the spectra of Ti oxidized in phosphoric acid solution while both P and Ca signals can be detected from the analysis of samples anodized in the solution containing

calcium and phosphate ions.

Fig. 2. XPS survey spectra of Ti samples oxidised in electrolytes containing: (light blue) calcium and phosphate ions, (yellow) phosphoric acid, (black) sulphuric acid.

### CONCLUSION

By tuning the anodic oxidation conditions it is possible to tailor the TiO<sub>2</sub> surface morphology and to include specific chemical species in the oxide matrix. ASD is therefore a viable strategy for biomaterial development.

## Surface Modification by a Catalyst Free Covalent Layer-by-Layer Approach of Clickable Elastin-Like Recombinamers

[igonzalez@bioforge.uva.es](mailto:igonzalez@bioforge.uva.es)

### INTRODUCTION

To improve the success ratio of the implant integration the Layer by Layer (LbL) technology is a good candidate, because it is an easy approach to perform a consecutive self-assembly of layers of at least two distinct materials onto substrates<sup>1</sup>.

Recently, our group has developed a new family of hydrogels based on the crosslinking of at least two modified bioactive Elastin-like recombinamers through a catalyst free click reaction (ELR-CFCGs)<sup>2</sup>. In this work these materials will be applied in the LbL technique to surface modification with the idea of combining the control and efficiency of the LbL approach with the stability and robustness of the covalent bonding.

### EXPERIMENTAL METHODS

Several substrates, polystyrene, titanium, glass and PS beads as simple surface systems were modified. In addition, a more complex structure, such as a coronary stent was also coated to get a continuous layer that helps to its integration after implantation. Two methodologies were employed. The first approach consists in consecutive immersions of the substrate inside two different ELRs clickable solutions, in such a way to the first solution will react forming a covalent bond with the second ELR solution (till 5 immersions on each solution). The first layer is adhered to the plasma activated substrate by electrostatic interactions. In the second approach, an additional washing step was introduced after each layer deposition. In this way, the thickness and topography of the LbL structure can be controlled.

### RESULTS AND DISCUSSION

Microscopy (optic, florescence, and SEM) offers us a first sight of the coating effectiveness, showing a good covering from the first layer where the surface topography is covered to the fifth layer, where a thicker, soft and continuous ELR click layer covers completely the substrate irregularities.

FTIR and XPS results evidence the variation at atomic level of the superficial layers of the surfaces. A clear evolution from the typical spectra of each substrate to the specific spectra of the ELRs can be observed in the results from both techniques.

Contact angles values underscore the variation of the surface hydrophobicity before and after the plasma cleaning and after the ELR-click layers deposition. Rising till contact angles values around 100°, which means a substantial increase in the surface hydrophobicity for the samples.

According to the AFM results, a good and complete covering of the substrates was observed. Substrates were covered by layers that provide a completely different nano-topography than the general aspect of the

bare substrates. Moreover, the mechanical properties change yielding lower Young's modulus with each new layer. Thus, the surface mechanical properties of the system can be controlled by the number of layer used to form them

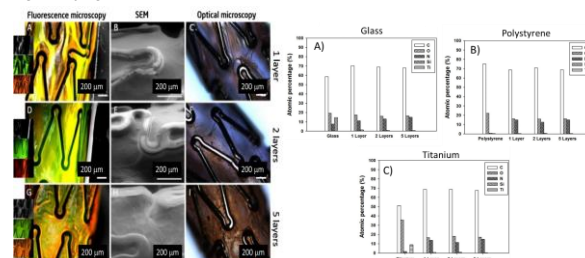

Figure 1. Fluorescence, SEM) and optical micrographs of coronary stents after the LbL process. And Evolution of the atomic percentage on the outer surface as function of the number of layers

We show an alternative catalyst free click covalent LbL method based on catalyst free click chemistry applied to ELRs. This originate a completely cytocompatible technology to biofunctionalize surfaces. Short times and mild conditions are adequate for cell encapsulation applications, combining cells and materials in the same LbL approach, which are currently being evaluated in our laboratory..

### CONCLUSION

In this work, structures, as simple as flat pieces or as complicated as 3D metallic grids, made of several materials, have been biofunctionalized by LbL techniques by using clickable ELRs and without the need of any other molecules. The use of an ELR having a bioactive sequence as RGD will improve the cell adhesion to these functionalized surfaces. Moreover, any other peptide domains that can be incorporated to the ELR backbone can be also used under this same approach.

## INTRODUCTION

Surface modification of biomaterial devices is commonly used to reduce the risk of infection. Polyelectrolyte multilayer (PEM) coatings have become an original way to functionalize these surfaces by immobilizing drugs or active molecules in multilayer films according to the Layer-by-Layer technique (LbL) [1]. In these kinds of system, cyclodextrin polymers (polyCD) can be especially used to embed hydrophobic drug with preserved activity. The present work focus on a PEM system based on two oppositely charged cyclodextrin polyelectrolytes and applied to a textile substrate for drug delivery of model molecules. After optimization, the cytocompatibility, drug release and antibacterial activity of multilayer assemblies were assessed.

## EXPERIMENTAL METHODS

The virgin textile PET (PET, 65 g.m<sup>-2</sup>) samples were preliminary functionalized by *pad-dry-cure* process to obtain negative charges on the surface [2]. The weight gain of this anionic layer was fixed at 6 and 20% wt (respectively 1.6 and 6.5  $\mu\text{mol}$  of COOH/cm<sup>2</sup> of textile). The build-up of the multilayer assembly was monitored in situ by Optical Waveguide Lightmode Spectroscopy (OWLS) on the one hand and was assessed by gravimetry on the other hand when applied onto the textile substrate. The dip-coating process used for the LbL build-up was performed at room temperature with both positive and negative CD polyelectrolytes solutions in water at their natural pH, synthesized according the method of Junthip and al. [3] (the positive polyEPG-CD-X was prepared by reacting  $\beta\text{CD}$  with epichlorohydrin (EP) in presence of glycidyltrimethylammonium chloride (GTMAC, X= molar ratio GTMAC/CD was 1 or 10) and the negative polyCTR-CD was prepared by reacting  $\beta\text{CD}$  with citric acid (CTR) in presence of sodium hypophosphite as catalyst). The incorporation of 4-tert-butyl benzoic acid (TBBA) as drug model molecule was carrying out by dipping the textile into polyCTR-CD/TBBA and polyEPG-CD-X solutions. The release of TBBA was determined by UV-visible spectroscopy at 235 nm. The cytocompatibility of the modified textile was evaluated with epithelial cells (L132) according to the ISO 10993-5 standards. The antibacterial activity was determined by the time-dependent bacterial reduction (Kill Time) on *Staphylococcus aureus*, CIP224 and *Escherichia coli* K12.

## RESULTS AND DISCUSSION

The weight gain of assembly changed with both the nature of polyEPG-CD-X and thermofixed layer of polyCTR-CD. A better LbL deposition was found with the polyEPG-CD-10 even in 6 or 20% thermofixed layer used, and it was proportional to the amount of COOH groups of the thermofixed layer (Figure 1). Incorporation of TBBA disturbed slightly the build-up of the LbL system. A sustained release of TBBA until 7 days was also obtained particularly in 20%-polyEPG-CD-10 system. This system also exhibited a better intrinsic antibacterial activity against *S.aureus* and *E.coli*.

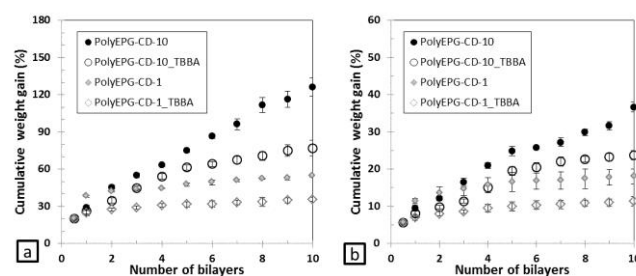

Figure 1: Evolution of cumulative weight gain of the textile with the number of bilayers of the PEM coating based on polyEPG-CD-X and polyCTR-CD in presence or in absence of TBBA. The textile samples were preliminarily treated by thermofixation corresponding to weight increases of (a) 6% of polyCTR-CD and (b) 20% of polyCTR-CD.

## CONCLUSION

We demonstrated the possibility to control the reservoir properties and the sustainability of the antibacterial activity through the extent of the multilayer deposition onto the PET support. The next steps should focus on the loading of various drugs with polyvalent therapeutic activity.

## INTRODUCTION

Microbial infection is probably the most detrimental side complication after orthopedic surgery. Moreover, the overuse and misuse of antibiotics have led to increasing resistance to these drugs. For these reasons, the research in this field is focus on the surface modification of biomaterials in order to achieve a high effective inhibition of bacterial colonization. To this end, we have modified the Ti6Al4V alloy surface with several antibacterial compounds such as carboxylic acids, with promising results [1, 2]. Herein, we report the structural characterization of carboxylate-derived Ti6Al4V for medical applications.

## EXPERIMENTAL METHODS

**Contact angle analyses.** A contact angle goniometer DO4224Mk1 (KRÜSS GmbH) was used. Droplets of pure water (4  $\mu$ L, 100  $\mu$ L min<sup>-1</sup>), diiodomethane (2  $\mu$ L, 50  $\mu$ L min<sup>-1</sup>) and formamide (4  $\mu$ L, 100  $\mu$ L min<sup>-1</sup>) were gently deposited on the surfaces and measured at room temperature (20 °C). Left and right contact angles for each drop were measured with Drop Shape Analysis 3 (DSA3) software implemented with Tangent 2 method. At least two drops of each liquid on at least two different samples were analysed. **Surface preparation.** The coated-Ti6Al4V disks (ELI grade 23, DKSH Ltd (SWZ)) were prepared under the optimal conditions previously reported by our group [1,2]. In brief, the disks were polished, etched in piranha solution (H<sub>2</sub>SO<sub>4</sub>:H<sub>2</sub>O<sub>2</sub> 1:1, 30 min, 45 °C), amino-silanized (aminopropyltrimethoxysilane 1M, 6 h) and cross-linked (24 h, 120 °C). Then, the disks were reacted with sorbic (0.156 M, 52 h, 60 °C) or benzoic (1 M, 24 h, 60 °C) acids solutions yielding ammonium-salts. Cleaning steps in ultrasonic bath after each treatment were set.

## RESULTS

Table 1 shows surface free energy and components for polished (PO), silanized (SL, after 1 min) and treated with sorbic (SR) or benzoic acids (BZ) Ti6Al4V alloy, what were analysed by using the van Oss model (1).

$$\gamma_{SL} = \gamma_S + \gamma_L - 2(\gamma_S^{LW} \gamma_L^{LW})^{1/2} - 2(\gamma_S^+ \gamma_L^-)^{1/2} - 2(\gamma_S^- \gamma_L^+)^{1/2} \quad (1)$$

Table 1. Surface free energy of coated and polished Ti6Al4V alloy.

Sample	Surface free energy (value $\pm$ SD) (mJ m <sup>-2</sup> )			
	$\gamma_S^{LW}$	$\gamma_S^-$	$\gamma_S^+$	$\gamma_S$
PO	39 $\pm$ 1	8 $\pm$ 1	1.3 $\pm$ 0.3	45 $\pm$ 1
SL*	41 $\pm$ 1	2.2 $\pm$ 0.3	0.20 $\pm$ 0.05	42 $\pm$ 1
SR	41 $\pm$ 1	18 $\pm$ 2	2.7 $\pm$ 0.4	55 $\pm$ 1
BZ	40.6 $\pm$ 0.8	4 $\pm$ 2	0.5 $\pm$ 0.2	43.2 $\pm$ 0.9

## DISCUSSION & CONCLUSIONS

Lifshitz-van der Waals component ( $\gamma_S^{LW}$ ), electron-donor ( $\gamma_S^-$ ) and electron-acceptor ( $\gamma_S^+$ ) parameters, and also surface free energy ( $\gamma_S$ ) were used to unveil the functional group oriented toward the external layer. High values of  $\gamma_S^-$  and  $\gamma_S^+$  demonstrate the presence of –COOH, instead low values are according with the phenyl group (Figure 1).

## INTRODUCTION

Biocompatible materials such as Titanium and related alloys are commonly used in the replacement of human hard tissues due to their adequate properties. However, bacterial colonization is one of the most important reasons of their failure that used to imply subsequent surgeries. In order to prevent bacterial adhesion and proliferation, many approaches have been proposed, searching also to enhance the biocompatibility of the material. In this line, we have modified the Ti6Al4V alloy surface with several antibacterial compounds such as carboxylic acids, aldehydes, antibiotics, etc. via their anchoring to a broad and well-defined poly(aminosiloxane) network [1,2]. Herein, we present the structural characterization of silver-mediated complexes with organic compounds on Ti6Al4V alloy surface, which have showed promising result in the inhibition of the bacterial adhesion.

## EXPERIMENTAL METHODS

### Surface preparation

The coated-Ti6Al4V disks (ELI grade 23, DKSH Ltd (SWZ)) were prepared under the optimal conditions previously reported by our group [1,2]. In brief, the disks were polished to a mirror finish, etched in piranha solution (H<sub>2</sub>SO<sub>4</sub>:H<sub>2</sub>O<sub>2</sub> 1:1, 30 min, 45 °C), amino-silanized (aminopropyltrimethoxysilane 1M, 6 h) and cross-linked (24 h, 120 °C) for stabilizing the coating. Then, the disks were reacted with silver acetate (1.8 mM, 48 h, 60 °C), and silver-containing surfaces were treated with sorbic (0.156 M, 72 h, 25 °C) or benzoic (1 M, 24 h, 25 °C) acids solutions yielding the silver-organic complexes. Cleaning steps in ultrasonic bath after each treatment were set. Polished disks were used as control.

### Contact angle analyses

A contact angle goniometer DO4224Mk1 (KRÜSS GmbH) was used. Droplets of pure water (4 µL, 100 µL min<sup>-1</sup>), diiodomethane (2 µL, 50 µL min<sup>-1</sup>) and formamide (4 µL, 100 µL min<sup>-1</sup>) were gently deposited on the surfaces and measured at room temperature (20 °C). Left and right contact angles for each drop were measured with Drop Shape Analysis 3 (DSA3) software implemented with Tangent 2 method. At least two drops of each liquid on at least two samples were analyzed.

## RESULTS AND DISCUSSION

Surface free energy ( $\gamma_s$ ) of polished (PO), silanized (SL), silver-derived (Ag), and complexed with sorbic (Ag-SR) or benzoic acids (Ag-BZ) Ti6Al4V alloy were

analysed by using the van Oss model. Lifshitz-van der Waals ( $\gamma_s^{LW}$ ) and acid-base ( $\gamma_s^{AB}$ ), as well as the electron-donor ( $\gamma_s^-$ ) and electron-acceptor ( $\gamma_s^+$ ) parameters were evaluated and the total surface free energy determined (Table 1).

Table 1. Surface free energy, components and parameters for modified Ti6Al4V surfaces.

Sample	Surface free energy (value $\pm$ SD) (mJ m <sup>-2</sup> )				
	$\gamma_s^{LW}$	$\gamma_s^{AB}$	$\gamma_s^-$	$\gamma_s^+$	$\gamma_s$
PO	39 $\pm$ 1	6 $\pm$ 1	8 $\pm$ 1	1.3 $\pm$ 0.3	45 $\pm$ 1
SL*	41 $\pm$ 1	1 $\pm$ 1	2.2 $\pm$ 0.3	0.20 $\pm$ 0.05	42 $\pm$ 1
Ag	40 $\pm$ 2	1 $\pm$ 2	2 $\pm$ 2	0.1 $\pm$ 0.4	41 $\pm$ 4
Ag-SR	43 $\pm$ 1	5 $\pm$ 1	7 $\pm$ 3	1.2 $\pm$ 0.2	48 $\pm$ 2
Ag-BZ	44.6 $\pm$ 0.9	3 $\pm$ 2	2 $\pm$ 1	0.8 $\pm$ 0.1	47 $\pm$ 2

All the surface treatments promote values of the Lifshitz-van der Waals component close to 40 mJ m<sup>-2</sup>, being higher for surfaces containing silver complexes. The acid-base component presents a high variability depending on the functional group that results oriented toward the external layer. Polar groups, such as those containing oxygen atoms do increase these values, while apolar substituent like phenyl lead to a significant decrease. The prevalent binding of such groups determines the hydrophobicity-hydrophilicity balance of these highly functionalized surfaces. Finally, the differences in the solid-surface free energy of these samples show high variation in their properties depending on the existence of polar or apolar groups.

## CONCLUSION

Contact angle goniometry show excellent results in order to determine the polar or apolar groups oriented to the external layer.

## INTRODUCTION

HAp (Hydroxyapatite ( $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$ )-coating has been examined to improve biocompatibility of metals and alloys applied as biomaterials. Plasma spraying, which is commonly used technique for producing HAp coatings on metallic implants, is hard to control the composition and structure of the HAp due to high-temperature during process. Moreover, it is a line-of-sight process. In contrast, cathodic deposition has advantages such as low-temperature process, ability to deposit on complex surface and low cost<sup>1</sup>. In the cathodic deposition process, HAp is not directly deposited by cathodic reaction. The reduction of water actually occurs as electrochemical reaction which induces local pH increase, then solubility of HAp decreases, resulting in HAp deposition. At the same time,  $\text{H}_2$  evolution leads to poor adherence of the HAp. One possible approach to improve adhesion of HAp is to employ pulse cathodic current<sup>2</sup>, because the pulse parameters such as pulse on and off time influence  $\text{H}_2$  evolution and pH changes. In the present study, the authors examined to form HAp coating on type 316L stainless steel by the pulse current cathodic deposition, then characterized the HAp layer with field emission-type scanning electron microscopy (FE-SEM) with energy-dispersive spectroscopy (EDS), X-ray diffraction (XRD) and fourier transform infrared (FT-IR) spectroscopy.

## EXPERIMENTAL METHODS

Material examined was type 316L stainless steel, the composition is as follow: Cr: 17.35, Ni: 12.18, Mo: 2.07, Mn: 1.20, Si: 0.63, P: 0.030, C: 0.011, S: 0.001, Fe: Bal. (wt%). The material was cut into square specimens with dimensions of 10 mm x 10 mm x 1 mm. The samples were polished with SiC abrasive paper up to #2000 and mirror-finished with 0.3, 0.03  $\mu\text{m}$  alumina powder, then ultrasonically cleaned in acetone and ethanol, followed by rinsing with deionized water and dried at room temperature. Electrochemical treatments were carried out in the solution containing 1.67 mM  $\text{K}_2\text{HPO}_4$ , 2.5 mM  $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$  and 138mM NaCl using a three-electrode electrochemical cell with a platinum counter electrode and Ag/AgCl as the reference electrode. The applied current densities were -100 mA/cm<sup>2</sup> and 0 mA/cm<sup>2</sup>, modulated as square wave, with various parameters ( $t_{\text{on}}$ : pulse on time and  $t_{\text{off}}$ : pulse off time).

## RESULTS AND DISCUSSION

Figure 1 shows SEM images of the depositions on type 316L stainless steels formed by constant current and various pulse currents. Regardless of the methods of current application, needle-like depositions were

Fig. 1 SEM images of deposits formed on type 316L stainless steel by constant current ((a), (e)) and pulse current cathodic deposition of  $t_{\text{on}}-t_{\text{off}} = 2-4$  ms ((b), (f)), 20-40 ms ((c), (g)) and 200-400 ms ((d), (h)) at 100 mA/cm<sup>2</sup> for 30 min. (a)-(d) low magnification and (e)-(h) high magnification.

observed. The depositions were identified as carbonate containing apatite by XRD and FT-IR analysis. The deposition formed by constant current was more aggregated than that formed by pulse currents. Focusing on the effect of pulse parameter, the deposition formed by pulse current of  $t_{\text{on}}-t_{\text{off}} = 20-40$  ms coated more widely than that formed by pulse current of  $t_{\text{on}}-t_{\text{off}} = 2-4$  ms and 200-400 ms. Furthermore, the amount of the deposition formed by pulse current of  $t_{\text{on}}-t_{\text{off}} = 20-40$  ms was larger than that of that formed by pulse current of  $t_{\text{on}}-t_{\text{off}} = 2-4$  ms and 200-400 ms. These results suggest that the effectiveness of the pulse current for the cathodic deposition of hydroxyapatite and to set appropriate pulse parameter can increase the deposition amount and reduce the aggregation of apatite.

## CONCLUSIONS

The pulse current cathodic deposition was examined for deposition of HAp on type 316L stainless steel, and the following conclusions are obtained:

1. Needle-like depositions were observed on the substrates applied both constant current and pulse current. The depositions were identified as carbonate containing HAp.
2. Appropriate pulse current can increase the amount of deposition and suppress the aggregation of apatite.

### INTRODUCTION

The performance of implant materials depends on their composition and bulk physical properties, but also, critically on their surface properties. Surface topography mediates cellular response at the implant/surrounding tissue interface<sup>1</sup>. Laser micro-machining is an emerging surface modification strategy that allows precisely controlled processing to obtain diverse textures on implantable metallic surfaces<sup>2</sup>.

### EXPERIMENTAL METHODS

Laser surface modification, by means of a UV nanosecond Nd:YVO<sub>4</sub> laser structuring, was conducted on two typical implant materials, stainless steel 316L and titanium alloy Ti6Al4V, to create different surface patterns and densities. In particular, two configurations were designed: a matrix of pits and a series of parallel grooves were machined into the surfaces, with different spacing, 50, 75 and 100  $\mu\text{m}$ . Surfaces were characterized with optical and scanning electron microscopy. Topographic characterization was also performed with a profilometer.

To study the effects of the topographic changes on cell behaviour we performed a viability assay with human bone derived cells (HBCs) isolated from trabecular bone by explant culture. Cells were seeded ( $10^4$ /sample) on the differently texturized metal surfaces. Differences in viability were quantified with the alamarBlue® method. A cleaning protocol was optimized to eliminate all organic residual matter to reuse the metallic surfaces in subsequent experiments.

### RESULTS AND DISCUSSION

Laser micromachining resulted in two distinct types of topographies, a matrix of pits and a distribution of parallel grooves. Spacing separating features was either 50, 75 or 100  $\mu\text{m}$ , which were achieved with high precision and reproducibility.

Cellular origin was checked by means of immunofluorescence of alkaline phosphatase and collagen type I, confirming an osteoblastic phenotype. Cells attached and were viable on all the surfaces tested, but we found differences in cell viability due to the different laser treatments. First, all laser treatments slightly reduced cell viability with respect to the untreated control samples. Cell viability was also slightly lower in the stainless steel samples with respect

to Ti6Al4V samples. Cells generally preferred the pit morphology to the grooves, and the larger the distance between the features the better, i.e. P100 was better than P50.

Fig. 1 Osteoblast viability as a function of surface topography; matrix of pits (P), grooves (G).

Further experiments will be performed to evaluate other cell parameters, in particular those relevant to cell adhesion and osteoblasts-like phenotype maintenance. The developed cleaning procedure, that included a plasma cleaning step, satisfactorily removed all organic matter from the biometal surfaces, as shown by carbon elemental (EDX) surface analysis.

### CONCLUSIONS

Surface microstructuring resulted in differences in cell viability. Ti6Al4V with a matrix of pits and 100  $\mu\text{m}$  exhibited the best results. The cleaning protocol was appropriate to eliminate residual matter from the surfaces.

These results indicate the potential of UV nanosecond laser treatment as a relevant tool to precisely modify implant surface micro-structuring and influence cell behaviour.

## INTRODUCTION

Adherent cells have the intrinsic property of binding, and reacting to the topographical features of their microenvironment. Such mechanisms are nowadays exploited for design of artificial surfaces controlling cell-behavior *in vitro*. We studied the cellular ability to recognize and to display preferential migration between different patterns. Furthermore, we evaluated the contribution of focal adhesions to the observed behavior.

## EXPERIMENTAL METHODS

For the experiments a multi-patterned culturing substrate (submicron and nanometric grooves/squares) was utilized. The individual patterned fields of 500x500µm<sup>2</sup> were enclosed by a smooth surface, allowing migrating cells to experience interfaces of patterns. It was hypothesized that cells with preference for a pattern would mostly enter the topographical field, while staying on the smooth surface in case of repulsion (Figure 1). Cell lines with differences in the expression

**Figure 1:** Theoretical model for cell-preferential migration on a multi-topographical substrate.

level of the focal adhesion dynamic regulating metalloproteinase MT1-MMP were cultured on the substrates over a period of 48 hours. The recorded time-lapse micrographs were analyzed for the cellular preference migration behavior. In the last part of the study the cell-line displaying the strongest pattern-loving behavior was co-cultured with cells that preferred the smooth surfaces to see the separation ability of the multi-patterned surface.

**Figure 2:** Topographical control over cell-repelling or attraction of a surface. A) Nano-sized squares can be used to avoid the interaction of the surface with primary mesenchymal cells B) Same pattern can be used for the attraction of a mineralizing osteoblast cell line. C) Simultaneously seeded mesenchymal and osteoblast cells are separated by the topography (from our own data, in progress for publication; A from Klymov et al. Acta biomaterialia 2015. B and C Manuscript in preparation)

## RESULTS AND DISCUSSION

In our results, we found a clear correlation between MT1-MMP expression and cellular behavior on patterns. The more dynamic the focal adhesions were, the more the cells tended to enter topographical fields, remain, and proliferate, slowly leading to filling up of the field (Figure 2). Moreover, cells with contrasting properties could be separated during co-culture on the multi-patterned surface.

## CONCLUSION

Cells feature a pattern recognition mechanism, which is mediated by focal adhesions. The here found mechanisms can be utilized during the design of various surfaces for the means of tissue regeneration. Moreover, it can deliver *in vitro* methods for separation of cells in co-culture models.

### INTRODUCTION

Titanium and its alloys are commonly used for medical applications because of their good mechanical properties and biocompatibility. The surface properties of titanium implants are key factors for rapid and stable bone tissue integration. Micro-rough surfaces are commonly prepared by grit-blasting and acid-etching. However, proteins and cells interact with implant surfaces in the nanometer range. During this last decade, titania nanotubes have attracted interest because of their favourable bone tissue integration by a phenomenon of mechano-transduction (1). Although bacterial infection are the most severe and devastating complication, scientifics also discover the presence of nano-particles around failing implants. The aim of the study is to realise a nano-bioactive surface on tracheal prosthesis and determine it adhesion onto the titanium substrate and the release of particles.

### EXPERIMENTAL METHODS

Titanium Commercially Pure (cp) prothesis were treated using an anodization process to form titania nanotubes. After rinsing, an annealing treatment was performed at 500°C for 2h. Surface morphology was investigated by FEG-SEM. Chemical and physical property were characterized by means of EDS, XPS, RAMAN and XRD analysis. Nanotubes adhesion were measured by scratch test and nanotribology assay. Prothesis were immersed in buffer solution in order to measure any nanoparticle release by using Laser Induced Breakdown Detection (LIBD). Data were statistically analyzed for significance using Mann-Whitney and Kruskal-Wallis statistical tests (p-value<0.05).

### RESULTS AND DISCUSSION

SEM observations showed a regular nanotubular surface with pores of 30 nm in diameter. EDS and XPS analysis reveals the migration of fluoride from the electrolyte into the newly formed oxide layer. It has been observed that the quantity of fluoride decreased with heat treatment due to the evaporation of TiF<sub>4</sub>. LIBD analysis reveals the presence of nanoparticle detached from the surface. Particules release was also observed in the water bath of the rinsing step. [TiF<sub>6</sub>]<sup>2-</sup> species are the main cause of this weak adhesion due to its solubility in water. These results were confirmed by scratch test analysis, for which we obtain a critical value of only 25 mN. Nanotribology assay also show a weak surface behaviour under wear and delamination are observed by individual nanotubes, by agregats or by plates.

### CONCLUSION

Nanostructured surface have been widely published to give promising biological results for biomedical application. However this study reveal weak mechanical properties of the oxide layer. Moreover nanoparticles released from this innovative surface and could be a risk to implants failure. Particules emissions is a current top as a new European regulation will take place this year regarding the incorporation of nanomaterials in medical devices.

[miguel.oliveira@dep.uminho.pt](mailto:miguel.oliveira@dep.uminho.pt)

### INTRODUCTION

The clinical gold standard for bridging peripheral nerve gaps of critical length is the transplantation of autologous nerve tissue, which is harvested from sensory nerves of the same patient<sup>1</sup>. In general, autologous nerve grafts provide optimal guidance cues for regenerating nerve fibers, such as peripheral glia cells and Schwann cells (SCs). They do not only produce regeneration-promoting factors but also line their basal laminae up to the so-called bands of Bungner, the guiding tubes within the distal nerve segments<sup>2</sup>. Undoubtedly, the use of autologous nerve tissue leads to loss of sensation at the site of harvest and the functional outcome after its utilization is described to range from extremely poor to satisfying. As an alternative to this, tubulisation strategies, using biomaterials, have been performed<sup>3-5</sup>. However, so far the results have been quite disappointing. To tackle this, new biomaterials have been developed that can easily be modified to provide an optimized environment for peripheral nerve regeneration and qualify as substitutes for autologous nerve grafts. Chitosan is among the biodegradable polymers that demonstrate good properties for neural tissue engineering<sup>6</sup>. It is an attractive material to produce as an inner guidance of nerve conduits, because it can easily be blended with other materials or be processed in different ways provide guiding and structural cues supporting axonal growth<sup>7</sup>.

### EXPERIMENTAL METHODS

Chitosan (CS) powders from Altakitin (Portugal) were supplied and its cytotoxicity was assessed. Using these biomedical grade powders, biodegradable scaffolds were developed to support neuronal regeneration using the electrospinning technique to produce nanofibers from chitosan solutions. Random and aligned nanofibers were produced and characterized, using techniques such as Fourier Transform Infrared Spectroscopy (FTIR), Scanning Electron Microscopy (SEM), Atomic Force Microscopy (AFM), Differential Scanning Calorimetry (DSC) and Contact Angle. *In vitro* tests to characterize L929 cells viability (MTS assay) and proliferation (DNA quantification) on nanofibers scaffold were performed.

### RESULTS AND DISCUSSION

Medical grade CS powders were found to be non-cytotoxic. To produce a mesh of random chitosan fibers with no beads or other defects, a 5% chitosan solution in trifluoroacetic-acid and dichloromethane as solvents, in the proportion of 70:30 was used. The produced

nanofibers are super hydrophilic, defect-free and have an average diameter of  $184 \pm 36$  nm. Yarns of aligned chitosan fibers were obtained using two blades placed in line set up, with the exact same conditions used to obtain random nanofibers. Cell viability and proliferation increased over time showing this is a suitable substrate for cell adhesion.

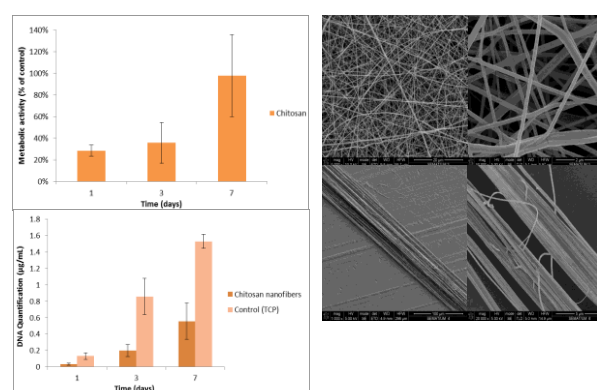

Figure 1 – Random and aligned nanofibers were produced. L929 cells adhere and proliferate up to 7 days.

### CONCLUSION

After physico-chemical analyses, was shown that the fibers produced did not undergo any relevant chemical modification after processing. Biological assays indicated that the scaffold is non-cytotoxic and allowed cellular proliferation over time. Therefore, it can be concluded that the scaffold can find promising applications in peripheral nerve regeneration, specifically as guiding luminal filler.

## The Concurrent-Electrospinning of Polylactide and Gelatine Fibres as a Way of Obtaining Advanced Hybrid Materials

Anna Magiera<sup>1</sup>, Stanisław Błazewicz<sup>1</sup>

<sup>1</sup>Faculty of Materials Science and Ceramics, Department of Biomaterials, AGH University of Science and Technology, Poland

[asocha@agh.edu.pl](mailto:asocha@agh.edu.pl)

### INTRODUCTION

During the electrospinning (ES) process fibrous form of a material (mainly polymer) is obtained from its liquid state<sup>1</sup>. Nanocomposite fibres can be produced due to functionalisation of a polymer precursor with nanoconstituents. Electrospun fibrous structures have already been applied in numerous fields<sup>2-4</sup>, which makes this technique extremely versatile and worth further developing. The concurrent electrospinning (co-ES) technique is a modification of the standard ES method in which more than one jet is simultaneously generated from multiple polymer sources<sup>5</sup>.

This work focuses on the obtaining of the individual poly(lactic acid) (PLA) and gelatine (GEL) fibres via ES technique and the composite PLA/GEL material by co-ES method. The fibrous samples were analysed using scanning electron microscopy (SEM).

### EXPERIMENTAL METHODS

#### MATERIALS

To obtain polymeric fibres the PLA (Ingeo™ Biopolymer 3251D) and GEL (POCH, analytical grade) were used. As solvents dichloromethane (DCM) (POCH, analytical grade), N,N-dimethylformamide (DMF) (POCH, analytical grade) and concentrated (99,5-99,9 %) acetic acid (CH<sub>3</sub>COOH) (POCH, analytical grade) were used. The PLA solution in the concentration of 15 % (wt/v) was prepared in mixed solvents DCM, DMF 3:1 (wt:wt)<sup>6</sup>. The GEL (in the concentration of 20 % (wt/v)) was dissolved in concentrated acetic acid<sup>7</sup>.

#### ELECTROSPINNING PROCESS

The ES experiments were conducted using a device constructed at the Department of Biomaterials, AGH-UST. A 10 ml syringe, ended with a needle having a diameter of 0,9 mm, was loaded with the polymer solution. The voltage of 12 kV was applied between the needle tip and the collector, moving grounded roller covered with an aluminium foil. The tip-to-collector distance was 3 cm. The electrospinning processing conditions were determined in previous experiments<sup>6,7</sup>.

#### SCANNING ELECTRON MICROSCOPE ANALYSIS

The samples obtained were coated with gold and analysed using scanning electron microscope, SEM (JROL 5400 microscope with EDS analyser).

### RESULTS AND DISCUSSION

Individual PLA and GEL fibres have been obtained using the ES experimental setup constructed at the AGH University of Science and Technology. Nanofibre diameters and porosity of the resulting fibrous samples were determined from the SEM images. The

microphotographs FIG. 1A-1B illustrate the extent of porosity between the nanofibres of nonuniform fibre distribution. The microstructure of samples is characterized by high amount of interconnected open pores up to 95 %, and the pore sizes were in micron scale. A slight variation in fibre diameter distribution was found.

Hybrid PLA/GEL structure has been obtained as it is shown in FIG. 1C. An interaction between the two simultaneously generated jets results in an increasing nanofibre-to-nanofibre contact and decreasing sample porosity.

FIG. 1. SEM images of (A) PLA, (B) GEL, and (C) PLA/GEL fibres. Scale bars 20 μm.

### CONCLUSION

The aim of this work was to obtain the hybrid polylactide (PLA) and gelatine (GEL) fibrous structure via the concurrent electrospinning (co-ES) technique. The experiments performed proved the possibility of manufacturing polymeric fibres under relatively low voltage conditions (12 kV) using a simple, laboratory scale device. The co-electrospun composite of PLA/GEL has been successfully obtained. Further functionalisation of the hybrid polymeric structure should be performed in the future as it constitutes a promising path towards the manufacture of specialised multifunctional materials.

[carla.cunha@ineb.up.pt](mailto:carla.cunha@ineb.up.pt)

### INTRODUCTION

Cell therapies for IVD regeneration presently rely on transplantation of IVD cells or stem cells directly to the lesion site. Still, the harsh IVD environment given by low irrigation and high mechanical stress, poses problems to cell administration and survival. Our approach, instead, explores tissue regeneration via endogenous cell migration and/or signalling to the lesion site. MSCs have been shown to induce regenerative features in the IVD and MSC trafficking to the lesioned IVD has been shown in organ culture and *in vivo*.

### EXPERIMENTAL METHODS

In this study, we administered allogeneic bone marrow MSCs intravenously into a rat IVD lesion model, which has been previously developed in the lab by caudal needle puncture. Allogeneic dermal fibroblast transplantation has been performed in parallel. We have quantified parameters of degeneration and herniation within the IVD by radiological (X-rays), histological (Safranin staining and IHC) and gene expression analysis (qPCR), 2 weeks after transplantation. Analysis of the systemic immune response has also been quantified by cytometry.

### RESULTS AND DISCUSSION

Percentage of disc height index and histological grading score indicate a less degenerative phenotype within the IVD for the MSCs transplanted group. Moreover, this group has significantly less herniation. Gene expression analysis indicates no alteration in the main ECM components (Coll1, Coll2 and Aggrecan) at 2 weeks post-lesion for the transplanted groups, while showing a significant upregulation in these genes in the control lesion group. The results for the systemic immune response associated with MSC transplantation seem to indicate an immunosuppressive effect in the MSCs transplanted animals. Also, we found an increase in B lymphocytes and a decrease in T lymphocytes in the blood, associated with the lesion.

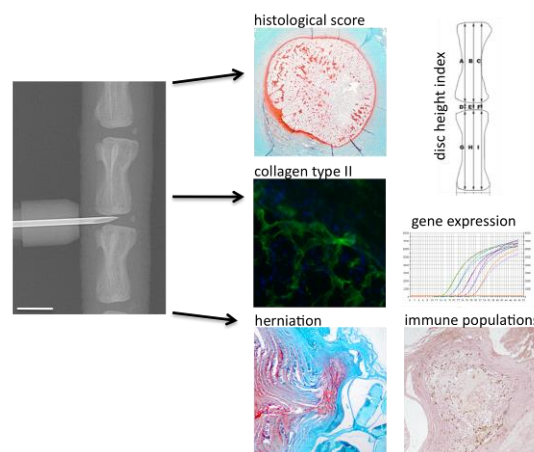

Figure 1 IVD injury model created by 21-G needle puncture, with analysis of IVD degeneration performed 2 weeks after MSC systemic transplantation by measurement of disc height index, histological grading score, determination of hernia volume, quantification of ECM components and immune populations present in the hernia site. Scale bar: 5 mm.

### CONCLUSION

Overall, our results seem to indicate a positive effect of systemically transplanted MSCs on *in situ* IVD regeneration.

## Evaluation of the Efficiency of Mechanical Agitation Method in Heart Decellularization Process

Ana Paula Brandão<sup>1</sup>, Jonathas Haniel<sup>1</sup>, Betânia Soares<sup>1</sup>, Rosana Cruz<sup>1</sup>, Marcos Pinotti<sup>1</sup>.

<sup>1</sup>Department of Mechanical Engineering, Engineering School, Federal University of Minas Gerais, Brazil  
[jonathashaniel@hotmail.com](mailto:jonathashaniel@hotmail.com)

### INTRODUCTION

Cardiac transplantation has been shown continuous growth in Brazil<sup>1</sup>. However, lack of a good immune-suppression, inability to monitoring and control rejection, and the donor shortage has prompted to looking for new alternative approaches as cell transplantation, gene therapy and tissue engineering<sup>2</sup>.

Decellularized tissues have been successfully used in a variety of tissue to application in regenerative medicine. More recently decellularized organs have been utilized as the first stages to organ engineering<sup>3</sup>. The aim of decellularization process is isolate the extracellular matrix (ECM) from the organ without its loss, damage, or disruption, while removing completely the cellular components<sup>4,5</sup>. The ECM can be used for subsequent repopulation with new contractile, vascular muscle tissue<sup>6</sup>. This bioartificial tissue could be generate fewer effects in immune response.

Thus, the objective of this study was to evaluate the efficiency of the chemical method already proposed in the literature, using an alternative method to immersion with mechanic agitation.

### EXPERIMENTAL METHODS

Heart chicken was used in a decellularization pilot assay. Entire cold heart were weighed, measured and fixed on a support through the aorta and immersed in a beaker. The chemical method by perfusion has been proposed by Weymann *et. al.*<sup>7</sup> and consists in the use of phosphate-buffered solution (PBS) 1X and 4% p/v sodium dodecyl sulfate (SDS) in PBS. In this study, mechanical agitation was used for delivering the decellularization agents without temperature control. The structure was placed on a magnetic stirrer and initially immersed with PBS 1X to remove the coagulated blood and tissue debris. After, the organ was immersed in 4% p/v SDS with PBS 1X for 12 hours. During this process, every three hours, the hearts were immersed in PBS 1x for 15 minutes in order to remove residual substances. The final washing step after SDS treatment included immersion with PBS 1X for another 24 hours to remove remnant detergents and cell debris. At the end of assay the heart was cut and observed visually.

### PARTIAL RESULTS AND DISCUSSION

After 3 hours was possible to observe the start of decellularization process. This process was more pronounced and faster in the upper region of the heart where the tissue is thin. After 6 hours of washed, the atrial region and mainly blood vessels showed whitish,

translucent and more pronounced at the final of decellularization process. The ventricular region became more clearer than natural color but there was remaining muscle tissue after 37 hours. The heart increased its weight and size compared to initial condition. The aorta supported the heart's weight during all decellularization process without disrupt. After the cut was possible to see only an external decellularized layer in the heart lower region. Ventricles are thicker than atria. So, the cellular removal using the proposed method was inefficient in those regions. .

The mechanical agitation method showed inefficient to deliver the decellularization agents in a heart when compared to perfusion described by Weymann *et. al.*,<sup>7</sup> probably because chemical and controlled mechanical methods together are necessary to complete lysis and remotion of the cellular debris.

### PARTIAL CONCLUSIONS AND PERSPECTIVES

The method used in this assay was not enough to completely decellularization of the heart. Therefore, the use of a vascular network for fluid movement in the organ can be an alternative to increase the efficiency of the decellularization process in complex tissues.

The next steps in this study include quantitative and histologic analysis, tension and deformation mechanical tests, and temperature control using perfusion methods.

[mike.barbeck@kgu.de](mailto:mike.barbeck@kgu.de)

## INTRODUCTION

The present study analyzes the influence of granule size of two biphasic bone substitutes (BoneCeramic® 400-700 µm and 500-1000 µm, Fig. 1) on the induction of multinucleated giant cells (MNGCs) and implant bed vascularization in a subcutaneous implantation model in rats. Furthermore, cellular degradation mechanisms were studied by transmission electron microscopy (TEM), and the influence of the addition of (human) monocytes to both materials and its impact on the tissue reactions were analyzed in immunodeficient mice.

## EXPERIMENTAL METHODS

To conduct this study an established subcutaneous implantation model was used in 61 female 6-8 week-old Wistar rats and 12 female 5-week-old SCID mice<sup>1</sup>.

Primary monocytes were isolated from the peripheral blood of two donors from whole blood donations in accordance with ethical approval in cooperation with the Transfusion Center of the University Medical Center Mainz. Furthermore, established histological methods, i.e., specialized (immuno-) histochemical staining methods, and histomorphometrical methods were applied<sup>1</sup>. For TEM analysis previously described methods were used<sup>2</sup>.

## RESULTS AND DISCUSSION

Both materials induced tissue reactions involving primarily mononuclear cells and only small numbers of MNGCs (Fig. 1). Higher numbers of MNGCs were detected in the group with small granules starting on day 30, while higher vascularization was observed only at day 10 in this group. Thus, no correlation between the occurrence of MNGCs and the implant bed vascularization was found.

TEM analysis revealed that both mono- and multinucleated cells were involved in the phagocytosis of material, exhibiting typical subcellular elements of this process. The MNGCs were identified as foreign body giant cells in this analysis by a lack of typical osteoclastic organelles. The analysis of the size of phagocytized particles showed no differences between the two groups.

The added human monocytes were detectable either as mononuclear cells or as (components of chimeric) MNGCs within both groups without an increase in the total number of MNGCs, but with increased vascularization.

**Fig. 1.** SEM images of the both biphasic bone substitutes (upper row) and histological images of the tissue reaction to the materials (BC) at day 10 (red arrows = vessels, black arrows = mononuclear cells, arrowheads = MNGCs, CT = connective tissue) (lower row).

## CONCLUSION

The results show that synthetic materials can induce tissue reactions similar to those of some xenogeneic materials, leading to a need to determine their “ideal” physical characteristics<sup>3</sup>. The results also raise the question of the differentiation of material-induced MNGCs and their induction especially in the context of the “inflammatory” tissue reaction to biomaterials. Finally, the addition of monocytes to biomaterials is shown to increase implant bed vascularization. Thus, monocyte addition provides a basis for a new tissue regeneration concept.

### INTRODUCTION

Heart diseases are leading causes of death in developed countries. The total organ transplantation is most commonly used procedure for end-stage of heart failure; however the treatment is limited by the shortage of donors and the antigenicity of the transplanted organ which may lead to rejection frames<sup>1</sup>.

Therefore, the field of tissue engineering has great potential in the search for new transplant strategies for a better quality of life.

A serious difficulty of tissue engineering is the creation of scaffolds that can be used for the development of complex three-dimensional tissue or even whole organs<sup>2</sup>. One solution would be to use the extracellular matrix (ECM) from own organ that you want to transplant performing its decellularization. In this process, occurs the withdrawal and lysis of the cellular materials, creating a bioartificial scaffold<sup>3</sup>.

Among the challenges of decellularization is to build a device capable of allowing the complete removal of cellular debris with perfusion trials covering all regions of the organ without affecting the structural capacity of the ECM<sup>4</sup>. The aim of this work is to design and develop the decellularization equipment to provide the necessary conditions for this process.

### EXPERIMENTAL METHODS

The design and construction of this equipment must meet the needs of perfusion and heart fixing.

The perfusion allows the transport of decellularization solution and remove cellular debris from the tissues<sup>5</sup>. To date, our group has conducted tests with decellularization protocol to lift all the needs of the equipment. The perfusion is designed to occur with the action of a positive displacement pump with rollers, which has continuous flow with little vibration.

The fixation of the heart will be made through structures which will cannulate its two large vessels, connecting it to the product cover, and also allowing the perfusion which will occur mainly via these vessels. Thus, following the isolated heart perfusion method of Langendorff<sup>6</sup>, this may also facilitate the subsequent repopulation and maintenance *in vitro* of the ECM.

Another strategy used will be submerge the organ in the solution, using the buoyant force to help support, reducing the tension strainer in the aorta and vena cava, and to facilitate the decellularization in the epicardium.

### PARTIAL RESULTS

We considered, during development, the possibility of controlling the pressure and flow of perfusion, whereas they are determined by the pipe diameter and the rotational speed of the rollers. The flow capacity ranges from 30 to 3000 ml / min.

Moreover, before starting the circulation in the organ, the solution will go through a heat exchanger, enabling that the temperature of decellularization can be controlled to meet the many existing decellularization protocols.

A filter will also be added to the system to minimize the effect of particles that can hinder the circulation.

### PERSPECTIVES

The next steps are the construction of the entire sustaining and fixing system. It is expected that the equipment can help in the study of characterization and improvement of the decellularization process, apart from allow futures adaptations to the process of recellularization and use in different organs.

## Mechanical Properties of Chitosan/Collagen Composites Modified by Sodium Alginate

Alina Sionkowska<sup>1</sup>, Beata Kaczmarek<sup>1</sup>, Marta Michalska<sup>1</sup>

<sup>1</sup>Department of Chemistry of Biomaterials and Cosmetics, Faculty of Chemistry, Nicolaus Copernicus University in Toruń, Poland  
[as@chem.umk.pl](mailto:as@chem.umk.pl)

### INTRODUCTION

Biodegradability, biocompatibility and bioactivity are the most important properties of natural polymers through which they play an important role in medicine, pharmacy and tissue engineering<sup>1</sup>. Collagen and chitosan are natural polymers widely used in tissue engineering. They are resorbable with a high biocompatibility and stability to foster the tissue regeneration<sup>2,3,4</sup>. Chitosan is polysaccharide derived by deacetylation of chitin<sup>5</sup>. Collagen is the most abundant protein in animals. It is the main component of connective tissue, tendon and skin<sup>4</sup>. Collagen extracted from natural sources sometimes does not have mechanical properties required for several biomedical applications. To improve the mechanical properties of collagen scaffolds, other natural polymers or cross-linking agents have to be added<sup>6,7</sup>. In this study to the mixtures of collagen and chitosan the cross-linking agent, sodium alginate was added and mechanical properties were studied.

### EXPERIMENTAL METHODS

Chitosan (CTS) sample has a degree of deacetylation of 78% with a viscosity average molecular weight of  $0.59 \times 10^6$ . Collagen (Coll) was extracted in our laboratory from rat tail tendon. Chitosan and collagen mixtures were prepared by mixing two solutions in weight ratio 50/50. Sodium alginate as a 1% solution in 0.1 M acetic acid was added as a cross-linking agent in weight ratios 2 and 5%. To obtain total miscibility few drops of 2M hydrochloric acid were added. Hydrochloric acid did not change the final pH of the mixture. Solutions were mixed and put into a polystyrene container, frozen at -80°C, then the frozen mixtures were lyophilized at -55°C and 5Pa for 48h (ALPHA 1-2LD plus, CHRIST, Germany). Samples with pure chitosan, collagen and their mixtures were left as control samples. Mechanical properties were measured by mechanical testing machine (Z.05, Zwick/Roell, Germany). Samples were located between two discs and pressed. All measurements were carried at room temperature and humidity.

### RESULTS AND DISCUSSION

Compressive modulus and the tensile strength for chitosan/collagen composites with and without sodium alginate are shown in Table 1. Sodium alginate was used in two concentrations of 2 and 5 %. The properties of materials were compared. The highest compressive modulus and tensile strength was observed for chitosan's scaffolds. The scaffold made of collagen had

compressive modulus almost four times lower than pure chitosan scaffolds. Young modulus for composites mixture of collagen and chitosan was medial compared to collagen and chitosan separately. However, the tensile strength for chitosan/collagen composites was much lower than for scaffolds made of chitosan and/or collagen. The addition of 5% of sodium alginate to chitosan/collagen mixture led to the increase of Young modulus. The addition of 2% of sodium alginate was not sufficient to improve mechanical properties of chitosan/collagen composite and even led to the decrease of Young modulus.

Specimen	E <sub>mod</sub> [kPa]	F <sub>max</sub> [kPa]
CTS	4.93±0.70	12.88±0.47
Coll	1.27±0.87	5.59±0.90
CTS/Coll	2.43±0.16	1.19±0.43
CTS/Coll/2SA	1.89±0.29	1.12±0.26
CTS/Coll/5SA	3.03±0.60	1.23±0.09

Table 1. Compressive modulus (E<sub>mod</sub>) and tensile strength (F<sub>max</sub>) for chitosan/collagen (CTS/Coll) composites in 3D structure with 2% (CTS/Coll/2SA) and 5% (CTS/Coll/5SA) of sodium alginate.

### CONCLUSION

Mechanical properties of new materials based on the blends of chitosan and collagen can be modified by the addition of sodium alginate. The addition of 2% of sodium alginate causes decrease in Young modulus and tensile strength in 3-D chitosan/collagen scaffolds. The addition of 5% of sodium alginate can lead to material with improved mechanical properties.

### INTRODUCTION

Advancements in engineering and cell biology have led to the development of advanced therapy medicinal products (ATMPs). Such approaches often require removal of cells from their optimal tissue context and propagation in a far from physiological *in vitro* microenvironment to attain suitable numbers. However, bereft of their optimal *in vivo* niche, cells perform poorly, lose their functionality and with it their therapeutic potential. To this end, research efforts have been directed towards reconstruction of more functional *in vitro* microenvironments by modulating biophysical (e.g. surface topography, macromolecular crowding), biochemical (e.g. oxygen tension) and biological (e.g. growth factor supplementation, gene transfection) cues to maintain permanently differentiated cell phenotype and to direct stem cells towards specific lineage (1-4).

### EXPERIMENTAL METHODS

Herein, the influence of macromolecular crowding on tenogenic phenotype maintenance and the potential of anisotropic scaffolds (extruded collagen fibres and electro-spun polymeric fibres) on differentiation of other cell populations towards tenogenic lineage were assessed.

### RESULTS AND DISCUSSION

Macromolecular crowding, the addition of inert macromolecules in the culture media, effectively emulates the dense *in vivo* extracellular space, resulting in amplified deposition of extracellular matrix (ECM) *in vitro* and subsequent production of cohesive and rich in tissue specific ECM living substitutes.

**Figure 1a:** Densitometric analysis of SDS-PAGE demonstrated that human tenocytes in the presence of macromolecular crowders (75µg/ml carrageenan; CR) deposited the highest ( $p < 0.0001$ ) amount of collagen I

after 6 days at 5% FBS. Standard (STD): 100µg/ml collagen type I.

**Figure 1b:** The addition of carrageenan (CR) in human tenocyte culture results in tenogenic phenotype maintenance and enhanced tendon-specific matrix deposition, even in the presence of low serum.

### FUTURE WORK & CONCLUSION

Preliminary *in vitro* data indicate that anisotropic collagen fibres induce differentiation of non-tendon permanently differentiated cells towards tenogenic lineage. Overall, *in vitro* microenvironment modulators will allow us overcome current bottlenecks in *ex vivo* cell culture and consequently enable clinical translation and commercialisation of cell-based therapies.

## INTRODUCTION

Anatase-type TiO<sub>2</sub> is an n-type semiconductor with an energy band gap of  $E_g=3.2$  eV, which displays a relatively high photocatalytic activity under light irradiation at wavelengths of  $\lambda < 380$  nm and has high chemical stability. In addition, TiO<sub>2</sub> is known to absorb water on its surface, resulting in the formation of hydroxide groups. When an n-type semiconductor is immersed in an aqueous solution, an up-hill potential gradient is produced towards the surface in the conduction and the valence bands. Under ultraviolet (UV) irradiation, electrons and holes are formed in the conduction and the valence band, respectively. These photogenerated charges are then spatially separated by the potential gradient.

The purpose of this work was to investigate the adhesion/proliferation behaviour of cells under UV irradiation on TiO<sub>2</sub> showing the characteristic surface reaction mentioned above.

## EXPERIMENTAL METHODS

Anatase-type TiO<sub>2</sub> film was synthesised on commercial purity Ti disks ( $\phi 6 \times 2$  mm) by the combined chemical-hydrothermal treatment<sup>1</sup>.

Primary osteoblasts, isolated from new-born mouse calvariae, were used in this study. The cells were seeded at  $2.5 \times 10^3$  cells/well on specimens in 96-well microplates and then incubated at 37 °C for 4-72 h in a controlled humidified 5% CO<sub>2</sub> atmosphere. During the incubation, the UV irradiation with a centred wavelength of  $\lambda=365$  nm was applied intermittently for 1 h just after the seeding and every 24 hours. In addition, continuous UV irradiation was also examined.

After the incubations, the cells on the samples were stained with 5% Giemsa staining and observed by optical microscope. The number of cells was also evaluated by the WST assay. In addition, fluorescence imaging was also performed in order to investigate the number and the placement of desmosomes.

## RESULTS AND DISCUSSION

Basically the number of cells monotonically increased with incubation periods on both Ti and TiO<sub>2</sub> under darkness. In contrast, the cells decreased in 4 h-incubation under continuous UV irradiation. The decrease on the TiO<sub>2</sub> was statistically significant. Direct UV irradiation is known to damage to the cells. In this case, the cells might be additionally received some sort of stimulus from the surface of TiO<sub>2</sub>. The number of desmosomes was decreased by the UV irradiation. In the incubation for 72 h, most cells dead without proliferation regardless of the samples.

Figure 1 shows optical density of cells, measured by the WST, on Ti and TiO<sub>2</sub> after 4 h-incubation with 1 h-UV irradiation at the initial stage. Cells decreased in the

wells without samples under UV irradiation. In contrast, the numbers of cells increased on Ti and TiO<sub>2</sub> even in the UV irradiation. The increase on TiO<sub>2</sub> with the UV was statistically significant. The formation of Ti-OH groups on the TiO<sub>2</sub> seems to be facilitated by the UV irradiation. As a result, adhesion of cells to the samples might be improved. Actually the cells could be confirmed to spread their pseudopods (Fig. 2).

Figure 1 Adhesion of cells on pure Ti or TiO<sub>2</sub> under darkness or UV irradiation. PS indicates that without samples. \*:  $p < 0.01$  in Student *t*-test.

Figure 2 Morphology of cells, incubated for 4 h, on TiO<sub>2</sub> under darkness (a) or under intermittent UV irradiation (b).

## CONCLUSION

The intermittent UV irradiation might promote the adhesion of cells on TiO<sub>2</sub>. This must be closely related to functional groups on the TiO<sub>2</sub> induced by the photochemical reaction.

## INTRODUCTION

Cardiac tissue engineering has emerged as a promising approach to replace or support an infarcted cardiac tissue and thus may hold a great potential to treat and save the lives of patients with heart diseases. The development of scaffold for biografts for the repair of myocardial tissue is particularly challenging but holds great potential. Electrospinning is one of the most effective methods for providing new, bio-mimicking natural matrices. The aim of this research is to develop poly ( $\epsilon$ -caprolactone) and Sodium Alginate, blended nanofibrous scaffolds as a patch for cardiac tissue-engineering applications [1,2].

## EXPERIMENTAL METHODS

The polymer solution with concentration of 10 wt% was prepared by dissolving PCL and Alginate with a weight ratio of 70:30 in acetic acid and stirred for 24 hr at room temperature. The solution was electrospun from a 5ml syringe with a needle diameter of 0.49 mm and mass flow rate of 1 ml/h. The properties of PCL/ Alginate nanofibrous patches were measured by SEM, FTIR and contact angle measurement, while the in vitro biodegradability of the nanofibrous patches were determined by measuring their weight loss when immersed in phosphate-buffered saline (PBS), pH 7.2, at 37 °C. on.

The adhesion and proliferation cardiac progenitor cells were assessed on patches cut into 7 mm diameter circles. The prepared scaffolds were sterilized under UV light overnight and  $5 \times 10^4$  cells were seeded. After 3days the adhered cell morphologies were observed by SEM.

## RESULTS AND DISCUSSION

PCL/ Sodium Alginate blend nanofibers have average diameters of  $350 \pm 73$  nm vs.  $150 \pm 40$  for pure PCL (Fig.1a&b). Although the PCL nanofiber was hydrophobic (CA= $110 \pm 5^\circ$ ), the presence of Sodium Alginate significantly improved the water affinity, such as the water contact angle (CA=  $60 \pm 4^\circ$ ). It was also found that the biodegradability rate of PCL/ Sodium Alginate blend nanofibers was faster than the pure PCL nanofiber (Fig.2). Finally, SEM observation of cell culture (Fig.3) showed that PCL/ Alginate nanofibrous patches support adherence and monolayer growth of cardiac progenitor cells.

## CONCLUSION

We produced PCL/ Sodium Alginate nanofibrous patches and showed that they allowed efficient cardiac

cells adhesion. Therefore, novel electrospun Sodium Alginate and PCL blend to be a biomaterial may provide the development of contractile myocardial patch in cardiac tissue engineering.

### INTRODUCTION

Microencapsulation presents not only an interesting way to protect active compounds against external degradation, but also offers a controlled release of encapsulated compounds, thus enhancing their bioavailability. Natural polysaccharides have emerged as promising materials for delivery system conception due to their biocompatibility and biodegradability, as well as their broad range of mechanical properties. In this context, an exopolysaccharide (EPS) secreted by a deep-sea hydrothermal bacterium *Vibrio diabolicus*<sup>1</sup> was used to elaborate biofunctional microassemblies using microfluidic technology. Microfluidic manipulates fluidic flows on microscale and provides a new means to generate monodispersed droplets<sup>2</sup>. In order to evaluate the potential of microassemblies formed as delivery systems, encapsulation of a model protein was assessed.

### EXPERIMENTAL METHODS

HE800 EPS was produced by *Vibrio diabolicus* hydrothermal bacterium by the fermentation process<sup>1</sup>. Native high molecular weight (HMW) HE800 EPS was firstly depolymerized to obtain low molecular weight (LMW) derivatives (DR). HPSEC-MALS was used to determine the molecular weight,  $M_w$  of the derivatives obtained. Gel formation was set in the presence of different divalent cations. Microfluidic flow-focusing devices (FFD) were used to structure HE800 DR into microassemblies. Two-channels FFD device was designed to produce microfibrils, whereas three-channels FFD device was elaborated to obtain microparticles. Fluorescein isothiocyanate labelled bovine serum albumin (BSA-FITC) encapsulation within HE800 microassemblies was then assessed. BSA-FITC release from microassemblies was studied in PBS, HEPES, MES and DMEM media at 37°C. The amount of released protein was analysed by fluorescence spectroscopy.

### RESULTS AND DISCUSSION

In the present study, microfluidic technology was used for the first time to structure HE800 EPS into microparticles and microfibrils. HE800 EPS displays an interesting glycosaminoglycan (GAG)-like structure close to hyaluronan<sup>3</sup> and was previously shown to promote both collagen structuring and extracellular matrix settle by dermal fibroblasts<sup>4</sup>. This natural EPS can thus be considered as an innovative GAG-like compound to design biomaterials for tissue engineering and repair. In the first step, the ability of cross-linking

between carboxylic groups of polysaccharide glucuronic acids and divalent cations, which leads to gel formation, was assessed. To promote the cross-linking, native HMW HE800 EPS ( $>10^6$  g/mol) was firstly depolymerized and two LMW derivatives of 100 000 g/mol and 300 000 g/mol were obtained. Both LMW derivatives were only able to gel in the presence of copper cations. In the next step, microfluidic devices were used to structure HE800 DR into functional microassemblies. Two-channel FFD device was designed to produce microfibrils, whereas three-channel FFD device was elaborated to obtain microparticles. Both microassemblies were shown to be stable in copper solution. It was assessed that the morphology of microparticles formed depends on the polysaccharide concentration and its molecular weight. The potential application of the microassemblies formed in the controlled release of active compounds by encapsulation of a model protein, BSA-FITC, was evaluated. Encapsulation using microfluidic devices is highly advantageous since all active compound is integrated within microassemblies formed. BSA-FITC was successfully microencapsulated within both microassemblies. The protein release was studied in different buffers and culture media. It was observed that even if microassemblies were progressively destructured during incubation, the quantity of protein released was low most likely due to the interaction with the polysaccharide.

### CONCLUSION

In the present work, HE800 bacterial EPS from marine origin having GAG-like properties was shown to be able to form microassemblies such as microfibrils and microparticles through the cross-linking with copper ions. The use of these microassemblies as controlled release systems was assessed. The microencapsulation of active compounds and their progressive release within hydrogel scaffolds used for bone and cartilage engineering will now be investigated.

## INTRODUCTION

The regeneration of the central nervous system (CNS) is one of the major challenges that the regenerative medicine faces nowadays. In order to promote *in vitro* neural cell regeneration, the use of artificial substrates may provide support for the neural cell growth and axon regeneration<sup>1</sup>. Membranes of biodegradable and biocompatible polymers have been proven as promising substrates to promote cell adhesion and proliferation<sup>2</sup>. In our previous work<sup>2</sup>, flat Poly( $\epsilon$ -caprolactone) (PCL) membranes with adequate morphology to allow neuronal tissue growth have been fabricated by phase inversion. Additionally, the scaffolds should present high nutrient transport properties to favor cell proliferation and tissue regeneration in a bioreactor. Therefore, in this work, the transport properties of those PCL membranes will be evaluated.

## EXPERIMENTAL METHODS

PCL membranes were prepared by phase inversion, following the procedure previously reported<sup>2</sup>. The coagulation baths were either ethanol (PCL/EtOH) or isopropanol (PCL/IPA).

The clean water flux (CWF) of PCL membranes during 8 hours was measured at a constant transmembrane pressure of 0.4 bars, using a cross-flow configuration system. Cross-sectional SEM images were performed to evaluate the membrane thickness ( $\delta$ ) and morphology before and after the CWF experiments.

The significance of the statistical difference of the water flux at steady state and the thickness of the PCL/EtOH and PCL/IPA membranes was analyzed by t-Student method ( $p < 0.05$ , with  $n \geq 3$ ).

## RESULTS AND DISCUSSION

Figure 1 shows the change in water flux with the time during the cross-flow water transport experiment. The steady state, reached after 5 hours of experiment, showed similar average CWF values ( $J_w^{ss}$ ) of 66 and 55  $\text{L} \cdot \text{m}^{-2} \cdot \text{h}^{-1}$ , for PCL/EtOH and PCL/IPA membranes, respectively.

The CWF decline between the initial and steady state conditions was about a 97%. This phenomenon might be attributed to membrane compaction<sup>3</sup>, caused by the pressure applied during CWF experiments, which would produce the reduction of the effective porosity of the membrane. In order to evaluate this theory, SEM images before and after CWF experiments were performed (Figure 2). The SEM images did not show significant difference in membrane thickness or in porous morphology before and after CWF experiments. According to the mechanical properties of PCL membranes previously reported<sup>4</sup>, this effect could be explained because at 0.4 bars the PCL membranes were under the elastic region, and therefore the compaction

would not be permanent once the load was removed.

Figure 1. Change of CWF ( $J_w$ ) with time of PCL/EtOH and PCL/IPA membranes at 0.4 bar.

	Before CWF experiment (x1000, scale bar 10 $\mu\text{m}$ )	After CWF experiment (x250, scale bar 20 $\mu\text{m}$ )
PCL/EtOH		
	$\delta$ ( $\mu\text{m}$ ) = $100.44 \pm 0.04$	$\delta$ ( $\mu\text{m}$ ) = $104.95 \pm 4.75$
PCL/IPA		
	$\delta$ ( $\mu\text{m}$ ) = $105.23 \pm 0.18$	$\delta$ ( $\mu\text{m}$ ) = $108.75 \pm 8.15$

Figure 2. Cross-sectional SEM images and thickness ( $\delta$ ) of PCL/EtOH and PCL/IPA membranes before and after CWF experiments.

## CONCLUSION

Flat PCL/EtOH and PCL/IPA membranes fabricated by phase inversion present high porosity expecting important transport properties. However, the CWF decline with time, attributed to reversible membrane compaction, limits the actual transport properties at steady state. Currently, research under conduction focuses on the improvement of the mechanical stability of the PCL membranes working under pressure in a bioreactor.

## *In situ* Forming and H<sub>2</sub>O<sub>2</sub>-generating Gelatin Hydrogels via Glucose Oxidase- and Horseradish Peroxidase-catalyzed Reaction

Bae Young Kim, Jin Woo Bae, Yunki Lee, Dong Hwan Oh, Ki Dong Park

Department of Molecular Science and Technology, Ajou University, Suwon, Korea  
[kdp@ajou.ac.kr](mailto:kdp@ajou.ac.kr)

### INTRODUCTION

A horseradish peroxidase (HRP)-catalyzed crosslinking reaction has recently received much attention as a promising approach to developing *in situ* forming hydrogels suitable for cell delivery<sup>1</sup>. As both HRP and H<sub>2</sub>O<sub>2</sub> greatly contribute to control of the degree and density of crosslinking, each role in designing *in situ* forming hydrogels has been well identified. In addition, H<sub>2</sub>O<sub>2</sub> plays a pivot role in a wide range of biological and processes, including aging, signaling, immune reactions, cancer development, wound healing, and serve as a marker for numerous diseases<sup>2</sup>. Therefore, generation of low levels of continuous oxidative stress (H<sub>2</sub>O<sub>2</sub>) is hypothesized to support wound healing. In this study, gelatin-based hydrogels were first prepared using the co-enzymatic cross-linking, and their physicochemical properties such as gelation time and elastic modulus, H<sub>2</sub>O<sub>2</sub> generation were investigated by varying HRP, GOx and glucose.

### EXPERIMENTAL METHODS

The gelatin-poly(ethylene glycol)-tyramine (GPT) conjugate was synthesized by conjugating tyramine to gelatin backbone using the PEG as a hydrophilic linker. The gelatin-based hydrogel were prepared in the presence of HRP, GOx and glucose as shown Fig. 1. We indirectly supplied H<sub>2</sub>O<sub>2</sub> to the HRP-catalyzed hydrogelation system using GOx as an oxidoreductase that catalyzes the oxidation of glucose to H<sub>2</sub>O<sub>2</sub> and glucono-*d*-lactone. The gelation time and mechanical properties were investigated with different GOx and glucose concentration. *In vitro* cell studies were carried out to evaluate the effect of contained GOx on cell viability and proliferation. Furthermore, we employed this material as an *in vitro* continuously H<sub>2</sub>O<sub>2</sub> generating hydrogel.

Figure 1. Schematic representation of *in situ* forming hydrogels via HRP- and GOx-mediated reaction.

### RESULTS AND DISCUSSION

The gelatin-based hydrogels were successfully prepared and the mechanical strength of the hydrogels was fairly well controlled by changing the glucose concentration (2-20 kPa). The gelation times decreased from around 600 s to 30 s with increasing GOx concentration from 1 U/mL to 100 U/mL. On the other hand, the gelation

times were relatively independent of HRP concentration but dependent on GOx concentration. In previous research, the gelation time slightly increased from 18 to 30 s, when H<sub>2</sub>O<sub>2</sub> concentration increased from 4 to 12 mM, which might result from the HRP oxidation to an inactivated form by excess H<sub>2</sub>O<sub>2</sub><sup>3</sup>. In contrast, GOx-mediated hydrogelation system did not show HRP activity loss due to the normal H<sub>2</sub>O<sub>2</sub> concentrations. The H<sub>2</sub>O<sub>2</sub> generation rate and amount were determined by varying the concentration of GOx and glucose in the hydrogels. As shown in Fig. 2, higher concentration of GOx in the hydrogels would lead to increasing H<sub>2</sub>O<sub>2</sub> production rate. These data show that the production of H<sub>2</sub>O<sub>2</sub> is tunable over concentration glucose, allowing them to act as dependent adjustment parameter to produce the desired dose.

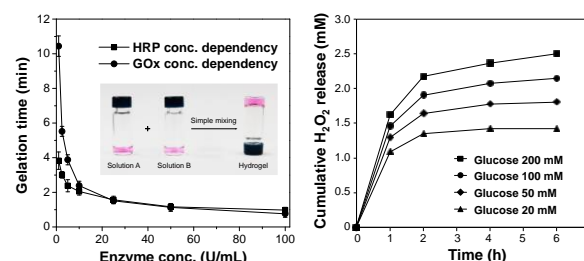

Figure 2. Gelation time of GPT hydrogels as a function of catalyst concentration and cumulative H<sub>2</sub>O<sub>2</sub> release with different glucose concentration in hydrogels.

### CONCLUSION

*In situ* cross-linked gelatin hydrogels via HRP- and GOx-catalyzed reaction have been developed as H<sub>2</sub>O<sub>2</sub>-generating materials. The physico-chemical properties of the hydrogels could be controlled by varying the concentration of HRP, GOx, and glucose. Furthermore, this system can be dynamically tuned to provide constant generation of H<sub>2</sub>O<sub>2</sub> at a desired physiologic rate. The obtained results demonstrated that the *in situ* forming and H<sub>2</sub>O<sub>2</sub>-generating gelatin hydrogels via HRP- and GOx-catalyzed reaction have great potential for biomedical applications.

### INTRODUCTION

Melt electrospinning writing (MEW) is an additive manufacturing (3D printing) process that enables polymer fibers to be accurately placed with a translating collector.<sup>1, 2</sup> Compared with traditional solution electrospinning, MEW offers high control over fiber disposition as well as fiber diameter. MEW provides a printing method with high degree of tunability to achieve the desired 3D pattern.

In the past, sacrificial materials have been used to produce 3D porous hydrogels with pore dimensions between 6 and 1000  $\mu\text{m}$ , but below 20  $\mu\text{m}$  the channels start to lose their precision.<sup>3, 4</sup> For example, sacrificial 2D gelatin fibers with features as small as 6  $\mu\text{m}$  tend to swell during embedding leading to poor reproduction of the fibers.<sup>5</sup> MEW produces fibers typically around 5-12  $\mu\text{m}$  which we hypothesize could fill the gap of low micron 3D printed pores with high fidelity.

Poly(2-alkyl-2-oxazoline) (PAOx) hydrogels are biocompatible, can be functionalised via end groups and side chains and can be synthesised in facile, biological relevant crosslinking conditions. Thus making PAOx hydrogels an ideal candidate material to demonstrate the utility of fiber templating using MEW scaffolds.<sup>6, 7</sup>

### EXPERIMENTAL METHODS

Sacrificial polycaprolactone (PCL) scaffolds were produced using MEW, whereby scaffold fibers were deposited onto a computer-programmed x-y stage as collector.<sup>2</sup> The PCL melt was electrospun onto the stage at a distance of 15 mm from needle tip to collector using a flow rate of 20  $\mu\text{L/hr}$  and 11.7 kV potential.

Hydrogels were formed around pre-printed 3D PCL scaffolds, by submersion of the scaffold into precursor solutions, or by printing onto pre-produced hydrogels, before addition of extra precursor solution. Crosslinking of PEtOx-ButenOx copolymers was achieved by using Irgacure 2959 as and dithiolthreitol (DTT) as crosslinker, using UV irradiation.<sup>6</sup>

Washing with or without sonication of the 3D constructs was done in acetone/water, until complete dissolution of the scaffolds occurred.

### RESULTS AND DISCUSSION

MEW was used to successfully print PCL scaffolds as templates to engineer the microenvironment of PAOx hydrogels. The MEW scaffolds directly influenced the pore architecture of the resulting hydrogels, which can be seen in the images of Figure 1 and Figure 2.

**Figure 1.** Left to right: SEM of MEW printed PCL fibers, optical microscopy (OM) of fibers embedded in gel, OM of partial leached fibers showing channels, confocal microscopy of channels backfilled with fluorescent probe. Scale bar = 100  $\mu\text{m}$

**Figure 2.** Left to right: SEM of MEW printed 3D PCL scaffold, OM of leached scaffold showing channels, confocal microscopy of channels backfilled with fluorescent probe. Scale bar = 100  $\mu\text{m}$

### CONCLUSION

The work has demonstrated the addition of controlled porosity to hydrogels via MEW for the first time. Such materials may have use in 3D microfluidics, tissue engineering (as cell guides or for improving nutrient transport) and soft machines.

## INTRODUCTION

Reconstruction of bone defects caused by trauma or surgical resectioning of a bone tumor is a major issue in orthopedic surgery. Due to the fact that the natural bones contain mainly collagen and hydroxyapatite, calcium phosphate ceramics (CaP) with addition of collagen (Col) are widely used in bone regeneration<sup>1</sup>. Collagen is the common protein (about 30% of the human body) and it is found in most of the animal connective tissues<sup>2</sup>. To improve a physical properties of the collagen biomaterials, especially resistance of degradation and mechanical properties, the crosslinking is used. Different chemical and physical crosslinking methods are used for crosslinking of collagen materials<sup>3</sup>.

This paper is focused on the development of a novel Col/CaP composites using a new method. This study explores the effect of the different crosslinking method on the mechanical properties of Col/CaP scaffolds.

## EXPERIMENTAL METHODS

Collagen suspension with concentrations 2% (w/w) was prepared from lyophilized collagen in deionized water using an IKA disintegrator<sup>4</sup>. Col/CaP scaffold were created by deposition of calcium phosphate within collagen matrix in two steps using freeze-drying process before immersing samples in calcium solution. To improve a physical properties of prepared scaffolds crosslinking with carbodiimide (EDC/NHS) and dehydrothermal treatment (DHT) was used.

Compression tests were performed for dry, lyophilized scaffolds as well as for scaffolds soaked in PBS (pH 7.4) during testing. The presented values are the average values calculated from five measurements. All testing was carried out using a mechanical testing machine (Z.05, Zwick/Roell, Germany) at room temperature.

## RESULTS AND DISCUSSION

Mechanical properties of Col/CaP scaffolds were presented in Figure 1.

DHT and EDC/NHS crosslinking improved the mechanical properties of samples. Compressive modulus ( $E_c$ ) increased from 1155 kPa for non-crosslinked Col/CaP samples to 1960 kPa for DHT crosslinked samples.

In conditions of full hydration the materials become more elastic, as indicated by decrease of the value of compressive modulus. Compression test performed for the samples soaked in PBS during the test showed that

the  $E_c$  of DHT or EDC/NHS crosslinked samples were higher in comparison with non-crosslinked Col/CaP samples.

Fig. 1. Compressive modulus [ $E_c$ ] of scaffolds obtained by calcium phosphate precipitation within collagen matrix and crosslinked by two different methods: a) dry scaffold, b) scaffold soaked in PBS

## CONCLUSION

Col/CaP scaffolds were successfully produced by the precipitation method. After freeze-drying process, the samples exhibited 3D porosity structure. EDC/NHS and DHT as crosslinking agents lead to an increase of mechanical properties of Col/CaP scaffolds. In conditions of full hydration the materials become more elastic. This is caused by the high swelling capacity and porosity structure of Col/CaP scaffolds.

## Chitosan Solution as the Effective Liquid Phase for Composite-type Bone Cements

Joanna Czechowska, Aneta Zima, Dominika Siek, Anna Ślósarczyk

Department of Ceramics and Refractories, AGH University of Science and Technology, 30 Mickiewicza Av. 30-059, Krakow, Poland

### INTRODUCTION

Calcium phosphate bone cements (CPCs) are a family of chemically bonded materials, composed of powder and liquid phase which when mixed together create a mouldable paste. After introduction into the bone defect it sets *in situ* filling tightly the void<sup>1</sup>. The main advantages of CPCs include excellent biocompatibility, low setting temperature and mouldability. In order to improve some properties of CPCs such as: mechanical strength, injectability or resorption rate the composite bone cements with the inorganic (calcium sulphate, magnesium phosphates, calcium carbonate) or/and organic (alginate, sodium hyaluronate) additives were developed<sup>2-3</sup>. In the present studies calcium sulphate was used as a rapidly resorbable component of chemically bonded materials. Furthermore, chitosan was applied as the CPCs constituent due to its biocompatibility as well as the antibacterial and antifungal activity<sup>4</sup>. A number of studies regarding chemically bonded materials on the basis of calcium phosphate have already been conducted. Nevertheless still some substantial understandings of these composite-type cements in terms of their setting chemistry and physicochemical properties need to be gained.

### EXPERIMENTAL METHODS

Chemically bonded biomaterials consisting of calcium sulphate, hydroxyapatite doped with titanium ions (TiHA) and chitosan were developed. A raw TiHA as well as the heat treated TiHA powders were applied. Initial powder batches composed of 60wt% of calcium sulphate hemihydrate and 40wt.% of raw (THCS-1) and calcined TiHA (THCS-2, THCS-3). Chitosan was introduced into the materials with the liquid phase as the 1% wt. chitosan solution in acetic acid. Setting times of cement pastes were determined using Gillmore needles. Physicochemical properties of the set cement bodies, namely: phase composition (XRD, D-2 Phaser, Bruker), compressive strength (Universal Testing machine, Instron) as well as microstructure (SEM) and porosity (MIP, Auto Pore IV, Micromeritics) were determined. The results were presented as mean  $\pm$  standard deviation (S.D.).

### RESULTS AND DISCUSSION

All developed implant materials possessed excellent handling properties. Results of XRD studies revealed that after setting cements THCS-1 and THCS-2 composed of hydroxyapatite and calcium sulphate dihydrate. Material THCS-3 consisted also of non-fully hydrated calcium sulphate as well as perovskite ( $\text{CaTiO}_3$ ) and  $\alpha$ TCP, which were products of TiHA

thermal decomposition. The setting time values remained between 6 – 23 min - initial and 7 - 69 min - final. The set cement bodies consisted of both platelet-like and needle-like crystals of calcium sulphate. Hydroxyapatite was mainly present in the form of agglomerates embedded in calcium sulphate matrix (Fig.1).

Fig.1. SEM micrograph of the set cement body and EDS results.

The mechanical strength of the materials was close to the cancellous bone and ranged from 2MPa to 9MPa. Porosimetric studies revealed that all of the composites were characterized by bimodal pore size distribution. The open porosity of set cement bodies remained between 46-52 vol.%.

### CONCLUSION

The cement pastes as well as the hardened bodies properties were evaluated. The properties of developed THCS-1 and THCS-2 composites are acceptable from the medical point of view and allow to suppose that the above materials may be use in non-load bearing areas. Material THCS-3 need to be excluded from the further *in vitro* experiments. The results of conducted researches imply that chitosan solution in acetic acid may serve as the effective liquid phase of bone cements on the basis of calcium phosphate and calcium sulphate. Further *in vitro* and *in vivo* studies need to be done to confirm biocompatibility of the materials.

## INTRODUCTION

Calcium phosphates (CaPs) such as hydroxyapatite (HA) and  $\beta$ -tricalcium phosphate ( $\beta$ -TCP) are widely used in hard tissue replacement because of their excellent biological properties. The interesting alternative for high-temperature calcium phosphate ceramics are calcium phosphate cements (CPCs) which are not only biocompatible but also mouldable and self-setting<sup>1</sup>. Nevertheless, these materials have also some drawbacks which limit their clinical use. Their disadvantages include: relatively slow setting reaction, lack of macroporosity and low mechanical strength. Furthermore CPCs degrade at very low rates which are not optimal for bone regeneration. Combining a stable hydroxyapatite with more soluble  $\alpha$ -tricalcium phosphate or calcium sulphate (resorbability: CS >>  $\alpha$ -TCP > HA) may lead to development of materials with gradual resorption<sup>2-5</sup>. The aim of the study was to develop and evaluate the new implant materials based on calcium phosphates and calcium sulphate.

## EXPERIMENTAL METHODS

Hydroxyapatite was synthesized by the wet chemical method and then calcined above 700°C (HA/c). Powder phase was prepared by mixing HA/c with  $\alpha$ -tricalcium phosphate ( $\alpha$ -TCP) or calcium sulphate (CS). Calcium sulphate and  $\alpha$ -tricalcium phosphate were the setting components in the studied cement-type materials. Distilled water, chitosan, methylcellulose and alginate solutions served as the liquid phases. Liquid to powder ratio (L/P) was adjusted for each material. The phase composition (XRD, Bruker), initial (I) and final (F) setting times (Gillmore Needles), open porosity (Auto Pore IV, Micromeritics) and compressive strength (Instron 3345) were checked. The chemical stability and bioactivity were evaluated *in vitro*.

Table 1 Initial composition of the cements.

Material	Powder phase	Liquid phase	L/P [g/g]
A	CS, HA/c	distilled water	0.54
B		chitosan solution	
C	$\alpha$ -TCP, HA/c	methylcellulose solution	0.50
D		alginate solution	

## RESULTS AND DISCUSSION

Cements based on CS showed shorter setting times. They set from  $3 \pm 1$  (I) to  $14 \pm 1$  (F) min, while cements with  $\alpha$ -TCP set from  $10 \pm 1$  (I) to  $30 \pm 1$  (F) min. Material B revealed the highest ( $9.4 \pm 1$  MPa), while

material D the lowest ( $2.7 \pm 0.6$  MPa) compressive strength. Developed cements (Fig. 1) exhibit a bimodal pore size distribution (open porosity: ~50 vol.%) with pores below 1.4  $\mu$ m (A and B) and 0.5  $\mu$ m (C and D).

Fig. 1 Pore size distribution curve of cement A and D.

*In vitro* studies revealed that materials with calcium sulphate (A and B) are potentially more degradable than those with  $\alpha$ -tricalcium phosphate (C and D). SEM observations showed that, as soon as after 7 days of incubation in simulated body fluid (SBF), surfaces of tested materials were covered by the cauliflower-like CaPs structures what indicates on their bioactivity. Implant materials based on calcium sulfate (A and B) and  $\alpha$ -TCP (C and D) varied in the morphologies of apatite layers on their surfaces after soaking in SBF. The reason of observed differences is a higher susceptibility of calcium sulphate to both disintegration and biodegradation.

## CONCLUSION

New biodegradable and bioactive materials based on calcined hydroxyapatite and  $\alpha$ -tricalcium phosphate or calcium sulphate were developed. The impact of the setting component ( $\alpha$ -TCP or CS) on the physicochemical properties of the final products was confirmed. It was found that the resorption rate of hydroxyapatite based materials can be controlled by the addition of appropriate amount of more soluble and resorbable phase.

## Effect of Liquid Phase on the Basic Properties of Chemically Bonded Material

Joanna Czechowska, Dominika Siek, Aneta Zima, Anna Ślósarczyk

Department of Ceramics and Refractories, AGH University of Science and Technology, 30 Mickiewicza Av. 30-059, Krakow, Poland  
[jczech@agh.edu.pl](mailto:jczech@agh.edu.pl)

### INTRODUCTION

Calcium phosphate cements (CPCs) are mouldable bone grafting materials with exceptional biocompatibility and the ability to adapt to the shape and size of bone defect<sup>1</sup>. These chemically bonded materials are widely applied in surgical procedures that require augmentation of the bone tissue in non-load bearing areas. In the recent years, the increasing attention has been paid to  $\alpha$ -tricalcium phosphate ( $\alpha$ -TCP) as the constituent of CPCs due to its self-setting properties and ability to hydrolyze to calcium-deficient hydroxyapatite (CDHA), which is very similar to the mineral phase of bone<sup>2,3</sup>. The main goal of this work was to study the effect of liquid phase on the physicochemical properties of calcium phosphate bone cement on the basis of  $\alpha$ -tricalcium phosphate.

### EXPERIMENTAL METHODS

In the present studies the powder phase of CPCs consisted of  $\alpha$ -TCP synthesized via wet chemical method. Methylcellulose and chitosan solutions were applied as the liquid phases. Initial (I) and final (F) setting times of the cement pastes were determined with Gillmore needles. The phase composition of the hardened cement bodies was characterized using XRD method (D2Phaser, Bruker) and the compressive strength measurements were conducted (Universal Testing Machine, Instron). The open porosity of the final materials was evaluated by mercury porosimetry (AutoPoreIV, Micromeritics). The chemical stability as well as the bioactive potential of developed materials *in vitro* was evaluated via pH, ionic conductivity as well as ICP-OES measurements. Their bioactive potential was assessed on the basis of SEM observations and EDS studies after different periods of immersion in SBF.

### RESULTS AND DISCUSSION

The new, surgically handy bone substitutes on the basis of  $\alpha$ -tricalcium phosphate were developed. The initial  $\alpha$ -TCP powder was obtained using the wet chemical method. The results of XRD measurement revealed that the hardened cement bodies consisted of various amount of  $\alpha$ -TCP and HA phases. It was demonstrated that the final phase composition of materials depended on the type of applied liquid phase. Cement prepared with the use of methylcellulose solution contained higher amount of hydroxyapatite. Initial (I) and final (F) setting times of the cement pastes differed in the range of 4-32 min (I) and 9-77 min (F). All examined materials were characterized by a bimodal pore size distribution however they differed in the range of pore sizes (5nm - 0,67  $\mu$ m). Open porosity of the chemically

bonded material was similar for all investigated compositions (40vol.% - 46vol.%) regardless of the liquid phase. Mechanical strength depended on the kind of liquid. The highest compressive strength was noticed for cement obtained by mixing  $\alpha$ -TCP powder with methylcellulose solution ( $16 \pm 3$  MPa). The results of pH and ionic conductivity measurements demonstrated that the developed materials were chemically stable. The thick, apatite-like films exhibiting the typical cauliflower like morphology were formed on the surfaces of all cement samples (Fig.1).

Fig.1. SEM micrograph and EDS of apatite layer on the cement sample after 7 days of incubation in SBF.

### CONCLUSION

The obtained results proved that calcium phosphate bone cement on the basis of  $\alpha$ -TCP has the potential to be applied for bone augmentation. It was confirmed that the physicochemical properties of cement paste and final material depended on the nature of the liquid phase.

# Cement-type Implant Material Based on Ca and Mg Phosphates with Adjustable Setting Time and Improved Resorption

Aneta Zima, Joanna Czechowska, Dominika Siek, Anna Ślósarczyk

Department of Ceramics and Refractories, AGH University of Science and Technology, 30 Mickiewicza Av. 30-059, Krakow, Poland  
[azima@agh.edu.pl](mailto:azima@agh.edu.pl)

## INTRODUCTION

To overcome the main disadvantages of prefabricated bioceramics and obtain superior handling properties a new generation of calcium phosphate biomaterials has been developed, namely calcium phosphate bone cements (CPCs)<sup>1</sup>. It has been more than thirty years since Brown and Chow<sup>2</sup> developed first calcium phosphate bone cement and now many commercial products are available on the market<sup>3</sup> however their properties are of different complaints. Undoubtedly too slow resorption not adjust to the resorption rate of bone tissue is one of the main CPCs drawbacks. Furthermore, initial and final setting times, rheological properties of cement pastes as well as the cohesion and mechanical strength after setting often need to be improved<sup>4,5</sup>. Preparation a new bone cement, based on calcium and magnesium phosphates was the main goal of this study. Designed material would combine the advantages of both: the calcium phosphate (brushite cement - fast resorption in the body) and magnesium phosphate (struvite cement - high mechanical strength).

## EXPERIMENTAL METHODS

The powder phase was produced by the selection and combination of the following powders: high reactive  $\alpha$ -tricalcium phosphate, calcium carbonate, magnesium phosphate and ammonium dihydrogen phosphate. As the liquid phases distilled water, 0.5wt.% methylcellulose solutions and 1.0wt.% sodium alginate solution were used. Setting times of cement pastes were determined using Gillmore needles. Physicochemical properties of the obtained material like: phase composition (XRD, D-2 Phaser, Bruker), porosity (Mercury Intrusion Porosimetry, Auto Pore IV, Micromeritics) microstructure (SEM) and compressive strength (Universal testing machine, Instron) were determined. The chemical stability *in vitro* was evaluated by the measurements of changes in pH of simulated body fluid (SBF) and ionic conductivity of distilled water during the samples incubation at 37°C (Pol-Eko).

## RESULTS AND DISCUSSION

The setting time of the developed cement ranged from 6 min (initial setting time) to 28.5 min (final setting time). In the phase composition of the hardened bodies two dominant phases, namely brushite (57-68 wt.%) and struvite (21-39 wt.%) were observed. XRD analysis showed the presence of a small amount of hydroxyapatite (up to 6 wt.%) and trace amounts of other phases, such as hannayite or biphosphammite. The open porosity of the tested materials was in the range

from 34.8 to 37.0 vol.%. Microscopic observations after incubation in SBF confirmed the bioactive potential of the developed cement-type material. After soaking in SBF the apatite layer on the surface of cement samples was observed (Fig.1).

Fig.1. SEM and EDS studies of struvite-brushite cement after soaking in SBF.

The compressive strength increased from the value 10 MPa (for samples where distilled water was applied) to approximately 16 MPa (for samples with sodium alginate solution as the liquid phase) (Fig.2).

Fig.2. Mechanical strength of developed struvite-brushite cement.

The developed bone cement on the basis of calcium and magnesium phosphates had a high chemical stability. After 28 days of incubation in SBF, pH of the solution around the samples was in the range of 7.35 - 7.15 i.e. remained close to the biological conditions.

## CONCLUSION

The setting process as well as the phase composition and mechanical strength of hardened cement strongly depended on the kind of liquid applied for paste preparation. The 1wt.% sodium alginate solution was found to be the most favorable liquid phase. The high chemical stability and bioactivity of the new struvite-brushite cement were confirmed. The final evaluation will be possible after further research, including biological studies.

[tezcaner@metu.edu.tr](mailto:tezcaner@metu.edu.tr)

**The present work deals with development of scaffolds with silk fibroin, and modified citrus pectin, by periodate oxidation and amidation.**

## INTRODUCTION

Natural polymers are gaining interest in biomedical applications like in developing proper scaffolds since they are biocompatible materials with good mechanical properties that have already many roles in biochemical pathways<sup>1</sup>. The objective of this study was to 3D porous scaffolds by crosslinking silk fibroin (SF) and citrus pectin (PEC) in the presence of sodium tetra borate (borax). Pectin was oxidized and amidated individually and reacted with silk fibroin to prepare the cross-linked hydrogel which was obtained by Schiff's base reaction between aldehyde groups of oxidized pectin and amino groups of fibroin and amidated pectin blend.

## EXPERIMENTAL METHODS

Silk fibroin solution was extracted from *Bombyx mori* cocoons as given in study<sup>2</sup>. Citrus pectin was oxidized with sodium periodate as given in literature<sup>3</sup>. The amidation was executed from methyl ester units of citrus pectin chain by reacting with ethylenediamine.

## RESULTS AND DISCUSSION

FTIR-ATR analyses confirmed the chemical modifications of pectin. Degradation profiles of scaffolds were assessed to compare the crosslinking efficiency of the different borax concentration and in

vitro stability of the scaffolds. Silk fibroin-oxidized pectin and amidated pectin (O.PEC:A-PEC:SF) based scaffolds mixed with CaCl<sub>2</sub> and 0.015 M borax prior to molding had lower weight loss after 1 week incubation and highest water uptake. SEM analyses revealed that scaffolds had porous internal structures, with a polymer layer on surface.

**Figure 1** The comparison of water uptake (%) and weight loss (%) values of scaffolds crosslinked with different borax concentrations.

**Figure 2** The macroscopic images of scaffolds (a) thickness, (b) lateral view, (c) SEM image of scaffold prepared with 0.015 M borax and CaCl<sub>2</sub> which were treated with methanol after freeze drying (c) scale bar: 200 µm.

## CONCLUSION

Among all experimental groups the scaffolds crosslinked with 0.015 M borax and treated with methanol and calcium chloride retained structural stability with the lowest weight loses among all groups and high water uptake values. In vitro cell culture studies are being conducted for evaluating the biocompatibility of the scaffolds

## Fabrication Methods of Porous Biomaterials for Dental and Orthopedic Applications Using the Selective Laser Sintering Technique

Żaneta Anna Mierzejewska<sup>1</sup>, Jarosław Sidun<sup>2</sup>, Bartłomiej Wonsewicz<sup>3</sup>

<sup>1-3</sup> Faculty of Mechanical Engineering, Białystok University of Technology, Poland  
[a.mierzejewska@doktoranci.pb.edu.pl](mailto:a.mierzejewska@doktoranci.pb.edu.pl)

### INTRODUCTION

Metallic biomaterials, e.g. titanium and its alloys, are widely used in medical applications due to their biocompatibility, high strength and good corrosion resistance<sup>1</sup>. Porous biomaterials are used for dental and orthopedic implant manufacturing, because they allow to achieve the mechanical properties closer to the human bone and to improve the osseointegration process<sup>2</sup>. Porous surface improves mechanical interlocking between the implant biomaterial and the surrounding natural tissue, providing greater mechanical stability at this critical interface<sup>3</sup>. The most common technique used to create porosity in biomaterial are salt leaching, gas foaming, phase separation, freeze-drying and selective laser sintering<sup>4</sup>. Technological parameters of the SLS process are considered to be the key determinant of achieving the desired structural features and mechanical properties of materials. This paper defines the relationship between selected parameters of laser, structure and mechanical properties of implant elements made from titanium alloy (Ti-6Al-4V).

### EXPERIMENTAL METHODS

Samples were produced on the machine EOSINT M280 using SLS technology. For this purpose, a titanium alloy Ti-6Al-4V, characterized by such features as low weight, high specific strength, Young's modulus lower than other metallic biomaterials, very good corrosion resistance in the environment and high biotolerance tissue was used. Powder with a grain size of about 30 microns was used in the production process. Four series of ten element samples for testing the tensile strength (Very\_weak, Weak, Middle, Strong), of the size and shape conforming with the PN-EN ISO 6892-1 and four series of five element samples of cylindrical shape for structure research have been produced. Samples were sintered in a high vacuum environment, with presence of argon and limited to 0.1% oxygen content, which provided restricted surface reactivity of the titanium compound. Factors that differed each manufacturing process of the samples were settings parameters of the laser. Each series was sintered with the same laser power but with various powder surface scanning speed.

### RESULTS AND DISCUSSION

On the basis of fracture structures observed by electron microscope, it can be concluded that samples manufactured at a higher speed laser scanning are characterized by a higher porosity. This results from too short beam interaction with the powder layer. Strength

analysis of the tested samples showed that mechanical properties of obtained values are within the limits established by the manufacturer of the material. The differences are minimal and may be caused by other conditions prevailing within the process chamber, including low power laser. The exception, however, is the last series of samples (Strong), whose tensile strength reaches a value between the Weak and the Middle series of samples. The results do not differ from each other to a large extent, but may be the basis for determining the impact of technological parameters on mechanical properties of tested subjects.

Table 1 A comparison of the strength parameters for samples made by SL

Sample	A [%]	E [GPa]	Rm [MPa]
Very_weak	8,72	122,0	1137,8
Weak	9,45	119,4	1124,4
Middle	10,77	103,2	1104,6
Strong	10,98	101,9	1115

### CONCLUSION

Analysis of obtained results enables to conclude that modification of technological parameters of sintering process allows to change the properties of obtained element, depending on the requirements of the product. Appropriate selection of settings for laser and atmosphere in the working chamber is the key factor to achieve satisfactory results in the SLS technology applications.

# Mechanical Properties and Degradation of a Co(poly-lactide- $\epsilon$ -caprolactone) Braided Scaffold for ACL Tissue Engineering

Blandine Landrieu, Cédric Laurent, Rachid Rahouadj

Biomechanics/LEMTA, UMR 7563 CNRS  
University of Lorraine, France  
2, avenue de la forêt de Haye, 54500 Vandoeuvre-les-Nancy  
[blandise.landrieu@univ-lorraine.fr](mailto:blandise.landrieu@univ-lorraine.fr)

## INTRODUCTION

Anterior crutiate ligament (ACL) tissue engineering would be an interesting alternative to current procedures which requires harvesting part of a healthy ligament. This last decade there has been a lot of research on appropriate materials for ACL reconstruction<sup>1</sup>. Among them, our group developed and characterized a braided scaffold in co(poly-lactide- $\epsilon$ -caprolactone)<sup>2</sup>.

The crucial point is tissue engineering is to be sure that the cells make new extracellular matrix (ECM) quickly enough to compensate the weakening of the biodegradable scaffold. Thus, studying both the degradation of the material and the growth and influence of cells is paramount<sup>3</sup>.

In the present contribution, we use a custom bioreactor<sup>4</sup> in order to study the evolution of the mechanical properties of seeded and non-seeded braided scaffolds in co(poly-lactide- $\epsilon$ -caprolactone) under physiological like mechanical stress.

## EXPERIMENTAL METHODS

First, the braided scaffold are checked for signs of cyclical creep after a week immersed in water at 37°C and subject to a mechanical stress routine aimed at mimicking the ACL loading of a recovering patient. Then the modification of the mechanical properties of scaffolds immersed in a liquid media at 37°C over the course of a four months period of time are characterized from tensile tests, and compared to the properties of seeded scaffolds cultivated in the cyclical bioreactor. During these experiments, the following parameters are checked: the evolution of the mass of the scaffolds; the pH of the surrounding liquid; and the health and differentiation of the pluripotent cells. Several imaging techniques are used to study both the geometrical evolution of the braided scaffold and the morphology and growth of cells.

## RESULTS AND DISCUSSION

Preliminary observations clearly confirmed cellular adhesion and proliferation on the scaffold as a result of 28-days static culture, and also after 3 days of dynamic culture in our custom bioreactor (Figure 1).

**Figure 1** Images issued from scanning electron microscopy at (a) Day 3 of culture (b) Day 28 of culture. Image issue from macroconfocal microscopy (c), at Day 3 of culture in the bioreactor and seeded with 600,000 cells.

Tensile tests were performed on different scaffold configurations (Figure 2) and confirm that the scaffold mimic the native ligament mechanical properties for the strains it endures.

**Figure 2** Curve linking force and true strain when the scaffold is made of increasing numbers of braided layers.

## CONCLUSION

The progressive transition between scaffold degradation and tissue regeneration is studied in the present contribution. The PLCL braided scaffold as well as the bioreactor system are clearly adapted to the formation of a neo-tissue. We bring new data concerning the evolution of such a substitute that help to evaluate its clinical relevance.

### INTRODUCTION

Tissue engineering of bone is still a field of growing interest in biomaterials research. Owing to a valuable profile of materials properties regarding processing and biocompatibility the polysaccharide chitosan is an excellent candidate for hard tissue substitution<sup>1</sup>. Since scaffold processing using spinning techniques is still established, future development focuses on chemical modification in order to improve materials properties or enhance biocompatibility. The present study reports on the assessment of several methods for sulfation and demonstration of remarkably positive effects on the activity of human mesenchymal stem cells (hMSC).

### EXPERIMENTAL METHODS

Chitosan (Heppe Medical Chitosan GmbH Halle/Germany), was spun to threads (Institute of Textile Machinery and High Performance Material Technology/TU Dresden) and embroidered to scaffolds. Sulfation was achieved by treating scaffolds with sulphur trioxide dimethylformamide complex (DMF/SO<sub>3</sub>) or chlorethan sulfonic acid (CLESA) or sulphur trioxide pyridine complex (Pyr/SO<sub>3</sub>), each optionally combined with chemical cross-linking using Genipin (GP)<sup>2</sup>. HMSC, isolated from human bone marrow, were transferred onto chitosan samples and cultivated in  $\alpha$ -MEM<sup>3</sup>. Osteogenic differentiation was induced by supplementation of 50  $\mu$ M ascorbate, 5 mM  $\beta$ -glycerophosphate and 10 nM dexamethasone after 3 days. Activity of lactate dehydrogenase (LDH) was determined to evaluate cell proliferation, relative activity of alkaline phosphatase served as indicator for differentiation, both evaluated after 1, 7, and 14 days of cultivation. All experiments were performed at least in triplicate. Confocal laser scanning microscopy (cLSM) with DAPI-stained cell nuclei and AlexaFluor 488-stained cell actin was applied for qualitative analysis of cell behaviour on chitosan samples.

### RESULTS AND DISCUSSION

Chitosan fibers with polypropylene using as an inert support fiber were processed to samples fitting exactly in 48-well plates. Seeding efficiency levelled out at 70-80% whereas solely cells attached directly to scaffolds where used for analysis. In general, all sulfation methods result in enhanced proliferation and enhanced osteogenic differentiation. During cultivation, Pyr/SO<sub>3</sub> scaffolds turned out to provide the best conditions in both of the disciplines (Fig. 1). After 14 days proliferation rate was about factor 2.5 compared to day

1 and factor 6 compared to non-modified control sample (GP). The ALP level was remarkably enhanced already on day 7 and about 3.5 times higher compared to GP. Results were confirmed by cLSM demonstrating that cells did not attach to PP thread, but formed a dense layer of spread actin skeletons completely covering the blue-appearing chitosan fibers (Fig. 1).

Fig. 1: Relative ALP activity of osteogenically differentiating hMSC cultivated on chemically modified chitosan scaffolds (left) and 3D reconstruction from cLSM image stacks showing nuclei (blue) and actin (green) on blue appearing fibers of Pyr/SO<sub>3</sub> chitosan.

### CONCLUSION

The results confirm sulfation to be a valuable method to enhance the biocompatibility of chitosan scaffolds. However, the results also highlight the importance of identifying the most suitable method for sulfation and also related processes like chemical cross-linking and washing. In the present study with pyridine/SO<sub>3</sub> a protocol was designed which resulted in remarkably enhanced performance in terms of proliferation of hMSC and differentiation into osteoblasts. Further experiments will include the differentiation of human monocytes into osteoclasts and co-cultivation of both cell lineages in order to investigate bone remodelling processes on the modified chitosan scaffolds.

### INTRODUCTION

Synthetic octacalcium phosphate (OCP) has become recognized as a highly osteoconductive bone substitute material based on *in vitro* and *vivo* studies <sup>1, 2</sup>. OCP enhances osteoblastic cell differentiation *in vitro* in a dose-dependent manner <sup>3</sup>. Furthermore, the dose-dependent stimulatory capacity of OCP was confirmed *in vivo* implantation with collagen matrix in rat critical sized calvaria defect <sup>4</sup>. OCP has higher solubility than be-ta tricalcium phosphate (be-ta TCP) therefore more resorbable than be-ta TCP *in vivo* <sup>5</sup>. It has been shown that OCP combined with collagen (OCP/Collagen) facilitates bone regeneration in comparison with OCP itself <sup>6</sup>. The osteoconductivity of OCP/Collagen has been demonstrated also in critical-sized bone defect at calvaria of dog <sup>7</sup>. After that, we examined the effect of OCP/Collagen on alveolar bone regeneration in human small bone defect and confirmed the healing at the defect <sup>8</sup>. In this study, we investigated bone regeneration in mandibular resection defect of dog by OCP/Collagen.

### EXPERIMENTAL METHODS

OCP was prepared according to a method of synthesis by mixing calcium and phosphate solution <sup>1</sup>. Particle size of OCP was 300 – 500 µm in diameter. OCP/Collagen was prepared from pepsin-digested atelocollagen isolated from the porcine dermis and OCP. OCP/Collagen was molded in the shape of a disc, 9 mm diameter, and 1 mm thick. Eighteen-months-old male beagle dogs were used in this study. The principles of laboratory animal care, as well as national laws, were followed. All procedures were approved by the Animal Research Committee of Tohoku University. Under general anesthesia, an incision was made along the inferior border of mandible. Skin, muscle and periosteum were ablated from mandible. Then we performed bone resection at left side mandible, the defect width was 15 mm that was a critical-size defect <sup>9</sup>. The mandible defect was kept by titanium plates and screws. After the defect was filled with OCP/Collagen discs, flap was repositioned and sutured. After that, we examined the bone generation by radiographically until 3 months.

### RESULTS AND DISCUSSION

Just after operation, the radiopacity was not marked because that of OCP/Collagen was very low. However, the radiopacity was observed in the defect at 1 month. The radiopacity increased and expanded at 3 months and both margins of bone defect was connected with hard tissue. Our results indicated that OCP/Collagen could make bone a bridge in mandibular resection defect. We will examine the specimens more by histologically in next time.

### CONCLUSION

In this study, it was demonstrated that OCP/Collagen could have a possibility as a bone substitute material at large bone defect.

### INTRODUCTION

Titanium (Ti)-based implants are one of the most widely used implantable devices due to their superior mechanical properties and the stability in a physiological conditions<sup>1</sup>. New approaches in Ti fabrication, especially grain refinement<sup>2</sup>, and modification of the Ti surface roughness at the micro- and nano-scales provides a lot of possibilities leading to improvement of mechanical strength, durability and biological features of Ti<sup>3</sup>.

The aim of our work was to evaluate the cytocompatibility of a commercially pure Ti (CP Ti, Grade 2) with the ultra-fine grain size of the bulk material and mechanically treated surface which provides an enhanced mechanical strength to the material. Due to intended future utilization of the material in dental and orthopaedic implantology experiments were conducted with appropriate human cell types – osteoblasts and mesenchymal stem cells.

### EXPERIMENTAL METHODS

The bulk Ti with 3 different grain sizes (1, 4.6 and 30 µm in diameter) was formed by the equal channel angular extrusion (ECAP-CONFORM). Subsequently, the surface was modified by polishing with a diamond paste (RMS 5-12 nm) or by grinding with an abrasive grinding paper 1200 (RMS 270 nm), resulting in a higher surface hydrophilicity. Cell line of human osteoblast-like cells (SAOS-2) and human mesenchymal stem cells (MSC) were used throughout all experiments. Evaluated parameters for cytocompatibility assessment were: a) cell number on Ti, b) cell area, c) metabolic activity of cells and d) cell morphology. Evaluations were performed after 2 and 48h of cultivation of cells on Ti samples, metabolic activity was measured only at the time point of 48h. Tissue culture polystyrene plastic (PS) was used as a control material. Presented data were derived from at least two independent experiments in doublets. Nonparametric Wilcoxon matched-pairs test was used for determining significant differences between the datasets from Ti samples and PS control. ANOVA was used for comparison of Ti samples to each other.

### RESULTS AND DISCUSSION

In the early phase of adhesion (2h), both cell types adhered onto Ti in a higher rate than onto PS control, while the cell area was comparable on both Ti and PS material. However, after 48 hours number of cells differs between the cell types – SAOS-2 still showed a significantly higher cell number on Ti than on PS yet

number of MSC on Ti was significantly lowered when compared to PS. Surprisingly, the cell area of all cell types was significantly smaller on Ti after 48 hours of cultivation. The metabolic activity of cells on Ti was mostly comparable with the activity of cells cultivated on PS. Comparing the cell types to each other, higher values of metabolic activity were detected for SAOS-2. Morphology of cells and formation of cell adhesion plaques was different depending on the surface treatment of Ti.

Presented results showed that primary adhesion (2h) of SAOS-2 and MSC on Ti is increased. Additionally, high proliferation and metabolic activity of SAOS-2 cells after 48h indicate that experimental Ti material enhance the growth of osteoblasts. Although proliferation of MSC after 48h was slightly decreased they remained metabolically active. Interestingly, cell area for both cell types did not increase so rapidly during time in comparison to PS control. Different cell morphology and arrangement and shape of focal adhesions confirmed that surface treatment has an influence on cell attachment and spreading<sup>4</sup>.

### CONCLUSION

Experimental Ti material with the specific ultra-fine grain size and surface topography can positively influence adhesion and growth of particular cell types, especially osteoblasts, which is very important for this type of Ti further application in dentistry and orthopaedics.

## The Effect of Alendronate-Loaded Polycaprolactone Scaffolds for the Enhancement of Osteogenic Differentiation *in vitro* and Bone Regeneration *in vivo*

Kwang-Won Park, Sung-Eun Kim, Young-Pil Youn, and Hae-Ryong Song

Rare Diseases Institute  
Korea University Guro Hospital  
Department of Orthopaedic Surgery  
[kwpark77@gmail.com](mailto:kwpark77@gmail.com)

### INTRODUCTION

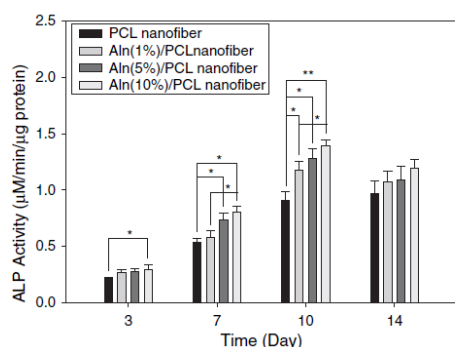

The purpose of the study was to investigate the effect of Alendronate (Aln)-loaded Polycaprolactone (PCL) scaffolds for the osteogenic differentiation *in vitro* and bone formation *in vivo*.

### EXPERIMENTAL METHODS

Aln/PCL scaffolds were prepared by using a Rapid Prototyping System (RPS). The characterizations of Aln/PCL were evaluated by scanning electron microscopy (SEM) and thermogravimetric analysis (TGA). The osteogenic effect of culturing adipose-derived stem cells (ADSCs) on Aln-loaded PCL nanofibrous scaffolds were evaluated by examining alkaline phosphatase (ALP) activity, calcium content, and expression of osteogenic differentiation genes *in vitro*. The capacity of Aln/PCL nanofibrous scaffolds to regenerate new bone was studied in a rat calvarial defect model *in vivo*. *In vivo* study was evaluated by radiography (X-ray), micro-computed tomography (micro-CT), and histological analysis.

### RESULTS AND DISCUSSION

The 10% Aln/PCL nanofibrous scaffolds showed more ALP activity, mineralization, and osteocalcin and osteopontin mRNA than the 1% or 5% Aln/PCL nanofibrous scaffolds. At 8 weeks after implantation, Aln/PCL scaffolds had a positive effect on bone formation and matrix formation by the results of X-ray, micro-CT, and histological analysis.

X-ray image (8 week)

Micro-CT image (8 week)

PCL Aln(1%)/PCL Aln(5%)/PCL Aln(10%)/PCL

### CONCLUSION

These results suggested that Aln/PCL nanofibrous scaffolds enhanced the osteogenic differentiation of ADSCs *in vitro* as well as bone formation *in vivo* compared with PCL scaffolds.

[veronique.larreta-garde@u-cergy.fr](mailto:veronique.larreta-garde@u-cergy.fr)

### INTRODUCTION

Fibrin hydrogels show promising biological properties for clinical applications in tissue engineering; however, they are not easily handled<sup>1</sup> when synthesized at the physiological concentration. To confer it good mechanical properties a fibrin network was entrapped inside interpenetrating polymer networks (IPN) architecture<sup>2</sup>. A co-network was synthesized by copolymerization of serum albumin (SA) - a protein conferring the network biodegradability - and PVA (polyvinyl alcohol) - a synthetic polymer giving the network rigidity - both modified with methacrylate functions. PVA-SA co-network were then associated with fibrin gel inside IPNs through a one pot - one shot process.

Their mechanical properties were evaluated by rheological measurements. Their biodegradability through enzyme hydrolysis was followed and the hydrolysis rate related to the protein content. Finally, fibroblast viability and growth on (2D) and inside (3D) the different IPNs were examined to demonstrate their biocompatibility.

### EXPERIMENTAL METHODS

**IPNs** were synthesized as follows: PVA and/or SA (total concentration 100 mg), both bearing methacrylate groups were mixed with 5 mg fibrinogen and a photoinitiator all dissolved in 1 mL buffer pH 7.4 containing CaCl<sub>2</sub> and NaCl, then thrombin was added. The biomaterial mechanical properties were characterized by rheology.

**Cell behavior** was followed using human fibroblasts. Viability tests were performed; nuclei, cytoskeleton and extracellular matrix components were stained and observed by CSLM.

### RESULTS AND DISCUSSION

#### *Synthesis and properties of the different IPNs*

While the co-network was carried out by free radical photopolymerization, the fibrin gel was synthesized by the enzymatic hydrolysis of fibrinogen by thrombin. Different IPNs were synthesized varying the PVA/SA ratio. The *in situ* synthesis of PVA<sub>100</sub>/Fb<sub>5</sub>, PVA<sub>50</sub>SA<sub>50</sub>/Fb<sub>5</sub> and SA<sub>100</sub>/Fb<sub>5</sub> IPNs has been developed. In each case, a solid material was obtained after 15 min and the addition of any synthetic co-network to a fibrin gel leads to a large increase in storage modulus (G') from 8 to 40 fold.

**Biodegradability** : The biodegradability of IPNs was then measured by incubation in a concentrated protease solution. Both the macroscopic appearance and the

degradation kinetics were followed. As suspected, the PVA<sub>100</sub>/Fb<sub>5</sub> IPN was not degraded by the protease while the degradation rate increased with the total protein concentration. Moreover, the hydrolysis process follows a Michaelis -Menten kinetics, indicating that the diffusion of the protease is not limited inside the solid material. These results show that controlling the protein total concentration allows tuning the IPN degradability.

**Cell viability:** Viability of cells in contact with the materials has been measured. Cells survived but did not proliferate on PVA<sub>100</sub> /Fb<sub>5</sub> IPN. Contrarily, the introduction of SA into the network allowed fibroblasts to proliferate up to total recovery of the material surface. Fibroblast cells at the surface of the IPNs also secrete and mature the extracellular matrix biomacromolecules (fibronectin, hyaluronic acid, collagens) and they are able to structure them into fibers (fibronectin, collagen I).

Fibroblast were then entrapped inside the biomaterial and 3D culture performed. Cell viability was higher than 90% after 5 weeks and the IPN network was significantly remodelled by the encapsulated fibroblasts. Development of long fibroblast pseudopodia was observed during cell culture accompanied by a significant synthesis of type I collagen, hyaluronic acid and fibronectin by the encapsulated cells. No contraction of the material was observed after cell culture.

### CONCLUSION

These co-network IPNs are the first ones to be potentially biodegradable through tunable fragmentation, then elimination. They also exhibit the unique feature for a protein-based biomaterial of being non-retractable when used as support for fibroblast culture. The materials are biocompatible and appear as excellent supports for 2D- and 3- cell culture. They present good potentiality as supports for skin construct.

### INTRODUCTION

Beside caries, periodontitis is also a very common degenerative disease affecting at least every second to third people is suffering once on this disease. It is characterized by a microbial alteration which leads to a inflammation resulting in the degradation of alveolar bone, root cementum and periodontal ligament. If the progressive destruction of these different tissues left untreated, it results to a tooth loss. A new treatment strategy uses different kinds of material which were placed in a defect area where progenitor/stem cells from neighbouring tissues can be recruited for in situ regeneration<sup>1</sup>. In the present study newly synthesized peptides were produced to form hydrogels which could be applied through an injection in a periodontal defect without a surgery. The peptides, called P11-4 and P11-8, consist of 11 amino acids which could be triggered by pH and salt concentration to form beta-sheet structures. Furthermore these beta sheet structures are able to form higher ordered structures like fibrils and fibres leading to a 3D network that serve as extracellular matrix (ECM).

### EXPERIMENTAL METHODS

To evaluate the characteristics of self-assembling peptides like P11-4 and P11-8, quartz crystal microbalance with dissipation monitoring (QCM-D) measurements were performed. Furthermore cell attachment and proliferation were studied using osteosarcoma cell line SAOS-2 and human primary periodontal fibroblast (hPDLF) in combination with different peptide hydrogels, at concentrations of 15, 20 and 30 mg/ml after 24h, 48h and 96h, respectively.

### RESULTS AND DISCUSSION

The viscoelastic properties of the different peptide hydrogels and the time which they need to build up, depend on the peptide sequence and their self-assembling behaviour. Furthermore as demonstrated in Figure 1, cell attachment and cell proliferation are directly depending on the net-charge of the peptide as well as on the viscoelastic properties. For example SAOS cells showed a higher cell attachment and proliferation rate on P11-4 hydrogels (Figure 1D), which are characterized by a negative net charge and a low viscoelasticity, than on P11-8 hydrogels (Figure 1C), known to have a positive net-charge with a higher viscoelasticity. On contrary hPDLF cells showed less attachment and proliferation if they were incubated on P11-4 hydrogels (Figure 1B) than on P11-8 hydrogels (Figure 1A). These results goes ahead with the different

phenotypes of the cells as e.g. for hPDLF are well spreaded on P11-8 hydrogels (Figure 1A), whereas on P11-4 hydrogels, hPDLF seem to be more roundish in shape and not well spreaded.

**Figure 1** show cell attachment of PDLF (1A, 1B) and SAOS (1C, 1D) on P11-8 (Figure 1A,C) and on P11-4 (Figure 1B,D) after 24 hours at a concentration of 6.35 mM. PDLF cells were stained with DAPI and TRITC-conjugated Phalloidin. A magnification of 40x was used in the study.

### CONCLUSION

It could be demonstrated that in consideration of the specific characteristics of the natural microenvironment like e.g. soft connective tissue for hPDLF, provide a possible scaffold where cells are able to attach, spread and proliferate into newly tissue. Therefore P11-peptides could be used as a new treatment strategy in periodontal therapy.

## Evaluation of Bone Formation Using Solid Freeform Fabrication-based PCL/PLGA Scaffolds Containing Bone Morphogenetic Protein-2

Sung-Eun Kim, Kwang-Won Park, Young-Pil Youn, and Hae-Ryong Song

Rare Diseases Institute  
Korea University Medical Center, Guro Hospital  
Department of Orthopaedic Surgery  
[sekim10@korea.ac.kr](mailto:sekim10@korea.ac.kr)

### INTRODUCTION

The aim of this study was to develop novel polycaprolactone/polylactic-co-glycolic acid (PCL/PLGA) scaffolds with a heparin-dopamine (Hep-DOPA) conjugate for controlled release of bone morphogenetic protein-2 (BMP-2) to enhance osteoblast activity *in vitro* and also bone formation *in vivo*.

### EXPERIMENTAL METHODS

PCL/PLGA scaffolds were prepared by a solid freeform fabrication method. The PCL/PLGA scaffolds were functionalized with Hep-DOPA and then BMP-2 was sequentially coated onto the Hep-DOPA/PCL/PLGA scaffolds. The characterization and surface elemental composition of all scaffolds were evaluated by scanning electron microscope and x-ray photoelectron spectroscopy. The osteoblast activities on all scaffolds were assessed by cell proliferation, alkaline phosphatase (ALP) activity and calcium deposition *in vitro*. To demonstrate bone formation *in vivo*, plain radiograph, micro-computed tomography (micro-CT) evaluation and histological studies were performed after the implantation of all scaffolds on a rat femur defect. Hep-DOPA/PCL/PLGA had more controlled release of BMP-2, which was quantified by enzyme-linked immunosorbent assay, compared with Hep/PCL/PLGA.

	PCL/PLGA	Hep/PCL/PLGA	Hep-DOPA/ PCL/PLGA
Carbon (%)	71.6	68.8	64.7
Oxygen (%)	28.4	26	30.9
Nitrogen (%)	0	4.7	3.7
Sulfur (%)	0	0.5	0.7

### RESULTS AND DISCUSSION

The *in vitro* results showed that osteoblast-like cells (MG-63 cells) grown on BMP-2/Hep-DOPA/PCL/PLGA had significantly enhanced ALP activity and calcium deposition compared with those on BMP-2/Hep/PCL/PLGA and PCL/PLGA. In addition, the plain radiograph, micro-CT evaluation and histological studies demonstrated that the implanted

BMP-2/Hep-DOPA/PCL/PLGA on rat femur had more bone formation than BMP-2/Hep/PCL/PLGA and PCL/PLGA *in vivo*.

(A) H&E staining

(B) Tri chrome staining

### CONCLUSION

This study suggested that a BMP-2-eluting Hep-DOPA/PCL/PLGA scaffold system would be a good and promising platform to develop the next generation of scaffolds for regenerating bone defects in the field of orthopedics.

[Teodoro.Palomares@ehu.es](mailto:Teodoro.Palomares@ehu.es)

### INTRODUCTION

Chitosan (CS) and chitin nanofibers (CHNF) have become the focus of interest in biomedical research for tissue engineering, due to their structural properties such as mechanical strength and low density and functional properties like biocompatibility, antimicrobial activity and biodegradability<sup>1-3</sup>.

We have recently developed novel foams based on CS as matrix, CHNF as functional nanofibers and genipin (G) as a natural cross-linker. The aim of this study is to evaluate the potential of the foams (GCS:CHNF) in terms of cell response for its application in osteoarticular damage.

### EXPERIMENTAL METHODS

Genipin-cross-linked foams based on CS and CHNF were prepared by freeze-drying processing method. First, three different compositions (CS:CHNF = 1:2; 1:1 and 1:0.5) were prepared by dispersing the CHNF in a GCS solution. Then the samples were frozen at -20 °C for 72 h and lyophilized. The ensuing foams were characterized in terms of physicochemical and mechanical properties and cell response. We used murine fibroblasts L929 (according to ISO 10993-12) to determine biomaterials cytotoxicity (MTT assay), cell adhesion (SEM) and cell viability (Live/Dead). Statistical significance was determined by ANOVA test.

### RESULTS AND DISCUSSION

The ensuing foams showed to be stable with a high and interconnected porosity morphology (pore diameter ranging from 90 µm for GCS up to 300 µm for GCS/CHNF = 1:2 foams). In addition, the introduction of CHNF induced a significant increase on mechanical properties. The Young modulus jumped from 200 to 900 kPa for GCS and GCS:CHNF = 1:2 foams, respectively.

None of the biomaterials exhibit cytotoxic effect in the murine fibroblasts. However, the foam GCS:CHNF = 1:0.5 showed higher proliferation rate than GCS:CHNF = 1:1 and 1:2 foams compared to the control at 24, 48 and 72 h.

Regarding cell adhesion, L929 cell line attached properly onto the three biomaterials. Nonetheless, as occurs with proliferation, at 72 hours, the foam GCS:CHNF=1:0.5 presented higher adherent cells than the materials with 1:1 and 1:2 proportions (Figure 1).

**Figure 1:** Cell adhesion of L929 on material GCS:CHNF = 1.0.5 (A), GCS:CHNF = 1:1 (B) and GCS:CHNF= 1:2 (C) at 72h.

With respect to cell viability, murine fibroblasts were able to proliferate and adhere not only to the surface but also inside the foam porous within 7 days (Figure 2).

**Figure 2:** Viability of L929 on material GCS:CHNF = 1.0.5 (A), GCS:CHNF = 1:1 (B) and GCS:CHNF= 1:2 (C) at 7 days. The scale bar represents 100 µm.

### CONCLUSION

1. The cell response characterization of the three foams revealed optimal cell proliferation and adhesion, so these materials have high potential application to repair osteoarticular damage.
2. The foam GCS:CHNF = 1:0.5 showed to be more appropriate than GCS:CHNF = 1:1 and 1:2 concentrations.
3. The data showed that the final properties of the foams can be controlled by the content of CHNF incorporated in the GCS matrix.

## Effect of Solvent Type on Material Properties of Solution-cast Poly( $\epsilon$ -caprolactone) Films

M. Dziadek<sup>1</sup>, B. Zagrajczuk<sup>1</sup>, K. Cholewa-Kowalska<sup>1</sup>

<sup>1</sup> Department of Glass Technology and Amorphous Coatings, Faculty of Materials Science and Ceramics, AGH University of Science and Technology, 30 Mickiewicza Ave., 30-059 Krakow, Poland, [dziadek@agh.edu.pl](mailto:dziadek@agh.edu.pl)

### INTRODUCTION

One of the material, which is used to produce a three-dimensional highly porous scaffolds for bone tissue engineering is poly( $\epsilon$ -caprolactone) (PCL). PCL is slowly degrading polymer and highly compatible with osteoblasts, hence, it may be suitable for long-term bone implant applications<sup>1</sup>.

Before a material can be considered for use as a scaffold, its surface properties must be first properly characterised and optimised. Films are often used for this purpose in biomaterials research<sup>2,3</sup>.

It is currently well recognized that behaviour of cells in contact with biomaterials depends on the several material parameters. According to recent works<sup>2,4</sup> the cellular adhesion and proliferation of cells are influenced by the crystallinity of polymer materials. The crystallinity of polymer matrix affects also the material bioactivity<sup>5</sup> and also degradation kinetics<sup>1</sup>. Furthermore, the properties of material surface such as topography and wettability are factors controlling cell adhesion, proliferation, migration, phenotype maintenance and intracellular signalling<sup>2,3</sup>.

### EXPERIMENTAL METHODS

PCL films were prepared by solution-casting method using three different solvents: dichloromethane (DCM), 1,4-dioxane (DIOX) and tetrahydrofuran (THF). The surface of the films in contact with glass Petri dish and exposed to the gas phase was denoted the GS and AS surface, respectively. Both surfaces of films were characterised in terms of surface properties: morphology (SEM), roughness (contact profilometer), wettability (contact angle goniometer). Also tensile strength, Young's modulus and crystallinity (DSC) of films were evaluated.

### RESULTS AND DISCUSSION

The results showed that the use of various solvents affected the surface properties such as morphology, topography, wettability; matrix crystallinity and also mechanical behaviour of the PCL films.

Figure shows the AS surface morphology of the solution cast PCL films. The surface of the DCM cast was rough with visible discontinuous spherule-like aggregations (diameters from 120 to 180  $\mu\text{m}$ ) present on the entire surface of the film. The aggregations were partially connected together, resulting in irregular pores on the surface. PCL films cast from DIOX exhibited rough and highly porous surface morphologies comprised numerous irregular filamentous PCL aggregations. As with DCM, the surface of the THF cast PCL film was made up of fused spherule-like aggregates (diameters from 5 to 20  $\mu\text{m}$ ). However, in

contrast to PCL film cast from DCM, the surface was more porous.

Furthermore, results show that opposite surfaces (GS and AS) of the same films differed in studied surface parameters. The use of various solvents influences both the overall crystallization process – degree of crystallinity and the morphology as well as surface area, and roughness of the PCL films.

### CONCLUSION

The results indicate the possibility to use different solvents to obtain polymer films with various, but controlled, surface and mechanical properties as well as degree of crystallinity. It could be useful to control of other material properties such as degradation rate, bioactivity and also cellular response.

### INTRODUCTION

Ceramic materials called bioglasses are characterized by the ability to create permanent and stable bond with bone tissue, and can stimulate the bone tissue to faster regeneration. Bioglasses can be obtained by melting method or sol-gel process. Gel-derived bioglasses show higher bioactivity than melted ones due to high surface area and lower temperature processing resulting in retaining SiOH groups on the surface<sup>1</sup>. Incorporation of gel-derived bioactive glass into a polymer creates possibility of obtaining the new composites with controlled biological activity as well as other useful properties<sup>2</sup>. In our research assumed that chemical composition of gel-derived bioglasses used as composites modifiers is primarily responsible for both the creation *in vitro* of surface HAp layer in simulated body fluid SBF indicating the bioactivity and the cellular response being a result of a contact of cells with biomaterials.

### EXPERIMENTAL METHODS

Several gel-derived biomaterials of CaO-SiO<sub>2</sub> and CaO-SiO<sub>2</sub>-P<sub>2</sub>O<sub>5</sub> systems differing from each other in the ratio of CaO:SiO<sub>2</sub> were produced in the form of powders. The molar ratio of CaO:SiO<sub>2</sub> in CaO-SiO<sub>2</sub> and CaO-SiO<sub>2</sub>-P<sub>2</sub>O<sub>5</sub> gel-derived bioglasses was: 1:4; 2:3; 1:1; 3:2. These powders were incorporated into polymer PLGA matrix in order to obtain 2D composites (foils) by solvent casting method. The various CaO:SiO<sub>2</sub> ratio determines the type of created by Si anions groups Q<sup>n</sup> (n - number of bridging oxygen ions in Si nearest environment) and it was examined by <sup>29</sup>Si MAS NMR. For produced composites, the *in vitro* test in simulated body fluid SBF was conducted in order to estimate the bioactive properties by determination of the structure of surface layer forming during contact with SBF using SEM/EDAX, XRD and FTIR methods. Moreover, the series of biological *in vitro* tests, designed to assess the stimulation of osteogenesis by composite biomaterials, were carried out. Cells cultured on experimental materials analyzed for the cellular level and activity of liver-bone-kindly alkaline phosphatase (ALP) which increases markedly at early stages of osteoblast differentiation. In addition, expression levels of several osteogenic markers that include both osteogenic transcription factors and bone-like tissue extracellular matrix proteins were evaluated in cells grown on experimental biomaterials.

### RESULTS AND DISCUSSION

All of gels were transparent and after heat treatment up to the temperature 800°C transformed to the white powder. The <sup>29</sup>Si MAS NMR spectra show that by

decreasing of SiO<sub>2</sub> content in gel-derived materials the network de-polymerisation was observed which is evidenced by increase in intensities of Q<sup>2</sup> and Q<sup>3</sup> species derived from Si-units with two (Q<sup>2</sup>) and one (Q<sup>3</sup>) non-bridging oxygen ions<sup>3</sup>. The glass with the highest concentration of CaO is invert glass and there are also present Q<sup>1</sup> groups (3 non-bridging oxygen ions). Disrupted network structure results in higher solubility and the same time faster Ca/P rich layer formation during immersion in simulated body fluid.

Fig. 1. Microstructure of bioactive invert glass/PLGA composites after immersion in SBF for 7 days.

Biological tests indicated that chemical composition of gel-derived bio-glasses determines biological activity of composite materials although there is no simple correlation between CaO:SiO<sub>2</sub> ratio and cell behaviour stimulated by biomaterials ALP-activity levels of cells and ability to promote both osteoblast and osteoclast formation were higher on biomaterials with higher CaO:SiO<sub>2</sub> ratio while silica-rich bioglasses enhanced cells proliferation and osteoinductive properties.

### SUMMARY

**Our study confirmed thesis that chemical composition of gel-derived bioglasses used as composite modifiers affects the bioactivity and osteoinductivity of composites.**

### INTRODUCTION

Human dental pulp stem cells (hDPSCs) are multipotent mesenchymal stem cells found in the teeth and constitute a readily source of stem cells. There are a few studies reporting that boron derivatives promote bone and teeth growth *in vivo* and *in vitro*. Our hypothesis was fabricating boron (B) doped nano hydroxyapatite coated chitosan (Ch/B-nHAp) scaffolds, using biomimetic method supported by microwave energy in order to promote odontogenic differentiation of hDPSCs and pulp-dentin complex regeneration.

### EXPERIMENTAL METHODS

In this study, hDPSCs were isolated from third molars of healthy female individuals (aged 16-25) with enzymatic digestion. Freeze-drying method was used to fabricate porous chitosan scaffolds<sup>1</sup>. Biomimetic nHAp and B-nHAp coating procedure with 10xSBF like solution were applied to scaffolds<sup>2</sup>. In addition, to improve cell attachment, fibronectin (Fn) immobilized to the scaffolds. Cells were seeded into Ch, Ch+Fn, Ch/nHAp+Fn and Ch/B-nHAp+Fn scaffolds (2mm x 9mm). Then, the bioactivity of scaffolds was investigated. Suspension of hDPSCs at a concentration of  $1.2 \times 10^5$  cells/scaffold were cultured with odontogenic/osteogenic differentiation medium ( $\alpha$ -MEM containing 15% (v/v) FBS, 10 mM  $\beta$ -glycerol phosphate, 50  $\mu$ g/mL ascorbic acid and dexamethasone  $10^{-8}$ M) up to 21 days under static conditions. Cell viability and proliferation were analyzed by PrestoBlue<sup>®</sup> assay. SEM analysis was carried out for morphological observation. Expression level of odontogenic differentiation markers (ALP, collagen-I, RUNX2, osteocalcin and osteopontin) were determined using RT-PCR.

### RESULTS AND DISCUSSION

SEM images of hDPSCs seeded on Ch, Ch+Fn, Ch/nHAp+Fn and Ch/B-nHAp+Fn scaffolds after 14 days are presented in Fig. 1. The results showed that, chitosan scaffolds (Fig.1a) were not able to support attachment and spreading of hDPSCs as we expected. Certainly, much more hDPSCs were shown on Ch/B-nHAp+Fn scaffolds when compared to Ch/nHAp+Fn scaffolds (Fig. 1c and d). It is obvious that hDPSCs attached, spread and grew well on Ch/B-nHAp+Fn scaffolds. Also PrestoBlue<sup>®</sup> analysis indicated that the presence of boron enhanced the cell attachment and proliferation (Data not shown). In addition the results obtained from RT-PCR analysis

showed that odontogenic differentiation of hDPSCs was better on Ch/B-nHAp+Fn scaffolds than that of hDPSCs on the other scaffolds (Data not shown).

**Fig. 1:** SEM images of hDPSCs after 14 day cell culture period on a) Ch 5000x; b) Ch+Fn 1000x; c) Ch/nHAp+Fn 1000x and d) Ch/B-nHAp+Fn 1000x; scaffolds.

### CONCLUSION

In conclusion, it was determined that B enhances proliferation and odontogenic differentiation of hDPSCs and Ch/B-nHAp+Fn scaffold could be considered as a potential scaffold for dental tissue engineering applications. For the first time, we have identified that, Fn immobilized Ch/B-nHAp scaffolds with optimized surface modification improve adhesion and proliferation of hDPSCs and therefore they have interesting potential for *in vivo* transplantation

### INTRODUCTION

Poly(L-lactide-co-D/L-lactide) (PLA), a synthetic biodegradable polymer, can be used to produce matrices which are structurally similar to the extracellular matrix and could thus be suitable for tissue engineering purposes. An *in vivo* study demonstrated that the inflammatory tissue response following implantation of electrospun PLA meshes was strictly localized to the implant site and declined from an acute to a chronic phase<sup>1</sup>, further illustrating their potential applicability. However, implanted biomaterials might also cause systemic immunological reactions initiated by the different inflammatory and immune cells involved in the local cellular response, such as macrophages in their role as antigen-presenting cells as well as T and B lymphocytes. In previous studies, we could demonstrate the occurrence of specific IgG antibodies against several synthetic polymers such as polyurethane and cellulose acetate<sup>2</sup> or polyester<sup>3-5</sup>. Therefore, the aim of the present study was to examine the immunogenicity of PLA following repeated implantation by detection of specific antibodies in rats.

### EXPERIMENTAL METHODS

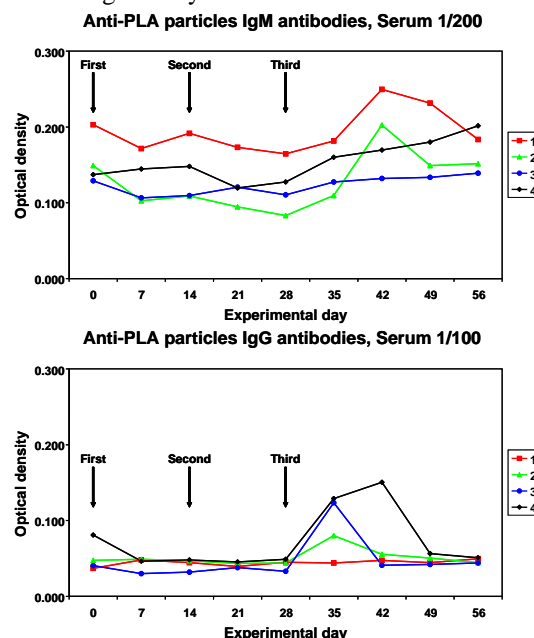

**In vivo study.** Male Lewis rats (n=4) received one piece (5×5 mm) of an electrospun PLA mesh<sup>1</sup> implanted into their neck musculature. After 14 and 28 days, additional implantations were performed after removal of the previous implants. Blood was collected before the first implantation and in weekly intervals until day 56.

**Antibody detection.** Anti-PLA IgG and IgM antibodies were detected using a PLA particle suspension as assay target. Unspecific binding was blocked with BSA. Diluted serum samples were incubated with the particle suspension in microplates with V-shaped wells. Following stringent washing by repeated centrifugation/resuspension, particles were incubated with anti-rat IgG- or IgM-specific peroxidase conjugates. After washing, the particles were resuspended in chromogenic solution and transferred into a flat-bottom microplate. Following addition of sulphuric acid, optical density was measured at 490/630 nm wavelength.

### RESULTS AND DISCUSSION

After the first two implantations, no anti-PLA IgG or IgM antibodies were detectable in any animal. Only after the third implantation, an anti-PLA IgG and IgM response was observed in 3/4 rats, respectively. This is in accordance with a previous study in which single implantation of vascular grafts with a PLA-containing coating did not elicit coating-specific antibodies<sup>5</sup>. However, these results for PLA differ from previous experiments with polyester as anti-polyester antibodies

were detected in rats already after the first implantation and further boosted by additional implantations<sup>3</sup>. The anti-PLA IgG response was not as pronounced as for polyester, indicating a lower immunogenic potential for PLA. Furthermore, extent and duration of antibody formation was not uniform among individual animals. The animal with the highest IgM level remained negative for IgG antibodies, and the only animal without IgM antibodies had the second-highest IgG response. Furthermore, the anti-PLA IgG and IgM response was generally short-lived.

**Figure 1:** Time course of anti-PLA IgM and IgG antibodies after repeated implantation of electrospun PLA meshes into 4 individual rats. Arrows indicate implantation time points.

### CONCLUSION

Repeated implantations of the resorbable polymer PLA induced a moderate and transient anti-PLA IgG and IgM response with a broad individual variability. While these results indicate a low immunogenicity of PLA compared to other investigated polymers, they should be kept in mind for its clinical application.

## INTRODUCTION

Hybrid natural-synthetic polymeric biomaterials are intensively studied for tissue regeneration. We developed various hydrogels based on gelatin – poly(vinylpyrrolidone) (G-PVP) that could be assembled into scaffolds with personalized architecture and controlled functionality for skin grafts applications. Freeze-dried hydrogel layers and mats of electrospun submicronic fibers have been obtained.

## EXPERIMENTAL METHODS

**Hydrogel synthesis.** A first type of hydrogel consists in bicomponent polymer systems with various compositions (G:PVP 6:1, 3:1, 2:1). The polymer solutions were prepared by direct dissolution in distilled water followed by semi-interpenetrated polymer network generation, as reported elsewhere<sup>1</sup>. The total solid content (T%) was adjusted to 20 and 30%, respectively. Porous membranes were generated by freeze-drying, after crosslinking the protein with glutaric aldehyde. Porous mats of submicronic fibers were obtained using a modular electrospinning set-up developed by our team. All the membranes were characterized with respect to their affinity for simulated physiologic aqueous media relevant for the target application (including swelling kinetics, equilibrium water content - EWC and dehydration kinetics), capacity to generate porous scaffolds through freeze-drying, tensile behavior of the hydrated samples (using a Brookfield CT3 texture analyzer equipped with a dual grip assembly TA-DGA), dynamic oscillatory measurements on fully hydrated samples (using a stress controlled rheometer Kinexus Pro, Malvern). In addition, morphology examination was performed using Scanning Electron Microscopy (SEM): QUANTA INSPECT F SEM device equipped with a field emission gun with a 1.2 nm resolution.

## RESULTS AND DISCUSSION

The synthesized materials reach the maximum swelling relatively fast (< 6 hours) the composition being the main factor to control this behavior. Increasing the content of synthetic polymer (while T is constant) leads to faster swelling; decreasing PVP leads to an increase of the dehydration rate probably due to the formation of denser networks. Accordingly, the elasticity of the resulting bicomponent materials is also strongly influenced by (i) the G:PVP ratio (augmenting G leads to less elastic hydrogels) and (ii) T% (higher T values decrease the elasticity of the membranes). The mechanical properties are consistent with the results of

the study regarding the affinity for simulated physiologic aqueous media.

It was confirmed that porous scaffolds with various thickness, porosity and pores' architecture can be obtained. Figure 1 is relevant with this respect. In addition, the porous membranes can be combined with the mats of electrospun submicronic oriented or random fibers.

Fig.1 shows the morphology of A - cross-section of a porous hydrogel membrane G-PVP (T=30%), B – mat of electrospun G submicronic fibers

## CONCLUSION

Porous membranes and mats of electrospun fibers based on G-PVP and G, respectively, were obtained. The synthesized materials can be assembled into multilayer scaffolds with personalized architecture and tunable functionality for skin grafts applications. The mechanical and morphostructural properties of the obtained hydrogels can be easily tailored through the composition of the initial polymer solutions. The ratio between the natural and synthetic polymer and the total solid content value have a strong influence on the overall behavior of the hydrogels, allowing the control of the properties to the best possible outcome for skin graft applications.

## INTRODUCTION

The aim of this development is to optimize a bone substitute for use in tissue engineering. This is achieved through the combination of three phases in a biocomposite (BCO), in which each is reabsorbed in the site of implantation and replaced by autologous bone (patient's own). The inorganic phases are composed of irregular particles (150-300 microns) obtained by milling and sieving of a biphasic bioceramic (BC) of hydroxyapatite (HA of bovine origin) with 40 % (wt.)  $\beta$ -tricalcium phosphate ( $\beta$ -TCP, obtained by wet chemical synthesis) and Bioglass (BG) (45SiO<sub>2</sub>-24,5CaO-24,5Na<sub>2</sub>O-6P<sub>2</sub>O<sub>5</sub>, in % wt.). Instead, the biological matrix consists mainly of collagen extracted from Wharton's jelly (WJ), obtained from human umbilical cords, subject to proprietary physical and chemical processes.

## EXPERIMENTAL METHODS

The BC is produced by mixture of HA and  $\beta$ -TCP (< 45 $\mu$ m) and moulding by gelcasting with albumin in aqueous solutions, drying and sintering at 1200°C for 2 hours. The BG is obtained from the mixture of the oxides, melting at 1350°C and cast onto metal. Each phase and BCO is subjected to studies by electron microscopy an energy dispersive energy, X-ray diffraction and infrared spectrometry.

The histological chrono-dynamics of tissue response to BCO is evaluated, using the experimental model of *laminar implant*<sup>1</sup> in Wistar rats (n = 40) from the time of implantation up to 60 days. The BCO shaped as micro-implants (1 x 6 x 0.5 mm<sup>3</sup>), was implanted in both tibias. Euthanasia of animals was performed by overdose of anaesthesia at T0, T1h, T24h, T7D, T14d, T30d and T60d of post- implementation times. The tibias were resected and fixed in 10% formalin, were radiographed, and demineralised, obtaining histological sections stained with HE.

## RESULTS AND DISCUSSION

BCO provided an adequate biocompatibility at different evaluated times. From the first hour (T1h-T24h) good hydrophilic, surrounded with abundant erythrocytes and the subsequent clot formation at the site of implantation were observed. At 7 days (T7D) formation of granulation tissue with abundant fibroblasts was observed. From T14d bone tissue formation around BC and BG particles, interconnected through bone bridges, and was identified. Bone tissue was reticular after 14 days (T14) and laminar like after 30 days (T30 and T60) (Fig.1).

Fig. 1: Radiography at first hour and after 30 days of implanted BCO (top) in SEM images (middle) and histological section study (bottom).

## CONCLUSION

The new BCO synthesized and characterized, used as scaffold for bone tissue engineering is highly biocompatible. It allows the formation of laminar bone interconnecting BG and BC particles, making it suitable for potential clinical application in implant and maxillofacial surgeries, which have begun in several Institutes.

[shahram.ghanaati@kgu.de](mailto:shahram.ghanaati@kgu.de)

## **INTRODUCTION**

The aim of the present study was to assess the vascularization and cellular reaction to five different collagen-based materials after their application either in human or animal tissue. The focus was on material integration, degree of degradation, transmembranous vascularization and the inflammatory cell types involved in the tissue reaction.

## **EXPERIMENTAL METHODS**

The five different collagen materials in this study were used for socket preservation, lateral augmentation and vestibuloplasty in humans. The same materials were histologically assessed in wild-type mice over a time period of 60 days (Fig. 1). Biopsies of these materials have been excised, processed and investigated histologically with special focus on material stability, vascularization and induction of a multinucleated giant cell triggered foreign body reaction using established histological and histomorphometrical methods<sup>1-3</sup>. Analysis of variance and subsequent LSD post-hoc statistical tests were employed to study significance.

## **RESULTS AND DISCUSSION**

The histological analysis showed distinct differences concerning the cellular reactions to the different collagen membranes depending on material-specific characteristics and processing techniques (Fig. 1). Cellular reactions consisted of either mononuclear cells (e.g. macrophages) with absence of a foreign-body-reaction or, alternatively, multinucleated giant cell-triggered granulation tissue, and were observed for the materials in both species (Fig. 1). These two different tissue reactions significantly influenced the material stability and premature degradation.

## **CONCLUSION**

In periodontology and implantology collagen-based membranes serve as versatile barriers, which should separate different tissues and cell types involved in the healing process regarding the process of the Guided Tissue Regeneration (GTR). For clinical application of collagen membranes a detailed knowledge of the cells involved in the tissue response to materials is of great importance. These cells, either mononuclear or multinucleated cells can significantly influence material stability and integration. The latter two parameters have distinct influence on the clinical outcome and successful application of collagen membranes.

**Fig. 1** shows exemplarily the different tissue reactions to three collagen membranes (A: Bio-Gide (BG), B: Mucoderm (MD), C: Collprotect (CP)) at day 15 within the subcutaneous connective tissue (CT). Thus, the BG membrane induced a mild tissue reaction based on mononuclear cells such as macrophages (green arrowheads) and other cells (black arrow heads), while multinucleated giant cells (red arrowheads) were involved in the tissue reactions to the other two membranes. Mononuclear cells are shown as black arrowheads (red arrows in B = vessels).

### INTRODUCTION

Interactions of human mesenchymal stem cells (hMSCs) with collagen-based scaffolds were studied with the aim of bone surgery application. The scaffolds should imitate an extracellular bone matrix and support hMSCs adhesion, proliferation and their osteogenic differentiation. The scaffolds should degrade after appropriate time. Collagen-based scaffolds are widely researched due to collagen positive effect on many cell types, its lattice-like organization ability and biocompatibility<sup>1</sup>. However, the fast biodegradation rate and the low mechanical strength of the untreated collagen very often complicate *in vitro* and *in vivo* applications<sup>2</sup>. The stability of collagen scaffolds can be enhanced by cross-linking. Thus, in this study, various cross-linking agents were used, e.g. genipin<sup>3</sup>, EDC/NHS/EtOH or EDC/NHS/PBS<sup>4,5</sup>.

### EXPERIMENTAL METHODS

The cell metabolic activity (Cell Titer 96 Aqueous One Solution Cell Proliferation Assay, MTS, Promega, USA) of the cells cultivated in scaffolds infusions (cytotoxicity determination), the metabolic activity of cells seeded on scaffolds, number of cells adhered on scaffolds and fluorescent visualization of cell/scaffold interactions (nuclei and actin were stained) were determined. All procedures were performed after short (48 h) and long (168 h) cell cultivation. Tissue culture treated polystyrene (PS) (TPP, Switzerland) was used as a positive control. hMSCs were isolated from a bone marrow blood of three healthy donors to simulate a stem cell variability naturally occurred among individuals.

### RESULTS AND DISCUSSION

Composite scaffolds (consisting of natural collagen as matrix, poly(DL-lactide) electrospun nanofibers, calcium phosphate as dispersed filler supplemented by sodium hyaluronate) cross-linked by EDC/NHS/EtOH, EDC/NHS/PBS or genipin, were tested *in vitro*. The scaffold infusions were tested to check a releasing of any cytotoxic agents from individual scaffolds to cultivation medium. After 48 h, the metabolic activities of hMSCs cultivated in all three scaffolds infusions were comparable and slightly higher than the PS control. After 168 h, the metabolic activities of the cells

treated by genipin and EDC/NHS/EtOH cross-linked scaffolds infusions remained similar as after 48 h. However, the metabolic activity of hMSCs treated by EDC/NHS/PBS cross-linked scaffold infusion markedly decreased to 83 % of PS control. Metabolic activity of the cells seeded on scaffolds was almost comparable among all three scaffolds in both incubation times. The value reached cca. 50 % of the control cells. The reduced cell adherence on the scaffolds in comparison to the control cells seeded on PS surface was predicted due to the different character of both surfaces. Fluorescent visualization determined the cell ability to adhere on all tested scaffolds. After 48 h, hMSCs on the genipin cross-linked scaffold revealed the best morphology and symmetric distribution. Interestingly, after 168 h, cells on all scaffolds were similarly organized with comparable appearance. Thus, the genipin cross-linked scaffold provided the best conditions for cells after both 48h and 168h cultivation time. In addition, it maintained constant mechanical properties in contrast to the rest of cross-linked scaffolds.

### CONCLUSION

It could be concluded that the genipin cross-linked scaffold is the best one with ideal mechanical and biological properties for subsequent *in vitro* 3D analyses and *in vivo* experiments.

### INTRODUCTION

The key drawback of using demineralized bone matrix (DBM) is its low initial mechanical stability due to the severe depletion of mineral content. Although the ingrowth of new bone undoubtedly restores the mechanical strength of the DBM-filled bone defect, it is not known whether this restoration ever gets complete or if there is a residual depletion in some elements. In the present study we investigated the long term regeneration of DBM in a critical size bone defect model and investigated the remineralization after six months.

any of these minerals, it induces a faster and more complete regeneration process.

### ACKNOWLEDGMENTS

Sponsored by a research grant to Semmelweis University from Lacerta Technologies GmbH

### DISCLOSURES

Dr. Lacza is founder and CEO and Dr. Hornyák is an employee of Lacerta Technologies GmbH, which holds a pending patent of the technology.

### MATERIALS AND METHODS

Critical size bone defects were created in the cranium of male Wistar rats which were filled with DBM or left empty as negative controls. In vivo bone formation was monitored with computed tomography after 11, 19 and 26 weeks postoperatively. After 6 months, parietal bone pieces were harvested and subjected to microCT. Images from the CT scan were analyzed to determine bone density. Circular region of interest (ROI) was set on the 11th postoperative week for every defect. Reference points were used to set the same ROI at each time point. Area of the remaining bone defect was measured from the CT scans. Mineral content was determined with inductively coupled plasma optical emission spectrophotometer (ICP-OES) analysis.

### RESULTS

After 11 weeks the DBM-filled bone defects were completely closed, while empty defects were still open. Bone density of the DBM-treated group increased significantly while the controls remained unchanged. Quantitative analysis by microCT confirmed the in vivo results, bone volume / tissue volume was significantly lower in the controls than in the DBM group. The demineralization procedure depleted the key minerals of the bone to a very low level, in case of Calcium it was below 1%. Sulphur and several micro-elements such as Fe and Cu were unaffected by demineralization, indicating that the protein volume of DBM is largely intact. Six months after implantation Ca, P, Na, Mg, Zn, and Cr contents were completely restored to the normal level, while K, Sr and Mn were only partially restored.

### DISCUSSION AND CONCLUSIONS

The remineralization process of DBM is largely complete by the 6th month after implantation in terms of bone density, structure and key mineral levels. Although DBM does not provide sufficient sources for

## Development of a Bioactive and Biodegradable Poly( $\epsilon$ -Caprolactone)-Based Prosthetic Ligament

### INTRODUCTION

Current therapies for anterior cruciate ligament (ACL) injuries are transplants, and for very specific cases, the use of artificial prostheses designed from poly(ethylene terephthalate) (PET) fibers. In particular, data from short to medium term follow-up studies supports the ongoing use of the Ligament Augmentation and Reconstruction System LARS<sup>TM</sup> as a safe surgical technique with low complication rate<sup>1</sup>. Besides, to enhance the interaction of the LARS ligament with fibroblasts and osteoblasts, a radical graft polymerisation of polystyrene sodium sulfonate (PNaSS) onto PET had been developed<sup>2</sup>. Indeed, PNaSS grafting allowed a stronger fibroblast adhesion, a better cell spreading, a more homogeneous cell distribution over the material surface, and an increase in the cell collagen secretion<sup>2,3</sup>. Moreover, PNaSS grafting enhanced ALP secretion in osteoblasts, had a positively significant impact on the *in vitro* mineralisation, as well as enhanced direct ligament-to-bone contact with a decrease of fibrous scar tissue at the bone/ligament interface<sup>4</sup>.

Lately, ACL reconstruction using connective tissue engineering has emerged and recent researches focus on the development of biodegradable structures that could allow graft functioning while enhancing host integration. Based on the results obtained with the bioactive LARS system, our work aims to develop a bioactive and biodegradable prosthetic ligament based on poly( $\epsilon$ -caprolactone) (PCL) fibers grafted with PNaSS. The present study brings out the graft polymerization of PNaSS onto PCL fibers by different processes.

### EXPERIMENTAL METHODS

PURASORB PCL fibers were supplied by Luxilon and used after scouring. PCL-based constructs were developed by associating 20 fibers of 10 cm length. PCL constructs were activated by 2 different processes and thereafter immersed in styrene sodium sulfonate (NaSS) solution allowing the polymerization to occur up to 17 hours for process 1 and 60 minutes for process 2.

After washing to remove the ungrafted NaSS, the evidence of PNaSS grafting was provided by a colorimetric method, elemental analyses and infrared spectroscopy. SEC, DSC and SEM analyses as well as tensile tests were carried out to characterize the PCL construct before and after PNaSS grafting.

### RESULTS AND DISCUSSION

For different grafting processes, the PNaSS grafting was obtained in a very homogeneous way over the fiber-based constructs. The grafting density increased with the polymerization time as shown in Figure 1; however, the process 2 was faster than process 1.

Characterization of PCL constructs before and after PNaSS grafting did not reveal any variation in the molecular weights and characteristic temperatures of PCL, neither in fiber diameter and mechanical properties of the construct.

Figure 1: Concentration of grafted pNaSS on PCL constructs as a function of polymerization time.

### CONCLUSION

Our work brings out two easy and versatile ways of immobilizing bioactive PNaSS onto PCL fibers through 2 different activating processes. This can provide a new generation of scaffolds which could be “biointegrable” and be used for ligament tissue regeneration. For further investigation, it is necessary to investigate the cell response *in vitro* and *in vivo*.

[lucy.kind@fhnw.ch](mailto:lucy.kind@fhnw.ch)

### INTRODUCTION

Dental Caries is one of the most prevalent chronic diseases worldwide with significant impacts on global healthcare systems<sup>1</sup>.

Commonly, carious attacks start off with sub-surface demineralization by acid secretion from bacteria. Arresting the process in early stage is crucial to avoid cavitation of the surface resulting in costly tooth restoration and replacement. Therefore non-invasive, regenerative methods to treat early caries in tooth enamel are drawing more and more attention.

Biomimetic mineralization is a very promising method. It is induced by a peptide (P11-4) which self-assembles into a supramolecular fibrillar 3D network that triggers the nucleation of de-novo hydroxyapatite<sup>2</sup>. Previous studies showed a significant increase of remineralization in artificial induced early caries lesions confirming in-vivo results<sup>3</sup>.

Additionally and due to the limited availability and great structural variety of human teeth a bioceramic tooth model (BTM) was developed mimicking natural human dental enamel. This study should facilitate the possibility to establish enamel-like and dentin-like BTM as a standardized test system for further studies in caries treatment by biomimetic mineralization.

### EXPERIMENTAL METHODS

#### De-/Remineralization of natural human tooth

Artificial sub-surface lesions on human enamel were induced by incubation in acidic demineralization buffer. P11-4 was directly applied on sub-surface lesion and the tooth was subsequently incubated in saliva simulating remineralization buffer for 2 weeks. The remineralization state was analyzed by micro-computed tomography ( $\mu$ CT).

#### Bioceramic tooth model (BTM)

BTMs are based on mixtures of hydroxyapatite and porosifying agent (porosifier) and the ratio reflects the degree of porosity and density of BTMs. The mixtures were pressed into tablets and sintered at 1250°C. The models were characterized by  $\mu$ CT, scanning electron microscopy (SEM) and Brunauer-Emmett-Teller (BET) in order to compare them with human dental enamel.

### RESULTS AND DISCUSSION

Fig. 1B shows an overlaid 3D image reconstructed from  $\mu$ CT data of an artificial lesion in human enamel tooth slice.

The overlay includes the lesion demineralized before peptide treatment (A) and the lesion remineralized (C). By comparing the results an increase of density was clearly visible after 2 weeks incubation in remineralization buffer.

Fig. 2 presents  $\mu$ CT images of BTMs with different ratio of hydroxyapatite (HA) and porosifier (P) (A-80(HA):20(P) w% and B-100(HA) w%) and the corresponding SEM images of interface. C represents human enamel slice as a reference.

BTMs could be successfully produced comparable with human enamel concerning density and surface.

### CONCLUSION

Diffusion of self-assembling peptide into carious lesions of human teeth and their remineralization demonstrates the non-invasive regeneration potential of the peptide P11-4.

Mixing porosifier with hydroxyapatite powder, compressing the mixture and sintering, showed a comparable structure to enamel useful for further research.

## Glycomer™ 631 in Tendon Tissue Engineering: an Old Material in New Ventures

Kyriakos Spanoudes,<sup>1</sup> Geoffrey Hanley<sup>1</sup>, Yves Bayon,<sup>2</sup> Abhay Pandit,<sup>1</sup> Dimitrios I Zeugolis,<sup>1</sup>

<sup>1</sup>Network of Excellence in Functional Biomaterials, National University of Ireland, Galway, Ireland

<sup>2</sup>Covidien - Sofradim Production, Trevoux, France

[dimitrios.zeugolis@nuigalway.ie](mailto:dimitrios.zeugolis@nuigalway.ie)

### INTRODUCTION

Tendon tissue engineering is becoming increasingly important, as current surgical treatment modalities based on tissue grafts and non-degradable polymers have numerous drawbacks, including (inter-species) disease transmission, foreign body response and scar tissue formation. Although electro-spun scaffolds based on biodegradable polymers have demonstrated promising results in both *in vitro* and *in vivo* setting, long-term implantation studies indicate suboptimal mechanical resilience [1-3]. Herein, we hypothesise that Glycomer™ 631, composed of 60% glycolide, 26% trimethylene carbonate and 14% dioxanone will maintain tenogenic phenotype *in vitro* and promote functional repair and regeneration *in vivo*.

### EXPERIMENTAL METHODS

Glycomer™ 631 was dissolved in hexafluoro-isopropanol (HFIP) at 100mg/ml concentration. Using a rotating collector (1400 RPM) anisotropic electro-spun fibres were produced. Human patellar tendon tenocytes were expanded up to passage 3 in DMEM media, supplemented with 10% foetal bovine serum and 1% penicillin / streptomycin. 50,000 cells / cm<sup>2</sup> were subsequently cultured for up to 5 days. Fibre orientation was assessed with Scanning Electron Microscopy (SEM). The influence of electro-spun fibres on cell viability and metabolic activity was assessed using Live/Dead® and alamarBlue® assays respectively. Cell morphometric analysis was carried out using DAPI and rhodamine conjugated phalloidin and subsequent image analysis (ImageJ).

### RESULTS AND DISCUSSION

**Figure 1:** Collector rotation speed of 1400 RPM resulted in anisotropically orientated (>80% axial alignment) Glycomer™ 631 electro-spun fibres.

**Figure 2:** Tenocytes remain viable & metabolically active up to 5 days in culture.

**Figure 3:** DAPI (blue) and rhodamine conjugated phalloidin (red) staining indicates bidirectional nuclei and cytoskeleton orientation, parallel to the scaffold orientation.

### CONCLUSION

These preliminary *in vitro* data indicate that anisotropic electro-spun Glycomer™ 631 scaffolds provide a suitable microenvironment for tenocyte growth. Further mechanical analysis, protein and gene assays and *in vivo* studies are under way.

## Efficacy of Platelet Rich Plasma in Treatment of Plantar Fasciopathy

Lukasz Nagraba<sup>1</sup>, Tomasz Mitek<sup>1</sup>, Jarosław Deszczyński<sup>1</sup>, Artur Stolarczyk<sup>1</sup>

<sup>1</sup>Orthopaedics and Rehabilitation Department II Medical Faculty, Medical University of Warsaw, Poland  
[nagraba@gmail.com](mailto:nagraba@gmail.com)

### INTRODUCTION

Plantar fascia is a strong, connective tissue structure with its proximal insertion in calcaneal tuberosity and distal ends on bases of distal phalanges of all toes. Fasciopathy is one of the most common causes of pain problems in this area in adults. It is estimated that such patients constitute about 1% of people seeking help of orthopedic surgeon. In plantar fasciopathy chronic, regional inflammation and remodeling process lead to collagen necrosis, angiofibroblastic hyperplasia and calcification of extracellular matrix.

PRP (Platelet Rich Plasma) is an autologous concentrate of blood platelets in low volume of plasma. Platelets release seven basic growth factors responsible for tissue healing process (three isoforms of PDGF, TGF- $\beta$ , TGF- $\beta$ 2, VEGF and EGF). Previous studies showed synergistic action of several growth factors in PRP and their optimal ratios to enhance the healing. Taking into consideration degenerative nature of fasciopathy, the use of platelet rich plasma in treatment of this illness should be justified and efficient.

### EXPERIMENTAL METHODS

The aim of the study was to assess the efficacy of platelet rich plasma treatment in patients with plantar fasciopathy.

The study included 30 patients diagnosed with plantar fasciopathy, verified by ultrasound or MRI examination. All patient included in the study had suffered heel pain for at least 6 month prior to inclusion and underwent extensive physical therapy for at least 3 months without satisfactory result.

Study protocol included autologous PRP injection and following physiotherapy. Investigators evaluated patients quality of life and pain symptoms by means of: visual analog scale, EQ-5D questionnaire and Foot Function Index. Biodex Balance System was utilized to acquire data for objective evaluation.

### RESULTS AND DISCUSSION

The treatment, carried out by following study protocol, resulted in significant pain reduction and increase in health related quality of life. The majority of patients also improved their score in balance and fall risk tests during the final evaluation.

### CONCLUSION

Single injection of autologous platelet rich plasma followed by carefully planned physical therapy is an efficient treatment option for patients with chronic plantar fasciopathy. Currently the investigators carry out further studies to compare the efficacy of presented protocol to other widely spread treatment methods such as TOPAZ and ESWT.

### INTRODUCTION

Valvular heart disease represents a common disorder that causes significant morbidity and mortality rates worldwide. Current surgical approaches include the replacement of the diseased valve with a mechanical or a bioprosthetic valve. Nevertheless, these valve replacements have severe drawbacks, such as the necessity for chronic anti-coagulation therapy with the mechanical valves<sup>1</sup>, and the limited durability of the bioprosthetic valves<sup>2</sup>. Tissue engineered heart valves (TEHV) have emerged as a promising solution for heart valve replacement<sup>3</sup>.

The aim of this work was to develop and characterise a decellularised mitral valve scaffold suitable for mitral valve replacement.

### EXPERIMENTAL METHODS

Whole mitral valves (MVs) from 6 month old German Landrace pigs were harvested under sterile conditions. The valves were disinfected, placed in hypotonic buffer and treated with 0.5% Triton X-100 for 24h and 0.5% SDS for a further 24h. The valves were washed extensively and finally sterilised with 0.1% peracetic acid. Radial sections comprising annulus, leaflet, chordae tendinae, and papillary muscle were analysed histologically by H&E, DAPI, Elastica van Gieson and Masson's trichrome. The presence of the  $\alpha$ -gal epitope was assessed by immunohistochemistry. Tissue sections were visualized using standard bright-field microscopy and fluorescence microscopy (Nikon Eclipse TE300).

The biocompatibility of the decellularised valves was assessed using contact and extract cytotoxicity assays to examine any potential cytotoxic effects of the decellularisation method.

### RESULTS AND DISCUSSION

H&E and DAPI staining revealed that the decellularised MV components, including the leaflets, papillary muscles, chordate and annulus were free of cells and cell nuclei. The treatment resulted in a decrease of the  $\alpha$ -gal epitope (Fig. 1A, B), whereas it preserved the histoarchitectural integrity of the MV tissue (Fig.2A-D).

Figure 1: Alpha-gal staining of native (A) and decellularised (B) leaflet.

Moreover, the produced scaffold was not cytotoxic, as indicated by the contact and extract cytotoxicity assessment.

Figure 2: Masson's trichrome and van Gieson staining of native (A,C) and decellularised leaflet (B,D).

### CONCLUSION

A protocol that effectively removed cells, whilst grossly maintaining the MV histoarchitecture and was developed. The problem with the presence of  $\alpha$ -gal could be potentially overcome by the use of whole MVs from either  $\alpha$ -gal-knockout or human donors. The decellularised whole MV scaffolds did not show any cytotoxic effects on the cell viability of L929 murine fibroblasts.

Future work will focus on the optimisation of the decellularisation protocol in terms of the  $\alpha$ -gal removal, as well as on further assessing the decellularised scaffolds in terms of DNA removal and biomechanical and hydrodynamic assessment.

## INTRODUCTION

Rapid Prototyping technologies are increasingly demonstrating the great potential for fabricating biocompatible 3D structures with precise control of the micro- and macro-scale characteristics<sup>1,2</sup>. Despite it being the first commercialized RP technology, the use of Stereolithography (SL) in Tissue Engineering has not been significantly explored, probably due to the lack of commercially available implantable or biocompatible materials<sup>3</sup>. An ideal scaffold design should be able to provide the necessary properties to satisfy simultaneously the biological and mechanical requirements for optimal bone tissue regeneration<sup>4</sup>. Stereolithography is able to reproduce with high resolution 3D complex structures that can simultaneously control the external shape anatomically matching the bone defect and creating a well-defined internal structure to enhance an optimum vascularization and then bone reconstruction. In this work, a novel divinyl-fumarate-Polycaprolactone (VPCLF) has been synthesized using Sn-free catalyst in order to realize refined 3D scaffolds for bone tissue regeneration.

## EXPERIMENTAL METHODS

In this work, a Sn-free catalyst has been used for the ROP of  $\epsilon$ -Caprolactone (CL) with a high monomers conversion at room temperature, with hydroxyethyl vinyl ether (HEVE) as both initiator and photo-curable functional group. Following the synthesis of the vinyl-terminated PCL (VPLC), its reaction with fumaryl chloride (FuCl) results in chains containing photocrosslinkable vinyl units at both ends and in the middle of the chain in order to obtain a divinyl-fumarate-PCL (VPCLF). Networks were formed from VPCLF-F by UV irradiation (365 nm) using Lucirin TPO as a biocompatible initiator, Orasol Orange G as dye and N-Vinyl-2-pyrrolidone (NVP) as reactive solvent (Figure 1).

Figure 1: proposed structures of photo-crosslinked VPCL-F/NVP using Lucirin TPO as photoinitiator.

## RESULTS AND DISCUSSION

The resulting polymer was characterized by its specific molecular weights, functional end groups and transition temperatures, using several techniques including Rheometry, Nuclear Magnetic Resonance (NMR), Fourier Transformed Infrared Spectroscopy (FTIR), Differential Scanning PhotoCalorimetry (DPC) and Differential Scanning Calorimetry (DSC). Photo crosslinked disk-shaped specimens (diameter 6 mm) of VPCLF/NVP were seeded with human mesenchymal stem cells (hMSCs) to assess biocompatibility. Mathematically defined porous structures with Gyroid architecture were prepared using the VPCLF/NVP resin. SEM images show structures with an open pore and fully interconnected architecture, allowing cell seeding and proliferation (Figure 2).

Figure 2: SEM images of Gyroid structure at different magnifications (scale bars represent respectively (A) 3 mm and (B) 500  $\mu$ m)

## CONCLUSION

The major objective of this study was to create biocompatible PCL scaffolds with a controlled internal structure for bone tissue engineering. Results proved that it is possible to obtain mathematically refined scaffolds with a homogeneous micro architecture by stereolithography technique using VPCLF/NVP photocurable resin.

### INTRODUCTION

Bone TE scaffolds have to fulfill some basic requirements. They are typically made of porous biodegradable materials which structure has to allow osteoprogenitor cells migrate into inner structure of scaffold followed by their proliferation and matrix formation. Incorporation of biologically active molecules can facilitate regeneration process and is also of special interest in bone TE.

The meltblown is a nonwoven technology, which produce fine fibers (1-5µm). Structurally the meltblown materials are destined to be the bone or knee cartilage scaffold for their diameter of fibers, random orientation of fibers, three-dimensional structure, high porosity, optimal pore size etc. Electrospinning is generally well known technology for polymer nanofibrous materials production with respect to application in medicine and tissue engineering.

### EXPERIMENTAL METHODS

**Scaffold fabrication:** Solution of PCL in chloroform/ethanol was prepared for electrospinning. The production equipment set-up consisting of meltblow and needle-less electrospinning ("all in one"). The study compare materials: i) meltblown material (M) and ii) meltblown material combining with electrospun fibers (ME). Dry scaffolds were characterized in term of morphology by a scanning electron microscopy. The biocompatibility of the material, cell proliferation and migration was tested *in vitro*.

**In-vitro culture of MG-63 osteoblasts:** human osteoblasts (MG63) were maintained in EMEM with 10% FBS and 1% ATB. Cells were maintained in a incubator (37 °C/5% CO<sub>2</sub>).

**Sample preparation, cell seeding:** from prepared layers were cutted discs (diameter 15mm, thickness 5mm) which were sterilized (70% Et-OH, 30min) and washed in PBS (pH7.4) prior the cell seeding. MG63 cells were seeded 1\*10<sup>5</sup> cells per sample.

**MTT assay for the cell proliferation:** Cell proliferation was monitored after 1, 3, 7, 14 and 21 days by MTT assay. Samples were incubated in solution of MTT in sample medium (EMEM) for 3 hours at 37 °C/5% CO<sub>2</sub>. Absorbance of the formazane solution was measured at 570 nm (reference at 650nm).

**Microscopy analysis (SEM and fluorescence):** After 1, 3, 7 and 14 days of cell seeding, the cell-cultured scaffolds were processed for microscopy analysis. **SEM:** the scaffolds were fixed by 2.5% glutaraldehyde and dehydrated with upgrading concentrations of Et-OH. Samples were analysed by scanning electron microscope (Tescan, VEGA3 SB easy probe).

**Fluorescence microscopy:** The cells were fixed in frozen methanol and stained with propidium iodide. The layers were analyzed using fluorescence microscope (NICON Eclipse Ti-E)

### RESULTS AND DISCUSSION

Morphology characteristics were studied by SEM visualization of the produced fibrous structures (Fig. 1.).

Fig 1: scaffold morphology observed by SEM for four tested materials – meltblown material (M); meltblown material combining with electrospun fibers (ME), scale bar is 50µm.

*In vitro* tests reveal similar rates of adhered MG-63 osteoblasts in all kinds of tested materials. However from the 7<sup>th</sup> day after cell seeding the significant differences in the cell proliferation rates had been observed. Osteoblasts on samples containing electrospun fibers (ME) showed significant increase in proliferation. Microscopy also confirms osteoblasts proliferation into the inner structure of the materials with the significantly higher rate in materials containing nanofibers (ME).

### CONCLUSION

Good porosity of tested materials allows osteoblasts to proliferate into the sample inner structure with the significant contribution of nanofibers content to the cell proliferation rate.

### INTRODUCTION

Through self-assembly, macromolecules with chemical complementarity form supramolecular structures, which are held together by weak bonds. Thus, exogenous cross-links are required to produce stable constructs. Specifically in collagen-based scaffolds, chemical, physical and biological cross-linking methods are under investigation to control the biophysical, biochemical and biological properties of the produced devices (1-3). However, biological and physical methods are not suitable for load-bearing tissues, due to the weak-induced stability. Chemical stabilisation methodologies are associated with foreign body response. Although the potential of multi-functional poly(ethylene glycol) systems as stabilisation and functionalisation agents for collagen hydrogels / sponges has been shown (4, 5), it is still unclear whether such agents can induce proportional stability to traditional cross-linking methods, without associated cytotoxicity. Herein, we hypothesise that 4-star poly(ethylene glycol) ether tetrasuccinimidyl glutarate (PEG) can produce cytocompatible collagen fibres with biophysical, biochemical and biological properties, superior to customarily used chemical approaches.

### EXPERIMENTAL METHODS

Collagen fibres were fabricated and cross-linked with PEG, carbodiimide (EDC/NHS) and glutaraldehyde (GTA) based on established protocols (1-3). Non-cross-linked fibres (NXL) acted as control. Structural characteristics were assessed with Scanning Electron Microscopy (SEM). Thermal stability was assessed with Differential Scanning Calorimetry (DSC). The extent of cross-linking was assessed with ninhydrin / collagenase assays. Mechanical properties were assessed with tensile testing. *In vitro* cytocompatibility was assessed with human skin fibroblasts.

### RESULTS AND DISCUSSION

**Fig. 1:** SEM analysis revealed that only PEG stabilised fibres maintained the anisotropic nano-texture surface topography, induced by the fibrillar substructure.

**Fig. 2:** Ninhydrin assay revealed that GTA had the lowest amount of free amines, followed by PEG and EDC/NHS.

**Table 1:** DSC analysis indicated that PEG induced similar thermal stability to GTA fixation and higher than EDC/NHS stabilised fibres (n=5).

Sample	Peak (C)	Onset (C)	Heat J/g
NXL	43.91 ±1.04	40.67 ±1.25	-4.16 ±6.1
PEG	77.78 ±8.25	75.78 ±9.13	-16.19 ±21.88
GTA	74.52 ±0.76	71.64 ±1.24	-4.53 ±2.04
EDC/NHS	60.68 ±4.41	55.59 ±3.27	-6.22 ±10.3

### CONCLUSION

Stabilisation of collagen fibres with PEG maintained the surface anisotropic nano-texture appearance, responsible for cell attachment and growth. Further, PEG induced stabilisation efficiency, as judged by ninhydrin and DSA analysis, similar to traditional chemical (GTA and EDC / NHS) approaches. Mechanical and biological analyses are under way.

### INTRODUCTION

Cell-based therapies require removal of cells from their optimal *in vivo* tissue context and propagation *in vitro* to attain suitable number. However, bereft of their optimal tissue niche, cells lose their phenotype and function. To this end, biophysical, biochemical and biological strategies are at the forefront of scientific and technological research and innovation (1, 2). Biophysical properties, such as surface topography and substrate stiffness, have been shown to maintain permanently differentiated cell phenotype and to direct stem cells towards specific lineage (3, 4). Herein, we assess simultaneously the influence of topographical features and substrate rigidity on permanently differentiated cell phenotype and on stem cell lineage commitment.

### EXPERIMENTAL METHODS

PDMS substrates with varying ratios of monomer to curing agent (1:1, 5:1, 10:1, and 20:1) were fabricated based on established protocols. Grooved substrates were created using a silanated wafer with groove dimensions of  $2\mu\text{m} \times 2\mu\text{m} \times 2\mu\text{m}$ ; planar control groups were created using flat glass. The aforementioned PDMS solutions were poured onto the wafer/glass and cured at  $200^\circ\text{C}$ . X-ray Photoelectron Spectroscopy (XPS) was used to determine the elemental composition of the substrates. Atomic Force Microscopy (AFM) and Scanning Electron Microscopy were used to assess the topographical features of the substrates. Dynamic Mechanical Analysis (DMA) was used to determine the mechanical properties of the substrates. The simultaneous effect of surface topography / substrate rigidity on cell phenotype and function was assessed using human permanently differentiated cells and various morphometric and gene / protein assays.

### RESULTS AND DISCUSSION

**Figure 1:** XPS analysis showed that surface composition did not change as a function of monomer to curing agent ratio.

**Figure 2:** AFM analysis revealed that topographical features were not maintained at soft PDMS substrates.

**Figure 3:** The more rigid PDMS substrates retained their topographical features for up to 21 days.

### CONCLUSION

The softer substrates did not retain their topographical features. Preliminary *in vitro* data indicate that surface topography and substrate stiffness play crucial role in determining cell fate, with substrate stiffness overwhelming surface topography.

## Stimulating Cellular Response via Cross-linking in Tissue Engineering Scaffolds

Kendell M. Pawelec<sup>1</sup>, Gloria Ramírez-Rodríguez<sup>2</sup>, Monica Sandri<sup>2</sup>, Simone Sprio<sup>2</sup>, Suzan van Dongen<sup>1</sup>, Bas Kluijtmans<sup>1</sup>

<sup>1</sup>FUJIFILM Europe B.V., Tilburg, Netherlands

<sup>2</sup>Institute of Science and Technology for Ceramics, Faenza, Italy

[kendell\\_pawelec@fujifilm.eu](mailto:kendell_pawelec@fujifilm.eu)

### INTRODUCTION

The mechanical properties of tissue engineering scaffolds are known to be an import signal for cell differentiation and metabolism<sup>1-2</sup>. As the most widespread method of stabilizing the mechanical properties of tissue engineering scaffolds, cross-linking has a profound effect on mechanical properties and swelling. Many cross-linking methods have been reported in the literature to stabilize biological polymers<sup>3</sup>. However, while the cytotoxic effects of cross-linking agents have been discussed, as well as their influence on scaffold mechanics, potential changes in cell behaviour with cross-linking have rarely been investigated<sup>4</sup>. It has already been shown that mesenchymal stem cells preferentially differentiate into bone like lineages as the stiffness of their substrate increases<sup>2</sup>. Therefore, it was hypothesized that through careful consideration of cross-linker, stem cell differentiation and mineralization could be induced for bone tissue engineering.

### EXPERIMENTAL METHODS

Linear scaffolds were created from synthetic collagen-like peptide (SCP), Figure 1. According to van Bortel et al<sup>5</sup>, to create linear structures ice was nucleated at the base of a cylindrical mold and allowed to grow upwards, resulting in linear channels of between 350–400 µm in diameter. Scaffolds were cross-linked by various cross-linking methods. Murine mesenchymal stem cells (mMSCs) were seeded onto the scaffolds and the mineralization was evaluated after two weeks *in vitro*.

### RESULTS AND DISCUSSION

No changes in the structure of the scaffolds were observed using the different cross-linking methods. In contrast, large differences in the mechanical properties were noted. Scaffold elasticity strongly depended on the cross-linking method.

The linear SCP scaffolds were able to support cell growth and infiltration throughout the entire pore volume, regardless of cross-linker, Figure 1. The cell response was sensitive to the cross-linking. While little attention is generally given to the cross-linker once cytocompatibility is demonstrated, these results show that it is an important factor in the final outcome of tissue engineering scaffolds.

Figure 1. Scaffolds were anisotropic, as seen via scanning electron microscopy (SEM) in the (a) transverse (b) longitudinal direction. Cells could attach and proliferate, (a) SEM in the longitudinal direction and (b) live/dead fluorescent staining (green: live, red: dead, blue: nucleus). Scale bars: (a) 300 µm (b) 1 mm, (c-d) 100 µm.

### CONCLUSION

Cross-linking has a significant effect on the mechanical properties of tissue engineering scaffolds. Cell response is sensitive to these changes, as demonstrated in this study, using mMSCs. Cross-linking does more than just stabilize tissue engineering scaffolds, but can affect the functional outcome of the repair by altering mechanical properties and cellular response.

## Control over Anisotropic Permeability in Aligned Tissue Engineering Scaffolds

Kendell M. Pawelec<sup>1</sup>, Huib van Boxtel<sup>1</sup>, Bas Kluijtmans<sup>1</sup>

<sup>1</sup>FUJIFILM Europe B.V., Tilburg, Netherlands  
[kendell\\_pawelec@fujifilm.eu](mailto:kendell_pawelec@fujifilm.eu)

### INTRODUCTION

For bone tissue engineering, the optimization of scaffold structure has a large impact on the final outcome of tissue regeneration. Scaffolds must encourage cell and nutrient diffusion while maintaining adequate mechanical properties<sup>1</sup>. For bone tissue engineering, a pore size of 200-400  $\mu\text{m}$  and interconnections above 100  $\mu\text{m}$  have been shown to aid bone formation and capillary innervation<sup>1-4</sup>. Anisotropic pore architectures can also impact tissue regeneration, and aligned scaffolds appear to encourage the growth of an organized lamellar bone rather than the woven bone, which is formed in equiaxed structures<sup>3</sup>. Unlike the traditional measures of scaffold structure, permeability is sensitive to all scaffold features and additionally, has a direct link to the diffusion of nutrients<sup>5</sup>. However, there is little information on how permeability relates to traditional measures of scaffold architecture or how this metric can be tailored. It was hypothesized that permeability could be controlled in anisotropic scaffolds, offering researchers a better functional measure of scaffold architecture.

### EXPERIMENTAL METHODS

Aligned scaffolds were created from synthetic collagen-like peptide (SCP) as described by van Boxtel<sup>6</sup>. To create linear structures, ice was nucleated at the base of a cylindrical mold and the temperature was raised to allow ice to grow upwards at a set freezing temperature and freezing slope. Pore size was measured via SEM micrographs at the base and top of the scaffolds and permeability was tested in the longitudinal and transverse direction using a falling head method<sup>5</sup>.

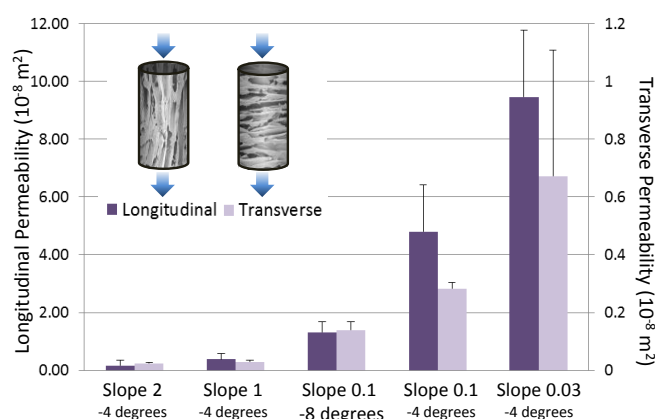

Figure 1. Scaffold permeability was anisotropic. In both the longitudinal and transverse direction, shown schematically in the inset, the permeability was affected by the freezing protocol. (average  $\pm$  standard deviation)

### RESULTS AND DISCUSSION

By varying the set freezing temperature and the freezing slope, the pore size of the linear scaffolds was controlled. With decreasing set freezing temperature and increasing freezing slope, the pore size decreased significantly. The pore size ranged from 85  $\mu\text{m}$  to 650  $\mu\text{m}$ . Decreasing the set freezing temperature from led to a decrease in pore size of around 200  $\mu\text{m}$ .

It was found that the permeability of linear scaffolds was proportional to the scaffold pore size, both in the transverse and longitudinal direction. As the pore size was affected by the way in which ice grew in the aqueous solution, the permeability was also dependent on the freezing protocol, Figure 1. However, in the transverse direction, the permeability was an order of magnitude lower than in the longitudinal direction.

The scaffold structure formed during ice-templating techniques is dependent on ice growth within an aqueous slurry. With decreases in the freezing slope, the ice had a longer time to grow and anneal, resulting in larger pores. As the size of the pores increased, the ease of fluid movement through the scaffold also increased, which would have a significant effect on the diffusion of nutrients and growth factors *in vivo*. This study demonstrates that the parameters used to form scaffold structure can also be used to tailor scaffold permeability.

### CONCLUSION

It has been demonstrated that scaffold permeability has a direct relationship to the pore size of the scaffold. By controlling the freezing protocol, the permeability can be tailored for optimal performance in tissue engineering and regenerative medicine applications.

<sup>3</sup>Instituto de Investigaciones en Materiales, UNAM, 04510, México DF, México.

## INTRODUCTION

Tissue engineering is a novel approach and it is major goal is to regenerate tissue lost by trauma and disease and this regeneration strategy is supported by three factors: cells, molecular signalling and scaffolds<sup>1</sup>. Periodontitis is an infection caused by accumulation of dental plaque onto the tooth surface and leading to the tooth lost through destruction of the attachment apparatus and tooth-supporting structures affecting the quality of life of the patients<sup>2</sup>. Periodontal regeneration therapy is based on arrest periodontal disease progression and trying to recovering the tissue structures destroyed during the periodontal phases. Osseous grafting and guided tissue regeneration are the two techniques goals used for periodontal regeneration. Recently the synthesis of fibres scaffold open a new strategy for understanding the applications on the periodontal regeneration because the scaffold could be similar to the extracellular fibrous matrix of the tissue. The aim of the study is to evaluated the poly-lactic acid fibre scaffold synthesized by air jet spinning and evaluated the biological response of dental pulp stem cells, in order to intent to replace tissue lost by periodontitis disease<sup>3</sup>.

## EXPERIMENTAL METHODS

A commercially available airbrushed was used to fabricate nanofiber scaffolds. Nanofiber scaffolds were airbrushed from a solution containing 10 % of poly lactic acid (W/V) dissolved in a 90% chloroform, 10% ethanol (V/V) solution. Scaffold porosity, fibre diameter and interaction cell-scaffold were evaluate by SEM. Chemical stability of PLA scaffold was evaluated by FTIR and RAMAN. In order to determinate if the nanofiber airbrushed scaffold shows better biological properties in comparison with PLA film, adhesion, proliferation and mineralization assays were performed cultured dental pulp stem cells.

Figure 1. SEM image of PLA nanofiber scaffold.

## RESULTS AND DISCUSSION

SEM images show random nanofiber architecture of the scaffold with an average of 250 and 500 nm diameter of the fibre. Dental pulp stem cells show a better attachment when places onto the scaffold in comparison with film scaffold.

Figure 2. Dental pulp cells show significant differences in cell attachment.

## CONCLUSION

Air jet spinning is a novel technique that allows to fabricate nanofiber scaffolds faster, easier and saver way. Moreover dental pulp stem cells showed better biological response like attached and proliferation when comparing with thin film scaffold. This nanofiber scaffold open the possibility to use as biomaterial for periodontal tissue regeneration therapy.

### INTRODUCTION

The development of polymer based three-dimensional scaffolds is one of the current challenges in bone tissue engineering. The porous structure of such scaffolds should be precisely designed as it is related with cell adhesion, proliferation, differentiation and vascularization. The permeable pore network with micro and macro pores is also required for nutrient delivery to bone cells and waste exchange [1].

In this work the morphology as well as sorption properties of the cellulose/hydroxyapatite scaffolds were evaluated.

### EXPERIMENTAL METHODS

For the morphological characterisation of the obtained scaffolds scanning electron microscopy (Quanta 200 FEG, FEI Company, Netherlands) and micro-computed tomography  $\mu$ CT40 (Scanco Medical AG, Switzerland) were used.

Water retention of the scaffolds was determined gravimetrically using the phosphate buffer solution, pH 7.4. Glucose diffusion within the scaffolds was evaluated using a „side-by-side” cell. The amount of diffused glucose was determined by means of the phenol-sulfuric acid method.

### RESULTS AND DISCUSSION

There are many studies reporting variety of techniques for the fabrication of a desired structure, including freeze-drying (lyophilization), electrospinning, solvent casting/particulate leaching, gas foaming, phase separation, rapid prototyping (stereolithography, selective laser sintering, fused deposition modelling, three-dimensional printing) or even combinations of them [2]. In this work lyophilization was chosen to create highly porous cellulose/hydroxyapatite scaffolds with an optimal pore size required for successful bone regeneration. It was found that a porous structure of the scaffold depended on the solvent in its discontinuous phase prior the drying process. Changing the solvent in the discontinuous phase the morphology of the lyophilized matrix varied from macroporous to dense. The matrix of the desired morphology with micro and macro pores was obtained by lyophilization of the composite which was filled with the ethanol solution in water. The porosity of the scaffolds varied from 65 to 72%, when microhydroxyapatite ( $\mu$ HA) and nanohydroxyapatite (nHA) were used, respectively.

Fig. 1. 2D image of the scaffolds: a) cellulose/ $\mu$ HA and b) cellulose/nHA.

The average size of the pores was 490  $\mu$ m and 540  $\mu$ m of cellulose/nHA and cellulose/ $\mu$ HA, respectively.

The water retention experiment showed that cellulose/nHA and cellulose/ $\mu$ HA composites could absorb large quantities of water (303–405%). This property substantiates high hydrophilicity of the scaffolds, which reveals biocompatibility with biological systems.

It is important to note that both scaffolds were permeable to the glucose solution. After 24 h, the concentration of glucose was approximately equal in both chambers, revealing that the structure of cellulose-based scaffolds was suitable for the transport of nutrients.

### CONCLUSION

The morphology of the prepared scaffolds for bone tissue engineering meets the requirements of materials which are implanted in the bone defect. The porosity of the scaffolds varied from 65 to 72% when microhydroxyapatite and nanohydroxyapatite were used, respectively. The cellulose/hydroxyapatite scaffold showed a permeable pore network for glucose thus revealing its suitability for fast diffusion of nutrients and metabolites.

### INTRODUCTION

PCL is a good bone scaffold material because it can take several years to degrade *in vivo* and is biocompatible, relatively inexpensive, and available in large quantities. However, there are a few problems when considering the practical use of PCL for tissue engineering. PCL lacks bioactivity, so that when used in bone tissue engineering, the new bone tissue cannot bond tightly to the polymer surface. Therefore, it is important to incorporate reinforcing fillers into PCL matrix in order to result in a promising combination of bioactivity, biodegradability, and strength<sup>1</sup>. This comparative study aims to investigate the synergistic effect of different additives on mechanical and biological properties of PCL scaffolds.

### EXPERIMENTAL METHODS

In the present study, PCL biocomposites containing 2.5 wt% of either fumed silica nanoparticles (SiO<sub>2</sub>), multi-walled carbon nanotubes (MWCNTs), montmorillonite (MMT) or modified montmorillonite (MMT15A) were prepared by melt mixing in a Haake-Buchler Reomixer at 110°C at 50 rpm for 10 min. Films of the samples were received using a hydraulic press, at 100°C. Measurements of the tensile mechanical properties of the prepared nanocomposites were performed on an Instron 3344 dynamometer, in accordance with ASTM D63. Enzymatic hydrolysis was studied in aqueous solutions containing 0.025% w/v of *Pseudomonas cepacia* lipase, at 37°C and pH=7.8. Contact angle measurements were carried out by the sessile drop method using a Krüss DSA 100 apparatus. After ultrasonic cleaning in acetone and rinsing with distilled water, all the samples were soaked in a simulated body fluid (SBF) for 14 and 28 days in order to assess their bioactivity. Furthermore cell culture studies were performed using Mesenchymal stem cells derived from Wharton Jelly. DMEM supplemented with 10% FBS and 1% penicillin-streptomycin was used to culture MSC's. Proliferation and morphology of MSC's on the scaffolds was observed using fluorescence microscopy, Scanning and Transmission Electron Microscopy. Cell viability on the scaffolds was measured using MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay.

### RESULTS AND DISCUSSION

Concerning the mechanical properties, all stress-strain curves exhibited the same pattern, which is similar to the one of neat PCL. Except in the sample containing

MMT15A, due to the plasticizing effect of the montmorillonite's organic modifier<sup>2</sup>, for all the other samples a small increase was observed in the Young's modulus, reaching a maximum improvement of 19% for the sample containing SiO<sub>2</sub> (Table 1). Enzymatic hydrolysis rates of the nanocomposites were significantly different from those of neat polyester. PCL showed the fastest enzymatic degradation among the tested samples, while PCL/nanocomposites showed a slower rate. Additionally, due to the addition of nanoparticles all nanocomposites have higher hydrophilicity than neat PCL and present much lower contact angles. This fact affected on the biocompatibility of the samples as the metabolic activity of the cells differentiated on the tested surfaces.

**Table 1.** Mechanical properties of PCL and its nanocomposites.

Sample	Strength at Yield (MPa)	Strength at break (MPa)	Elongation at break (%)	Young's Modulus (MPa)
PCL-neat	19.5 ± 0.3	22.7 ± 0.8	567 ± 24	282 ± 10
PCL-MMT 15A 2.5% w/w	18.5 ± 1.1	20.6 ± 0.6	479 ± 29	283 ± 16
PCL-MMT 2.5% w/w	18.1 ± 0.7	20.7 ± 0.4	481 ± 6	290 ± 20
PP-SiO <sub>2</sub> 2.5% w/w	20.9 ± 0.7	19.8 ± 1.6	460 ± 21	336 ± 27
PCL-MWCNTs 2.5% w/w	20.4 ± 1.0	19.3 ± 1.9	367 ± 60	317 ± 30

### CONCLUSION

A series of nanocomposites based on the biodegradable PCL matrix were prepared by adding Cloisite®Na+ (pristine MMT), Cloisite®15A (organomodified MMT), fumed silica nanoparticles (SiO<sub>2</sub>), or MWCNTs. The composites were characterized with respect to their biological and mechanical properties. Both biocompatibility and mechanical properties were found to depend on the filler type.

### INTRODUCTION

Alginate is a relevant biopolymer for tissue engineering applications due to its ability to form a gel at close to physiological conditions, and its biological inertness. However, the alginate can be made biologically active through grafting of bioactive molecules<sup>1</sup>. The biopolymer is a linear polysaccharide composed of  $\beta$ -D-mannuronic acid (M) and  $\alpha$ -L-guluronic acid (G), where mainly G-blocks give alginate its ability to form a gel with divalent cations<sup>2</sup>. The mechanical properties of the alginate gel can be designed by enzymatic<sup>3</sup> and chemical<sup>4</sup> modifications of the alginate. In this study, gels of alginate with a high G-content mixed with partially oxidized alginate were made, and mechanical properties were determined.

### EXPERIMENTAL METHODS

Alginate was partially oxidized with metaperiodate according to literature<sup>5</sup> and established protocols in our laboratories. Alginate gels composed of different ratios of high-G alginate ( $F_G = 0.68$ ) and partially oxidized alginate of varying oxidation degrees ( $P_0$ ) were made by internal gelation with  $\text{CaCO}_3$  and GDL as previously described<sup>6</sup>. Reference gels were made with high-G alginate ( $F_G = 0.68$ ). The Young's modulus, force and compression at rupture and syneresis were measured for the gels.

### RESULTS AND DISCUSSION

The Young's modulus measured for the gel cylinders made of both high-G alginate ( $F_G = 0.68$ ) and partially oxidized alginate showed an overall decrease in gel strength with increasing amount of partially oxidized alginate incorporated in the gel. A decrease in gel strength was also observed when increasing the oxidation degree of the modified alginate mixed in the gels. However, the gels largely retained their Young's modulus when 25% of the gelling alginate was substituted with oxidized material. The gels all disrupted at a compression of approximately 60% of the gel height, but the force needed to rupture varied from  $37.2 \pm 2.3$  N for the reference gel to  $2.8 \pm 0.6$  N for a gel of 100% oxidized material with a degree of oxidation of 8%. The results concur with the expectation that partially oxidized alginate would give gels with reduced mechanical properties compared to gels consisting only of high-G alginate<sup>4,7</sup>: The ring opening of oxidized monomers is expected to perturb the gelling sequences of the alginate. This is possibly due to smaller G-block length<sup>7,8</sup>, as the oxidation reaction of alginate favors oxidation of G-units<sup>9</sup>. In addition, the oxidized monomers can give higher flexibility of the alginate chain<sup>10</sup>, which can also influence the gelling properties of the alginate.

The syneresis of the gels containing partially oxidized alginate was slightly reduced compared to the reference gels. The syneresis of alginate gels is shown to depend on the composition of the alginate<sup>11</sup>. Possibly, the difference in syneresis of the gels seen in this experiment can be caused by change of the length of G-blocks or of the MG-blocks. This will result in destabilization of gelling segments<sup>4,7,11</sup>, and thus the alginate gel network. Future studies will focus on measuring the mechanical properties of gels containing both high-G alginate and partially oxidized alginate covalently bound with biomedical relevant ligands.

### CONCLUSION

The mechanical properties of the alginate gels were reduced with the introduction of alginate with varying compositions of partially oxidized alginate, however the Young's modulus was maintained at high values for mixtures of alginate with 25% oxidized material. Hence, the mechanical properties may be tuned with the mixing in of oxidized material, giving the potential to design alginate gels with desired strength and e.g. bioactivity when the oxidized material is further modified with bioactive ligands.

### INTRODUCTION

Demineralized bone matrix (DBM) is a widely used allogenic graft with osteoconductive and osteoinductive properties that promote bone regeneration. Material is rich in potent proteinaceous components stimulating osteogenesis like growth factors, e.g. bone morphogenetic proteins. Diverse array of DBM-containing composite products<sup>1</sup>, as well as deep-frozen bone grafts<sup>2</sup> for clinical applications, are available from tissue banks and commercial companies. However, differences in DBM preparation and processing methods are reported and can impact properties and clinical performance<sup>1</sup>.

In this study, we investigate the level of pro-osteogenic factors passively released from mineralized and demineralized bone matrix granules and powders – a waste product of bone matrix processing.

### EXPERIMENTAL METHODS

Tested bone materials were provided by the Department of Transplantology & Central Tissue Bank in Warsaw. Initially, all bone samples were defatted, optionally decalcified (demineralized), milled and sterilized. Samples were classified into two categories. Group I included granules, which are ready to use bone grafts derived from donor 1, while group II contained milling waste products - bone powders derived from donor 2. Following samples were subjected to GF quantification:

#### Group I

1. Demineralized bone matrix granules (DBM)
2. Mineralized bone matrix granules (MBM)

#### Group II

1. Demineralized bone powder (DBP)
2. Mineralized bone powder (MBP)

200 milligrams of each material were incubated in 1 ml of Dulbecco's Modified Eagle Medium in 37°C for 24 hours. Samples were centrifuged and supernatants were collected. Using the ELISA method, in all samples following growth factors were quantified: BMP-7, TGF- $\beta$ 1, FGF-2 and VEGF (R&D Systems).

### RESULTS AND DISCUSSION

Our results for group I indicate that decalcification of bone resulted in the release of significant amounts of BMP-7, TGF- $\beta$ 1 and VEGF with undetectable amounts of FGF-2, while mineralized granules released significant amounts of FGF-2 and undetectable level of BMP-7 and TGF- $\beta$ 1. For samples from group II we observed significant release of BMP-7 from demineralized powders and VEGF from mineralized. Our approach of passive extraction and the following measurement of released factors allows to estimate their real availability in the graft site. It differs from methodology based on enzymatic or chemical extraction of proteins trapped in DBM and frequently used by others<sup>3</sup>.

### CONCLUSION

Our results demonstrate that powders – a waste product of bone graft preparation can be an attractive source of growth factors, especially VEGF and BMP-7. Additionally, we are showing, that the process of decalcification completely eliminated FGF-2 from the granules. It demonstrates that methods of DBM processing have significant impact on quality and quantity of released factors.

## Modulation of Cell Microenvironments with Oxygen Tension and Macromolecular Crowding: A Multifactorial Approach Towards *In Vitro* Organogenesis

Abhigyan Satyam<sup>1</sup>, Pramod Kumar<sup>1</sup>, Diana Gaspar<sup>1</sup>, Abhay Pandit<sup>1</sup> and Dimitrios Zeugolis<sup>1</sup>

<sup>1</sup>Network of Excellence for Functional Biomaterials (NFB), National University of Ireland, Galway, Ireland

[diana.alves.gaspar@gmail.com](mailto:diana.alves.gaspar@gmail.com)

### INTRODUCTION

Advancements in tissue engineering have enabled the development of scaffold-free substitutes; a technology termed *Tissue Engineering by Self-Assembly*<sup>1</sup>. Despite efficacious *in vitro* and *in vivo* results, very few products have been commercialised, primarily due to prolonged time required to develop an implantable device<sup>2,3</sup>. It has been demonstrated that macromolecular crowding (MMC)<sup>4,5</sup> and low oxygen tension<sup>6,7</sup> enhances deposition of extracellular matrix (ECM). Here, we assessed the potential of combining MMC technology with low oxygen tension.

### EXPERIMENTAL METHODS

Human skin fibroblasts (WS-1) were cultured under various MMC conditions [dextran sulphate (DxS); Ficoll™ (FC) & carrageenan (CR)] in a range of foetal bovine serum (FBS), human serum (HS) concentrations (0.0-10%) and oxygen tension (0.5%, 2%, 20%). ECM deposition was assessed by SDS-PAGE, immunocytochemistry (ICC), atomic force microscopy (AFM), scanning electron microscopy (SEM) and mass-spectrometry (MS). The influence of crowders on cell morphology, cell viability and metabolic activity were evaluated using phase-contrast microscopy, Live/Dead® and alamarBlue® assays respectively. NIPAM based thermo-responsive polymers were developed to facilitate detachment of ECM-rich cell-sheets.

### RESULTS AND DISCUSSION

**Figure 1:** Densitometry of SDS-PAGE demonstrated that MMC significantly increase type I collagen deposition ( $p < 0.0001$ ) at all tested serum concentrations (maximum deposition was in 2 days & 0.5% FBS or HS).

**Figure 2:** ICC, AFM and SEM further confirmed enhanced deposition of fibrillar ECM in presence of MMC.

**Figure 3:** Thermo-responsive pNIPAAm failed to produce intact cell-sheets, whilst coating with 65% NIPAM / 35% N-tert-butylacrylamide facilitated detachment of intact ECM-rich cell sheets.

**Figure 4:** Complementary ICC for MS validation confirmed the enhanced deposition of collagens (I, III, IV, V, VI) and other ECM molecules (laminin, fibronectin, hyaluronic acid, decorin, lysyl oxidase), without changing other tested proteins.

**Figure 5:** Relative fluorescence intensity measurement for ICC demonstrated that MMC with 2% oxygen supply significantly increase collagen-I, III, V and fibronectin deposition ( $p < 0.001$ ) at all tested serum concentrations.

### CONCLUSION

Modulation of the *in vitro* microenvironment with polydispersed MMC and low oxygen tension enhances ECM deposition, even under low serum supply.

## INTRODUCTION

Collagen type II is the most abundant constituents of cartilage extracellular matrix (ECM), Chondroitin Sulphate (CS) is the main and most abundant glycosaminoglycans in cartilage ECM. Cartilage scaffolds containing collagen II and Chondroitin Sulphate have been formed and characterised widely in the field of cartilage tissue engineering. EDC-NHS crosslinking have been investigated in several studies as the chemical method for improving the mechanical properties of scaffolds<sup>1</sup>. To date, the majority of collagen scaffolds were produced from insoluble naturally fibrillar collagen whilst atelocollagens (monomeric collagen devoid of telopeptide) have been used in only a few studies<sup>2</sup>. Telopeptide elicit antigenicity and atelocollagen has the advantage of not being antigenic due to excluding (not comprising) telopeptide in their structure<sup>3</sup>. In this study, cartilage scaffolds is fabricated from reconstituted fibrillar atelocollagen (type II) crosslinked to CS via EDC-NHS reagents.

## MATERIALS AND METHOD

Reconstituted fibrillar collagen type II has been produced by fibrillogenesis of Type II atelocollagen monomers extracted from foetal calf cartilage in lyophilized form. Chondroitin sulphate A from bovine trachea was supplied by Sigma-Aldrich. In order for fibrillogenesis to occur, 1% w/w atelocollagen solution in acetic acid is mixed with TBS and placed in 37°C oven for 8hrs. Atomic force microscopy (AFM) and TEM images of the fibrils confirmed the formation of collagen fibrils. Reconstituted fibrillar collagen solution is then centrifuged and washed to remove TBS, subsequently CS is added to collagen followed by EDC-NHS crosslinking process. EDC-NHS molar ratio of 2:1 has been used. Rheology studies of the collagen solution, Fourier Transform Infrared (FTIR) spectroscopies, Scanning Electron Microscopy (SEM), mechanical testing, dissolution study and cell culturing have been performed to assess the effect of crosslinking on scaffold properties.

## RESULTS AND DISCUSSION:

Rheology results of Crosslinked Collagen-CS solution illustrate higher viscosity, loss modulus and storage modulus compared to those of Collagen II only solution. It shows that addition of CS and also crosslinking improves the visco-elastic behaviour of collagen solution which subsequently influences the pore structure and mechanical stiffness of the scaffolds. Results of cell culturing on crosslinked Collagen-CS scaffolds and Collagen only scaffolds exhibited much higher cell proliferation on crosslinked scaffolds compared to uncrosslinked collagen only scaffold. This could be due to the higher mechanical integrity of scaffolds in cell culture media, as it was observed that the collagen only scaffolds were dissolved and lost in media rapidly.

Moreover, CS could have stimulatory influence on cell growth. Histology analysis and FTIR results both showed the presence of CS in crosslinked scaffolds which ensures the covalent attachment of CS to collagen. Collagen only scaffolds dissolve and disintegrate in TBS in couple of hours; however dissolution studies exhibits that crosslinked scaffolds were stable in TBS for the period of four weeks. The pore size decreases by crosslinking but they are still in an appropriate range for cell infiltration and growth. The most significant advantage of crosslinked scaffold is their improved mechanical stability which enhances cell growth and exhibits higher resistance against load when implanted.

SEM image of Crosslinked Collagen-CS Scaffold

## CONCLUSION

The use of afibrillar collagen type II initially and creating fibrillar collagen and its further attachment to CS for cartilage scaffolds showed promising results as it can closely mimic the native cartilage structure. Enhanced mechanical properties and cell culture results confirmed the advantage of this scaffold to naturally fibrillar collagen or uncrosslinked reconstituted collagen II scaffolds.

### INTRODUCTION

Hydrogels are a class of materials widely used in medicine for many years. Proteins, such as collagen, due to the presence of a large number of functional groups are easily wettable by polar solvents and can create hydrogels. The supramolecular network capable to swelling is created by cross-linking of the biopolymers using various reagents [1,2]. Many cross-linking agents has been tested for last years, however, researchers still are looking for a new, more secure reactants. Squaric acid, 3,4-dihydroxy 3-cyclobutene 1,2- dione, is a very strong acid, which possess flat and rigid structure. Due to the presence of two carboxyl groups the squaric acid willingly reacts with amino groups of collagen [3]. The main purpose of this study was to investigate the influence of addition of squaric acid on the chemical, physical and biological properties of collagen materials.

### EXPERIMENTAL METHODS

The collagen type I was extracted from rat tail tendons and 1% solution in 0.1 M acetic acid was prepared. The samples were cross-linked by the addition of 5%, 10% and 20% of squaric acid. The mixtures of all reagents were incubated 30 min on magnetic stirrer and then dialyzed against deionized water.

### RESULTS AND DISCUSSION

The FTIR spectra show that the collagen structure is not changed by cross-linking by squaric acid. Although the mechanical properties of the collagen material deteriorate, the temperature of thermal denaturation of collagen increases after cross-linking, what indicates that the protein network was created. The lyophilized collagen gels exhibit porous structure and the pore size decreases with the higher addition of squaric acid. Also

the swelling ability is lower after the cross-linking. The in vitro study demonstrates that the materials are attractive for 3T3 cells.

### CONCLUSION

The addition of squaric acid causes formation of cross-linking bonds in the collagen materials. The changes of physicochemical properties of the material are typical for cross-linking process, except mechanical properties – it requires further experiments. However, the results let us to conclude that squaric acid is a suitable cross-linker for protein materials.

### INTRODUCTION

Bone regeneration by autogenous cell transplantation is one of the most promising techniques in orthopedic surgery. This technique would eliminate problems of donor site scarcity, immune rejection and pathogen transfer. Several materials have been developed and analyzed to be used to this purpose. Chitosan has been widely used for its capacity to promote growth and mineral rich matrix deposition by osteoblasts in culture<sup>1</sup>. In addition, chitosan is biocompatible, biodegradable and can be manufactured into porous structures. In this study we report on the preparation and characterization of an innovative scaffold made starting from chitosan cross-linked with genipin, a natural extract of *Gardenia Jasminoides Ellis*<sup>2</sup>.

### EXPERIMENTAL METHODS

Chitosan scaffolds were prepared by freeze-drying technique. Chitosan solutions (medium Mw, 75% DD, Sigma Aldrich) were prepared by suspending 1.5 g of chitosan in 100 ml of acetic acid 0.1M in a glass flask and stirred for 6 hours at 4°C till complete dissolution. Afterwards, genipin was added to solution and stirred for another hour. Batches with different genipin concentrations were prepared in order to obtain samples with different degrees of cross-linking and properties. In particular, two different concentrations of genipin were used: 0.25 M and 0.50 M. The resulting mixture, GN1 (0.25 M genipin) and GN2 (0.50 M genipin), were poured into round moulds and thermal treated at 37°C for 30h in order to activate the crosslinking reaction. Afterward GN1 and GN2 hydrogels were frozen at -40 °C (freezing rate of 1°C/min) then lyophilized. Samples with 6 mm diameter and 2 mm thickness were obtained by cutting the obtained dry samples by means of a surgical punch (biopsy punch – Kai Medical BB-807). The morphological, physicochemical, and mechanical properties of materials have been evaluated and performed by means SEM analysis, degradation, swelling and compression tests. Furthermore, preliminary biological analysis by using human osteosarcoma cells (MG63) to estimate the cytocompatibility of scaffolds at two different cross-linking degree were performed by means MTT assay.

### RESULTS AND DISCUSSION

The chitosan-genipin scaffolds developed in this study presents great potentiality for applications in tissue engineering. The SEM images proves that the freeze-drying method allow to obtain a highly interconnected porosity, with pores at different shape and diameter, according to the different genipin concentration and cross-linking degree. GN1 presents round shape pores

with diameter ranging between 20-150 µm, while GN2 hexagonal pores, ranging 20-300 µm. The porosity looks isotropic in both the samples. The macrostructure of GN1 and GN2 scaffold is presented in Fig. 1.

Effects of cross-linking degree on degradation kinetics and swelling ability of the scaffolds were also measured, as well as their mechanical properties in compression. The *in vitro* degradation tests conducted both in PBS and PBS with lysozyme, showed a gradual dissolution of the scaffolds over time, but maintaining their integrity even after 28 days of incubation. GN1 samples show faster degradation kinetics than GN2 ones in both solutions. The results of the swelling test at 24h in PBS are likewise bound to the degree of cross-linking and show that GN1 scaffolds are more able to fluid uptake. The compression tests showed that as the cross-linking degree increases, a decrease in the mechanical strength is produced at low strain values.

Fig.1 SEM images of GN1 chitosan-genipin scaffold (A) and GN2 one (B).

The biological tests performed in EMEM supplemented of FBS (10%), penicillin (100 U/mL) and streptomycin (100 mg/mL) demonstrated that the cell proliferation increases with time during the *in vitro* culture period, suggesting that the materials are nontoxic, not affecting the cell proliferation and showed good biocompatibility profile. No proliferation difference was found between GN1 and GN2 scaffold at every time points.

### CONCLUSION

This study has demonstrated the possibility to generate a novel cross-linked chitosan scaffold with an highly interconnected and homogeneous structure. Porosity in the range of about 20 µm to 300 µm is in agreement with the dimensional characteristics required for the scaffolds used in bone regeneration applications. The degradation profile, in combination with swelling and mechanical values, confirms their suitability in the field of bone tissue regeneration.

### INTRODUCTION

Various approaches have been considered to treat damaged gastric epithelium due to gastric ulcer and/or following the removal of cancer. Epithelial stem cells drive perpetual renewal of glandular cells secreting mucus, acid, pepsinogen, and various hormones or peptides. Little is known about the differentiation program and self-renewal of these stem cells. A recently established immortalized mouse gastric stem (mGS) cell line with features of undifferentiated morphology<sup>1</sup> (2) and expressing stem cell-specific markers: Notch3, DCAMK11 and Oct4 (3,4) represents a useful tool to study these rare cells<sup>2,3</sup>. Recent developments in regenerative medicine and tissue engineering could provide possibilities for improving the quality of life following gastrectomy. Differentiation of epithelial stem cells into any or all of these stomach cells upon culture on previously tailored scaffold is expected to provide an alternative modality for the treatment of damaged gastric epithelium. This study investigates the potential differentiation of mouse gastric stem cells (mGS) upon culture in a 3D culture system at different pH values. Three types (nonporous, microporous, and fibrous) of polycaprolactone (PCL) scaffolds were tested for the growth and differentiation of mGS cells at various normal and acidic pH values.

### EXPERIMENTAL METHODS

Polycaprolactone (PCL) scaffolds; non-porous, microporous, and microfibrous, were fabricated and characterized using scanning electron microscopy (SEM) and mechanical testing. The mGS cells were initially seeded on PCL scaffolds and allowed to grow for up to 3 days. Upon screening and based on cell viability results, microfibrous PCL scaffolds were seeded with mGS cells for up to 12 days. Cell growth and differentiation were monitored using PicoGreen assay of DNA quantification, SEM and lectin-/immunocytochemistry, and quantitative RT-PCR. In addition, the viability of mGS cells grown onto 3D scaffolds using RPMI media at pH ranging from 3 to 7.4 was tested using Calcein and Propidium iodide assays. The wound-healing method was used to examine the effects of acidic pH on mGS cell migration.

### RESULTS AND DISCUSSION

SEM features and mechanical properties of the scaffolds revealed similarities with connective tissue elements of the stomach wall.

A change in the number and size of the cells with time was observed suggesting their differentiation. Analysis of cryosections of scaffolds containing cells probed with N-acetyl-D-glucosamine-specific lectin and anti-trefoil factor 2 antibodies indicated that within 9 days of culture, around 50% of the mGS cells differentiated into mucous neck cells. Lower pH values decreased cells viability, while no significant change in viability was observed at pH  $\geq 5.5$ . In addition, RT-PCR revealed upregulation (3 folds) of mucous cell-specific gene, MUC5ac after 3-day culture at pH 5.5.

### CONCLUSION

Microfibrous PCL scaffolds support not only growth of mGS cells, but also their differentiation into mucus-secreting cells, showing their potential in stomach tissue engineering. Acidic pH value of culture media around 5.5-6.0 modulate the mGS cells proliferation program and speed up their differentiation into mucous cells.

## INTRODUCTION

Tissue engineering is a promising approach for reconstructing damaged tissues and organs. Polytetrafluoroethylene (PTFE) is a synthetic material which confers non-biodegradability due to its highly crystalline nature. PTFE is widely used in medical implants due to a combination of mechanical performance, corrosion resistance and biocompatibility<sup>1</sup>. However, the use of this polymer as scaffolds for tissue engineering is often limited because of the poor retention of cells on its hydrophobic surface<sup>2</sup>.

Another group of materials which attracts interest as scaffolds is polyhydroxyalkanoates (PHAs)<sup>3</sup>. They are a family of biopolymers of microbial origin possessing excellent biocompatibility and biodegradability, and a wide range of physical and mechanical properties<sup>4</sup>. PHAs promote cell attachment and they can combine with different groups of materials including polymers, ceramics, and metals.

To overcome the limitations of PTFE, a composite scaffold was developed. The aim of this study was to investigate whether composite polytetrafluoroethylene/polyhydroxyalkanoate scaffolds promote cell attachment and proliferation.

## EXPERIMENTAL METHODS

PTFE porous plates were coated with poly(3-hydroxybutyrate) to create composite scaffolds with the method of dip coating. In order to study the ability of scaffolds to promote cell attachment we seeded them with fibroblasts NIH 3T3. The tissue culture polystyrene (TCPS) was used as a positive control. Cell viability was assessed by fluorescent microscopy using LIVE/DEAD staining (Molecular Probes) 24, 72, 168 hours after seeding. To investigate cell proliferation, MTT test was performed 24, 72, 168 hours after seeding.

## RESULTS AND DISCUSSION

Figure 1. Cell viability after 7 days of culture on uncoated (a), coated (b) scaffolds and control tissue culture polystyrene (c) with LIVE/DEAD staining.

Cell viability was reduced after the cultivation on PTFE scaffolds. The number of cells adhered on the composite scaffolds was not significantly different when compared to the cell number on TCPS. Thus, coated scaffolds seem to provide the good adhesion of cells.

Figure 2. MTT assay for NIH 3T3 on scaffolds.

The obtained results in MTT test after 3 and 7 days of culture show consistent cell proliferation. Comparing the composite and PTFE scaffold, the cell viability and proliferation was improved by hydrophilic PHA-coating. However, the number of metabolically active cells on both, PTFE and composite scaffolds was lower compared to that of polystyrene seven days after seeding; on the composite scaffolds it was about 3 times higher than on PTFE.

## CONCLUSION

We have developed a new approach to increase cell attachment to PTFE porous scaffolds coating it with PHAs to scaffold artificial tissues.

## INTRODUCTION

Dental implants represent the most reliable and long lasting therapeutic solution for tooth loss. However, peri-implantitis, an inflammatory disease mainly caused by bacterial infection and which induces a slow and gradual destruction of the implant supportive tissues, results in implant loss within 12 months in about 20% of the patient<sup>1</sup>. Healing of the peri-implant tissue is a slow process resulting in a scar tissue of lower quality, which lacks periodontal ligament and specific tissue fiber orientation in the peri-implant mucosa. Such inadequate healed tissue accounts for its sensitivity to bacterial invasion.

If biodegradable synthetic polymers (polyesters) shaped as dense or nanofibrillar membranes for guided tissue regeneration have been developed in the context of periodontal diseases, their fast resorption rate are likely to allow early wound healing, but not to provide efficient mechanical behaviour supporting tissue maturation. Furthermore, no biomaterial which would allow efficient cellular colonization has been proposed as scaffold for tissue regeneration among peri-implantitis therapeutics. Interestingly, jet-spraying, a method based on polymer diffraction by airflow, has recently been described as a successful way to create highly porous polycaprolactone (PCL) nanofibrillar scaffolds that allow extensive cell colonisation and tissue formation, unlike electrospinning<sup>2</sup>.

With this consideration in mind, we hypothesized that such open nanofibrillar structures composed of different biodegradable polymers, and therefore of distinct mechanical behaviours over time, would allow to enhance the quality of peri-implant scar tissue while providing improved handling and controlled shrinkage around the implant.

To investigate these hypotheses, we developed composite nanofibrillar matrices containing different ratio of PCL and poly(lactic-co-glycolic acid) (PLGA) nanofibers using the versatile jet-spraying approach, and evaluated their structural, mechanical, shrinkage and degradation properties.

## EXPERIMENTAL METHODS

Parameters to create PLGA (50/50, MW 153000 g/mol) nanofibers by jet-spraying were investigated with a 3<sup>4</sup> factorial design. Composite nanofibrillar matrices were obtained by concomitantly jet-spraying PCL (MW 80000 g/mol) and PLGA on the same collection point with two distinct setups. Modulation of each polymer in the nanofibrillar composite was achieved by selective shielding and ratio determined by selective PLGA dissolution in DMSO. Structure of the resulting matrices was characterized by SEM, mechanical properties by tensile testing and degradation by 3 weeks incubation in PBS at 37°C. Porosity and shrinkage in PBS, at RT, were determined by direct measurements.

## RESULTS AND DISCUSSION

Production of PLGA nanofibrillar matrices by jet-spraying was straight forward, controlled, highly productive (0.9 to 21 mm/hour thick) and resulted in high porosity (93 to 98%). Microscopically, PLGA nanofibers were smooth and homogeneous (Fig. 1A), with median diameters that could be adjusted from 0.24 to 1.43  $\mu$ m by increasing polymer concentration. Composite matrices of PLGA and PCL nanofibers (diameter 600 nm) were similarly easily produced. The nanofibers from each polymer were intimately entangled in porous structures while their respective structure and diameter was retained (Fig. 1B).

Fig. 1. PLGA (red arrows) and PCL (green arrows) jet-sprayed nanofibers (A) and resulting composite (B).

The ratio of each polymer could be adjusted at will, which resulted in fine modulation of the composite properties. Young's modulus showed a sharp and tuneable increase as compared to PCL and PLGA matrices alone (up to 2 and 4 fold respectively) (Fig. 2) while ultimate tensile strength followed the same trend, possibly due to a decrease of overall porosity by arrangement of smaller PCL fibers between PLGA's. By increasing PCL ratio, shrinkage of the composite matrices during incubation could as well be improved in a controlled fashion.

Fig. 2. Effect of composite PLGA ratio on mechanical properties(A) and shrinkage over incubation (B).

## CONCLUSION

Overall, these results present a simple and efficient approach, based on jet-spraying, to create composite nanofibrillar matrices of controlled and improved properties. Ongoing degradation experiments will further determine the selective modulation of mechanical properties over time.

## INTRODUCTION

Liver diseases and cirrhosis deteriorate microcirculation; liver cirrhosis is the most common cause of death in men and in women in Europe and USA<sup>1</sup> and this condition is largely associated with primary liver cancer. An artificial material<sup>2</sup> that simulates the liver from the point of view of mechanical properties was produced to perform mechanical measurements and to test theoretical models. These materials, made of polyurethane, are porous and have the mechanical characteristics (elasticity and visco-elasticity) similar to those of the liver tissue. They were subjected to perfusion tests with different flow rate (0-78 ml/min) and their hydrodynamic behaviour was found to be similar to that of the liver. The next step, to be discussed in this work, is to perform compression experiments in perfusion at different pressures to evaluate the poroelastic behaviour of these materials.

## EXPERIMENTAL METHODS

Mechanical measurements were made through indentation tests using a testing machine with a maximum load of 500 N (Zwick/Roell Z0.5) with the experimental set up shown in Fig.1. The samples, perfused with water, were compressed with different values of the inlet pressure from 0 to 10 cmH<sub>2</sub>O (step of 2 cmH<sub>2</sub>O) to study the poroelastic behaviour in the undrained condition.

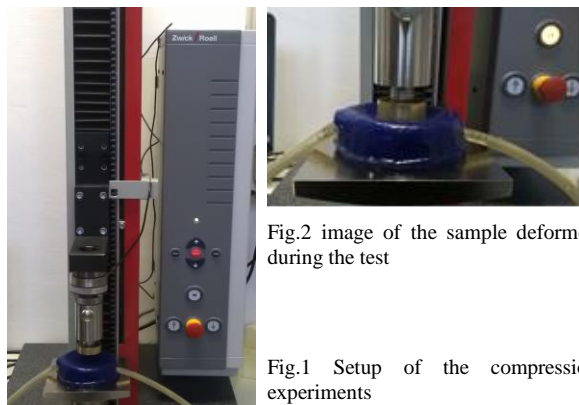

Fig.2 image of the sample deformed during the test

Fig.1 Setup of the compression experiments

The inlet tube was connected to a reservoir with water, which was initially positioned at the same height of the sample's inlet tube ( $p=0$  cmH<sub>2</sub>O) and for each test was lifted of 2 cm; the outlet tube was closed. The load was applied to the sample through a cylindrical indenter of 35 mm diameter. This method permits to neglect the change of shape of the sample during the deformation; it was positioned in the centre of the sample to avoid boundary effects. The values obtained were processed using a relationship between force and displacement<sup>3</sup> from which the Elastic Modulus can be calculated by the following expression:

$$E = \frac{2(1-\nu)}{3\pi(1+\nu)} \frac{F h^3}{\delta a^4} \quad (1.1)$$

where  $\nu$  is the Poisson coefficient (in this case it is considered equal to 0.2),  $F$  is the applied force,  $\delta$  the vertical displacement,  $h$  the actual height of the sample and  $a$  the radius of the indenter. In all tests the maximum deformation of the samples was 10% of its height. The preload velocity was 50 mm/min and the initial preload was 0.05 N.

## RESULTS AND DISCUSSION

The Elastic Modulus of the tested samples increase with pressure as shown in Fig.3; there is a little decrease of this value during the test at an inlet pressure of 6 cmH<sub>2</sub>O (0.6 kPa) and this seems to be a poroelastic feature of the material.

Fig.3 Elastic modulus vs. pressure for different values of compression

Fig.4 Elastic modulus vs. strain for different values of pressure

The value of the elastic modulus increases with strain (Fig.3) in the whole range of the applied pressures. As it is possible to see from the plot, the modulus at very low strain is quite similar to that of a healthy liver<sup>4</sup> (about 5 kPa).

The second step of this work is to explain these results with an analytical model of a poroelastic material.

## CONCLUSION

These materials subjected to indentation tests show that the elastic modulus increases with the pressure and the deformation. They reflect properly the behaviour of the liver and it will be necessary to make further experiments to make quantitative assessments.

### INTRODUCTION

Hydroxyapatite  $[\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2]$ , HA] is a primary constituent of vertebral animal's hard tissues and synthetic HAP has attracted attention due to its utility in the fields of bioceramics, catalyst, adsorbent, and so on. Because of the high stability and flexibility of the apatitic structure, a great number of substitutions, both cationic and anionic are possible.  $\text{Ca}^{2+}$  ion sites can be replaced by various divalent cations including  $\text{Sr}^{2+}$ ,  $\text{Ba}^{2+}$ ,  $\text{Pb}^{2+}$ ,  $\text{Cd}^{2+}$ ,  $\text{Mg}^{2+}$ , etc. In recent times, strontium hydroxyapatite  $\text{Sr}_{10}(\text{PO}_4)_6(\text{OH})_2$  (Sr-HAP) has received enormous attention of researchers because of its crystallochemical similarity to calcium hydroxyapatite. In particular, an increasing interest in strontium incorporation into biomaterials for hard tissue repair is justified by the growing evidence of its beneficial effect on bone [1]. Strontium is present in the mineral phase of bone, mainly in the regions of high metabolic turnover. *In vitro*, it increases the number of osteoblasts and reduces the number and activity of osteoclasts; *in vivo*, it inhibits bone resorption and improves bone formation. Strontium can replace calcium in the HA structure for the whole range of compositions, inducing a linear variation in the lattice constants. This study reported an evaluation of the substitution effect of strontium-modified hydroxyapatite gels (Sr-HA) on physicochemical, morphological and biological properties of hydroxyapatite materials prepared by sol-gel approach for periodontal tissue regeneration.

### EXPERIMENTAL METHODS

Sr-HA gels containing 5 - 10 - 15 and 20 mol %  $\text{Ca}^{2+}$  replaced by  $\text{Sr}^{2+}$  were synthesized at room temperature by using calcium nitrate tetrahydrated  $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  and di-ammonium hydrogen phosphate  $(\text{NH}_4)_2\text{HPO}_4$  as precursors and using water as solvent. Strontium nitrate  $\text{Sr}(\text{NO}_3)_2$  was dissolved in water and used to replace  $\text{Ca}^{2+}$  ions. The chemical composition of Sr-HA and the effect of strontium on viscosity properties have been evaluated by physicochemical (FTIR, XRD) and rheological analysis (rheometer ARES). The morphology of the materials was characterized by using SEM and TEM microscopy. Furthermore, biological tests were performed to estimate the effect of strontium on cellular behaviour by using human periodontal ligament cell.

### RESULTS AND DISCUSSION

A preliminary investigation showed a difference in the gelification time of the biomaterials prepared at different Sr concentration. In particular, gels prepared at 0, 5 and 10 mol% of Sr reached a final setting after 1hr

of stirring at 40°C. Meanwhile, the gels prepared at 15 and 20 mol% of Sr showed a slight delay, their gelation time was achieved after 2-3 hrs. This different behaviour probably is due by the ionic substitutions in the crystallographic sites of the hydroxyapatite lattice that generally cause changes in the values of the cell parameters dependent on the different sizes and amount of the ions, which are directly or indirectly responsible for the gelification time and for the general features of the material. In fact, TEM analysis demonstrated that in 10 and 20mol% Sr-doped HA the particles were changed in size than hydroxyapatite (l:  $40 \pm 2.7\text{nm}$ ; Ø:  $10 \pm 1.6\text{nm}$ ), in fact a length of  $40 \pm 2.7\text{nm}$  and diameter of  $10 \pm 1.6\text{nm}$  were detected. Moreover, the structural analysis of the powders of hydroxyapatite (HA) and hydroxyapatite doped with strontium 15mol% (HA-15Sr), done by X-ray diffraction, allowed us to identify the hexagonal hydroxyapatite crystalline phase. From the microstructural analysis we have found that 15mol%Sr doping reduces the domain size along all crystallographic directions while expanding the cell volume. The respond of periodontal ligament cells cultured onto the Sr-doped HA showed that material is not cytotoxic and have good biocompatibility. The potential of differentiation of periodontal ligament cells were evaluated by expression of bone related molecules by gene expression and our results showed that Sr-HA material have good potential for therapeutic application on periodontal defects where bone is need to be regenerated.

### CONCLUSION

The strontium incorporated in the hydroxyapatite structure decreases the domain size along all crystallographic directions with some effects on physicochemical and rheological properties. Moreover, the gel materials with strontium show better osteogenic differentiation by the expression of specific gene markers. This work confirms the ability of the hydroxyapatite modified Sr materials resulted in a solid gel to show good osteogenic properties for periodontal tissue regeneration.

### INTRODUCTION

The chemical similarity of synthetic hydroxyapatite  $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$  (HA) and natural bone mineral has led to its use as a bone grafting material, both in phase-pure and substituted forms. A particularly successful substitution in HA-based orthopaedic materials is silicon, which plays an important role in connective tissue health<sup>1, 2</sup>. Silicate substitution limits are typically ~2 wt% Si before phase decomposition occurs with heat-treatment. Equally, while high levels of zinc are known to be cytotoxic<sup>3</sup>, low substitution levels in calcium phosphates have been investigated for their potential to stimulate bone formation, act as an anti-microbial and, slow osteoclast (OC) resorption. Therefore, we have synthesised and characterized a doubly substituted material, ZnSiHA, at various concentrations of Si and Zn in an attempt to combine several desirable characteristics of singly substituted HAs.

These materials were characterized using XRD, FTIR and XRF. The objective of the work presented here was to assess whether the materials could support the growth of primary human osteoblasts (hOB). Osteoblast growth and Collagen type I production were all measured on ZnSiHA discs and singly substituted controls with similar Zn and Si concentrations. Additionally, staining for mineral nodule growth was carried out after 21 days.

### EXPERIMENTAL METHODS

hOBs were isolated from minced trabecular bone, expanded until confluent, and then passaged. Samples were seeded at a density of 200 cells.mm<sup>-2</sup> or 14,540 hOBs per HA disc. A Cyquant cell proliferation kit (C7026, Molecular Probes, Invitrogen, Life Technologies, Paisley, UK) was used to determine the cell number at 21 days.

Type I collagen synthesis was measured by immunoblotting medium aspirates taken at 7, 14 and 21 days.

Twenty four hours prior to termination of cell culture medium containing 9  $\mu\text{gml}^{-2}$  was added to label mineral. At termination, the cells were fixed with 4% paraformaldehyde for 10 minutes and rinsed with 1X PBS. The samples were mounted with Vectashield containing DAPI and imaged using a fluorescence microscope to assess mineral nodule formation.

### RESULTS AND DISCUSSION

Both ZnHA and the higher Zn and Si concentration ZnSiHA sample showed significantly ( $p < 0.05$ ) more cells compared to HA, as shown in Figure 1.

**Figure 1. Cell numbers on co-substituted and singly substituted control HA discs at day 21 (# indicates a significant difference with HA,  $p < 0.05$ ).**

Collagen I synthesis was significantly ( $p < 0.05$ ) increased on SiHA, ZnHA and ZnSiHA with high amounts of Si, at day 14 compared to phase-pure HA. Physiological mineral formation was observed on each sample after 21 days despite the lack of supplemental glucocorticoids and  $\beta$ -glycerophosphate.

### CONCLUSION

This study showed that newly developed ZnSiHA materials could support the growth of primary hOBs isolated from human tissue for up to 21 days *in vitro*. hOBs showed signs of differentiation and produced new mineral deposits on all samples. These results pave the way for testing the anti-microbial efficacy of ZnSiHA, which could be used to deliver a higher amount of Zn to combat bacterial infections, while retaining a desirable OB response.

### INTRODUCTION

The capability of the central nervous system (CNS) to regenerate and development crucially depends on the mutual interaction of the neural stem cells with the biomimetic microenvironment (scaffold) resembling a natural stem cell niche. In the existing state of knowledge, there is no clinically effective therapy for CNS regeneration [1,2]. The bi-component collagen-chondroitin sulfate (Col-CS) scaffold can possess very poor biological activity or be very bioactive depending on detailed structural features.

### EXPERIMENTAL METHODS

In this *in vitro* study, human induced pluripotent (iPS) stem cells committed to neural precursors were seeded into a biochemical highly standardized 3D porous collagen (Col) scaffold with covalently immobilized chondroitin sulfate (CS). Building up “biomimetic” microenvironment Col-CS sponge-like scaffold was based on two stage process: multiple freeze-drying followed by carbodiimide modification.

### RESULTS AND DISCUSSION

Of particular importance was spectroscopy (FTIR) observation that the collagen triple helix was preserved during bond-forming between Col and CS. Moreover, these scaffolds had average pore diameter of 31 µm and

relatively large surface area per pore volume. This scaffold has low autofluorescence and allows for proper visualization of immunostained experimental cells. The human induced pluripotent cells neurally *committed* (nestin positive) easily adhere to the surface of the scaffold and acquire markers of neuronal (β-tubulin III) and glial (GFAP, GalC, PDGFRα) cell population.

### CONCLUSION

Such results indicate feasibility of Col-CS scaffolds as “niche-like” microenvironment for human iPS-derived neural stem cells.

[krystyna.pietrucha@p.lodz.pl](mailto:krystyna.pietrucha@p.lodz.pl)

### INTRODUCTION

Nowadays, the important approach towards neural tissue engineering involves the *in vitro* culturing of stem cells on biodegradable and bioactive collagen (Col) scaffold to form hybrid tissue-like structure feasible for implantation into the injured site of brain or spinal cord. Such scaffold must have especially stable micro-architecture and biophysical properties. The main focus of our previous studies was the enhancing the functional properties of collagen by cross-linking using carbodiimide [1,2].

### EXPERIMENTAL METHODS

In this study we are interested in activation of collagen with biocompatible 2,3 dialdehyde cellulose (DAC). Synthesis of scaffold was done in three steps: (i) preparation of 2,3 DAC, (ii) construction of 3D collagen sponge, (iii) modification of sponge by solution of DAC and lyophilization. Collagen scaffolds modified by DAC were seeded with induced pluripotent stem cells.

### RESULTS AND DISCUSSION

The results obtained suggest that intermolecular cross-links occur primarily between the free amine groups of collagen macromolecules and aldehyde groups in DAC. Of particular importance was spectroscopy examination that only small changes in the absorption ratio  $A_{1235}$  to  $A_{1450}$   $\text{cm}^{-1}$  was observed that unambiguously indicate that secondary structure of triple helix of collagen not altered significantly. An extremely important feature of collagen cross-linked by DAC is fact that scaffold is occupied by a size pore regime of 20-160  $\mu\text{m}$ . Some

rheological properties of scaffold which play an essential role in cell fate will also be presented and discussed. Col-DAC scaffolds were seeded with induced pluripotent stem cell-derived neural precursors which adhere in a good manner and differentiated into more advanced phenotypes expressing neuronal (b-tubulin III, Map2, Doublecortin) and glial (GFAP, GalC, PDGFRa) markers.

### CONCLUSION

Collagen modified by dialdehyde scaffolds may serve as the carriers for the specific population of neuronal cells.

## Study of Poly(lactic acid) Hybrid Systems for Preparation of Interconnected Porous Scaffolds

Ioanna-Georgia Athanasoulia, Maria Kanidi, Petroula A. Tarantili

Polymer Technology Lab., School of Chemical Engineering, National Technical University of Athens, Greece  
[taran@chemeng.ntua.gr](mailto:taran@chemeng.ntua.gr)

### INTRODUCTION

Poly lactic acid (PLA) is one of the most widely used materials in biomedical applications due to its interesting characteristics, such as tuneable mechanical properties, degradation into natural metabolites and biocompatibility<sup>1</sup>. However, the brittleness and degradation rate of PLA, as well as its inherent hydrophobicity have limited its applications<sup>2</sup>. To overcome these problems, chemical modification as well as the use of amphiphilic mixtures have been investigated. Since poly(ethylene glycol) (PEG) is known to be miscible with PLA in the amorphous phase, it has been utilized as a component to be blended with PLA. PEG is a hydrophilic polymer widely used in the field of biomedicine, due to its lack of toxicity, good biocompatibility and elimination from the human body when its molecular weight is low. PLA/PEG blends vary from completely miscible to partially miscible, depending on the PEG concentration.

Scaffolds for tissue engineering should have a specific three dimensional shape, appropriate pore size, high porosity and pore interconnectivity to achieve better nutrient transport and cell migration. Also, they should possess sufficient mechanical strength to provide the necessary physical support for tissue reconstruction. Available techniques for fabricating polymer porous scaffolds, such as solvent casting, particle leaching, gas foaming, electrostatic spinning, freeze drying and phase separation have already been widely used<sup>3</sup>.

In this work, PEG/PLA blends were studied and the salt leaching technique was applied in order to obtain a porous PLA with interconnected cells. Combination of inorganic (NaCl) and organic (PEG) porogens in particulate leaching method were also examined.

### EXPERIMENTAL METHODS

PLLA (Resomer - L210 Boehringer Ingelheim) and PEG ( $M_w=3000$  g/mol, Merck) blends, with various PEG concentrations (20, 30 and 50%) were prepared by dissolution in dichloromethane using sonication for 15 min. The obtained films were characterized by differential scanning calorimetry (DSC) and thermogravimetric analysis. PEG/PLLA films were immersed in deionized water for removal of water soluble PEG. In PLA and PEG/PLLA systems, sieved NaCl (200-300  $\mu$ m particle sizes) was added and salt leaching by immersion in deionized water was studied. Optical and Scanning Electron Microscopy (SEM) were used for observation of the obtained material morphologies.

### RESULTS AND DISCUSSION

DSC analysis of PEG/PLLA blends revealed that the presence of PEG enhances the crystallization of PLLA

phase, whereas a decrease in the crystallization ability of PEG was recorded. Minor decrease in melting temperatures of both phases was observed.

Sample PEG/PLLA	$T_{m,PEG}$ (°C)	$T_{m,PLLA}$ (°C)
PLLA	-	181.2
20/80	43.1	178.5
30/70	59.0	179.6
50/50	61.2	178.0
PEG	61.0	173.9

Table 1. DSC results of PEG/PLLA blends.

Thermogravimetric analysis of PLLA/PEG gave two stages of thermal degradation: the low temperatures area corresponds to PLA and that at the higher temperatures area corresponds to PEG degradation. The presence of PEG shifts the onset of PLA thermal degradation to lower temperatures, whereas no significant effect in the degradation rate of PEG phase in the blend was observed.

PEG/PLLA w/w	$T_{onset}$ (°C)	$T_{peak,PLLA}$ (°C)	$T_{peak,PEG}$ (°C)
PLLA	336.6	360.3	-
20/80	304.1	347.8	392.2
30/70	298.4	338.3	397.1
50/50	279.6	317.1	401.1
PEG	384.0	-	402.9

Table 1. TGA results of PEG/PLLA blends.

### CONCLUSION

The incorporation of PEG in PLA matrices decreases the thermal stability of PLA phase, whereas no significant changes can be recorded for that of the PEG phase. The presence of PEG enhances the crystallization ability in PLLA phase, whereas that of PEG was lower, in comparison with respective pure polymers. The formation of porous PLLA scaffolds is expected to proceed via the NaCl particles leaching method and the interconnectivity of pores might be improved by the combined action of the polymeric porogen of PEG.

## INTRODUCTION

Nanofibrous materials are commonly applied in the field of biomedical engineering due to their properties: high area to volume ratio, fiber diameter corresponding to natural extra cellular matrix, suitable mechanical properties, etc. However, stable and efficient production of high amount of the nanofibers remains challenging. Thus, researchers proposed combination of common technologies - electrospinning and meltblowing – known as solution blow spinning (SBS)<sup>1</sup>. In present work we investigated possibilities to design nanofibrous product of SBS for tissue engineering applications by controlling process parameters.

## EXPERIMENTAL METHODS

Solution blow spinning technique was applied for polyurethane nanofibers production. Briefly, the system contains concentric nozzle: inner for polymer solution flow, outer for air flow; compressor and syringe pump. Details are described in our previous work<sup>2</sup>. Solutions of three concentrations of polyurethane (PU, Elastollan 1185A, BASF, Germany) were prepared: 4, 6 and 8% w/w in tetrahydrofuran (THF).

Rheological properties of the solutions were investigated in Rheotest 2.1 (VEB MLW, Germany). Resulting nanofibers diameters, morphology, alignment, and cell culture evaluation were made based on scanning electron microscope (SEM, Phenom™, Phenom World) images. Porosity of materials was measured by gravimetric technique. For wettability measurements DSA 100 goniometer (Krüss, Germany) was used, and for single nanofiber wettability calculations the meta-stable Cassie Baxter equation was applied. Cytotoxicity and proliferation analysis were made based on ISO 10993-5 standard, with MTT assay on L929 fibroblasts cell line cultures. Investigation of cells migration through the nanofibrous material was conducted in confocal microscope (LSM 880, Zeiss, Germany), with AlexaFluor 488 Phalloidin staining of L929 filaments.

## RESULTS AND DISCUSSION

Flow curves for all concentrations present the rheological properties of investigated polymer solutions. In figure 1 we present the dependence of average fiber diameter in function of process parameters (solution concentration, air pressure). Nanofibers size varies from about 100nm to about 800nm. Alignment of the nanofibers within the material depends on collector rotational speed, and porosity of the material on nozzle-collector distance. Wettability measurement shows slight hydrophobic properties of non-woven material,

but calculations for single fiber indicate the hydrophilic properties. MTT assay shows both, cytotoxicity evaluation and proliferation of the L929 fibroblasts on the materials. PU nanofibers exhibit nontoxic property, allowing cells to migrate through the material's pores – effect illustrated by confocal microscopy.

Figure 1. Average nanofibers diameter in function of applied air pressure and polymer concentration; SEM insert, scale-bar 6μm

Presented results indicate the importance of processing parameters control for production of proper nanofibrous biomaterial from polyurethane for tissue engineering applications by solution blow spinning. Additionally, the investigation of cells behavior, not only on the surface of the biomaterial, shows the importance of designing the internal structure of solution blow spun nanofibers.

## CONCLUSION

Solution blow spun polyurethane nanofibers with potential application in the field of biomedicine exhibit proper physical and biological properties, when the production process is consciously controlled. The resulting biomaterial promotes cells migration on the surface and within the material structure, lacks cytotoxicity and promotes proliferation of cells.

### INTRODUCTION

Bone tissue engineering using biphasic calcium phosphate bioceramics as scaffold saturated by autologous mesenchymal cells in autologous environment of host living organism as bioreactor is one challenge for substitution of autologous bone grafting [1-2]. Role of autologous mesenchymal cells for biologisation of inorganic bone substitutes to improve their osteogenic properties is contradictory between healthy bone and compromised bone and environments. The fate of transplanted mesenchymal cells is discussed between new bone formation [3-4] and early death with release of some osteotrophic growth factors [5] and mediators for cell recruitments remains unknown.

### EXPERIMENTAL METHODS

Experimental osteoporosis was induced in 8 2,5 years female rabbits by ovariectomy and 1 mg/kg of methylprednisolone daily for 8 weeks. On 4 animal the holes was created in bouth angles of lower jaw; on the left side filled with a biphasic calcium phosphate bioceramics (HAP/TCP 90/10) granules; on the right side the same granules mixed with autologous fat tissue-derived mesenchymal cells. The two control groups each had 2 rabbits – with the analagous defect of osteoporotic jaw bone without bioceramics and without of any defect. After 3 months bone samples for Hem/Eoz staining and mBiotin-streptavidin method for immunohistochemical detection of collagen I, osteonectin and osteopontin were prepared. Semi-quantitative counting method was used for quantification of relative frequency of immunohistochemically detected tissue degrading collagen I, osteonectin and osteopontin. Relative frequency of the collagen I type, osteonectin, osteopontin was analyzed in three visual fields of a single section. The diameter of the visual field was 1.8 mm when the enlargement was 100x, or the diameter the visual field was 0.9 mm when the enlargement was 200x. No collagen I type, osteonectin or osteopontin positive cells in the visual field were marked -, rare positive cells were marked 0/+, few positive cells +, moderate ++, numerous +++, a lot of positive collagen I, ON and OP cells were marked ++++.

### RESULTS AND DISCUSSION

Evaluation of histological slices stained with hem/eoz revealed different response of host tissue around implanted Hap/TCP granules. In healthy bone granules

mainly were embeded in new formed bone, but in osteoporotic bone surrounded by fibrous tissue layer more thick in samples where mesenchymal cells were added.

Table 1. Average expression of collagen I, ON and OP in osteoporotic jaw bone defects.

<i>Osteoporotic jaw bone defect</i>	<i>collagen I type</i>	<i>ON</i>	<i>OP</i>
<i>Defect without filling</i>	+++	++	++
<i>Filled with HAP/TCP 90/10 granules</i>	++++	++++	+++
<i>Filled with HAP/TCP granules and mesenchymal cells</i>	+++	+++	+++

### CONCLUSION

Integration of HAP/TCP granules in defect of osteoporotic rabbit jaw is through encapsulation by fibrous tissue while in healthy bone osseointegration occurs. The addition of autologous mesenchymal cells resulted in more thick capsule without significant influence on collagen I expression, ON or OP. No signs of inflammation were detected.

### INTRODUCTION

Graphene is a flat monolayer of carbon atoms tightly packed into a two-dimensional (2D) honeycomb lattice and is a basic building block for graphitic materials of all other dimensionalities with unique physical, chemical, and mechanical properties. Graphene and graphene oxide (GO) layers have become a hotspot so far and have been actively investigated to build new composite materials. It has been shown that graphene induces no obvious toxic effects *in vivo* [1]. It possesses the large aspect ratio, high mechanical strength, and superior electrical conductivity and the presence of abundant epoxide, hydroxyl and carboxylic groups on the GO basal plane could provide enormous reactive sites for chemical interactions. Thus, it has been regarded as an important component for making various functional composite materials.

In this work, we present the results of the applications of graphene and GO in biomedical application with focus on regenerative applications. Different mixtures of both graphene and GO with chitosan at different ratios were prepared in sheet-like structure in order to characterize the synergic combination of the composite materials.

### EXPERIMENTAL METHODS

Expandable graphite flakes (GIC), intercalated with a mixture of sulfuric acid and nitric acid, were obtained from Anthracite Industries (EG 3772). A content of 3.5 wt% of intercalate was reported on the technical data sheet. GIC, after a rapid heating at 700°C for 2 min, is transformed in expanded graphite (EG) characterized by a volume of about 250 cm<sup>3</sup>/g and a carbon content of about 99.5%. EG flakes were further disaggregated by sonication in water, acetone and chitosan solutions leading to expanded and sonicated graphene stacks (EGS) [2]. Graphene oxide (GO) was then produced by using the Hummer's method. EGS were characterized with X-ray diffraction (XRD) and dynamic light scattering (DLS). GO solutions were characterized with X-ray photoelectron spectroscopy (XPS) and Raman Spectroscopy. The rheological properties of Graphene and GO-chitosan mixtures were characterized with a rotational rheometer. The mechanical properties of the Graphene-Chitosan and GO-chitosan composite films were evaluated in comparison with those of pure chitosan samples. The cell morphology and cell spreading pattern interaction of human Mesenchymal Stem Cell (hMSC) onto composite materials sonicated at different time was evaluated by confocal laser scanning microscopy (LSM 510, CarlZeiss).

The biocompatibility of graphene/chitosan composite

films was checked *in vitro* by alamar blue colorimetric assay.

### RESULTS AND DISCUSSION

XRD and DLS analyses showed a time dependence particles dimensions. In particular longer sonication times lead to a lower particle dimension. A higher degree of exfoliation was achieved when EGS were further sonicated in presence of chitosan. Both XPS and Raman spectroscopy show an excellent conversion of EGS to GO. The morphology analysis by Transmission Electron Microscopy (TEM) confirmed a good exfoliation of graphene.

The cell adhesion result showed that the cell can adhere to and develop on the graphene/chitosan composite films, indicating that the composite films have good biocompatibility. Furthermore, according to the data it can be found that the number of hMSCs increases with time during the *in vitro* culture period; suggesting that the materials are nontoxic, not affecting the cell proliferation and showed good biocompatibility.

**Fig.1: Confocal microscopy of hMSC cultured on composite films after sonication treatment (8hours).**

### CONCLUSION

In this study, we have proposed a new technique for a direct exfoliation of graphite with chitosan allowing to obtain graphene flakes in a polymer matrix. The combination of this technique with Hummer's method allowing to obtain chitosan-graphene oxide composite films. The new composite materials may have wide range of potential applications, e.g. for conducting composites, optoelectronic, and in biological or medical research.

### **INTRODUCTION**

Due to its complex architecture at different length scales, the hierarchical structure of bone is not easily replicated in the laboratory. One strategy to overcome this obstacle when engineering synthetic bone tissue scaffolds is to provide a simpler material which inherent or implanted cells can remodel into natural bone. We have previously developed an alginate-calcium phosphate (CaP) composite material which shows good potential in this regard<sup>1</sup>. We envisage the formation of constructs which include beads, fibres and/or films with different mineral phases, content or mineralising potential, and the possibility to co-culture different cell types, such as osteoblasts and osteoclasts, in order to provide a synthetic matrix to stimulate remodelling of the composite and the formation of new bone.

The goal of this study was to develop *in situ* tools to study temporally and spatially resolved gel formation and mineralization of hydrogels simultaneously using a range of physicochemical characterization techniques.

### **EXPERIMENTAL METHODS**

The flow cell consisted of a microscope slide and a cover slip separated by a polymer film. A 10  $\mu$ L drop of alginate containing various concentrations (0 to 1 M) of sodium phosphate was placed between the slides creating a thin disc.  $\text{CaCl}_2$  gelling solution (50 mM to 1 M) was then introduced into the cell to initiate gelling and mineral formation.

Gelling kinetics, mineral formation, and local pH evolution were monitored using optical microscopy (Olympus IX70) and confocal microscopy (Leica SP5/SP8) of fluorescently labelled alginate and pH-sensitive fluorescent dyes.

To monitor the chemical composition of the mineral phases, Raman microscopy was used (Renishaw InVia Reflex Spectrometer System equipped with 532 nm and 785 nm lasers).

A selection of flow cell experiments were quenched during the gelling process by submerging the sample into acetone pre-cooled with liquid  $\text{N}_2$  and critical point dried (Emitech K850) before imaging with a SEM (Hitachi S-5500 S(T)EM).

### **RESULTS AND DISCUSSION**

The thin disc of hydrogel simulated the cross-section of a bead or a fibre and allowed us to follow gelling and mineralisation under different initial conditions. Freezing the samples in the process of gelling followed by critical point drying enabled us to study the mineral distribution and morphology with high resolution SEM-imaging at chosen time points after gelling had been initialized.

**Figure 1:** Optical microscopy images before and during gelling/mineralising. The blue arrows indicate the gelling front, the red arrow indicates a belt of minerals following the gelling front, and the green arrows show the position of spatially resolved Raman spectra. **Inset:** SEM-image of DCPD-crystal in an alginate matrix.

Figure 1 shows optical phase contrast images of a gelling sample with accompanying Raman-spectra of different positions on the sample. The inset is a density-dependent colour SEM-image, where the red channel is the BSE-signal and green channel is the SE-signal. This technique generates a larger contrast between the gel matrix and the denser mineral. The Raman-scattering technique could detect non-crystalline precipitates as well as spatially resolve the different phases that formed. In addition this approach, along with pH changes detected by fluorescence (data not shown), allowed *in situ* monitoring of mineral phase transformation, which occur in composites prepared with this method.

### **CONCLUSION**

We have developed a system which enables simultaneous study of spatially and temporally resolved gelling kinetics and crystallisation of hydrogel-mineral composite materials. The system is compatible with a range of physicochemical and optical characterization techniques. Results from these experiments can be compared with theoretical models and will be used to improve understanding of crystallisation processes and gelling kinetics of hydrogel-mineral composite materials.

[katarzyna.wierzbicka@inmat.pw.edu.pl](mailto:katarzyna.wierzbicka@inmat.pw.edu.pl)

### INTRODUCTION

Electrospinning is a versatile technique which enables fibers production from nano to micro size. Production of the fibers can be obtained not only by single needle electrospinning but also by co-axial spinning of two separate solutions. From polymers solution to the electrospun mats with adequate parameters such as voltage, solution concentration, needle to collector distance single fibers and core-shell fibers are produced<sup>1</sup>. Biomedical purposes of electrospun fibers require specific conditions. The fibers should be biocompatible, bioactive and biodegradable. Several materials have been used to fabricate fibers. In our studies we have used novel polyhydroxyalcanoates polymer obtained from biomass and as an additives the protein was incorporated<sup>2</sup>. This material is of the high potential for tissue engineering due to its degradation ratio and non-toxic product hydrolysis (R)-3-hydroxybutyric acid which is a normal constituent of human blood. The main goal for tissue engineering is to design scaffold which can ideally mimic native Extracellular Matrix (ECM). The aim of the studie was to prepare core-shell and single fibers with controlled release of model protein and material cell response to the obtained fibers.

### EXPERIMENTAL METHODS

Electrospun mats were produced using electrospinning with single needle and co-axial method. Nanofibrous mats were analyzed using Scanning Electron Microscopy (SEM) and Confocal Laser Scanning Microscopy (CLSM). Mechanical properties of electrospun fibrous membranes were investigated with electromechanical testing machine. Water contact angle measurements were determined to obtain wettability of produced fiber mats. The cytotoxicity effect of nanofibrous mats was examined. Additionally ATR-FTIR spectrum was recorded. The amount of released protein was evaluated using spectrophotometer UV-Vis. The human Mesenchymal Stem Cells (hMSC) were seeded on the prepared fibers.

### RESULTS AND DISCUSSION

Optimization of electrospinning parameters allowed for proper fiber preparation. By varying different parameters including feeding-rate, polymer concentration and other important parameters for core-shell (CLSM micrographs (Fig. 1)) and single fibers preparation the scaffolds were obtained. The obtained scaffolds can be used in bone tissue engineering with fibers diameters in the range up to 900nm. The ideal scaffold should possess ideal structure mimicking ECM that is why fibers were produced by random electrospinning.

Figure 1. CLSM images of electrospun co-axial nanofibers with FITC-BSA (fluorescein conjugate -bovine serum albumin) in core.

### CONCLUSION

Our studies present the controlled release profiles of the model protein from co-axial and single polyhydroxyalcanoates fibers and its influence to Human Mesenchymal Stem Cells (hMSC) response to the obtained materials. Fibers morphology and designed properties of the obtained material is suitable for bone tissue engineering.

### INTRODUCTION

Among the ceramic materials used in bone reconstructive surgery, calcium carbonates are of interest. Not only aragonite – which is the most widely investigated  $\text{CaCO}_3$ , but also calcite, can be taken into account as bone supporting ceramic. Interestingly, although those materials are identical in their chemistry, the difference of the crystallographic form results in different response to the ionizing irradiation – often used for sterilization of medical devices. As revealed by the electron paramagnetic resonance (EPR), radiation sterilization of aragonite induced the presence of a stable signal assigned to the  $\text{CO}_2^-$  – characteristic for bone mineral<sup>1</sup>. In contrast, there are no such paramagnetic centers registered after irradiation of calcite. Since this signal is characteristic for bone mineral we wondered if this phenomenon may be connected with biological activity of the materials. In particular, we focused on the differentiation and maturation of human osteoclasts in contact with both the materials, because these are the cells responsible for involving ceramic substitutes in bone remodeling.

### EXPERIMENTAL METHODS

Two different crystallographic forms of calcium carbonate, i.e. aragonite or calcite were added in the form of a powder to the culture of human osteoclast precursors (Lonza). Both quantitative and qualitative analysis was performed on day 7, 11 and 21. Morphological analysis was based on Tartrate-resistant acid phosphatase staining (TRAP), as well as on Scanning Electron Microscopy examination and time-laps observation. TRAP5b was measured by ELISA and concentration of calcium ions in the supernatants was determined in a colorimetric assay. The EPR analysis both before and after cell culture was performed.

### RESULTS AND DISCUSSION

All the results indicated that aragonite (material exhibiting a bone-like paramagnetic signal after irradiation) have significantly stronger impact on differentiation and maturation of osteoclasts precursors as compared to calcite (material with no  $\text{CO}_2^-$  signal after irradiation). Particularly, in the presence of aragonite powder there were more TRAP-positive multinucleated cells (optical microscopy), which were organized earlier in the culture (time-laps) and finally visible as giant cells in SEM (Fig. 1). It was accompanied by the higher amount of TRAP5b, which is considered as a marker of osteoclasts, in all time

points. Also, the higher concentration of calcium ions in supernatants indicates the more advanced degradation of aragonite as compared to the calcite, which shows the higher osteoclasts activity. Decreasing  $\text{CO}_2^-$  signal in aragonite during the culture additionally confirms its degradation.

The more efficient stimulation of osteoclasts by aragonite as compared to calcite may have some impact on bone remodeling in the presence of  $\text{CaCO}_3$ -based bone substitutes

### CONCLUSION

We demonstrate that osteoclasts differentiation and maturation *in vitro* in the presence of calcium carbonate depends on the crystallographic form of the material. It is more advanced in contact with aragonite, which express the EPR signal characteristic for bone mineral after irradiation, than with calcite, which do not have such a signal.

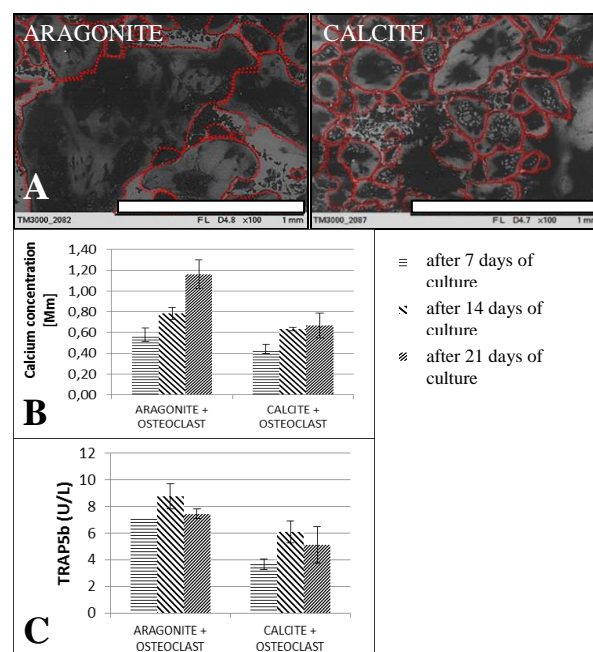

Fig. 1. SEM images of osteoclast after 21 days of culture (A); Concentration of calcium ions (B) and production of TRAP5b in supernatant (C) after 7, 11 and 21 days of osteoclast culture; scale bar, 1mm.

### INTRODUCTION

Apatite materials in the form of hydroxyapatite (HA) are very demanded in bone tissue engineering for repairing, replacing or regenerating defects in human bones or teeth due to the similarity in mineral composition. To respond to the current demands in orthopedical and dental repairing of bone defects, new biological sources of HA are being investigated. One of these sources is the shark tooth, which is an abundant by-product of enormous interest. In addition, it is also known that besides hydroxyapatite, shark tooth contains other bioceramic, called fluorapatite, exhibiting improved mechanical properties with respect to HA as a greater stiffness, higher elastic modulus and greater hardness(1).

### EXPERIMENTAL METHODS

Type I collagen was isolated from *Prionace glauca* skin as previously described(2). Apatite granules were obtained through pyrolysis (950°C, 12h) of shark teeth (*Isurus oxyrinchus*, *P. glauca*), followed by a ball milling and sieving processes. Scaffolds with different formulations (collagen:hydroxyapatite ratios of 100:0, 70:30, 50:50, 30:70), were prepared with in situ crosslinking followed by freeze-drying, evaluating two crosslinkers (HMDI and EDC/NHS). Hydroxyapatite grain sizes were 20-63 µm. To evaluate scaffolds stability, structures of each condition were incubated in culture medium for up to 15 days. Bioactivity of the scaffolds was evaluated by immersion in Simulated Body Fluid (SBF) and evaluating the formation of new calcium phosphates by SEM and micro-CT morphological analysis. Mechanical properties were evaluated by compression tests. Cytotoxicity evaluation was performed, addressing cell metabolic activity (MTS assay) and cell proliferation (DNA quantification). The most promising scaffolds in terms of stability, pore size, interconnectivity and bioactivity were chosen for human adipose derived stem cells (hASC) cell seeding, and their ability to promote the differentiation into osteoblast-like cells was evaluated.

### RESULTS AND DISCUSSION

An homogeneously distribution of hydroxyapatite granules into the scaffold structure were confirmed by SEM and micro-CT analysis. Crosslinking of collagen was shown to be more effective with EDC/NHS, producing stable scaffolds in culture medium up to 15 days. Depending on the crosslinking conditions, different porosities, interconnectivities, and mechanical properties were achieved. Scaffolds crosslinked with EDC/NHS were the ones showing less cytotoxicity, being the ones chosen for the assessment of hASCs differentiation.

### CONCLUSION

- Possibility to obtain collagen/apatite composite scaffolds, by valorisation of marine by-products, with an homogeneous distribution of apatite particles;
- Incorporation of apatite particles into the collagen matrix contributed to increase the scaffold stability;
- Mean pore size of these collagen/apatite scaffolds was in the proper range for bone tissue engineering;
- Lower cytotoxicity was demonstrated for EDC/NHS crosslinked scaffolds;
- Scaffolds crosslinked with 12.5% EDC/NHS promoted higher mineralization and their morphological features (pore size, porosity and interconnectivity) make them the best candidate for cell differentiation studies.

## INTRODUCTION

Implantation of bone graft material into the human body causes a cascade of processes on enzymatic and cellular level. Once implanted, biomaterial gets in contact with blood and leads to the adsorption of proteins. Inflammatory foreign body reaction starts with an acute sterile inflammatory response and changes into a chronic fibrotic response. Macrophages and their precursor cells, monocytes, play a key role in innate immunity. They recognize and attach foreign objects as well as they secrete inflammatory mediators for initiating inflammation<sup>1</sup>.

Recent studies presented the direction of macrophage polarization into pro-inflammatory M1 or anti-inflammatory M2 by engineering morphology of material surface. Particular surface structures in range of micrometer polarize macrophages in the direction of M2 that promotes healing<sup>2</sup>.

The present study refers on macrophage polarization cultured on triphasic silica/collagen/calcium phosphate xerogels.

## EXPERIMENTAL METHODS

Xerogels were produced by sol-gel-process. Tetraethoxysilane (TEOS) was hydrolysed to orthosilicic acid and mixed with a homogenous suspension of fibrillar bovine collagen and a calcium phosphate phase. Calcium phosphate phase was used in defined amount and size ranges. After atmospheric drying of the intermediate hydrogel a xerogel resulted. Surfaces of the samples were investigated using scanning electron microscopy.

Monocytes, isolated from human buffy coats, were matured and polarized into activated macrophages. For maturation basic medium (Dulbecco's MEM alpha modification containing fetal bovine serum, human serum and penicillin/streptomycin) was supplemented by macrophage-colony stimulating factor (M-CSF) was used. Polarization on 2D was performed using basic medium supplemented by interferon- $\gamma$  (IFN- $\gamma$ ) with day five until day seven for M1 direction and supplemented by interleukin-4 (IL-4) for M2 direction. For polarization studies on 3D basic medium was only supplemented by M-CSF. Light microscopy and

confocal laser scanning microscopy (cLSM) was applied for qualitative analysis of cell behaviour.

## RESULTS AND DISCUSSION

By the help of cytokine supported maturation as well as polarization of human monocytes into macrophages, morphology, phenotype and expression of typical M1 or M2 specific proteins were evaluated on 2D (polystyrene) as basis for the cultivation on 3D. Surface structuring of composites based on silica, collagen and calcium phosphate phase influences polarization of human macrophages *in vitro*. First results suggest the hypothesis that larger patterns support M2 phenotype, small patterns promote M1. The results are in accordance with previous studies of Bartneck *et al.*<sup>2</sup>, Garg *et al.*<sup>3</sup> and Paul *et al.*<sup>4</sup> concerning the possibility of modulating macrophage phenotype by surface morphology. So, inflammatory potency of a biomaterial could be influenced by modification of its topography and thus biocompatibility of the implant could be affected<sup>4</sup>.

## CONCLUSION

Controlling immune response affected by macrophages could be a step further in improvement of implant compatibility. The study demonstrated that promoting macrophages with pro- or anti-inflammatory response can be directed by modifying surface topography. Mechanisms which are involved in molecular events of controlling macrophage phenotype by topography are still not known.

## INTRODUCTION

Thermoresponsive polymers are of essential relevance for numerous applications in tissue engineering and regenerative medicine (TERM)<sup>1</sup>. Due to their reversible switchability from a hydrophilic to a hydrophobic state by a convenient temperature trigger, these smart materials are of particular importance in the field of cell sheet engineering<sup>2-3</sup>. The key concept of this technique is the attachment and growth of cells on substrates, which have been surface modified with thermoresponsive polymers, at 37°C under standard cell culture conditions. Controlled detachment of confluent grown cell sheets is accomplished by simply cooling below the lower critical solution temperature (LCST) of the thermoresponsive polymer coating<sup>4</sup>. The state of the art coating is based on extensively studied poly(*N*-isopropylacrylamide) (PNIPAAm) which is commercially available on cell culture dishes (UpCell™)<sup>5-7</sup>. However, PNIPAAm coated surfaces suffer from limited biocompatibility. Polymer coatings that have been recently designed to overcome these drawbacks are based on oligo(ethylene glycol) methacrylates (OEGMA)<sup>8-9</sup>.

In this study, we evaluate linear copolymers based on glycerol as a potent alternative to currently applied thermoresponsive materials for cell culture<sup>10</sup>.

## EXPERIMENTAL METHODS

Thermoresponsive poly(glycidyl ethers) were synthesized by anionic ring opening copolymerization (AROP) of glycidyl methyl ether (GME) and ethyl glycidyl ether (EGE) with adjustable comonomer ratios, molecular weights and narrow PDIs ( $\leq 1.2$ ). The cloud points (CP) of the copolymers were determined by turbidimetry measurements ( $\lambda=500\text{nm}$ ) in phosphate buffered saline (PBS, pH 7.4) and cell culture medium (DMEM) with 10% fetal calf serum. NIH/3T3 mouse fibroblast viability was assessed by fluorescent live/dead staining of a harvested cell sheet from thermoresponsive polymer coated gold substrates.

## RESULTS AND DISCUSSION

In our study we synthesized statistical thermoresponsive copolymers using AROP (Fig. 1A). By varying the molar ratios of the monomers GME and EGE we were able to finely tune the CPs of the corresponding polymers by simply adjusting the hydrophobicity of the copolymer side chains.

GME/EGE	0:1	1:5	2:3
CP (PBS)	18.7±0.3°C	23.5±0.3°C	32.8±0.2°C
CP (DMEM)	18.8±0.4°C	25.2±0.5°C	32.6±0.1°C

The cloud points of polymers with varying GME/EGE ratio (0:1, 1:5, 2:3) are given in Table 1 at a

concentration of 0.5 mM in the presence (DMEM) and absence (PBS) of proteins. Turbidity curves demonstrated a very sharp phase transition during multiple heating and cooling cycles as well as negligible hysteresis. Only very small differences in CP temperatures are observed from measurements in the presence and absence of proteins indicating no significant interaction of proteins with the polymers below the LCST.

We further immobilized self-assembled monolayers (SAMs) of these copolymers on gold substrates. Fibroblasts easily attach and grow on these thermoresponsive coatings above the respective LCST of the copolymer and detach spontaneously by simply lowering the temperature. Live/dead staining reveals excellent viability, which provides evidence for the biocompatibility of these switchable surfaces (Fig 1B).

**Figure 1.** (A) Structure of thermoresponsive polyglycidyl ethers. (B) Viability of fibroblasts in a confluent cell sheet grown and harvested on/from a copolymer coated gold substrate using a live/dead assay.

## CONCLUSION

Due to their finely adjustable LCST and their good biocompatibility, thermoresponsive poly(glycidyl ethers) are promising candidates for the application in cell-sheet engineering.

## Long-term Propagation of Cells in 3D Culture Effects Cell Morphology and Behaviour

Alisha Chhatwal<sup>1</sup>, Stefan Przyborski<sup>1,2</sup>

<sup>1</sup>School of Biological and Biomedical Sciences, Durham University, Durham, UK

### INTRODUCTION

Conventionally cells are grown and passaged in 2D. However, 2D growth substrates force cells to flatten and lose their characteristic morphology (Fig 1). Thus, the artificial nature of 2D culture can produce physiologically irrelevant observations of cell behaviour. Using commercially available porous polystyrene Alvetex® Strata scaffolds, a method has been developed to propagate cells continually in 3D, allowing for an observation of the long-term adaptation cells undergo when placed in an *in vivo*-like environment. This is a fundamental question in cell biology and understanding the adaptation process will help elucidate tissue formation. We hypothesise that changes in focal adhesion signalling networks lead to cytoskeletal reorganisation and down-stream perturbation in gene expression, directly linking a more tissue-like morphology to more physiological cell behaviour.

Fig. 1. Cells show a more 3D tissue-like morphology when grown in 3D culture, compared to their 2D counterparts, as indicated by a change in cytoskeletal F-actin staining.

### EXPERIMENTAL METHODS

Using a conventional cell line such as HepG2 hepatocytes, were seeded onto Alvetex® Strata 6-well membranes (5x10<sup>5</sup>) and grown for 5 days in 3D culture. Cells were removed, counted, re-suspended and plated again onto fresh inserts every 5 days. This process was conducted in parallel with HepG2 cells maintained in 2D culture. The phenotype of cells passaged in 2D and 3D was analysed. Data are presented as mean ± SEM.

### RESULTS

Cells maintained in 3D culture adopted rounder morphologies than their 2D counterparts (Fig 2A); this increase in circularity is maintained when cells are re-introduced into 2D, indicating that changes are hard-wired into cells, allowing for priming to 3D culture. This was shown by introducing 2D and 3D maintained cells into a 3D cell-suspension aggregate model (Figs 2B and 2C). 2D and 3D adapted cells behave differently: 3D primed cells show markedly reduced expression of phosphorylated FAK (pFAK) (a key molecule in cell-ECM signalling and indirectly involved in control of cell shape) (Fig 2D).

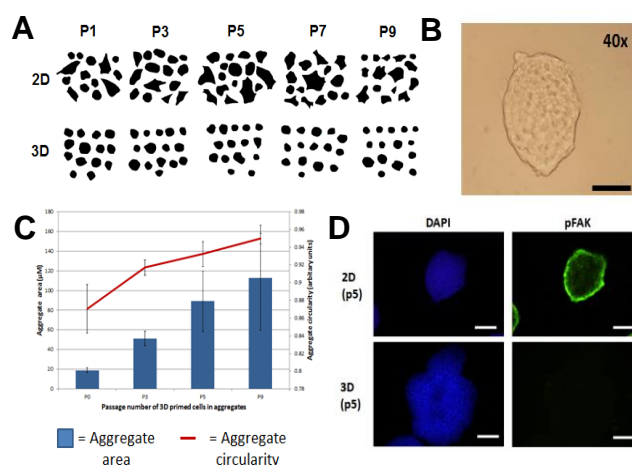

Fig. 2. Cells on Alvetex® Strata adapt to the 3D micro-environment when continually maintained in 3D culture. Cytoskeletal reorganization over the adaptation period allows cells to acquire a rounder 3D phenotype (A). Cells become primed to 3D culture environments (B,C), and show differences in FAK signalling (D).

### DISCUSSION & CONCLUSIONS:

Cells primed for 3D growth maintained morphologies that more closely resemble primary tissue. The reduction in pFAK in 3D appears to be due to a switch in signalling pathway brought about by the change in physical microenvironment. Differences seen in aggregates grown from 2D and 3D primed cells are possibly due to changes in cell adhesion and cell-ECM signalling, a hypothesis supported by the change in pFAK expression which correlates with lower levels in real tissues. Further work into this pathway will show how cells adapt to 3D culture. Such mechanisms are fundamental to understanding tissue formation.

In conclusion, we have developed technology that enables cells to continually be propagated in 3D culture. We have demonstrated how cells adapt to these environmental changes and acquire a more 3D architecture that results in important molecular changes within the cells. We propose to develop this technology further to routinely propagate cells in 3D culture so that they are primed ready for subsequent analysis in 3D in vitro models and transplantation. This will have important implications for enhancing the predictive accuracy of in vitro assays and priming cells for transplantation in tissue engineering applications.

[safa.ouergemmi@ed.univ-lille1.fr](mailto:safa.ouergemmi@ed.univ-lille1.fr)

### INTRODUCTION

Glucosaminoglycans (GAGs) are polysaccharides of the extracellular matrix that play an important role in the proliferation and the differentiation of cells. Therefore, GAGs are often used as scaffolds for tissue engineering applications. Among the artificial scaffold elaboration processes, electrospinning is one of the most convenient approaches as the obtained nanofibrous mats mimic the structure of the extracellular matrix. As GAGs such as chondroitin sulphate, hyaluronic acid and heparin carry sulphate, aminosulfate, carboxylic groups, we imagined the concept of an artificial GAG, based on chitosan (CHT), whose amino groups were partially substituted by a disulfonated benzyl group (CHT2S) [1]. CHT2S was firstly characterized by FTIR and NMR, and then electrospun mixed with the minimal necessary polyethylenoxyde (PEO) ratio.

### EXPERIMENTAL METHODS

**Synthesis of CHT2S:** CHT (5g) was dissolved in 500 ml of 0.5% of aqueous solution of acetic acid. Methanol (650 ml) was added to the chitosan solution. Sodium cyanoborohydride (NaBH<sub>3</sub>CN) (10g) was dissolved in the solution under vigorous stirring and after 3 min aldehyde (4-formyl-1,3-benzenedisulfonic acid, disodium salt dissolved in 150ml of water was added. The resulting precipitate was filtered and washed with water and dried, yielding a powder [1].

**Electrospinning:** 7.6wt% of CHT2S/Polyethylene oxide (PEO) mixtures with different ratios (5/5, 6/4 and 7/3 (w/w)) were dissolved in 0.05M of NaOH aqueous solution. The solution was spun with a flow rate of 0.3ml/h using a syringe pump applying a voltage ranging from 10 to 20kV. The tip to-collector (grounded aluminium foil) distance was varied from 20 to 25 cm. The temperature and the relative humidity in the chamber were set at 20°C and 30%, respectively.

**Crosslinking:** The electrospun mats were exposed to glutaraldehyde (GA) vapour for 24h and then rinsed with water.

**Characterizations:** The chemical composition and the quantification of the degree of substitution of the glucosamine units of CHT were evaluated by Fourier Transform Infrared Spectroscopy (Perkin Elmer Spectrum one FTIR-ATR instrument) and <sup>1</sup>H NMR. The morphology of the chrome sprayed nanofibres was observed with a scanning electronic microscopy (Hitachi S-4700 SEM) operating with an acceleration voltage of 5 kV.

### RESULTS AND DISCUSSION

The chemical structure of the CHT-2S is represented in figure1.

Figure 1:  
Chemical  
structure of  
CHT2S

The CHT2S structure was confirmed by FTIR thanks to the new bands relative to sulfonic acid hydrates at 2400-2000 cm<sup>-1</sup> and 1230-1235 cm<sup>-1</sup>, and to substituted benzene groups below 800 cm<sup>-1</sup>. NMR spectrum evidenced the presence of the grafted aromatic substituent through peaks appearing above 7ppm and signals integrations revealed a degree of substitution of the CHT glucosamine repeat units in the range of 66.5%.

Nanofibres with bulbs were obtained (fig 2c) for the weight ratio CHT2S/PEO 7/3, therefore it was necessary to lower this ratio down to 6/4 and 5/5 to obtain perfect nanofibres (fig 2a-b)).

Figure 2: SEM observations of nanofibres obtained with different CHT-2S/PEO mass ratio a) 5/5 b) 6/4 c) 7/3

Furthermore, the electrospinning process parameters were investigated. It was observed that the increase of the tip to-collector distance from 20cm to 25cm allow to obtain bulb-free nanofibres. We noticed, that the greater the flow rate, the more polydispersed nanofibres diameters we obtained.

SEM analysis displayed that GA crosslinking improved the stability of the electrospun mats as the nanofibrous structure resisted to a prolonged stay in water and in PBS buffer (pH7.4). Cytocompatibility study and cell proliferation tests with fibroblasts NIH3T3 are now in progress in order to evaluate the biological properties of our obtained membranes and will inform on the relevance of this concept of CHT based artificial GAG.

### CONCLUSION

Stable and defect-free nanofibres were obtained by electrospinning of an artificial GAG, synthesized after chitosan modification, mixed with PEO. The obtained membranes are a suitable candidate for tissue engineering application.

## Electrospun Piezoelectric P(VDF-TrFE) Scaffolds and the Effect of Electrical Stimulation for Tendon Tissue Regeneration

Gemma Orpella-Aceret<sup>1</sup>, Marc A. Fernandez-Yague<sup>1</sup>, Matteo Palma<sup>2</sup>, Dimitrios Zeugolis<sup>1</sup>, Abhay Pandit<sup>1</sup> and Manus J. P. Biggs<sup>1</sup>

<sup>1</sup> Network of Excellence for Functional Biomaterials (NFB), National University of Ireland Galway

<sup>2</sup>Department of Chemistry, School of Biological and Chemical Sciences, Queen Mary, London

[gemma.orpella@gmail.com](mailto:gemma.orpella@gmail.com)

### INTRODUCTION

Tendon regeneration remains an important challenge in the field of tissue engineering. Up until recently, materials scientists have concentrated upon the physical characteristics of scaffolds (modulus, strength, stiffness), and more recently on chemistry and nanotopographical modification which can perturb or enhance cellular adhesion<sup>1</sup>.

Piezoelectric materials are promising as they can exploit the loading capacity of tendon tissue to produce stimulating current for tendon regeneration. Evidence is gathering on the complexity of the tendon electromechanical environment, and in particular collagen mediated streaming potentials and electric fields<sup>2</sup>. Polyvinylidene Fluoride Trifluoroethylene P(VDF-TrFE) is a polymer ferroelectric material that has piezoelectric properties that can be used to stimulate tendon tissue regeneration through electrical outputs. These scaffolds were assessed for piezoelectricity and compatibility with human dermal fibroblasts (HDF) and human primary tenocyte cells (HPT).

### EXPERIMENTAL METHODS

P(VDF-TrFE) was dissolved in DMF/Acetone and electrospun into fine fibers by varying the voltage, mandrel rotation speed and the distance between tip and collector with a constant flow rate. The scaffold morphology was studied by Field Emission Scanning Electron Microscopy (FESEM) and the electrical properties in response to cyclic loading were assessed with piezoresponse force microscopy (PFM).

HDF were used for optimization process and seeded onto the scaffolds for 1, 3 and 7 days under static and dynamic loading conditions and glass was used as main control. The cell viability of the cells was assessed by cell nuclei counting, and the metabolic activity of the cells was assessed by alamarBlue<sup>®</sup> assay. The analysis of focal adhesion formation was performed via vinculin labelling and samples were also stained for actin using rhodamine phalloidin and DAPI for nucleus. The alignment of the cells in the scaffolds was assessed using fluorescence images. Subsequent genomic profiling via RT-PCR to assess cell adhesion and phenotype maintenance, respectively with Human Primary Tenocytes was also conducted.

### RESULTS AND DISCUSSION

By varying the electrospinning parameters, it was possible to produced nanofibers with similar dimensions as collagen fibers and what is more, high aligned fibers. Furthermore the electrical output of the scaffold in response to mechanical loading was demonstrated with PFM. Finally, cytocompatibility studies showed high cell viability and alamarBlue<sup>®</sup> assay showed no difference in cell metabolic activity over all time points relative to control. Moreover, the cells growth parallel to the direction of the fibers showing high alignment.

Fig. 1- Characteristic hysteresis loop (butterfly loop) indicating ferroelectricity in PVDF-TrFE fibers.

Fig. 2 – Human dermal fibroblasts cultured on glass, P(VDF-TrFE) aligned and non-aligned scaffolds, showing the alignment of the cells parallel to the direction of the fibers.

### CONCLUSION

P(VDF-TrFE) demonstrate a piezoelectric response has a positive effect on cell adhesion. Moreover, high cell viability and no cell toxicity were confirmed by Live and Dead<sup>®</sup> assay. The scaffolds induced cellular alignment and promoted cell attachment.

### INTRODUCTION

Improving materials for bone regeneration are needed in medicine including prosthetic dentistry. Ameliorating biodegradable and bioactive materials supporting bone regeneration could satisfy this demand.<sup>1</sup>

Aerogels are used, among others, as tissue engineering materials.<sup>2</sup> Calcium phosphates, such as hydroxiapatite (HA) and  $\beta$ -tricalcium phosphate ( $\beta$ TP) have been described as bioactive and osteoinductive materials.<sup>3</sup>

SAOS-2 is a widely used and well characterized osteosarcoma derived cell line for in vitro osteoblast differentiation studies.<sup>4,5</sup>

The aim of this study was to examine newly developed aerogel-based composite materials if they are suitable for bone regeneration.

### EXPERIMENTAL METHODS

Highly porous composite materials made of  $\beta$ TP and/or HA, combined with silica based aerogel, was developed.<sup>6</sup> Five different ratio of  $\beta$ TP and HA was used to prepare this aerogel composite as follows: 100%  $\beta$ TP, 75%  $\beta$ TP and 25% HA, 50%  $\beta$ TP and 50% HA, 25%  $\beta$ TP and 75% HA, 100% HA.

SAOS-2 cells were seeded on the composites' surface. The differentiation of SAOS-2 cells to osteoblast were examined by laser scanning microscopy, qRT-PCR and western blot after 1, 2 and 3 weeks.

### RESULTS AND DISCUSSION

Five differently synthesized aerogel composite materials were used. Confocal imaging and gene expression analyses showed osteoblastic differentiation: collagen I and bone sialoprotein were

secreted and some of the measured osteoblast-differentiation specific gene expression (Runx2, BMP-2, osterix, osteopontin) were changed.

In a preliminary experiment, aerogel composite put into rat femur showed early signs of osteointegration.

Our result suggest that these aerogel-based composite materials are able to trigger differentiating of SAOS-2 cells to osteoblast.

### CONCLUSION

According to the results of our experiments, these aerogel composite materials could be used as a scaffold material for bone regeneration in dentistry.

# Fabrication and Evaluation of $\beta$ -TCP/ZrO<sub>2</sub>-Doped-Phosphate Bioglass Scaffolds for Bone Tissue Engineering

Ena A. Aguilar-Reyes<sup>1</sup>, Criseida Ruiz-Aguilar<sup>1</sup>, Carlos A. León-Patiño<sup>1</sup>, Ana E. Higareda-Mendoza<sup>2</sup>

<sup>1</sup>Instituto de Investigación en Metalurgia y Materiales, Universidad Michoacana de San Nicolás de Hidalgo, México

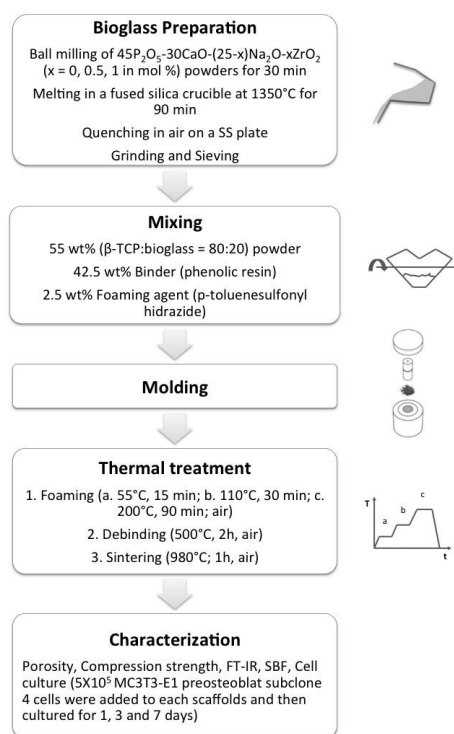

<sup>2</sup>Facultad de Ciencias Médicas y Biológicas, Universidad Michoacana de San Nicolás de Hidalgo, México

[aareyes@umich.mx](mailto:aareyes@umich.mx)

## INTRODUCTION

Scaffolds are an excellent alternative to regenerate bones; for this purpose they have to fulfill requirements such as biocompatibility, osteoconductivity, porosity, mechanical properties, controlled degradation, and formability. Beta-tricalcium phosphate ( $\beta$ -TCP) ceramics are biocompatible and osteoconductive materials that offer a chemical environment and a surface conducive to new bone formation. These are brittle materials and have low fracture resistance. Thus, it is necessary to add reinforcement materials to improve their properties.<sup>1-3</sup>

## EXPERIMENTAL METHODS

## RESULTS AND DISCUSSION

As-sintered scaffolds are presented in Table 1.

**Table 1.** Properties for sintered TCP/bioglass scaffolds.

Scaffold	Porosity (%)	Compression Strength (MPa)
SZ0 (0% ZrO <sub>2</sub> )	68-73	0.6
SZ0.5 (0.5% ZrO <sub>2</sub> )	75-86	1.4
SZ1.0 (1% ZrO <sub>2</sub> )	72-85	2

After immersion of scaffolds in SBF, FT-IR technique corroborated the main groups of HA phase at values of 1382, 1214 y 452 cm<sup>-1</sup> characteristic of CO<sub>3</sub><sup>2-</sup>, 3422 cm<sup>-1</sup> corresponding to OH<sup>-</sup> and 900-1200 cm<sup>-1</sup> corresponding to PO<sub>4</sub><sup>3-</sup>. HA phase can be also observed in the SEM images at 7 days of immersion in SBF, Fig. 1 (b), (d) and (f).

Cell adhesion and interaction with the scaffold surface of MC3T3-E1 preosteoblast subclone 4 cells 3 days is observed in Fig. 1 (a), (c), and (e).

**Fig. 1.** SEM images from as-sintered scaffolds after in vitro acellular and cellular tests.

## CONCLUSION

Beta-tricalcium phosphate mixed with ZrO<sub>2</sub>-doped phosphate bioglass seems to be a promising material for bone tissue engineering applications because of their physical and mechanical properties and biological response.

### INTRODUCTION

Magnetite nanoparticles ( $\text{Fe}_3\text{O}_4$ ) due to their physico-chemical properties currently belong to the most interesting materials considered for applications in medicine and biotechnology. The magnetic nanoparticles possess very low toxicity on the living cells [1]. They are used, among others, to enhance contrast in magnetic resonance imaging (MRI), in drug delivering system, in diagnosis and treatment of tumours [2,3,4]. Magnetite can also be used to modify polymer matrix of implantation materials. This work demonstrates an assessment of thermal and surface properties and also degradation process of composite materials consist of polylactide matrix and 0,5%wt magnetite nanoparticles. Biological tests were performed in MG63 cell cultures

### EXPERIMENTAL METHODS

The influence of added nano-size magnetite nanoparticles on polymer matrix were studied with differential scanning calorimetry (DSC). Composite was incubated in distilled water and artificial biological environment. During incubation measurements of pH and fluid conductivity were performed. The composites surface wettability was studied by measuring the contact angle (static drop method). Free surface energy was determined by Owens–Wendt method using double distilled UHQ water and diiodomethane. The roughness was measured using a static profilometer with ceramic head.

### RESULTS AND DISCUSSION

Thermal analysis confirmed that there were not significant differences between properties magnetite nanocomposites and pure polymer. We noticed slight increase of crystallinity degree (Table 1).

Table 1: Degree of crystallinity for polymer and its composite.

Parametr	PLA	PLA/0,5% $\text{Fe}_3\text{O}_4$
$W_c$ [%]	14,16	15,01

The magnetite addition to PLA does not significantly affect the change of the contact angle (wettability of

materials surface and also the surface tension. The roughness profile for the pure polymer was under 0,2  $\mu\text{m}$ , and the composite value increased to approx. 0,5  $\mu\text{m}$ . We noted slight differences in the values of both the contact angle and the surface roughness for different side of the sample. The pure polymers and composites incubation in water and artificial biological environment by six weeks revealed influence of the materials on the pH and conductivity of the medium. However, the biological study indicated no cytotoxicity effect of polymers and their composites.

### CONCLUSION

The addition of magnetite to the polymer matrix may give new properties. In our study addition of magnetite slightly changed properties of the composite such as surface properties, magnetic, mechanical or biological. We demonstrate that composites with 0,5%wt magnetite nanoparticles are comparatively little better surface properties. Also stable conditions during cell culture confirmed that applied materials can be successfully used as implants. The biological study confirm the materials have no cytotoxic properties. We conclude that polylactide modified with magnetite is biocompatible material.

[fricainj@aol.com](mailto:fricainj@aol.com)

### INTRODUCTION

Development of microvasculature and microcirculation is critical for bone tissue engineering<sup>1</sup>. To resolve the issue of a reduced vascular component, the reproduction of local microenvironment and the organization of cells are regarded as ultimate goals<sup>2</sup>. In biofabrication, parallel to inkjet printing and pressure-operated mechanical extruders, the Laser-Assisted Bioprinting (LAB) is an alternative method for the assembly and micropatterning of biomaterials and cells<sup>3</sup>. This technology allows fabrication of 2 and 3 dimensional tissue engineering constructs<sup>4</sup>. The objective of this work was to pattern Human Umbilical Vein Endothelial Cells (HUVEC) by seeding them on collagen patterns obtained by LAB, in order to promote the creation of tailor-made capillary-like structures with small diameter up to 30  $\mu\text{m}$ .

### EXPERIMENTAL METHODS

The LAB workstation used in this study comprised an infra-red laser ( $\lambda=1064$  nm, 30 ns), focused on a quartz ribbon that was coated with a thin absorbing layer of gold (60 nm) and a 30  $\mu\text{m}$  layer of collagen. This system was used to print collagen type I lines on agarose. HUVECs, obtained from cord blood, were seeded on these collagen patterns. The viability of cells, cytoskeleton and tubular organization were assessed by immunofluorescence at 2h, 24h, 48h and 72h.

### RESULTS AND DISCUSSION

The patterning of HUVECs in collagen was achieved with dimensions of 10mm length and width from 30 to 200  $\mu\text{m}$ .

Figures 1A and 1B show that HUVECs were adherent to collagen patterns after 2 hours in culture, and that morphology of the cells changed after 24 hours, respectively.

Figures 1C and 1D reveal respectively that the patterns were preserved after 48 hours and that HUVECs formed capillary-like structures after 72 hours. Diameter of the structure decreases during the process of cell organization and leads to small capillary-like structure. These results imply that LAB allows printing of collagen with micrometric resolution and organizing HUVECs when seeded on these collagen patterns.

Capillary-like structures can then be created on other hydrogels and will be included in 3D structures in order to promote angiogenesis.

### CONCLUSION

This study demonstrates that LAB is a relevant method for micropatterning HUVECs with an indirect method and is adapted to promote the creation of vascular-like structures and to control their distribution. Moreover, other applications could be developed, namely in neurogenesis.

## INTRODUCTION

The focus of this work is to understand the influence of Sr ions on the physicochemical properties of resorbable biphasic calcium phosphate (BCP) bioceramics composed of a controlled mixture of hydroxyapatite (HAp) and  $\beta$ -tricalcium phosphate ( $\beta$ -TCP) with special emphasis toward degradation. It has been established that HAp and  $\beta$ -TCP differ in degradation rates.  $\beta$ -TCP shows good ability to biodegrade up to 10-20 times faster than HAp, but in an unpredictable manner, so it may not provide solid scaffolding for new bone formation<sup>1,2</sup>. However, BCP is able to gradually degrade, leaving room for natural bone<sup>3</sup>.

In this work, at constant Ca/P ratio, we have varied Sr content and studied physicochemical properties and degradation behaviour of those compositions.

## EXPERIMENTAL METHODS

Calcium deficient hydroxyapatite (CDHAp) powders containing various amounts of Sr were synthesized through neutralization route. Starting suspensions of  $\text{Ca}(\text{OH})_2$  and/or  $\text{Sr}(\text{OH})_2$  were prepared of CaO and/or SrO, and deionised  $\text{H}_2\text{O}$  by “lime slaking” process followed by homogenization in planetary ball mill. Aqueous solution of 2 M  $\text{H}_3\text{PO}_4$  was added to starting suspensions at a slow addition rate ( $\sim 1$  ml/min). Synthesis temperature was maintained constant at 45 °C. Precipitates were left overnight to mature, filtered and dried at 105 °C for  $\sim 24$  h.

Obtained powders were uniaxially pressed ( $p=15$  kN) in cylindrical pellets ( $\varnothing$  20 mm) and sintered in air atmosphere at 1150 °C for 2 h.

Phase compositions of the CDHAp powders, pure BCP and Sr-containing BCP (Sr-BCP) were determined by X-ray diffraction analysis (XRD). Specific surface area (SSA) of the CDHAp powders was determined by BET method using nitrogen ( $\text{N}_2$ ) as an adsorbate. The bioceramics were examined using field emission scanning electron microscopy (FE-SEM) with incorporated energy dispersive X-ray spectroscopy (EDS) for microstructure and chemical analysis, respectively.

For degradation experiments the bioceramics were placed in polystyrene bottles containing Tris-HCl buffer solution. The bottles with the bioceramics and Tris-HCl were maintained at 37 °C for 3, 7, 21 and 28 days, respectively. Microstructural degradation in Tris-HCl was also observed as a function of time. The chemical dissolution of each bioceramic composition was measured by its release of Ca ions into a buffered solution.

## RESULTS AND DISCUSSION

In the case of Sr-containing CDHAp, the XRD peaks were found to be broader and less intense when compared to pure system (Fig. 1). This indicates the reduced crystallinity and size of the Sr-containing CDHAp crystallites due to partial substitution of Ca by Sr. Moreover, XRD analysis confirmed the formation of BCP with different HAp and  $\beta$ -TCP ratios after sintering at 1150 °C depending upon the Sr content.

Fig.1. XRD patterns of pure (green) and Sr-containing (orange) CDHAp powders

*In vitro* degradation tests showed that BCP bioceramics containing Sr is associated with higher degradation and dissolution than pure CaP with the same phase composition.

## CONCLUSION

The results proved that the phase composition of HAp and  $\beta$ -TCP in the prepared bioceramics is dependent on the initial Ca deficiency of the precursor powders. The presence of Sr reduced the nucleation and growth rate of CDHAp crystals when compared to pure system. Results showed that resorbable characteristics of BCP can be tailored by adding Sr.

## INTRODUCTION

One of promising application of hyaluronan (HA) is a development of hydrogel-based materials for use in biomedicine or tissue engineering.

In our previous work we presented new designed hyaluronan-tyramine derivatives (HA-TA), which are capable to form covalently crosslinked hydrogels with addition of horseradish peroxidase (HRP).<sup>1</sup> In this work crosslink reaction is initiated by highly diluted H<sub>2</sub>O<sub>2</sub> or enzymatic generated H<sub>2</sub>O<sub>2</sub>. We designed two systems of H<sub>2</sub>O<sub>2</sub> generators which led to hydrogelation of HA-TA solution. First system used H<sub>2</sub>O<sub>2</sub> generated by reaction of glucose (Glu) catalysed by glucose oxidase (GOx) and the second system used galactose (Ga) catalysed by galactose oxidase (GaO). Advantages and disadvantages of these three systems are evaluated in this work.

**Figure 1** Schemes of H<sub>2</sub>O<sub>2</sub> generation which led to hydrogelation of HA-TA solution.

## EXPERIMENTAL METHODS

Influence of enzymes concentrations (HRP, GaO, GOx) on gelation time and mechanical properties has been studied. The gel point (GP) was measured as the time at which the elastic moduli  $G'$  and viscose moduli  $G''$  were equal. Cross over point was determined at 37 °C. Following parameters were evaluated for hydrogel

mechanical properties: Young's modulus, compressive stress at breaking point and toughness. Measuring of mechanical properties has been repeated 3 times with variability  $\pm 10\%$ .

## RESULTS AND DISCUSSION

In situ forming hydrogels present a valuable system for cell or drug delivery in the field of regenerative medicine. For proper cell proliferation, it is necessary to ensure sufficient mechanical strength of hydrogels. Rapid gel formation prevents undesirable leakage of delivered material out of implantation, which could be used to fill out defects e.g. to regenerate articular cartilage or bone. HRP mediated crosslink of HA-TA derivatives initiated by addition of highly diluted H<sub>2</sub>O<sub>2</sub> leads to formation of hydrogels with desirable properties. The system allows preparation of hydrogels with wide range of mechanical properties from soft, viscous, tough to hard gels, which can be used as cell scaffolds.

The system of Glu-GOx is a promising approach for preparation in situ crosslinkable HA-TA hydrogels, mainly because gelation can occur in contact with human blood. Gelation rate ranges from slow to fast, depending mainly on the enzyme activity (HRP and GOx). This system is suitable for preparation of injectable acellular hydrogels.

Ga-GaO system is more suitable for prolongation of gelation, therefore in most cases also leads to preparation of soft hydrogels. HA-TA hydrogels are prepared by non-cytotoxic reaction that marks them as appropriate for the cell cultivation.

## CONCLUSION

All presented systems are suitable for preparation of biocompatible HA-TA hydrogels with range of mechanical properties from soft to hard and kinetics of gelation from few seconds to minutes. Hydrogels are suitable for in situ gelation and according to the system they could be acellular or contain appropriate cells. All these aspects predispose these materials for use in tissue engineering and regenerative medicine.

## Graphene-based Tissue Engineering Scaffolds Prepared by 3D Printing

Harri Korhonen, Le Hoang Sinh, Nguyen Dang Luong, Jukka Seppälä

Research Group of Polymer Technology, Aalto University, Finland

[harri.korhonen@aalto.fi](mailto:harri.korhonen@aalto.fi)

### INTRODUCTION

Graphene, a two dimensional monoatomic thick building block of a carbon allotrope, has received world-wide attention due to its exceptional properties.<sup>1</sup> In order to fully utilize and further explore new functions of graphene, a number of methods have been developed for fabricating 3D graphene foams. 3D graphene architectures not only have the inherent properties of graphene, but can also exhibit improved functions such as light weight, high porosity, large surface area, high electrical conductivity, and stable mechanical property.<sup>2</sup> As demonstrated in recent studies for mesenchymal<sup>3</sup> and neural<sup>4</sup> stem cells, graphene foams are promising candidates also as tissue engineering scaffolds.

The aim of this study was to investigate the suitability of stereolithography for the fabrication of graphene-based 3D architectures. Tissue engineering scaffolds could thus combine the designed 3D architecture with exceptional inherent properties of graphene.

### EXPERIMENTAL METHODS

Photocrosslinkable resin was prepared by dispersing 1 wt-% of graphene oxide with SLA resin (PIC100, Envisiontec). 3D structures were fabricated by a self-made projection stereolithography. Fabrications were carried out by using light intensity of 1100  $\mu\text{W}/\text{cm}^2$ , layer thickness of 30  $\mu\text{m}$ , and curing time of 7s for each layer. The dimensions of the samples were 10\*10\*4 mm. The designed scaffold model had a gyroid-like pore architecture and porosity of 50 %. After printings the 3D composites were pyrolysed under nitrogen to decompose and evaporate the crosslinked polymer and to convert graphene oxide to reduced graphene oxide (r-GO). In pyrolysis the temperature was stepwise raised up to 500°C during 10 hours.

### RESULTS AND DISCUSSION

Well-controlled 3D structures were obtained with the used fabrication parameters. As seen in figure 1, the prepared scaffolds closely followed the structure of the designed mode. In printed samples the graphene oxide flakes were found to be uniformly dispersed throughout the polymer matrix.

The xy dimensions of the original sample were 10\*10 mm, while after pyrolysis the same dimensions were about 2\*2 mm. Although pyrolysis of polymer matrix caused considerable shrinking, the r-GO scaffold had the similar pore structure as in the original scaffold. Shrinking is obviously due to the small 1 wt-% content of GO used in photocrosslinkable resin. In addition to GO content, shrinking ratio is probably affected by the used sample dimensions and the pore structure.

Figure 1. a) 3D-model, b) printed scaffold

Figure 2. Scaffold a) before, b) after pyrolysis

### CONCLUSION

The results of this study show that stereolithography can be used for the fabrication of graphene-based 3D composites that can be further pyrolysed to reduced graphene oxide scaffolds.

### INTRODUCTION

Cell-based therapies are promising new therapeutic approaches for bone regenerative medicine. The combination of mesenchymal stem cells (MSCs) and bone-graft substitutes offers an advanced strategy for the manufacture of restorative constructs for pathologically altered bone tissues<sup>1</sup>. Due to limitations associated to autologous cellular sources, alternative allogeneic sources have been considered. Human decidua-derived MSCs (hDMSCs) have several advantages (accessible tissue source, ethical aspects, high cell yielding...) over those obtained from human bone marrow (hBMSCs) and are attractive alternatives for tissue engineering purposes<sup>2</sup>. The healing and regeneration process induced by these therapies depends critically upon the MSCs response to the local microenvironment provided by cell-cell, cell-material and soluble factor-mediated interactions. Synthetic porous ceramic biomaterials based in tricalcium-phosphate ( $\beta$ -TCP) and hydroxyapatite (HA) are frequently used in clinical practice due to their biocompatibility, bioactivity and osteoconductive properties. Many studies have addressed the behaviour of BMSCs seeded on calcium phosphate scaffolds but there is very limited information about the growth, osteogenic potential or production of growth- and bone-related soluble factors of hDMSCs. Our study aimed to evaluate the in vitro viability and secretory profile of specific bioactive factors of hDMSCs seeded on calcium-phosphate  $\beta$ -TCP- and HA- based materials. For comparison purposes, hBMSCs and primary human osteoblasts (hOB) were also investigated.

### EXPERIMENTAL METHODS

hDMSCs of maternal origin were isolated from the extra-embryonic decidual membranes in full term human pregnancies and characterized at phenotypic and functional level. hBMSCs were isolated from bone-marrow aspirates obtained from the iliac crest of patients during orthopaedic surgical procedures. Primary hOB derived from osteoarthritic patients undergoing knee arthroplasty were also used. All procedures involving human cells were approved by the corresponding Ethical Committees. Cells were seeded on commercial Polybone ( $\beta$ -TCP-based; Kyungwon Medical Co., Ltd., Seoul, Korea) and commercial

Engipore (HA-based; Finceramica, Faenza, Italy) in block type and shaped in 100 mm<sup>3</sup> pieces. Cells were then seeded on materials and incubated for different time points up to 28 days. Culture medium was changed every 3 days. Metabolic activity was monitored using the Alamar Blue assay and soluble factors levels in culture media were quantified using the CBA Flex Set System (BD Biosciences) and ELISA kits.

### RESULTS AND DISCUSSION

hDMSCs, hBMSCs and hOB were able to adhere and grow on both calcium-phosphate-based materials. Independently of their origin, cells adhered and exhibited a higher growth capability on HA- than on  $\beta$ -TCP-based material. Levels of bioactive factors in culture media were quantified after 7 and 14 days of incubation. Compared to hOB, hDMSCs and hBMSCs released lower levels of IL-6, MCP-1 and VEGF. Secretion profile of these soluble mediators over time was dependent on the cell type and scaffold employed. In general, DMSCs showed good degree of reproducibility, interpreted as similar levels of release, in experiments performed at different cell passages that was not observed for BMSCs. MCP-1 and VEGF release from hDMSCs or hBMSCs after 14 days did not increase after 7 days in culture. However, IL-6 levels in  $\beta$ -TCP/ or HA/hDMSCs derived-culture media increased with time, an effect that was not observed in BMSCs. After 14 days in culture, hDMSCs released higher VEGF levels in HA constructs than in  $\beta$ -TCP-based substrates.

### CONCLUSION

To date, our data suggest that h-DMSCs in combination with commercial HA is a promising strategy for the development of constructs with applications in bone tissue engineering.

## Characterization of Human Neural Networks Cultured on Hydrogel Matrix

Tiina Joki<sup>1</sup>, Laura Ylä-Outinen<sup>1</sup>, Susanna Narkilahti<sup>1</sup>

<sup>1</sup>NeuroGroup/BioMediTech, University of Tampere, Finland  
[tiina.joki@uta.fi](mailto:tiina.joki@uta.fi)

### INTRODUCTION

In future, cell transplantation therapies and sophisticated 3D tissue models could offer clinically relevant treatments or diagnostic tools for patients having currently incurable neural deficits. In both cases, modelling and craft applications, biomaterials can be utilized as extra cellular matrix (ECM) mimicking substance. This artificial ECM serves as supportive growth matrix for the cells and as backbone of 3D cell-material construct. The demands for the optimal biomaterial are quite similar both *in vitro* and *in vivo*. Material needs to be non-harmful, easy to handle and support cell growth and survival. In stem cell based applications it is also desirable that the biomaterial could guide cell differentiation and maturation into desired cell types. Both chemical and physiological properties of the material are important<sup>1,2</sup>. In neural applications the hydrogels are most prominent, due to their properties that are similar as properties of native nervous system ECM<sup>2</sup>.

### EXPERIMENTAL METHODS

Human neural cells were obtained from human pluripotent stem cells by using growth factor based suspension differentiation method. Pre-differentiated immature neural cells were plated on 1) top of the hydrogels, 2) inside the hydrogels, and 3) under the hydrogels. Laminin protein coating was used as positive 2D growth control, non-coated cell culture plastic as negative control and PuraMatrix (BD Bionciences) as positive 3D growth control. Cells were cultured up to 4 weeks in the hydrogel matrix before analysis. The cultures were characterized using fluorescence based viability analysis, immunocytochemical stainings, time-lapse monitoring, confocal imaging and network level electrophysiological measurements (Micro electrode array, MEA).

### RESULTS AND DISCUSSION

Long term culturing of cells was successful either under or on top of the hydrogels (2D cultures) and embedded

inside the hydrogels (3D cultures). Cell viability on 2D cultures either on top of hydrogel surfaces or under the hydrogel block, was similar compared to positive 2D growth control. Viability in 3D cultures was also similar when compared to positive 3D control but lower in both cases when compared to 2D cultures. Hydrogel as growth matrix was able to support neural cell maturation both in 2D and 3D when comparing protein expression using immunocytochemistry.

Based on published literature it seems that human neural cells are more demanding when it comes to artificial ECM if compared to rodent primary neural cells. Finding suitable growth matrix for the neural networks is first step towards functional *in vivo* mimicking 3D cultures. Here we describe testing of one material with promising properties.

### CONCLUSION

According to our *in vitro* results the studied hydrogel was suitable culturing matrix for human neural cells due to it was able to support the neural cell viability, maturation and network formation in long term cultures.

[silvia.fare@polimi.it](mailto:silvia.fare@polimi.it)

### INTRODUCTION

The aim of this study is to evaluate *in vitro* an engineered construct constituted by hPDC populations encapsulated in pectin gels, interpenetrated in a CaPs/PU foam (namely: a functionally-graded hybrid, FGHY) scaffold, for osteogenic purposes<sup>1</sup>.

*In vitro* characterization was performed to assess the potential of the previously optimized FGHY scaffold to support growth and osteogenic differentiation of different hPDC populations when loaded inside the FGHY scaffold via pectin gels.

### EXPERIMENTAL METHODS

Functionally graded CaPs/PU scaffolds were prepared as described in Ref.1<sup>1</sup>. Human placentas (n ≥ 10) were obtained from healthy woman after delivery and processed immediately<sup>2</sup>. Phenotype and morphology of hPDCs were assessed as previously described<sup>3</sup>.

The study of hPDCs *in vitro* differentiation toward the osteogenic lineage was performed as follows: 1) cells seeded in tissue culture plastic plates (as previously described<sup>3</sup>) and 2) cells loaded in pectin gels injected into the FGHY scaffold. hPDC populations were cultured at different time points (at least 1, 2, 3 weeks) to set up and optimize the culture protocol. Alamar Blue assay was used to assess cell viability. Cell colonization and morphology onto the FGHY scaffolds were evaluated by SEM. Cytochemical staining with Alizarin Red was used to assess osteoblast differentiation.

### RESULTS AND DISCUSSION

hPDC demonstrated the ability to differentiate toward the osteogenic lineage *in vitro*, as demonstrated by the presence of calcium deposits detected by cytochemical staining (Fig 1).

Figure 1. Cytochemical staining using Alizarin Red

The proliferation of hPDCs encapsulated in pectin gel interpenetrated into FGHY scaffolds increased over time (Fig 2). Good cell adhesion was observed at 10 days post seeding: hPDCs formed cell extensions, bridging parts of the walls of the pores of FGHY scaffold, as shown by SEM (Fig 3a). At day 17, above

the cell layer, a high deposition of inorganic phase was observed inside the FGHY scaffold (Fig 3b).

Figure 2. Alamar blue assay performed on hPDCs encapsulated in pectin gel and seeded into the FGHY scaffold, compared to the control (cells)

Figure 3. SEM images of hPDCs seeded on FGHY scaffold: 10 (a) and 17 days (b) after seeding

### CONCLUSION

The ability of novel functionally graded CaPs/PU (FGHY) scaffolds to stimulate cell adhesion and proliferation and to support differentiation of hPDCs make these scaffolds excellent candidates for an use in bone regeneration. Differentiation of hPDCs into chondrocytes is now under evaluation to verify the potential of the scaffold for osteo-chondral defect repair.

### INTRODUCTION

Synthesis of materials that mimic the natural bone have become an objective of many research groups. Mimicking the natural bone composition, where the ratio of inorganic to organic phase is high, still is a challenge. It is well known that hydroxyapatite (HAp) is widely used in hard tissue regeneration due to its biocompatibility, bioactivity and osteoconductive properties. However the poor mechanical properties (brittleness and low plasticity) of HAp biomaterials limit their application<sup>1</sup>, thus new materials with improved properties are prospected. Introducing a polymer component into the HAp in order to form an organic-inorganic nanocomposite is a method most commonly used to overcome the mechanical weakness of HAp. Among biodegradable and biocompatible polymers, polyvinyl alcohol (PVA) has attracted attention for cartilage and orthopaedic applications<sup>2</sup>.

The aim of the current study was to combine biological properties of hydroxyapatite with high plasticity of polyvinyl alcohol and *in-situ* develop mineralization method that leads to high affinity integration of HAp particles inside the PVA hydrogel. HAp/PVA hydrogels with Ca/P molar ratio of 1,67 and 1,50 were obtained and characterized.

### EXPERIMENTAL METHODS

The HAp nanoparticles were synthesized *in situ* in the 5% PVA aqueous solution. Briefly, Ca(OH)<sub>2</sub> solution was added to the PVA and stirred for 1 hour. 2M H<sub>3</sub>PO<sub>4</sub> was then added drop wise to the reaction media until Ca/P molar ratio of 1,67 and 1,50 were reached. Finally, reaction media was matured for 12h and five freeze-thaw cycles were applied to obtain the hydrogels. In each cycle samples were frozen at -24°C for 12h and then thawed at room temperature for 12h. Obtained samples were freeze-dried and characterized using X-ray diffraction, scanning electron microscopy (SEM) and Fourier transform infrared spectroscopy.

### RESULTS AND DISCUSSION

Obtained results showed that it was possible to synthesize PVA/HAp composites where inorganic to organic phase ratio was 50:50wt%. Moreover, it was possible to vary the Ca/P molar ratio from 1,67 to 1,50 in the final nanocomposite. It was also found that the

number of freeze-thaw cycles for the hydrogel preparation depended on the Ca/P molar ratio. SEM studies revealed that the HAp particles were dispersed throughout the PVA matrix (Fig.1. A) and porous hydroxyapatite/polyvinyl alcohol nanocomposites can be prepared (Fig 1. B) with pore size ranging from 2-80 µm.

Fig. 1. SEM microphotographs of: A) HAp particles distributed in the PVA matrix; B) cross section of HAp/PVA nanocomposite.

### CONCLUSION

Current research has shown that nanocomposites with high inorganic to organic phase ratio as well as Ca/P molar ratio of 1,67 and 1,50 can be obtained by simple chemical route. The interconnected pore structure indicates that such composites can be promising materials for the cell ingrowth and can be good candidates in bone tissue regeneration.

## INTRODUCTION

During the last years, clay/polymer nanocomposites have received a significant attention as they can combine the structure and physico-chemical properties of organic and inorganic materials<sup>1</sup>. Modifying clays with biopolymers such as chitosan can be utilized to prepare polymer/clay nanocomposites for bio-applications<sup>2-4</sup>. Intercalants could increase interlayer distance of the clay. In modification process, intercalants should have opposite charge with clay surface to occur ionic exchange reaction between intercalants and clay layers<sup>5-7</sup>. Chitosan is a cationic biopolymer that was used to modify montmorillonite with negative charge<sup>5-6</sup>. In this study, bio-modified nanoclay was obtained by chitosan intercalation. Chitosan is a crystalline polysaccharide which is obtained by deacetylation of chitin, the second most abundant natural polymer<sup>6</sup>. Chitosan has been one of the most attractive biopolymers due to its remarkable properties such as; biocompatibility, biodegradability and antibacterial activity<sup>4-6</sup>. Polymer/clay nanocomposites are widely used in various fields such as; medical, drug delivery, wound healing and tissue engineering<sup>7</sup>. This study aims to incorporate chitosan molecules in the multilayer structure of montmorillonite nanoparticles and examine the antibacterial properties for tissue engineering applications.

## EXPERIMENTAL METHODS

### Materials

Chitosan with medium molecular weight was obtained from Sigma-Aldrich (Germany). Acetic acid (AA) was purchased from Merck (Germany). The montmorillonite -type clay utilized for this research supplied by Rockwood from USA.

### Preparation of chitosan/ montmorillonite nanoparticles

One gram of montmorillonite powder was dispersed in deionized water under magnetic stirring and two gram of chitosan powder was separately dissolved in 1% v/v acetic acid aqueous solution with the same condition. Then, chitosan solution was slowly added to montmorillonite solution. After the heat treatment, the mixture solution was centrifuged and washed with distilled water.

## RESULTS AND DISCUSSION

The interlayer expansion or d-spacing of unmodified montmorillonite and chitosan/ montmorillonite nanocomposite were determined by x-ray diffraction (XRD). As shown in Fig.1 XRD patterns demonstrated that peaks of montmorillonite and chitosan/ montmorillonite was at  $2\theta = 7.8^\circ$  (d-spacing=1.128 nm) and  $2\theta=3.7^\circ$  (d-spacing= 2.365 nm), respectively.

Figure 1: XRD patterns of montmorillonite and chitosan/ montmorillonite.

The XRD data was confirmed that chitosan molecular chains incorporated between the interlayer of montmorillonite by an ionic exchange reaction. In addition, the antibacterial properties of the modified nanoparticles indicated that the incorporation of chitosan molecules effectively induce a significant antibacterial properties which is useful for tissue engineering applications.

## CONCLUSION

The intercalation of chitosan biopolymer into montmorillonite, through ionic exchange method, resulted in polymer/clay nanocomposite which can be used in range of applications particularly in biomedicine. Intercalating chitosan molecular chains between montmorillonite layers increased the d-spacing which was shown by XRD data. The antibacterial results suggested that the modified nanoparticles can be used as an antibacterial agent for tissue engineering applications.

## INTRODUCTION

During the last decade, fabrication of nanofibrous scaffolds has gained a great deal of attention due to their high potential of mimicking extracellular matrix (ECM) <sup>1</sup>. Nanofibers provide high aspect ratio, high interconnected porosity and low density which are essential factors for increasing cell adhesion leading to enhanced cellular migration, differentiation and proliferation<sup>2-3</sup>. Among different methods electrospinning is promising and progressive technique to fabricate nanofibers<sup>4</sup>. In addition, this method makes it possible to produce nanofibrous scaffolds from different categories of non-polymeric materials, natural and synthetic polymers <sup>5-6</sup>. Preparation of nanofibrous scaffolds by electrospinning of polymer blends has specific properties which can be used in biomedical applications<sup>3-4</sup>. This paper reports a study to fabricate chitosan/PVA nanofibrous scaffolds by electrospinning method. Chitosan is a polysaccharide derived by deacetylation of chitin. It has different biological properties including: biodegradability, biocompatibility and antibacterial activity<sup>4-6</sup>. As well, PVA is a non-toxic, hydrophilic, and biocompatible material that has also been used for tissue engineering applications<sup>3-6</sup>. In this study, different amounts of chitosan were added as a polymeric blend into the structure of PVA nanofibrous scaffolds to observe the changes associated with this blending process on the physic-chemical characteristics of the final scaffolds.

## EXPERIMENTAL METHODS

### Materials

Chitosan with medium molecular weight was purchased from Sigma-Aldrich (Germany). PVA with average molecular weight and acetic acid (AA) was obtained from Merck (Germany).

### Preparation of chitosan/PVA nanofibers

PVA was dissolved in distilled water at a concentration of 5 wt% and chitosan was dissolved in 90 % acetic acid at a concentration of 3 wt%. The PVA solution 5 wt% was mixed with the chitosan solution 3 wt% at a weight ratio of chitosan/PVA (20/80). For electrospinning process the solutions were fed into the syringe pump, the applied voltage was 20kv, the feeding rate and the tip to collector distance was set at 0.02 mm/min and 10cm, respectively.

## RESULTS AND DISCUSSION

The morphology and microstructure of nanofibers were evaluated by scanning electron microscopy (SEM). As shown in Fig.1 in chitosan / PVA blend (weight ratio 20/80), the average fiber diameter was found to be  $79.85 \pm 21.21$  nm while in PVA and chitosan alone, the average fiber diameter was  $173.7 \pm 24.52$  nm and  $97.41 \pm 25.22$  nm, respectively.

Figure 1: SEM micrograph of the electrospun nanofibers. a)chitosan, b)PVA, c)chitosan/PVA(20/80)

In Fig.1 (a) droplets and beads are diffused on the surface and fibers are scarcely noticeable. While in chitosan/PVA (20/80) blend Fig.1(c) uniform and thin fibers are observed. The chitosan-containing scaffolds were used for *in vitro* cell culture, and they were found to exhibit the most balanced properties to meet the basic required specifications for tissue engineering applications. It was demonstrated that the addition of chitosan to the PVA scaffolds enhanced the differentiation and proliferation of the cells compared to PVA nanofibrous scaffolds and acted as a positive cue to support neurite outgrowth, indicating that the addition of chitosan to the PVA scaffolds is a promising polymeric blend suitable for tissue regeneration.

## CONCLUSION

In this study, chitosan/PVA nanofibrous scaffolds were produced by electrospinning method. Chitosan/PVA ratio of 20/80 was recognized as the optimum ratio for fabrication of nanofibrous scaffolds with uniform morphologies and minimum beads and defects which can be utilized in a variety of fields such as; medical, drug delivery, wound healing and tissue engineering.

## INTRODUCTION

The regeneration of critical size bone defects requires the use of implants/scaffolds able to instruct cells towards new bone formation by the release of suitable chemical signals. In this respect, hydroxyapatite phases (HA) endowed with low crystal order and multiple substitutions of calcium and/or phosphate with ions relevant for the regeneration processes (e.g.: magnesium, carbonate) are elective biomaterials for bone healing due to their high mimicry with the composition of newly formed bone.

Multiple substitutions with biologically-competent ion amounts can provide synergistic effects towards improved efficiency in bone regeneration. Moreover, nowadays interest is raising for the effect of ions with specific antibacterial effect, to be exploited in bioactive and osteointegrative coatings that may greatly improve the performance of metallic implants that very often undergo early failure due to the formation of biofilms.

In this respect the substitution of Calcium ion with Zinc in the HA lattice has recently attracted a lot of attention for its effect as substituting ion into the HA lattice due to their antibacterial properties.

Besides, Gallium is considered very promising for antibacterial activity but its effect when used as doping ion in biomimetic hydroxyapatite has not yet been thoroughly investigated. In this respect the present paper reports the synthesis of a new apatite containing both Mg and CO<sub>3</sub> ions as well as gallium ions in amount that can be suitable for exhibiting antibacterial effect.

## EXPERIMENTAL METHODS

New biomimetic HA phases with multiple ion substitutions were synthesized as nano-powders by the simultaneous dropping of H<sub>3</sub>PO<sub>4</sub> and NaHCO<sub>3</sub> in a stirred suspension of Ca(OH)<sub>2</sub>, MgCl<sub>2</sub> and Ga(NO<sub>3</sub>)<sub>3</sub> or Zn(NO<sub>3</sub>)<sub>2</sub> at the temperature of 40°C.

At the end of the synthesis the solution was stirred for 2h and left overnight for maturation. Then the product was washed 3 times with fresh water and dried in a ventilated oven at 40°C.

The as-synthesized materials were analyzed by X-Ray Diffraction (XRD), ICP-OES, Fourier Transform Infra-Red spectroscopy (FTIR), Thermo-Gravimetric Analysis (TGA).

## RESULTS AND DISCUSSION

The XRD analysis shows that all synthesized powder are composed by only low-crystallinity hydroxyapatite phase without the presence of any other calcium phosphate phase and exhibiting nanosize, as evaluated by both SEM and Scherrer equation. The elemental analysis by ICP and XRD analysis both confirmed the incorporation of the foreign ions in the HA lattice.

Together with TGA, used for the determination of carbonate, ICP shows that in respect of a high Ca/P ratio, the ratio of total cations/anions is always lower than 1,67 and this ratio is closer to natural bone.

The FTIR and TGA analyses reported qualitatively and quantitatively the effective carbonation in B position (i.e. substituting PO<sub>4</sub><sup>3-</sup> in the HA lattice).

## CONCLUSION

Various multi-substituted HA powders also containing Zn and/or Ga ions were successfully synthesized and characterized. These powders have Mg<sup>2+</sup> ions substituting Ca<sup>2+</sup> in biologically-competent amounts (i.e. Mg<sup>2+</sup>: 1-10 mol% and CO<sub>3</sub><sup>2-</sup>: 5-20 mol%).

The presence of Zn<sup>2+</sup> or Ga<sup>3+</sup> in the amount of 1-10 mol% and 1-5 mol%, respectively, have been determined and we have proved that, as the doping with Zn<sup>2+</sup> and Ga<sup>3+</sup> is competitive with the entering of Mg<sup>2+</sup>, the anionic substitution with CO<sub>3</sub><sup>2-</sup> results not affected.

These preliminary results encourage to further investigation to assess the actual antibacterial effect of these new materials and to test them as coatings for metallic implants/protheses.

## INTRODUCTION

In modern implantology special attention is paid to a long-standing problem of rapid degradation and progressive dysfunction implants. The cause of reoperation is mostly lack of proper interaction between bone tissue and the implant [4]. Appropriate combination of the two most important factors: the implant surface, the type of intermediate layer and the proper relation between implant deformation and bone tissue should allow to obtain the optimal solution to the problem of the bone and implant interface interactions [5]. The aim of this paper is theoretical analysis and the evaluation of biomechanical and biochemical conditions for the proper formation of the outer layer and the structure of the implant.

Modern implantology is dominated by components made from metallic materials. Because of structural role of bone, most commonly in the manufacture of implants metallic biomaterials was used [1]. Most willingly titanium alloys and austenitic steels are used. Alloys of aluminum and vanadium as documented cases of dissolution of Al and V, while it has been proven that Al affects on the development of Alzheimer's disease, and V is characterized by high cytotoxicity. In the new alloys generation included those having a lower modulus of elasticity and greater biotolerance, it is worth mentioning also highly biocompatible and osteoconductive [5]. Research on the quality of implants alloys of these metals is being conducted.

Condition for obtaining osseointegration of the bone implant is the formation of a hematoma, and it is converted into fibrous tissue. To osseointegration occurred it should be retained certain conditions, among others, the relative relationship of deformability and avoiding stress shielding in the surrounding the implant bone tissue as well as biocompatibility. Proper relationship of deformability is obtained by appropriate selection of the mutual stiffness (modulus of elasticity, shape cross-sectional geometry). Consequently with the occurrence of the phenomenon of bone remodeling - to adapt the structure of the bone to the current state of stress (Wolff's law), it is important that the size of the stresses after implantation was not different significantly from the state before the implantation [1]. In the case of the strong connection of the implant and bone, can be assumed that both materials are subject to the same deformation.

The ideal implant should have a modulus similar to the bone module, and occupy not greater area than the replaced tissue [3]. Currently the material that minimizes or would obviate the problem of stress-shielding is looking for. On the other hand, too large susceptibility of placed in medullary canal implant causes the existence of significant shear stresses in the boundary

layer, which destroys fresh tissue structure. As a result of the large difference in the deformability of the implant and bone it comes between them to micromovements. If these movements exceeding 100  $\mu\text{m}$  it may results in proliferation of connective tissue instead of the desired bone tissue leading to impaired mechanical stability. Moreover, they become the cause of the destruction of the fiber network and the new blood vessels [2]. The strength of the connection between the bone and the biomaterial should be close to the strength of the bone tissue. Today it is one of the weakest links in implantation.

## CONCLUSION

There are no documented studies that have shown clearly how to solve this problem. The analysis shows, however, that one of the conditions of use of hydroxyapatite is to reduce the hardness and brittleness. Conducted a study on the activation of collagen making hydroxyapatite structure similar to bone structure. The alternative seemed to be a layer of nanocrystalline diamond. Unfortunately, the diamond is too hard and too little resistant to abrasion. The analysis shows that the optimum solution would be implant made of titanium alloys containing Ta, and Nb-coated titanium oxide with the shaping of the open pores with appropriate sizes depending on the type of implant and the bone tissue quality. The hope are layers applied with sol-gel method, involving hydroxyapatite or metal oxides. As a result, the layers are obtained with greater flexibility and reduces the susceptibility to brittle fracture layer. Research follow in the direction of interaction studies on samples and tests shear strength, stretching and bending.

### INTRODUCTION

Osteonecrosis of femoral head (ONFH) is irreversible disease which treatment is almost depending on total joint replacement. The synergistic effect by co-transplantation of adipose-derived stromal cells (ASCs) in enhancing the osteogenic differentiation of bone marrow stromal cells (BMSCs) proved in critical sized calvarial defect model of rat in our previous study<sup>1</sup>. The purpose of this study was to evaluate the effect of co-transplanted ASCs and BMSCs at the ratio of 0.5 to 1 to heal the osteonecrotic lesion created in the minipig.

### EXPERIMENTAL METHOD

Six female minipigs (age: 23 to 25 months, weight: 55 kg) were used in this study. We made ONFH model on both hips of minipig with surgical procedures. Also we harvest bone marrow and adipose tissue. In laboratory, ASCs and BMSCs were co-cultures and transplanted to ONFH portion of minipig sealing with fibrin glue. In control hip, we only sealing with fibrin glue.

After transplantation of cells, we checked x-ray every 4 weeks. At 12 weeks, we sacrificed all the animals. The femoral heads were harvested and examined grossly. The specimen underwent computed tomography and histological examination.

### RESULTS AND DISCUSSION

In the results of x-rays and CT, defect of cells transplantation group was complete healed up with new bone tissue while control group had unfilled bone defect. Histological findings also corroborated the radiological findings. In the cell transplantation group, great number of regenerated trabecular bone rimmed with abundant osteoblast. In the control group, the lesion was principally filled with fibrotic or fatty tissue

### CONCLUSION

We observed very rapid and good quality osteogenesis in combined ASCs and BMSCs implantation group compared with control group.

### INTRODUCTION

Worldwide 500,000 cases of head and neck cancer are diagnosed each year<sup>1</sup>. After carcinologic surgery, the reconstruction of the mandible is often required. The technique of reconstruction described by Masquelet with the induced membranes is one of the strategies, but still exhibits limitations in an oncological context. The aim of our project is to develop an injectable osteoinductive and osteoconductive composite polymer composed of doped strontium hydroxyapatite (HA) dispersed within a polysaccharide-based scaffold<sup>2</sup> to fill the induced membrane instead of autologous bone. The aim of this work is 1) to synthesize and characterize HA doped by strontium with different ratios of strontium (Sr); 2) associate these nanoparticles with polysaccharide-based scaffolds, 3) analyze *in vitro* the cellular responses of mesenchymal stem cells (MSC) and progenitor endothelial cells (PEC) seeded within this matrix and then, 4) evaluate the fate of this composite polymer subcutaneously in mice.

### EXPERIMENTAL METHODS

**Synthesis of HA or Sr-doped HA:** HA was synthesized by wet chemical precipitation at 40 or 90°C. Different ratios of HA/Sr were tested (8 and 50 % w/w). **Characterization of HA or Sr-doped HA:** X-ray diffraction (XRD), Inductively Coupled Plasma (ICP) and Transmission Electronic Microscopy (TEM) were used to characterize the HA particles. **Cell culture and matrices seeding:** MSC were isolated from human bone marrow stromal cells according to our previous work<sup>2</sup> and PEC were obtained from human umbilical cord blood according to our previous work<sup>3</sup>. **MSC and PEC behaviour within the 3D scaffold:** After 7 and 14 days, Live/Dead Assay was used to confirm the viability of cells cultured within the composite polymer. Bone markers (runx2, ALP, OCN) and endothelial cells markers (CD31, VE-cadherin, vWF) were analyzed and quantified by quantitative polymerase chain reaction (qPCR). **Non osseous implantation of composite matrices in mice (subcutaneously):** Matrices were inserted into subcutaneous pockets in the dorsum of 12-week-old Balb/c mice. After 15 and 30 days samples were collected and analysed by micro-CT and histologically. **Micro-computed tomography (micro-CT):** Micro-CT was performed *ex vivo* and cross sectional slices were reconstructed (resolution: 14 µm, software: Microview). **Histological procedure:** Fixed samples

were decalcified, dehydrated and paraffin-embedded. Sections were then stained with Masson's Trichrome.

### RESULTS AND DISCUSSION

TEM analyses of HA particles revealed that whatever the temperature, HA forms aggregates constituted by 50 to 150 nm particles. Live/Dead Assay confirmed the cells viability of MSC and PEC cultured within 3D scaffold after 14 days of culture. HA particles were then dispersed at different ratios within the polysaccharide and analyzed by ESEM and ICP. Preliminary *in vivo* data (**Fig.1**) suggest that the composite polymer developed with a final ratio of 1.4% (w/v) of Sr within the matrix is able to stimulate tissue mineralization (**Fig.1A**), once implanted in ectopic site. Histological analyses confirmed the presence of osteoid structures within the implant (**Fig.1B**). Controls were performed using the polysaccharides based scaffold polymer (PUDNA) alone and using the scaffold supplemented with undoped HA (PUDNA-HA).

**Fig. 1**

### CONCLUSION

In conclusion, the use of osteoinductive composite scaffold doped with Sr could be an alternative of the autografts supplemented with BMP2 for the regeneration of large bone defects in a carcinological context.

### INTRODUCTION

Induced pluripotent stem (iPS) cells present great promise for future applications in personalized regenerative medicine, since they can be obtained from any adult tissues. On the other hand providing 3D biomaterial-based microenvironmental conditions, has proved to have protective and supportive functions for transplanted stem cells. We are currently investigating the mutual relationship between a collagen scaffold seeded with human iPS cells (or their committed progeny) and organotypic slice cultured neural tissue derived from the central nervous or dissociated peripheral nervous system neurons. For this purpose, collagen scaffolds seeded with iPS-derived neural cells were co-cultured with organotypic spinal cord slices or dorsal root ganglion explants. This system can be used to investigate aspects of CNS neuroregeneration by assessing cell developmental processes such as migration and neuronal outgrowth in 3D ex-vivo scenarios.

### EXPERIMENTAL METHODS

The porous, 3D collagen scaffolds were made from porcine collagen using a lyophilisation technique<sup>1</sup> and modified by carbodiimide cross-linking to provide appropriate thermal and mechanical properties. Prior to cell seeding, scaffolds were functionalized by incubation in a laminin-containing solution for 2h. A human iPS cell line was obtained from CD34+ cells of human cord blood using seven episomally expressed vectors (Oct4, Sox2, Klf4, c-Myc, Nanog, Lin28, and SV40 T) (Gibco). iPS cells were neurally committed according to Yan et al.<sup>2</sup> and further differentiated and seeded onto the laminin-functionalised modified collagen scaffolds. Such hybrid cell-scaffold preparations were co-cultured with organotypic spinal cord slices<sup>3</sup> or dorsal root ganglion (DRG) neurons for investigation of cell migration between the nervous tissues and the scaffold for up to 2 weeks culture. In order to track or identify the iPS-derived, neurally differentiated cells, green fluorescent CMFDA tracer or alternatively the anti-human mitochondria antibodies were used.

### RESULTS AND DISCUSSION

The iPS cells in serum-free and feeder-free culture conditions presented the markers of pluripotency (Oct4, Sox2, Nanog) while upon the neural differentiation

acquired nestin,  $\beta$ -tubulin III, MAP-2, Dcx, GFAP, GalC and PDGFR $\alpha$ , as revealed by immunocytochemical and RT-PCR analyses.

Seeding 3D collagen scaffolds with undifferentiated, iPS cells resulted with low cell attachment, limited viability, and limited differentiation, while iPS-derived neural stem cell (NSC) populations colonized the scaffold in a well defined manner. NSC progenitors adhered to the collagen scaffolds without losing differentiation markers, but did not show signs of migration. Moreover, laminin-functionalization of the scaffold enhanced neurite outgrowth from dissociated DRG neurons into the biomaterial. When scaffolds and iPS-derived cells hybrids were co-cultured with rat organotypic spinal cord (OSC) slices, migration of slice-derived cells into the scaffold was observed while there was no migration of human NSC from the scaffold into the tissue explant. This may be due to strong adhesive interactions between the iPS-derived cells and the supporting biomaterial niche.

### CONCLUSION

The highly porous collagen scaffolds/cell hybrids used in this study are suitable for testing mutual interactions between human iPS (and neurally committed iPS-derived cells) and organotypic CNS slices or dissociated PNS neurons. The uni-directional migration from the spinal cord organotypic slice into the biomimetic cell-seeded scaffold should be further investigated for exploitation in a range of tissue engineering and regenerative medicine applications.

## INTRODUCTION

Biomimetic nanofibers are becoming more and more popular for manufacturing tissue engineering scaffolds. Such types of materials offer new concepts and methods to design nano-biomimetic tissue Extracellular Matrix. At present, the ECM in a body is essentially constructed by nanofibrous network containing protein and glycosaminoglycans, with a diameter ranging from 50 to 300 nm<sup>1,2</sup>. An optimal scaffold should mimic the native ECM. It was already proved that the scaffold consisted from nanofibrous structure has improved the application of tissue engineering scaffolds to bone, cartilage, cardiovascular and nervous tissue regeneration with less scars<sup>3</sup>. Numerous findings support the hypothesis that fibrous carbon components can act as chondrogenic materials<sup>4</sup>. The carbonaceous materials, including carbon fibers and carbon nanotubes were successfully applied in the treatment of cartilage defects. The work describes experiments, results and selected characteristics of ex-PAN carbon nanofibers in the form of thin mesh as potential materials to support cartilage cell growth at nano scale.

## EXPERIMENTAL METHODS

A polyacrylonitrile copolymer consisting of 93-94 wt % acrylonitrile, 5-6 wt % methyl methacrylate and 1 wt % sodium allylsulfonate (Mavilon, Hungary) was used as carbon nanofiber precursor, and N,N-dimethylformamide (DMF) (POCH, Poland) as the polymer solvent. Spinning solutions were prepared by dissolving polyacrylonitrile powder in a determined amount to obtain a solution of the desired concentration. The PAN nanofibers were spun using a laboratory electrospinning set-up. Mechanical properties (tensile strength and elastic modulus) of samples prepared in the form thin mesh were determined in tensile uniaxial mode using Zwick testing machine model 1435. Prior to carbonization, PAN nanofibers were preliminarily oxidized in air followed by heat treatment up to 1000°C. To characterize the surface morphology of the nanofibers before and after carbonization, a scanning electron microscope (SEM; Nova Nanos 200, FEI COMPANY EUROPE) was used. The samples obtained were studied to determine fiber diameters and porosity of the resulting mesh samples. The contact angle of samples was measured by sessile drop method using an automatic drop shape analysis system DSA 10Mk2 (Kruss, Germany). Cytotoxicity of carbon fibrous samples was determined by indirect and direct contact cytotoxicity tests in accordance to EN-ISO 10993.

## RESULTS AND DISCUSSION

The fibrous material microstructure was visualized by SEM as shown in Fig.1. Depending on the processing parameters various samples were obtained and analyzed.

Fig. 1 SEM microphotographs of a) PAN nanofibers and b) ex-PAN carbon nanofibers

Results of the study demonstrated the increased elastic modulus and strength with a greater surface density of fibrous structure and its preferred nanofiber orientation (anisotropy). Carbon nanofibrous materials have been tested in contact with normal human cells chondroblasts. In vitro cytotoxicity and cell viability showed a high biocompatibility of the materials studied.

## CONCLUSION

By changing the processing parameters during electrospinning it was possible to change properties and microstructure parameters of fibrous mesh including nanofibers diameter, pores size, total porosity and preferred orientation of single nanofibers of mesh-based scaffolds. The results indicate that carbon fibrous samples differing in their microstructure perform good biocompatibility in contact with human chondrocytes and provide structures which seem to be promising as scaffolds to regenerate defective cartilage. Tunable mechanical properties of nanofibrous samples indicate the need for further study of such materials to optimize their properties for cartilage engineering scaffolds.

### INTRODUCTION

Skin is the largest and critically important organ of the body that serves as a physical barrier to the outside world, takes role in controlling the body temperature and hydration levels<sup>1</sup>. When these functions are damaged due to burns, diseases or other skin problems, wounded area become very susceptible to the bacterial infection which may result in extensive tissue loss. In such extreme cases routine applications cannot help to tissue restoration and regeneration. As alternatives, tissue engineering approaches are promising solutions. However, design of a bi-layer matrix having both the dermis and epidermis layers with proper functionality is still challenging<sup>2</sup>.

In this current study, a bilayer skin model was produced to mimic the natural organization of the skin. Thin layer collagen foams with small pores and suitable degradation rate will serve as the epidermis layer, which would enable oxygen permeability and prevent microbial infection. Sodium carboxymethyl cellulose (NaCMC) foams having larger pores and high water retention capacity are aimed to form the dermis layer, which would keep the hydration levels in required ranges and be scaffold for the cells to attach and proliferate for regeneration of the skin. To mimic the skin, human keratinocytes and dermal fibroblasts are loaded to the bilayer scaffolds.

### EXPERIMENTAL METHODS

Collagen solution was prepared in acetic acid, frozen at -80°C and lyophilized. Foams were crosslinked by dehydrothermal treatment (DHT) at 140°C for 24 h, and/or *via* glutaraldehyde (Glu) treatment. NaCMC solutions were prepared in distilled water and lyophilized and crosslinked with epichlorohydrin and by DHT at 140°C for 3 h. All samples were examined with stereomicroscope and SEM. *In situ* degradation profiles were studied by incubating the samples in PBS (pH 7.4) for two weeks. Enzymatic degradation of the collagen foams was also studied by incubating in Collagenase Type II (0.1 mg/mL in PBS pH 7.4) for 3 h at 37°C. At predetermined time points, the samples were taken out, lyophilized and weighed. Material loss was determined gravimetrically. Swelling of the NaCMC foams were determined after incubating in PBS pH 7.4 for 24 h, at 37°C. Weights of the samples were recorded in dry and swollen form. For the tests of biocompatibility, human keratinocytes (HS2) were seeded in the epidermis (collagen) layer, and human dermal fibroblasts (Detroit 551) were seeded in the dermis (NaCMC) layer with different seeding protocols. Cell attachment, proliferation and distribution within the scaffolds were examined.

### RESULTS AND DISCUSSION

SEM and stereomicroscopy images showed that NaCMC-5 (prepared from 5% solution) foams prepared at -80°C and -20°C yielded sheet like or circular pores, respectively (Figure 1A and B). *In situ* degradation profiles of all NaCMC foams were similar ( $p \leq 0.05$ ), where they lost about 35% of their initial weights after 14 days of incubation in PBS. For this reason, NaCMC-5 foams frozen at -20°C were chosen for the rest of the study to prepare bilayers. Bilayer structures were prepared by combining NaCMC-5 foams at bottom and collagen foams at top (Figure 1C). Collagen foams were highly stable *in situ* and against Collagenase type II enzyme and more than 80% of their initial weights remained after two weeks and 3 h of incubations, respectively. Cell culture and co-culture studies revealed that with earlier seeding of keratinocytes and subsequent seeding of dermal fibroblasts, it was possible to maintain the cellularized bi-layered skin like structure for up to 14 days.

**Figure 1:** SEM images. A) Frozen at -80°C, B) Frozen at -20°C, and C) Collagen and NaCMC-5 bilayer.

### CONCLUSION

Collagen foams with small pores and demonstrating certain stability in *in situ* PBS media as well as for enzymatic degradation were obtained to serve as the epidermis layer of the skin. NaCMC-5 foams that have uniform and interconnected pores and appropriate stability *in situ* were used as dermis layer. High water retention capacity of NaCMC-5 foams was suitable for hydration needs of the dermis layer. For the construction of the bilayer skin structures, the results are promising.

## INTRODUCTION

The development of radically new materials for biodegradable and bioresorbable implants in bone repair seeks to overcome the disadvantages implicit in the use of permanent implants. The challenge is to produce a material that is suitable to be replaced by mature bone without transient loss of mechanical support. Biodegradable polymers and magnesium (Mg) alloys have played an important role writing the history of resorbable implants. Very recently, a novel approach has emerged that consists on the development of polymer/Mg<sup>1</sup> composites as new bioresorbable materials for temporary medical applications.

This work elucidates the degradation behaviour of PLDA/Mg composites processed by injection moulding. Their degradation mechanism, morphological changes and mechanical performance under *in vitro* test conditions are studied. The effect of the crystallinity degree of polymeric matrix and Mg content on the degradation behaviour of these novel composites is also evidenced.

## EXPERIMENTAL METHODS

PLDA/Mg composites with 0.2 and 1 wt % of Mg content were manufactured by injection moulding. Two types of materials were studied: As injected samples (Q), which are amorphous materials with a very low crystallinity degree ( $f_c \approx 0.10$ ), and thermally treated samples (TT), which are materials subjected under a thermal treatment at  $125 \pm 1$  °C for 1 hour that yields a crystallinity degree close to 0.45.

The degradation behaviour of PLDA/Mg composites was followed by measuring the hydrogen release, pH evolution, mass variation and water accumulation during 3 weeks. Morphological changes were followed by optical microscopy. The change in mechanical properties was measured under compression tests before and after *in vitro* testing.

## RESULTS AND DISCUSSION

Hydrogen evolution rate is larger for materials with a higher crystalline degree and with higher amount of Mg (Fig 1). The higher hydrogen release and mass loss of crystalline composites in comparison with amorphous ones could be due to the non-uniform distribution of water within the semi-crystalline matrix. The preferential diffusion of water through the amorphous domains can induce a localized corrosion on Mg particles that enhances their degradation rate.

The pH of the immersion media that simulates the physiological environment remains neutral throughout the test.

Mg degradation takes place prior degradation of the polymeric matrix. Mg particles at the surface react with immersion media faster than particles localized at composite's core. The strength retention properties of the composites are highly dependent on the crystallinity degree of the polymeric matrix. After 3 weeks, amorphous composites show 100% strength retention, whereas thermally treated composites lost 20% of stiffness and 15% of compressive strength.

Fig 1. Accumulated amount of hydrogen released as a function of immersion time in PBS

## CONCLUSION

PLDA/Mg composites present controllable degradation rates that can be customized through polymeric matrix crystallinity or Mg particles content. Considering the *in vitro* results, these novel materials have great potential to be used as future materials for biodegradable implants.

## INTRODUCTION

The cell–substrate interaction is known to play an important role in spatio-temporal behavior of cells such as migration. The cell migration is essential for various biological processes including wound healing and tissue formation, immune response. However, there are only a few studies to investigate multi-cellular motility. In this study, we proposed a new method to quantify the effect of surrounding cells on direction of cell migration using chondrocyte migration on fibroin and ProNectin substrate as an example.

## EXPERIMENTAL METHODS

Chondrocytes harvested from rabbit joint were seeded on fibroin coated plates and ProNectin coated plates, and time-lapse phase contrast images were acquired during a 24-hour culture ( $n = 6$  for fibroin and  $n = 5$  for ProNectin). Every cell was tracked manually, and position data of each cell was measured. The effect of the nearest cell position on direction of migration was evaluated by *direction index*, which is the cosine of the angle between velocity vector and the relative position vector of the nearest cell (Fig.1). *Direction index* was stratified into six classes by the distance from the nearest cell to distinguish taxis from other phenomena. *Direction index* more than 65  $\mu\text{m}$  away from the nearest cells was stratified by the contact. Welch's t-test was performed for *direction index* in each class with a significance level of 0.05.

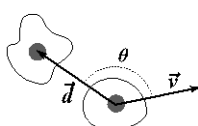

$$\text{direction index} = \frac{\vec{d} \cdot \vec{v}}{|\vec{d}| |\vec{v}|} = \cos\theta$$

Fig.1 Mathematical explanation and schematic drawing of *direction index*.

## RESULTS AND DISCUSSION

The cells less than 52  $\mu\text{m}$  away from the nearest cells on fibroin had higher *direction index* than that of ProNectin (Fig.2). Conversely the cells more than 65  $\mu\text{m}$  away from the nearest cells on fibroin had lower *direction index* than that of ProNectin (Fig.2). The *direction index* was different between the cells with the nearest cells in 65–78  $\mu\text{m}$  without contact on fibroin and those on ProNectin (Fig.3). This may suggest that some kind of taxis on chondrocyte migration may exist. One possible explanation for this interaction is the chemotaxis. Some growth factors and cytokines are reported to induce chondrocyte migration<sup>1</sup>. Another possibility is the influence of cell traces. For example, *P. aeruginosa* is reported to use its traces for the

guidance cues<sup>2</sup>. As chondrocytes produce cell traces composed of actin and integrin as they migrate<sup>3</sup>, there is a possibility that chondrocytes use traces on their migration.

Fig.2 *Direction index* stratified by the distance from the nearest cells. (\*:  $p < 0.05$  by Welch's t-test)

Fig.3 *Direction index* more than 65  $\mu\text{m}$  away from the nearest cells stratified by the contacts. (\*:  $p < 0.05$  by Welch's t-test)

## CONCLUSION

We proposed *direction index* to quantify the effect of surrounding cells on direction of cell migration, and used it to analyze chondrocyte migration on fibroin and ProNectin substrate. From this analysis, we suggest the existence of taxis on chondrocyte migration.

### INTRODUCTION

In recent years, autologous cell implantation has gotten a lot of attention as cartilage repairing treatments. It has been reported that chondrocytes cultured in the silk fibroin sponge form cell aggregation and synthesize cartilage matrices without dedifferentiation<sup>1</sup>, but so far the mechanism of aggregation has not been clarified yet. In this study, the cell migrations are classified by the cell distance, and the relationship between migration speed and direction of the cell migration was investigated.

### EXPERIMENTAL METHODS

The chondrocytes harvested from joints of 4-week-old Japanese white rabbits were once subcultured and were seeded on culture dishes coated with fibroin substrate and with ProNectin substrate. The chondrocyte migration was observed with time-lapse microscopy for 24 hour (n=6 for fibroin, n=5 for ProNectin), and the position of each cell was acquired manually. We analyze this position data using *field direction method*<sup>2</sup>, which is a new analysis method explained as following; a certain cell are focused on and relative position vector ( $\mathbf{d}$ ), velocity vector ( $\mathbf{v}$ ) of other cells toward the focused cell and their crossing angle ( $\theta$ ) are calculated (Fig.1-a), and repeat the same process focusing on the other cells (Fig.1-b). Two kinds of velocity, absolute and relative velocity, were applied to velocity vector. These data acquired here were classified into four classes by the relative distance ( $|d|$ ).

Fig.1 Schematic drawing of *field direction method*.

### RESULTS AND DISCUSSION

As shown in Fig.2, the regression coefficients of migration speed against direction were negative in the distance in 0–20  $\mu\text{m}$  class on both substrates. We called this phenomenon ‘*negative speed polarization*’<sup>3</sup> where the cell approaching speed is higher than that repulsing speed.

In comparison of absolute speed with relative speed, the average relative migration speed on fibroin was reduced by the cell distance. This may suggest co-migration of cells on fibroin substrate. There was a possibility that

this co-migration behavior on fibroin substrate promoted cell aggregation. In previous research, ProNectin substrate tends to show higher cell-substratum adhesive force than that of fibroin substrate<sup>4</sup>. Taking the above into consideration, different behaviors of the chondrocytes on two substrates were thought to be causally related to different adhesive force.

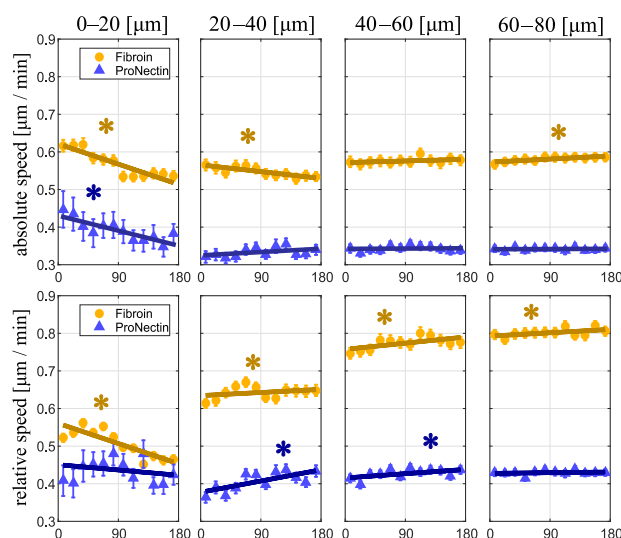

Fig.2 Classified chondrocytes' average migration speed and regression line on fibroin and ProNectin. (Error bars represent 95% confidential intervals. \*:  $p < 0.05$  of regression coefficients by t-test)

### CONCLUSION

The ‘*negative speed polarization*’ where the cell approaching speed is higher than that repulsing speed, was observed by *field direction method* on fibroin and ProNectin substrate. And co-migration behavior of the cells, where the averaged relative migration speed was reduced by the cell distance, was also observed on fibroin substrate.

[selcen.alagoz@metu.edu.tr](mailto:selcen.alagoz@metu.edu.tr)

### INTRODUCTION

Bone defects related with trauma, aging, diseases, tumors, and nonunion fractures increasingly create health problems. Each year, over 6.2 million bone fractures happen in the U.S. and 10% of them do not properly heal because of delayed union or non-union. Also, osteoporosis currently affects 10 million people and this is estimated to increase to 14 million by 2020<sup>1</sup>. Wet spinning is a simple approach that, does not require elaborate equipment and its products have pores and gaps that are randomly distributed and not uniform in size.

In this study, a poly(3-hydroxyalkanoate)-poly(lactic acid) (PHA-PLA) blend was used to fabricate a wet spun scaffold for use in bone tissue engineering. An elastin like recombinamer (ELR) with REDV sequences specific for endothelial cells<sup>2</sup> was introduced to the scaffold to make it attractive for endothelial cells so that it can be vascularized as needed in a thick implant which otherwise cannot maintain the viability of the cells that have penetrated deep into the scaffold.

### EXPERIMENTAL METHODS

PHA-PLA scaffolds were produced by wet spinning, mechanical properties were measured under compression, and fiber morphology and porosity were determined by SEM and micro CT. Scaffold chemistry was modified by exposing to oxygen plasma and contact angles were determined with a goniometer. After oxygen plasma treatment, surface of the fibers was coated with ELR by dip coating technique. Staining with Toluidine Blue and FTIR-ATR analysis were used to show the protein presence on the surface.

### RESULTS AND DISCUSSION

Average fiber diameter of the scaffolds was measured with NIH imageJ program as 100  $\mu\text{m}$ .  $\mu\text{-CT}$  images showed well defined, interconnected 3D structure with a porosity of approximately 77% (Figure 1).

**Figure 1:** Microscopic images of PHA-PLA scaffolds. Stereomicroscope (a) top, and (b) side views of scaffold. SEM micrographs (c) top view (scale bar: 1 mm), and (d) top view at higher magnification fibers (scale bar: 200  $\mu\text{m}$ ).

The ultimate compressive strength of the dry scaffolds under compression (5 mm/min) found to be  $1.25 \pm 0.10$  (MPa). This result indicated that PHA-PLA wet spun scaffolds are too soft for cortical bone and compact bone. The contact angle of the PHA-PLA films decreased from  $83^\circ$  to  $63^\circ$  after oxygen plasma treatment ( $p \leq 0.05$ ) indicating that the wettability of PHA-PLA blend was improved. Blue stains on the surface of ELR attached PHA-PLA films were observed after treatment with Toluidine Blue. FTIR-ATR showed that upon treatment with  $\text{O}_2$  plasma new peaks at around  $1530\text{ cm}^{-1}$  and  $1650\text{ cm}^{-1}$  were observed due to stretching of the carbonyl groups. After ELR attachment, these peaks became more intense. This was probably due to the amide I and amide II groups of ELR attached onto the PHA-PLA film<sup>3</sup>.

### CONCLUSION

The results of this study indicated that wet spinning technique could be used to obtain highly porous fiber mesh scaffolds from PHA-PLA blend. Compression test results showed that samples could more suitable for use non load bearing application. Plasma modification made the PHA-PLA surfaces more hydrophobic when compared with untreated PHA-PLA scaffolds and therefore they are more suitable for bone tissue engineering.

### INTRODUCTION

Hydroxyapatite (HAp) and calcium phosphate (CaP) have been successfully used as bone graft materials for the regeneration of bone defects due to their physical and chemical properties and their structural similarity to natural bone. CaP-based materials possess bioactive, biocompatible, and osteoconductive properties. CaP-based materials have been approved by the Food and Drug Administration (FDA) for clinical applications in the fields of dental and orthopedic surgery <sup>1</sup>.

On the basis of these results, we hypothesized that a CMC-based hydrogel containing BioC (biphasic calcium phosphate (BCP); tricalcium phosphate (TCP): hydroxyapatite (HAp) = 70:30) and bone morphogenic proteins-2 (BMP-2) would promote greater bone formation in a rat tibial defect model than would a CMC-based hydrogel containing BioC without BMP-2<sup>2</sup>.

### EXPERIMENTAL METHODS

**Animal study.** Eight-week-old Sprague-Dawley rats (Orient Bio Co., Seongnam City, Korea) were used for the in vivo evaluation of CMC/BioC, CMC/BioC/BMP-2 (0.1 mg), and CMC/BioC/BMP-2 (0.5 mg) groups.

**Plain Radiographs & Microcomputed Tomography (Micro-CT) Evaluation.** At 4 and 8 weeks after injection, samples were fixed in 3.7% paraformaldehyde solution. Radiographs of the specimens were obtained with a plain radiograph apparatus (In Vivo DXS 4000 Pro System, Carestream Health, Rochester, NY, USA), bone volume was obtained with a micro-CT system (Albira II Imaging System, Carestream Health). The CT image analysis was performed with a bone analyzer (Molecular Imaging Analysis software; Carestream Health Inc., Woodbridge, VA, USA).

**Histological Study.** The specimens were retrieved at 4 and 8 weeks. After decalcification, the samples were embedded in paraffin. The tissues were cross-sectioned at an 8  $\mu$ m thickness in the longitudinal parallel direction and stained with hematoxylin and eosin (H&E) and Masson's trichrome staining.

**Statistical Analysis.** Data are presented as mean  $\pm$  standard deviation. Statistical comparisons were carried out via one-way analysis of variance using Systat software (Chicago, IL, USA). Differences were considered statistically significant at  $*P < 0.05$  and  $**P < 0.001$ .

### RESULTS AND DISCUSSION

At 4 weeks after surgery, the plain radiographs revealed no mineralization at the defect area for the CMC/BioC group but slight mineralization for the CMC/BioC/BMP-2 (0.1 mg) and CMC/BioC/BMP-2

(0.5 mg) groups. At 8 weeks after surgery, both the CMC/BioC/BMP-2 (0.1 mg) and CMC/BioC/BMP-2 (0.5 mg) groups showed much more mineralization than did the CMC/BioC group. All three groups showed much greater mineralization at 8 weeks than at 4 weeks.

	BV/TV(%)		Tb.Th(mm)	
	4 week	8 week	4 week	8 week
CMC/Bio-C	36.22 $\pm$ 1.29	44.89 $\pm$ 2.24	32.91 $\pm$ 4.25	34.42 $\pm$ 4.05
BMP-2(0.1mg)/CMC/Bio-C	39.24 $\pm$ 1.19	*52.27 $\pm$ 3.16	*42.06 $\pm$ 3.27	*45.10 $\pm$ 2.06
BMP-2(0.5mg)/CMC/Bio-C	**48.53 $\pm$ 1.25	**67.46 $\pm$ 3.0	*51.13 $\pm$ 2.78	**66.08 $\pm$ 4.14

Table 1. Bone formation and bone remodelling. BV: Bone volume, TV: Total volume, Tb.Th: Trabecular thickness.

Our results suggest that CMC/BioC/BMP-2 hybrid materials induce greater bone formation at an earlier stage through release of BMP-2 than CMC/BioC hybrid materials. However, our in vivo study has some limitations. For example, long-term evaluation greater than 8 weeks is needed to compare the quality and architecture of new bone formation between control and implanted groups. More comprehensive analyses that include the histology and angiogenesis of new bone and biomechanical testing are needed. Finally, the effects of long-term release of BMP-2 require further investigation.

### CONCLUSION

CMC/BioC/BMP-2 (0.5 mg) hybrid materials implanted in a rat tibial defect model led to greater bone formation than did CMC/BioC and CMC/BioC/BMP-2 (0.1 mg) hybrid materials. Thus, CMC/BioC/BMP-2 hybrid materials may be useful in an injectable substrate for the clinical application of the regeneration of bone defects in the orthopedic field.

### INTRODUCTION

Dental implant has become a major treatment for lack of teeth. As the implant is inserted to alveolar bone directly, it lacks periodontal ligament (PDL) that can be got the feeling such as chewiness and firmness of foods and can prevent the infection. Moreover, in the case of the decreasing the alveolar bone for supporting the implant, the enlargement of bone is needed before or at the same time of implant treatment. Here, we investigated the reconstruction of the unit of periodontal tissue, including the alveolar bone, PDL matrix, and artificial tooth, as a novel treatment for periodontal tissue, expecting to implant it into the lack of alveolar bone. In this study, we prepared the decellularized mandible bone remained the PDL matrix and evaluated the reconstruction of the unit of periodontal tissue using artificial tooth, focusing the adhesion of PDL matrix and artificial tooth.

### EXPERIMENTAL METHODS

The units of mandible bone with molar were harvested from mouse. They were treated by high hydrostatic pressure and washed in order to remove the cells from tissue<sup>1)</sup>. After additional treatment of detergent, the molar were pulled out from the decellularized units. The decellularization was evaluated by H-E staining and DNA quantitation. For *in vitro* and *in vivo* study, PDL fibroblasts were harvested from rat PDL. The cells were seeded on the decellularized PDL matrix that was remained on the decellularized alveolar bone. After seeding of rat PDL fibroblasts to decellularized PDL matrix, they were implanted under the renal capsule of rats. As a model of artificial molar, molars that were obtained from decellularized units were used. They were demineralized and recalcified by alternate immersion of CaCl<sub>2</sub> in Tris-HCl and Na<sub>2</sub>HPO<sub>4</sub> solution<sup>2)</sup>. The recalcified molars were inserted to recellularized PDL matrix on decellularized mandible bone *in vitro*. They were implanted under the renal capsule of rats for three weeks. The adhesion of recalcified molar and decellularized PDL matrix were evaluated by H-E staining.

### RESULTS AND DISCUSSION

The units of mandible bone with molar were decellularized by high hydrostatic pressure treatment. In the case of the molar was pulled out from the mandible bone, the PDL matrix was usually attached on the molar. On the other hand, by detergent treatment before the pulling out the molars, the PDL matrix was

maintained on the mandible bone after molar extraction. In order to evaluate the recellularization of decellularized PDL matrix by PDL fibroblasts, the cells were seeded on the decellularized PDL matrix. The PDL fibroblasts were observed not only on but also inside the decellularized PDL matrix, although the orientation of the cells were not similar to original tissue. The decellularized mandible bones with PDL matrix were implanted under the renal capsule of rats after seeding the PDL fibroblasts. Three weeks after implantation, they were not observed the inflammation and absorption under renal capsule. Many cells were observed in decellularized PDL matrix. Moreover, the orientations of the cells in PDL matrix were similar to original, indicating the cells oriented along the collagen fiber of PDL matrix.

As a model of artificial molar, we here used the molars that were pulled out from decellularized mandible bones in order to fit the decellularized mandible bones. The molars were demineralized and recalcified by alternate immersion treatment. The observation of scanning electron microscope showed that the surfaces of recalcified molar were covered with calcium phosphate. The recalcified molar was inserted to decellularized mandible bone, and they were implanted under the renal capsule of rat. The artificial molars were adhered to PDL matrix on decellularized mandible bone. It indicated that the artificial tooth was able to adhere to the decellularized mandible bone by recellularization of the decellularized PDL matrix. Moreover, this result shows the surface characteristics of artificial tooth for adhesion to PDL matrix. For a future work, the artificial tooth that has an appropriate shape prepared by CAD/CAM would be needed surface modification to induce the adhesion to PDL matrix.

### CONCLUSION

Decellularized mandible bone with PDL matrix could reconstruct the unit of periodontal tissue using artificial tooth model. It suggested that it would become a novel treatment for periodontitis and mandible bone defect.

## INTRODUCTION

Extracellular matrix (ECM) scaffolds prepared by tissue decellularization preserve the composition, mechanical integrity, and biological activity of the native ECM. While ECM scaffolds are commonly used for various tissue reconstructions, including skin, muscles, bone, cartilage, trachea, lung or heart, there is little evidence of their use in CNS tissue reconstruction. The aim of this study is to prepare injectable ECM hydrogels from CNS and non-CNS tissues and compare their physical, biochemical and biological properties in vitro.

## EXPERIMENTAL METHODS

Four types of ECM hydrogels were prepared by the decellularization of porcine brain (BM), porcine spinal cord (SCM), porcine urinary bladder (UBM) and human umbilical cord (WJM)<sup>1</sup>. All materials were characterized in terms of their residual DNA concentration as well as their collagen and glycosaminoglycans content. The morphologies and mechanical properties of the hydrogels were characterized by scanning electron microscope (SEM), atomic force microscopy (AFM) and rheometry. The viability and migration of MSCs isolated from bone marrow (BM MSCs), adipose tissue (ASCs) and Wharton jelly (WJ MSCs) were evaluated using a WST assay and xCELLigence system. The neurotrophic properties of ECM hydrogels were assessed on dorsal root ganglion (DRG) explant cultures.

## RESULTS AND DISCUSSION

All ECM hydrogels showed a three-dimensional porous fibrillar structure (Fig.1). In terms of composition, WJM hydrogels contained the highest concentration of sulphated glycosaminoglycans and collagen.

Fig. 1. SEM images of ECM hydrogels from porcine brain (BM), spinal cord (SCM) and urinary bladder (UBM) and human umbilical cord (WJM).

## CONCLUSION

All types of ECM hydrogels promoted the proliferation and migration of hMSCs. Moreover, all types of ECM also promoted massive neurite sprouting out of DRG explants.

### INTRODUCTION

Mesenchymal stromal cells (MSC) – are currently a focus of many intense studies worldwide, aiming on both defining their nature and developing cell-based therapies for regenerative medicine (1). The constantly increasing use of human MSC (hMSC) in clinical trials calls for the development of robust, reproducible and, most importantly, safe methods for the expansion of these cells. Fetal bovine serum (FBS), despite many disadvantages such as its high variability between batches and ill-defined composition, still remains widespread applied as a medium supplement for hMSC cultures (2,3). SCC (supplement for cell culture) is a novel xeno-free cell culture supplement under development at Grifols that supports the growth of hMSC and several other cell lines (4). SCC is obtained from well-controlled human plasma starting material through Cohn-Oncley industrial plasma fractionation and manufactured under GMP rules.

### EXPERIMENTAL METHODS

hMSC of different origin (bone marrow, umbilical cord and adipose tissue) were purchased from commercial suppliers (Lonza and Promocell); furthermore non-commercial bone marrow-hMSC from 28-year old male donor were obtained from blood bank. Cells were cultured in home-made xeno-free media formulations supplemented with SCC for several passages and then characterized. Cell viability and cell yield were assessed with an automated cell counter. Immunofluorescence staining was used to qualitatively determine hMSC-characteristic cell markers. hMSC were further brought under adipogenic, osteogenic, chondrogenic and neurogenic differentiation. Differentiation was assessed by observation of cell morphology changes and by specific staining procedures. In addition, SCC was tested as a supplement for cryopreservation medium for hMSC.

### RESULTS AND DISCUSSION

The hMSC cultured in media supplemented with SCC maintained correct morphology and the expression of a set of characteristic surface markers. They were positive for CD29, CD44, CD90, CD105, CD146, CD166, and Stro-1, whereas they were negative for CD14 and CD19. hMSC cultured in SCC-supplemented media were characterized by an elongated, spindle-shaped morphology. The growth rates of hMSC cultured in xeno-free formulations were in general comparable to the ones observed in non xeno-free media – either commercial or home-prepared.

In SCC-supplemented media the growth of umbilical cord-hMSC was faster than BM-MSC and AT-MSC, which confirms the well-described high proliferation potential of neonatal MSCs. Moreover, their potential to differentiate into adipogenic, osteogenic, chondrogenic and neurogenic lines was preserved. Figure 1 shows AT-MSC brought under respective differentiation assays. The results of the present study imply that SCC possesses a high potential as a supplement for hMSC xeno-free culture media.

### CONCLUSION

hMSC were successfully expanded in SCC-supplemented xeno-free media formulations while maintaining their phenotype and differentiation potential. SCC can be considered a potential candidate for cell culture supplement in advanced cell therapies.

### **INTRODUCTION**

Biocompatibility is an essential characteristic that all biomaterials must have for their use in the field of tissue engineering<sup>1</sup>. One type of widely used biomaterials are hydrogels matrices, however their preparation involves mixing of various additives, which increase the risk of inducing cytotoxicity<sup>2</sup>. Hemocompatibility tests are important because they allow to evaluate the potential damage of blood cells due to its exposure to biomaterials<sup>3</sup>. Therefore, in this study three different hydrogels based on Polyethylene glycol (PEG) were studied.

### **EXPERIMENTAL METHODS**

PEG-chitosan, PEG-arm, and PEG-4000 hydrogels were embedded in blood samples from healthy volunteers. Subsequently, they were evaluated under the following *in vitro* hemocompatibility studies: hemolysis assay and platelet aggregation in blood samples of healthy volunteers, according to ISO 10 993-4 (1992). The authors certify that all research was done under full compliance with the Helsinki Declaration (2013).

### **RESULTS AND DISCUSSION**

Qualitative evidence of hemolysis was negative in samples that were in contact with the polymeric biomaterials. In the quantitative study it was found that all hydrogels exhibited less than 5% hemolysis. The higher hemolysis value was 1.72% in samples that were in contact with PEG-arm hydrogel (Fig. 1). In the study of platelet aggregation cells displayed a very similar morphology compared with the negative control and agglomerates were not observed (Fig. 2).

Fig.1. Direct *in vitro* hemolysis assay based on ISO 10993-4 (1992). A) Quantitative evaluation: 5% of human red blood cells (RBC) were incubated in direct contact with PEG hydrogel samples (60 min, 37 °C). The average absorbance of the positive control (+C) is considered as 100% hemolysis and the average absorbance of the negative control (-C) is considered as 0%, for each sample (n=3, *t* test: *p*<0.05). B) Qualitative assessment. Each tube contains 5% of RBC and (a) PEG hydrogel sample (b) isotonic saline solution (-C) and (c) distilled water (+C).

Fig 2. Micrograph of wright-stained platelet rich plasma (PRP) smear. Human platelets were in direct contact with PEG-chitosan hydrogel showing non-aggregated and rounded platelet. It indicates the absence of platelet activity (wright staining)

PEG has the characteristic of reducing cell adhesion<sup>4</sup>, this characteristic make it an excellent biocompatible material. In this study PEG-arm showed the higher percentage of hemolysis in direct contact with blood cells, this could be due to the additives used in the synthesis process. Although, the results showed that all PEG hydrogels guarantee a percentage of hemolysis below five and can be considered compatible with RBC.

### **CONCLUSIONS**

Studies showed that PEG based biomaterials are hemocompatible as they do not damage erythrocytes or platelets in the conditions studied, therefore PEG hydrogels have promising potential for their use in tissue engineering. Finally, it is necessary to expand studies evaluating blood cells in direct contact with PEG hydrogels and generate studies to study leukocyte behaviour in direct contact with PEG biomaterials.

[agirotti@bioforge.uva.es](mailto:agirotti@bioforge.uva.es)

### INTRODUCTION

Shoulder pain is the third most common musculoskeletal pathology, the rotator cuff injury affects more than 40% of patients over 60 years and causes disabling pain and loss of shoulder functionality<sup>1</sup>. Despite the recent improvements and advances in the surgery, there remains a failure rate of between 20% and 70%. To obtain the tendon repair augmentation new treatment strategies are directed to reinforce the mechanical properties and the biological healing capacity by implanting matrices, although the currently in use cause inflammatory reaction<sup>2</sup>. In this study we employed a modified version of an advanced matrix that has been demonstrating high efficiency as bioactive support<sup>3</sup> in regenerative medicine. It belongs to a family of (ELRs) the Elastin-like recombinamers with high mechanical performance designed as injectable thermogelling systems<sup>4</sup>. The matrix was co-injected with rabbit bone marrow mesenchymal stem cells (rMSCs), under physiological conditions to evaluate the effect of cell therapy on the tendon pathology.

### EXPERIMENTAL METHODS

ELRs were produced by DNA recombinant techniques and *E. coli* biosynthesis. Rabbit mesenchymal stem cells (rMSCs) were obtained from rabbit bone marrow and BrdU stained. New Zealand rabbits with critical defect in the infrapinatus tendon were randomly allocated into 3 groups (negative control, treated with ELRs matrix, treated with ELRs matrix and rMSCs). At 4 and 16 weeks the animals were sacrificed and their tendons removed to perform biomechanical tests and immunohistochemical analysis.

### RESULTS AND DISCUSSION

This study describes the use of injectable thermogelling scaffold whose applicability is focused specifically on regenerative medicine. The scaffold generated "in situ" under physiological condition was assayed in combination or not with rMSCs for an artificial matrix that improved tendon repair capacity. The results at 4 and 16 weeks were compared with which obtained adding ELR matrix and with the normal healing process the after injury of the infrapinatus tendon in rabbits.

Fig. Showed the BRdU stained rMSCs and the ELR matrix after 1 month in the rabbit tendon implantation.

In this work we observed a stronger and more physiological infrapinatus tendon repair using allogeneic rabbit mesenchymal stem cells in combination with an innovative ELRs thermogelling scaffold.

### CONCLUSION

The thermo-gelling property of the ELRs matrix has greatly facilitated the surgical technique as it is easier to handle (for injection), especially when used arthroscopically. The effects of adding rMSCs embedded in a matrix of ELR for the tendon suture repair of the infrapinatus tendon has been studied in New Zealand rabbits. The rMSCs showed a high proliferation rate in the ELRs matrix when implanted in the tendons and a reinforced structural was obtained as was proved through the biomechanical, histological and immunohistochemical assays.

## INTRODUCTION

Increasing activity and popularity in extreme sports is causing more injuries within the population and those requiring transplants often outlive the transplants [1]. With limited supply of both autograft (the gold standard) and allografts, an alternative is required that can replace damaged bones, leading to advances required to scaffolds and stem cells [2]. Ideal cell scaffolds require excellent biocompatibility and biodegradability, as well as sufficient porosity for transport of nutrients and waste. They should also have the ability to be moulded into different sizes and shapes [3]. One problem with current alginate scaffolds is the low viability of cells growing on the scaffolds [4]. The scaffold design that is proposed here is a way around this problem which involves the use of biodegradable strontium cross-linked alginate microfibers, made into porous scaffold structures to promote cell growth and potentially for the use of directing stem cell growth in tissue engineering.

The aim of the project is to create porous structured microfiber with tunable stiffness to promote targeted cell differentiation.

## EXPERIMENTAL METHODS

1.8% Alginate solution used to create microfibers by using a microfluidic device with a flow focusing T-junction combined with a narrow focal aperture to allow the formation of microbubbles within the microfibers. Microbubbles created with the use of N<sub>2</sub> and the microfibers gelled in a 0.1 M strontium chloride (SrCl<sub>2</sub>) solution.

Stiffness of the alginate microfibers was measured via nanoindentation using atomic force microscopy (AFM). The internal structure of the microfibers was characterised using scanning electron microscopy (SEM).

## RESULTS AND DISCUSSION

It was found that the stiffness of the fibres can be modulated with the inclusion of microbubbles. The stiffness ranges seen in the microfibers are from 65 mN/m for a plain microfiber, down to 30 mN/m for the largest diameter microbubble of 320 µm.

SEM analysis of the microfibers shows that the microfibers are highly porous (figure 1).

Figure 1: Shows the SEM of microbubbled microfibers. Left shows the voids created during the gelation process of the microfibers. Right shows the porous matrix of the microfiber.

MG63 human osteosarcoma cells were seeded upon the fibres and incubated for several days. It was found MG63 cells adhered and grew on the microbubbled regions but die on the plain regions (figure 2), suggesting the softer bubble regions may promote cell spreading and hence growth.

Figure 2: shows MG 63 cells stained with calcein AM and ethidium homodimer 1 (live/dead stain) after culture on fibers for 5 days. Cells stain red (dead) on plain microfiber (left) and green (alive) on microbubble microfibers (right).

## CONCLUSION

We have created highly porous alginate based scaffolds with the inclusion of microbubbles. The inclusion of microbubbles allows modulation of regions of stiffness to promote cell adhesion and proliferation on the surface.

### INTRODUCTION

In order to obtain biphasic scaffold for osteochondral lesions treatment combining two types of materials differing in structure and mechanical properties is required: the first one intended to replace bone tissue, while the second one of hyaline cartilage. Producing stable connection between them is a great challenge<sup>1</sup>. The aim of this study was to assess possibility of fabrication of hydrogel osteochondral plug with gradually changing level of mineralization. This approach can eliminate delamination occurring between two types of materials: with and without mineral phase. Further advantages of using hydrogels in this application are: biocompatibility, biodegradability, high water content and close fitting to implantation site<sup>2</sup>.

### EXPERIMENTAL METHODS

In the experiments polysaccharide gels containing 0.7% gellan gum (GG), 2.5 mg/ml alkaline phosphatase (ALP) and 0.03% CaCl<sub>2</sub> were used. After casting and gelation the samples were enzymatically mineralized by incubation in 0.1 M calcium glycerophosphate (CaGP) for 3 days. Enzymatic activity of ALP led to creation of inorganic orthophosphate group from CaGP and precipitation of the minerals inside the structure of polysaccharide hydrogel matrix<sup>3</sup>. To obtain gradient of mineralization, it was required to limit above mentioned reaction to only one part of the gel. This was achieved by closing the sample in a container that provided access to mineralization solution only from one side. Progress in mineralization was assessed by dry mass percentage measurement. Chemical composition in different parts of the material was measured by SEM/EDX method. Young's modulus and topography of native gels in aqueous environment were measured by atomic force microscopy (AFM, MFP 3D; Asylum Research, Santa Barbara, USA). Force-distance curves and Young's modulus maps were collected as well. Biological response to the produced samples was assessed in contact with osteoblast-like MG-63 cells. Viability, proliferation and morphology of the cells were assessed by Alamar Blue and live-dead tests.

### RESULTS AND DISCUSSION

Thanks to proposed method it was possible to produce mineralization gradient across the hydrogel material. This gradient was stronger in the samples with higher ALP concentration.

AFM measurements revealed that mineralized part was significantly stiffer than non-modified part of GG gel

(0.8 kPa and 32 kPa, respectively). Stiffness maps showed that mineralization was inhomogeneous at the nanoscale. The depth on which mineralized phase was formed did not exceed 2 mm due to CaGP diffusion limitation inside mineralized "outer part". Formed mineral phase prevented ALP release outside the gel thus provided preferable conditions to form higher mineralization gradient.

Differences in mineral phase concentration and stiffness between two phases were correlated with biological response of MG-63 cells. Sharp transitions of cell number and morphology were noted at the interface: non-mineralized – mineralized part of GG. Basically cells adhered and proliferated better on mineralized side of the gel, exhibited higher viability and had morphology of those growing on control tissue culture polystyrene (TCPS).

### CONCLUSION

Presented approach based on preventing substrate diffusion into deeper parts of the material seems to be one of the easiest production methods of gradiently mineralized hydrogels. This method preserves continuity of hydrogel matrix therefore eliminates delamination that may occur when two different types of materials are connected. Thanks to the blockage of ALP diffusion by inorganic precipitates it is possible to obtain strong transition between two phases of resulting material. However most notable limitation is that such method does not provide possibility to form thicker mineral phase. Biological response of osteoblast-like cell was considerably better on mineralized side of the samples.

## INTRODUCTION

In modern dental prosthetics, a special emphasis is put on the aesthetics of the reconstruction of both dental cavities, as well as permanent prosthetic restorations<sup>1</sup>. Translucency of the material of which the construction of prosthetic restoration is made is very important for their appearance, and thus for the ability to reproduce natural teeth by artificial crowns<sup>2</sup>.

The issue is important because in recent years the biggest effort of prosthetic materials producers is directed to improve the aesthetic qualities of dental restorations, which mainly depend on the optical properties of materials used<sup>3</sup>.

The objectives of the study described in the article consisted in comparing optical characteristics of selected Y-TZP materials used for manufacturing of permanent prosthetic restorations using CAD/CAM methods, as well as an attempt to determine the relationship between translucency and selected physical properties and microstructure of Y-TZP ceramics.

## EXPERIMENTAL METHODS

Comparative studies were based on the following zirconia ceramics: TZ and Zpex (Tosoh), N-100 (Saint Gobain), Prettau (Zirconzahn), CH (Jiazuo Wein) and TI (Treibacher AG) from which disc-like test samples ( $\phi 20\text{mm}$ ) were prepared in accordance with the manufacturer's instructions. The apparent density of the materials were determined by hydrostatic weighing. The evaluation of translucency and color was carried out by spectrophotometric method. Observation of microstructure was performed by scanning electron microscope with field emission. The grain size distribution of zirconia ceramics was verified by stereological method and the equivalent grains diameter  $E(d_2)$  was determined by planimetric method using computer image analysis.

## RESULTS AND DISCUSSION

Test results of apparent density showed that Zpex, CH, and TI materials were characterized by densities  $6,09 \div 6,10 \text{ g/cm}^3$ , which is a good standard in the group of Y-TZP ceramics<sup>4</sup>. The group of materials characterized by lower density ( $6,04 \div 6,07$ ) consist of TZ, N100 and Prettau ceramics.

Observations with the use of scanning electron microscope, showed significant differences in the microstructure what indicate differences in homogeneity of each material. The most dense materials (Zpex, Prettau), are characterized by a homogeneous microstructure without visible molding errors. A characteristic feature of the microstructure of TZ material consists of a large amount of small pores

(less than  $1\mu\text{m}$ ) occurring uniformly in the sample volume. In the case of TI the presence of large amount of isomorphic  $3 \div 5\mu\text{m}$  size pores and the lack of small pores of less than  $1\mu\text{m}$  has been observed. N100 is the least dense of all the materials tested. Many large pores of various shapes and sizes greater than  $30\mu\text{m}$  are present in its volume. Pores with sizes up to  $40\mu\text{m}$ , in the form of cracks and crevices, straight and branched can be observed as well.

On the basis of microscopic images of polished and etched cross sections of tested materials it can be concluded that all Y-TZP ceramics are characterized by fine-grained microstructure of varying size and isomorphic-shape grains. Excessively grown grains and grains of elongated shape have not been spotted. Equivalent grains diameter  $E(d_2)$  of tested materials comprises between  $0,19\mu\text{m}$  and  $0,87\mu\text{m}$ , depending mainly on the temperature of sintering.

Translucency of tested ceramics comprises between  $9,6 \div 31,9\%$ . Higher values correspond to materials of higher apparent density ( $6,09 \div 6,10 \text{ g/cm}^3$ ). Prettau material is an exception, as its density is not high ( $6,07 \text{ g/cm}^3$ ), but its translucency matched the best materials of all the ones tested.

## CONCLUSION

Based on the survey it may be concluded that the number of pores has a high influence on translucency of the material. Among the materials with similar density, these with a greater number of fine pores show lower translucency than the ones that had been well-sintered, but not that strongly compacted in the molding process. No relationship between translucency and grains size of Y-TZP ceramics has been observed.

The possible explanation of relationship between properties of Prettau ceramics, which combines high translucency and homogeneous microstructure with low apparent density, is complex. We might suppose that small amounts of substances of lower specific gravity, were added to chemically pure zirconia powder, and that altered the material's microstructure and optical performance.

## The Implementation of a Novel Process for the Preparation of Colored Zirconia Blocks for Dental Prosthetics

Zbigniew Jaegermann<sup>1</sup>, Zdzisław Wiśniewski<sup>1</sup>, Artur Oziębło<sup>1</sup>, Robert Michalik<sup>2</sup>

<sup>1</sup>Institute of Ceramics and Building Materials, Department of Ceramic Technology, Warsaw, Poland

<sup>2</sup>ROBOCAM, Warsaw, Poland

[z.jaegermann@icimb.pl](mailto:z.jaegermann@icimb.pl)

### INTRODUCTION

Common methods of preparation of colored zirconia substructures in dental prosthetics consist in the addition of pigments to the batch composition of ceramic material or in staining by impregnating biscuit sintered constructions by colored solutions<sup>1,2</sup>. Opinions of dental prosthetists as well as previous research have shown that staining by impregnating does not provide sufficient uniformity of color, because staining procedure and physical properties of the colored material have a too strong impact on color reproducibility<sup>3</sup>. Therefore an alternative method of preparing a wide range of homogeneously colored zirconia blocks was sought. It was considered that coloring ready to press zirconia powders can lead to the fulfillment of established requirements.

The aim of the work described in the paper was to develop and implement an innovative system of staining zirconia powders as well as to prepare colored zirconia blocks of Vita scale (A1, A2, A3, A3.5 shades).

### EXPERIMENTAL METHODS

Ready to press zirconia powders produced by Jiazuo Wein company and the coloring liquid in the form of aqueous solutions with different concentrations of  $\text{Fe}^{+3}$  and  $\text{Cr}^{+3}$  were used for the study. Staining process was carried out in a rotary unit, and the coloring liquid that watered the powders during the process of mixing, was sprayed through a special nozzle. Tests of spraying were carried out using nozzles which differ by inside diameters. A number of liquids were prepared with different concentrations of coloring ions ( $\text{Fe}^{+3}$ ,  $\text{Cr}^{+3}$ ). Colored powders were used for isostatic forming of test samples as well as CAD/CAM zirconia blocks that were fired at the temperature of 1500°C.

In order to evaluate the color of sintered samples the visual method (comparison with the color of the VITA scale) and determination of the values of color parameters (spectrophotometer) were applied. The impact of consecutive stages of staining (humidification, mixing, drying) on the powder properties, and particularly on agglomeration and destruction of granules was assessed by measuring the size distribution using laser diffraction method and observations its morphology using stereoscopic microscope. Quality of sintered zirconia material was evaluated on the basis of apparent density tests by hydrostatic weighing method and strength measurements by three-point bending test.

The study aimed not only to confirm the possibility of effective dying zirconia powders by coloring liquids, but was also a step towards the implementation of this technology into the production of colored zirconia blocks. For this purpose, a series of model blocks, made of colored zirconia powder and sent them to the prosthetic company - Robocam. Using CNC machine (milling machine Robomill 5), a series of model substructures in the form of a three-point bridgework were cut from the discs.

### RESULTS AND DISCUSSION

Apparent density tests showed that with increasing content of the pigment lowers the value of the apparent density from 6,10 g/cm<sup>3</sup> for not colored material and A1 shade to 6,07 g/cm<sup>3</sup> for A3.5 shade.

The results of size distribution analysis for starting powder and for selected samples of colored ones indicate that the average size of the granules is higher for colored powders. This may prove that the coloring process results in a slight agglomeration (clumping) of granules, especially the finest silt fraction. The presence of agglomerates of granules in colored powders is also confirmed by observations granules morphology in stereomicroscope. The staining time had a considerable influence on the agglomeration and destruction of the granules during mixing.

Coloring the powders by solutions based on ferric chloride causes a reduction in the bending strength of sintered zirconia materials, whereas the use of ammonium ferric oxalate does not affect the strength.

### CONCLUSION

Both the ability of the material to machining and the color uniformity after firing as well as other material properties were positively rated by manufacturer. Now the Robocam company as a producer of zirconia blocks offers the colored ones, which are very popular among the dental laboratories for manufacturing fixed dental restorations using CAD/CAM techniques.

### 3D Printing of Artificial Nerve-Guides may be Clinically Effective and may Bring Ethical Benefit

Antonio Merolli, Paolo Scialabba D'Amico

Gemelli Medical School, The Catholic University in Rome, Italy

[antonio.merolli@gmail.com](mailto:antonio.merolli@gmail.com)

#### INTRODUCTION

In 2006 a new concept of nerve-guide was proposed, termed "NeuroBox", which is flat, double-halved, not-degradable and rigid, and allows the use of cyanoacrylic glues instead of stitches [1,2]. The physical characteristics of the NeuroBox guide are quite different from traditional nerve-guides which are, basically, empty cylindrical conduits where the regenerating nerve can find protection and guidance [3]. "NeuroBox" was made of poly-methyl-metacrylate (PMMA) and its performance was compared with the well-known treated-collagen cylindrical shaped guides (TCC).

#### EXPERIMENTAL METHODS

In 2008 an off-the-shelf 3D printer was used to produce NeuroBox guides made of Poly-Lactic Acid. In 2009 a small number of 3D printed guides was implanted in the same Wistar Rat sciatic nerve model, as the "NeuroBox" and TCC. Analysis was performed by visible light microscopy (VLM) and transmission electron microscopy (TEM).

#### RESULTS AND DISCUSSION

Physical characteristics of nerve-guides can correlate with the effectiveness of regeneration and we found an effective nerve-regeneration in the 3D printed guides as well.

At that time we found that having implanted a 3D printed nerve-guide was of little relevance. We did not follow this route as far as traditional CAM machining of the PMMA was not more expensive or cumbersome than 3D printing. However, we underestimated that a possible translation into clinical practice in Humans could necessitate a strategic requirement: namely to provide a vast combination of diameters and lengths for the guides. We later discovered, while practicing with already CE-FDA approved guides in Humans [4], that it could be useful to have nerve-guides whose diameter increases with a step of 0.5 mm (from 2.0 to 7.0 mm) or whose length increases with steps not longer than 2.0 mm. These needs are presently satisfied by having industrial firms providing a set of diameters which increase of 1.0 mm on the average (even some 0.5 mm is available) and always having a maximum length (generally 25.0 or 30.0 mm) which can be trimmed during surgery. However, these are not the only requests. Sometimes particular architecture should be desirable like, for example, one-entry two-exit guides. Sometimes bented guides could be useful. None of all these clinical requests are technically demanding but they collectively bring to unacceptable raise in costs. Furthermore, even in the case that a whole kit of diameters and lengths would

be provided (at a reasonable cost), the questions remains about the waste for public Hospitals to buy artifacts that may not find an application; so it will be likely that the less common measures of the guides should be discharged after their expiry date.

Fig. 1: 3D printed artificial nerve-guides (l=14mm).

#### CONCLUSIONS

In our opinion, by demonstrating that 3D printing of artificial nerve-guide can be clinically effective and economically competitive we can certainly advocate to translate this technology into the operating room. In addition, we see as an ethical benefit that such technology will envisage two major advantages: *first*-a nearly tailor made guide can be produced for every occasion and; *second*-no unutilized guide in storage will be discharged when expired; actually the old concept of needing a relevant stock of guides in storage will be replaced by the new one of having the guides produced on demand.

## Implementation and Commercialization Process of the New Polish Extracorporeal Ventricular Assist Device

Małgorzata Gonsior<sup>1</sup>, Roman Kustosz<sup>1</sup>, Artur Kapis<sup>1</sup>, Agnieszka Szuber<sup>1</sup>, Paweł Jurkowski<sup>2</sup>, Zenon Narojek<sup>2</sup>

<sup>1</sup>Artificial Heart Laboratory (AH Lab), Foundation for Cardiac Surgery Development (FCSD), Poland

<sup>2</sup> WADIM PLAST Narojek SP. J., Poland

[gosiag@frk.pl](mailto:gosiag@frk.pl)

### INTRODUCTION

The innovative extracorporeal pulsatile ventricular assist device, called ReligaHeart EXT<sup>1,2</sup> (Fig.1), has been developed in Poland, as the new generation of POLVAD device, used in over 300 patients with the longest assistance duration over one year.

The following improvements of ReligaHeart EXT (70ml pump) were applied in order to increase its safety and reliability: optimized blood chamber construction, new low profile membrane system, original Polish tilting disc valves called Moll valves<sup>3,4</sup>, special cannulas protection system. The pump is made of innovative biocompatible polyurethane with modified surface structure (Bionate II, DSM Biomedical, USA). The modern manufacturing process has to be developed, utilizing advanced injection and lamination technology, as well as an automatized assembling. The special Technological Department of AH Lab. FCSD<sup>5</sup> was established (including clean room) for the ReligaHeart EXT production development.

Fig.1. ReligaHeart EXT blood pump, Moll valves

### EXPERIMENTAL METHODS

The advanced injection process of ReligaHeart EXT polyurethane hard elements (Fig.2.) was developed in WADIM PLAST Narojek Sp.J. The technology upscale was implemented: the optimization of injection molding process in the clean-room conditions, in order to achieve the best surface material properties, just after injection process, without any further post-processing for surface modification.

Fig.2. ReligaHeart EXT polyurethane hard elements

The polyurethane soft elements (0,3mm thick pump membranes) lamination process and complete pump assembly technology were developed in AH Lab FCSD (Fig.3.), utilizing original innovative automatized technological stands and specialized technological equipment: molds, holders, and actuators.

Fig.2. Technological stands in AH Lab FCSD

The Moll tilting disc valve consists of titanium ring and polymer disc. The precise valve elements numerically controlled machining (5 axis milling) was developed in WADIM PLAST. The special polishing technology was developed in order to obtain the titanium and polymer surface roughness allowing the elements to have proper contact with blood ( $R_a < 0,08\mu m$ ).

The special automatized assembling technology was developed by AH Lab FCSD, for valve assembling and mounting it within the ReligaHeart EXT pump. ETO sterilization process of the final product was validated.

### RESULTS AND DISCUSSION

ReligaHeart EXT pump production in compliance with ISO 13485 standard was established. Production process includes: blood pump's and valve's elements manufacturing, incoming elements quality control, valve assembling and qualification tests, blood pump manufacturing, quality control and examination for final medical product, and it's sterilization. Over 50 blood pumps were manufactured for pre-clinical and clinical study. System safety was confirmed during in vitro and long term in vivo trials. The prototype clinical parts were manufactured and utilized in the 1<sup>st</sup> phase of clinical study. The first 2 clinical applications confirmed ReligaHeart EXT's safety and proper manufacturing technology.

### CONCLUSION

The ReligaHeart EXT system has been introduced to the routine production, and the II phase of clinical trials is performed, in order to confirm the system effectiveness, CE certification and introduce to the market.

## Evaluation of Angiogenic Effect of Drug-Loaded Poly (DL-Lactic Acid) Porous Matrix Film for Wound Dressing Application by CAM Assay

Sasiprapa Chitrattha<sup>1\*</sup>, Thawatchai Phaechemud<sup>1</sup>

<sup>1</sup>Department of Pharmaceutical Technology, Faculty of Pharmacy, Silpakorn University, Nakhon Pathom, Thailand  
[sasi\\_toey@hotmail.com](mailto:sasi_toey@hotmail.com)

### INTRODUCTION

Poly (DL-lactic acid) (PLA) has been developed into the porous matrix film for wound dressing materials owing to its biodegradable and biocompatible abilities. Because of the outstanding properties of polyethylene glycol (PEG) which are essential for biomedical applications, PEG 400 was intently added into the structure to induce the pore interconnectivity of PLA matrix films<sup>1</sup>. Metronidazole (MZ) and gentamicin sulphate (GS) were incorporated into developed films for antimicrobial activities of these wound dressings. However, angiogenesis plays an important role during wound healing process in order to bring the nutrients and oxygen to the regenerating tissue<sup>2</sup>. The aim of this study was to investigate the morphology of prepared drug-loaded PLA porous matrix films and their angiogenic activity using chick chorio-allantoic membrane (CAM) model.

### EXPERIMENTAL METHOD

#### Preparation of drug-loaded porous matrix films

MZ 3% or GS 15% of polymer were loaded into the porous PLA matrix film, namely PPMZ and PPGS, respectively. Firstly, the drug was dissolved in PEG 400 (150% of polymer), then the obtained solution was mixed into PLA in dichloromethane solution (15%w/w). The mixtures were poured into the glass plate, placed at -20 °C for 24 h and dried in an oven at 60 °C for 24 h.

#### Morphology characterization

The morphology of the films was determined using scanning electron microscope (SEM) (Maxim 200 Camscan, Cambridge, England) with the BEI mode. The samples were sputter coated with gold before examination. SEM micrographs were obtained at an acceleration voltage of 15 kV.

#### In ovo angiogenesis test by CAM assay

*In ovo* method was performed as the method described previously<sup>3</sup> with some modifications. Briefly, the fertilized chicken eggs were incubated in a humidified incubator at 37 °C for 9 days. After incubation, small round window at the wide end was created. Subsequently, the disc of sample (diameter = 6 mm) was placed on the CAM surface. The open window was then sealed using parafilm. The chick embryos were then incubated for 3 days before observing the results. The amount of GS in PPGS discs were about 900 µg/disc, and MZ in PPMZ discs were about 180 µg/disc. Approximately 10 embryos per sample were used. Angiogenesis activity of the tested substances was scored as the following 4 levels<sup>4</sup>:

Score 0 = no blood vessel response to the tested substance

Score 1 = little response is observed; some large microvessels incline to the tested substance

Score 2 = moderate response is observed; the large microvessels certainly incline to the tested substance

Score 3 = strong response is observed; the large microvessels certainly incline to the tested substance and exhibit spoke wheel pattern

### RESULTS AND DISCUSSION

The morphology of PPGS and PPMZ films (Fig. 1b and 1c, respectively) displayed the porous structure that drug particles were inserted into the pore. However, PLA porous film without the drug (PPEG) showed only the porous structure (Fig. 1a). This indicated that drug loading into the PLA porous matrix film was successfully. The CAM assay of all of samples was shown in Table 1. The surrounding blood vessels of the positive control (asiaticoside 320 µg) disc (Ac) score was indicated as 2.25±0.5. However, average angiogenesis score of plain PLA film (PLA), PPEG, PPGS and PPMZ were similar to negative control (PBS pH 7.4). Therefore, they did not induce angiogenesis on the chicken embryo because a positive response of about 0.33±0.5 of the eggs was usually observed in negative control and was considered as background angiogenesis. Corresponding to previous research, GS did not promote angiogenesis<sup>5</sup>.

**Figure 1** SEM micrographs using BEI mode (x200) of cross section of films a) PPEG, b) PPGS and c) PPMZ.

**Table 1** Summary of CAM assay of samples detailing the total number of the used embryos, the dead embryos, the unable to be evaluated embryos (N/E), evaluable embryos and average angiogenesis score.

Sample	Total	Dead	N/E	Evaluable	Average score
PBS	10	1	-	9	0.33±0.5
Ac	10	1	1	8	2.25±0.5
PLA	10	4	-	6	0.33±0.5
PPEG	10	2	1	7	0.29±0.5
PPGS	10	3	1	6	0.33±0.5
PPMZ	10	1	1	8	0.50±0.5

### CONCLUSION

MZ or GS-loaded PLA porous matrix films was successfully prepared in this study. Nevertheless, they did not induce an angiogenesis by CAM assay. This result demonstrated that they had no angiogenic property.

## Bilayered Scaffolds Incorporated with Gold Nanoparticles: Fabrication, Characterization and Toxicological Evaluation as Potential Skin Substitutes

Ömer Aktürk<sup>1</sup>, Dilek Keskin<sup>12</sup>

<sup>1</sup>Engineering Sciences, Middle East Technical University, Turkey

<sup>2</sup>BIOMATEN, Center of Excellence in Biomaterials and Tissue Engineering, Middle East Technical University, Turkey  
[dkeskin@metu.edu.tr](mailto:dkeskin@metu.edu.tr)

### INTRODUCTION

Scaffolds in bilayered structure are widely used in skin tissue regenerative medicine<sup>1</sup>. Gold nanoparticles (AuNPs) recently gained an increased interest especially in tissue engineering applications<sup>2, 3</sup>. In this study, collagen/sericin film was combined with lyophilized collagen sponge to form the bilayered collagen based scaffolds (BLCS). AuNPs were synthesized and loaded into BLCS (BLCS-Au). Bilayered scaffolds were also cross-linked with glutaraldehyde (GTA) to form BLCS-X and BLCS-AuX.

### EXPERIMENTAL METHODS

AuNPs were synthesized with citrate reduction method and characterized with TEM. The effect of GTA and AuNPs on scaffold physicochemical properties (morphology, water swelling, oxygen permeability, water vapour transmission rate, aqueous and enzymatic stability, mechanical properties), in vitro biocompatibility (ISO 10993-5 extract cytotoxicity on L-929 fibroblast, adhesion and proliferation of L-929 fibroblast) and toxicological effects (ISO 10993-10 skin sensitization closed-patch test, ISO 10993-10 animal intradermal reactivity test and ISO 10993-3- OECD 471 bacterial reverse mutation test) were investigated.

### RESULTS AND DISCUSSION

Synthesized AuNPs demonstrated uniform particle size and mostly spherical shape (Figure 1).

**Figure 1.** Morphological evaluation of AuNPs: (A) TEM images of synthesized AuNPs, (B) particle size distribution analysis with histogram

Cross-linking decreased the hydrolytic and enzymatic degradation of scaffolds prominently. AuNPs seemed to increase the resistance against both hydrolytic and enzymatic degradation in long term incubation period. Cross-linking had increasing effect on water swelling of scaffolds, but AuNPs had no distinct influence. All the scaffolds had similar (about 1300 gr/m<sup>2</sup>/day) water vapor transmission rates and also excellent oxygen permeability, which was thought to be mainly controlled by collagen/sericin film layer. Tensile strength of BLCS increased with either cross-linking or AuNPs incorporation. AuNPs incorporation made the

scaffolds more brittle with high elastic modulus and low elongation at break.

**Figure 2.** SEM micrographs showing L929 fibroblasts proliferated on (A) BLCS, (B) BLCS-Au (C) BLCS-X and (D) BLCS-AuX groups in 3 days of incubation period.

The synthesized AuNPs at different concentrations (5, 10 and 20 ppm) and all the scaffold extracts were biocompatible (cell viability > 85%) according to cytotoxicity studies on L-929 cells. Cell seeding tests showed that, L-929 cells and keratinocytes attached and gained their natural morphology in 1 day and proliferated on the scaffolds during 3 days incubation period according to SEM analysis (Figure 2). Finally, the scaffold group containing all the possible toxic components, AuNPs and glutaraldehyde (BLCS-AuX) was confirmed to have no adverse skin reactions (intradermal irritation and skin sensitization), and no genotoxicity.

### CONCLUSION

The results signified that all the scaffolds fabricated in this study have good physicochemical properties and were safe toxicologically to be used as a promising skin substitute. Especially BLCS-AuX group could be a very promising material in skin tissue engineering applications

### INTRODUCTION

Sulfated hyaluronan (sHA) and chondroitin sulfate (sCS) derivatives are promising candidates for functional biomaterials since their sulfate groups modulate the binding of growth factors, thereby influencing their biological profile. The interaction of different glycosaminoglycan (GAG) derivatives with several growth factors like BMP-2/4 and TGF- $\beta$ 1 has previously been reported. These studies demonstrated that GAGs not only bind to these mediators in a sulfation- and carbohydrate backbone-dependent manner but also influence their interaction with receptors and therefore their bioactivity [1-3].

Angiogenic growth factors, like vascular endothelial (VEGF) and basic fibroblast growth factor (bFGF) play an important role during wound healing, since they both stimulate angiogenesis and in addition bFGF promotes skeletal muscle function and regeneration [4, 5].

Heparin is known to distinctly regulate VEGF and bFGF signalling by altering their interaction with the respective receptors [5, 6]. Hence we hypothesize that VEGF and bFGF interaction with different GAG derivatives influences their bioactivity depending on sulfation and carbohydrate backbone.

This might lead to important implications for the use of GAG derivatives as part of biomaterials for controlling angiogenesis during wound healing in health compromised patients.

### EXPERIMENTAL METHODS

The interaction of VEGF and bFGF with different sHA and CS derivatives was determined via surface plasmon resonance (SPR) using a BIACORE<sup>TM</sup> T100. VEGF or bFGF were immobilized onto a CM3<sup>TM</sup> sensor chip surface and different concentrations of solute sHA and CS derivatives were injected to reveal their binding strength. Additionally, ELISA experiments with immobilized GAG derivatives were performed to validate the SPR results. The influence of GAG derivatives on the capability of growth factors to bind to their respective receptors was again investigated by SPR, while the consequences of the GAG/growth factor interaction on bioactivity were studied in cell-based bioassays. Here the growth factors were pre-incubated with different GAG concentrations and added to the cells (e.g. mouse myofibroblast cell line C2C12 for bFGF). The growth factor-stimulated cell proliferation in the presence of the GAGs was determined via the lactate dehydrogenase (LDH) activity of the cells.

### RESULTS AND DISCUSSION

The binding strength of GAG derivatives to bFGF was clearly depending on sulfation degree and carbohydrate

backbone (Figure 1). For VEGF, however, this was less clear since low sulfated sHA (sHA1) and high sulfated CS (sCS3) showed a comparable binding strength. The different molecular geometries in the carbohydrate backbone of the GAGs might render the respective sulfated groups to interact differently. This is further emphasized in investigations with TGF- $\beta$ 1 where naturally sulfated heparin demonstrated a comparable binding strength to sCS3, even though it has a lower degree of sulfation [2]. Beside the GAG derivatives the structure of the growth factor might play a role for the interaction as well.

Fig. 1: Ranking of binding levels for the interaction of GAG derivatives with bFGF by SPR analysis at 37°C. D.U. = disaccharide units

The binding of growth factors to their respective receptors was modulated in the presence of GAG derivatives which implies an altered biological profile.

This could be verified in cell-based bioassays, since the presence of GAGs affected the growth factor-stimulated proliferation of the cells.

### CONCLUSION

The results imply that sulfated GAGs are promising candidates to be included in biomaterials or biomaterial coatings for controlling angiogenic and therefore healing processes.

## Electrospun Fibrous Scaffolds for Wound Dressing of Mucous Membranes

Gerlind Schneider<sup>1</sup>, Ralf Wyrwa<sup>2</sup>, Sibylle Voigt<sup>1</sup>, Katja Otto<sup>1</sup>, Matthias Schnabelrauch<sup>2</sup>

<sup>1</sup> Department of Otorhinolaryngology/Jena University Hospital, Jena, Germany

<sup>2</sup> INNOVENT e.V. Technologieentwicklung, Jena, Germany

[gerlind.schneider@med.uni-jena.de](mailto:gerlind.schneider@med.uni-jena.de)

### INTRODUCTION

Wounds in mucous membranes, such as the nasal and oral mucosa, have to heal without wound covering so far, due to limited access and the lack of required fixation. This often leads to crust formation, wound infection, and delayed healing.

Therefore, electrospun wound dressings were developed and tested to ensure fixation and haemostasis, protect the wound from infection and mechanical stress, and allow undisturbed healing for mucous membranes. Electrospun fibrous scaffolds made of biocompatible materials (e.g. polylactide) were developed and produced for the application as a wound dressing. For special requirements, the polymeric fibers can be loaded with active ingredients in a wide concentration range<sup>1</sup>.

### EXPERIMENTAL METHODS

The electrospinning of the scaffolds made of poly(L-lactide-co-D,L-lactide) (70/30, Resomer® 708) was carried out using commercial electrospinning machine E-Spintronic (Erich Huber GmbH, Gernlinden, Germany) under adapted process conditions.

Mechanical properties of pure and loaded electrospun scaffolds were tested, as well as their properties with regard to handling, sterilization, and drug release. Biocompatibility and cytotoxicity were tested using WST1 und LDH test on MC-3T3 and MRC-5 cells.

In a first animal study, pure scaffolds as well as scaffolds loaded with styptics (tranexamic acid, 20 %, or epinephrine, 10 % + 4 % cysteine), sterilized by gamma radiation, were tested for haemostatic effects and biocompatibility. 9 NZW rabbits underwent rhinotomy and a small artificial defect of nasal mucosa on both sides of the septum. On one side, a scaffold was used to cover the defect. After four weeks, the septum with the scaffold was explanted and examined after histological preparation.

### RESULTS AND DISCUSSION

The electrospun fibrous scaffolds showed good mechanical properties with small differences between loaded and unloaded fibers. Scaffolds made of pure polylactide fibers showed higher tensile strength, whereas drug-loaded scaffolds showed better adhesion to the moist mucosa.

Pure fiber mats as well as the scaffolds loaded with tranexamic acid are biocompatible. Epinephrine-loaded scaffolds showed higher cytotoxic effects (Fig. 1).

Fig. 1: Cell viability in WST 1 test on MC-3T3 cells (mouse); after 24 h, elution test.

The ongoing animal study gives reason to expect positive results with high effectiveness and good tolerability of the electrospun scaffolds.

Fig. 2: A scaffold is placed at the septum nasi (NZWR).

### CONCLUSION

The described problems of wound healing can be significantly improved using electrospun fibrous scaffolds. Extra healing time due to postsurgical complications can be shortened, and postoperative care can be reduced. In addition to the application in head and neck area, there is a large application potential in a variety of medical fields.

### INTRODUCTION

Cues of the extracellular matrix are considered to tightly control the polarization of macrophages along inflammatory versus regulatory pathways during wound healing. While *in vivo* studies do not allow for high-resolution in-depth analysis, *in vitro* systems frequently lack important physiological cues of the microenvironment like 3D matrices and controlled stiffness.

In our *in vitro* approach, we precisely control fibrillar architecture, stiffness and glycosaminoglycan (GAG) content of 3D biomimetic matrices namely reconstituted fibrillar networks based on collagen and fibrin. We are interested whether and in which context biophysical and biomolecular network properties influence macrophage polarization and how they can be implemented in the design of biomaterials scaffolds to support wound healing. In this context we ask how permanent and directional the polarization of macrophages between so-called M1 and M2 phenotypes in inflammatory and regulatory stages of wound healing occur.

### EXPERIMENTAL METHODS

3D fibrillar networks of either collagen I or fibrin were reconstituted with defined topology, elasticity and thickness. Network topology and elasticity is controlled by biopolymer concentration, pH of buffer during preparation and network cross-linking. Automated image analysis reveal diameter, density and distribution of network pores and fibrils.<sup>1</sup> Network elasticity was measured by colloidal probe spectroscopy. Using active-ester chemistry the networks were functionalized with GAG namely hyaluronan (HA) with varying degree of sulfation. HA content was quantified by fluorimetry and ELISA. Monocytes from human peripheral blood (CD14 depletion) were either cultivated and differentiated directly in the matrices or cultivated after pre-differentiation into inflammatory and wound healing phenotypes by granulocyte macrophage colony-stimulating factor (GM-CSF) and macrophage colony-stimulating factor (M-CSF), respectively. After cultivation of macrophages on different matrices the cells were activated by lipopolysaccharide and analyzed for expression levels of IL10, IL12 and CD206 by immunofluorescence and ELISA to characterize macrophage polarization by the IL10/IL12 ratio. Cell migration and differentiation was analysed within the 3D context of the biomimetic matrices using time-lapse microscopy. Automated image analysis revealed single cell trajectories, migration pattern, speed and morphology.

### RESULTS AND DISCUSSION

Biomimetic 3D collagen I and fibrin networks could be engineered with a defined topology and mechanics. Pore size and Young's moduli were controlled in a range of 5 to 15 µm and 20 Pa to 500 Pa. Stable covalent binding of hyaluronan and sulfated hyaluronan within the 3D networks was up to 10% mass content of GAG per collagen matrix. Fibrillar networks of fibrin exhibited a pore size in a range of 1 to 4 µm and Young's moduli between 200 and 800 Pa.

Depending on the collagen network stiffness and HA functionalization we observe an enhanced level of IL10/IL12 expression ratio on stiff networks (0.03 to 0.12) while introduction of HA reduces the IL10/IL12 ratio (0.12 to 0.05) analysed by ELISA of cell culture supernatant. Much lower IL10/IL12 ratios were found on controls of 2D environments on tissue culture plastics indicating the importance of 3D biomimetic environments for physiologically relevant studies. These observations were verified by immunofluorescent staining of intracellular IL10 and IL12 inside the matrices. IL10 and IL12 levels were found much higher in fibrin scaffolds in comparison to collagen scaffolds accomplished by significantly higher IL10/IL12 ratios (0.57). These observations suggest a support of a regulatory phenotype of macrophages in stiffer 3D environments, a regulatory function of GAG functionalization and a strong support of regulatory phenotypes in fibrin environments.

Single cell tracking experiments inside the scaffolds support the above findings on macrophages polarization showing a higher migratory activity and morphological polarization for regulatory phenotypes. An ongoing study on genotypic characterization of macrophages will substantiate the current results.

### CONCLUSION

Our studies demonstrated the importance of analysing macrophage behaviour in topologically and mechanically biomimetic 3D microenvironments in order to gain physiologically relevant results. Matrix stiffness, GAG modification and matrix composition were found to control macrophage polarization into a regulatory phenotype.

### INTRODUCTION

Materials which are used for medical applications but which are not drugs, are called biomaterials. Often these are intended for the manufacture of components for internal use to assist diseased organs and tissues, and with a predetermined time to be replaced. Biomaterials can include groups such as metals, bioceramics, glass, polymers and composite materials [1-3]. The aim of this study was to obtain a hydrogel material based on acrylic acid and chitosan modified with hydroxyapatite.

### EXPERIMENTAL METHODS

Hydrogel material with acrylic acid/chitosan matrix modified with hydroxyapatite was prepared and its properties were investigated. Investigation included 30-days incubation, oxidation, swelling research, chemical structure identification using IR spectroscopy and SEM imaging of the material's surface.

### RESULTS AND DISCUSSION

The research covered synthesis of the polymer matrix with addition of hydroxyapatite, physicochemical tests and in vitro incubation research. It was stated that the synthesized hydrogels are swelling both in distilled water and a solution of physiological salt. Additionally incubative studies of the synthesized samples were carried out in the following liquids: distilled water, Ringer solution and artificial saliva. The pH value of the solutions during the incubation period did not show significant differences among the hydrogel samples with a different hydroxyapatite content. Moreover, no rapid or significant changes of pH were observed, which confirms the compatibility of collected material with a particular environment. During the research, the biological activity of hydrogels was determined. The studies showed that the obtained exhibit this property. However, more advanced research, such as on the cell lines, is required to examine further the biological

activity of these materials. Analysis of the polymer matrix structure of the synthesized hydrogels, before and after the incubation, was also carried out using Fourier transform infrared spectroscopy (FT-IR).

### CONCLUSION

On the basis of the collected test results it can be concluded that modification of the surface characteristics of hydrogels with hydroxyapatite is possible, and can be done so to improve its compatibility with the components of the bone. This will allow to tailor the properties of the hydrogel materials for tissue engineering applications, especially in the process of bone regeneration.

## INTRODUCTION

Traditional methods of wound closure are suturing and stapling, but they are associated with pain, wound infection and low aesthetic results. As a result of these shortcomings, medical tissue adhesives are considered an attractive alternative since, besides wound closure, they can accomplish other tasks, such as haemostasis and the ability of sealing air leakages. The most used surgical glues nowadays are the fibrin based adhesives [1] and cyanoacrylates [2]. Fibrin based adhesives present several problems, e.g. immunogenicity and risk of blood transmission diseases such as HIV and BSE. Cyanoacrylates have been reported to degrade in aqueous media to produce formaldehyde, which causes inflammation and has got carcinogenicity potential. Other options are now being considered, and among them, photopolymerizable/photocrosslinkable adhesives are the most promising. UV curable adhesives offer major advantages, such as fast-curing rate, control of the polymerization heat evolution, superior control over the final properties of the material and are ideal for application to weakened and diseased tissue.

## EXPERIMENTAL METHODS

Photocrosslinkable biodegradable bioadhesives based on a low molecular weight poly(caprolactone diol) (PCL) and poly(lactic acid) (PLA) were developed and tested as a possible bioadhesives. PLA and PCL were modified with a recently developed compound from BASF: Laromer® 9000 (Lr9000). Lr9000 is an isocyanate-functional, unsaturated acrylic ester resin, based on allophanated hexamethylene diisocyanate. Its isocyanate groups may easily react with compounds containing hydroxylic groups (creating urethane linkages), such as the case of PLA and PCL, in order to obtain macromers with carbon-carbon double bonds (C=C). The accomplishment of this chemical modification was confirmed by Attenuated Total Reflectance – Fourier Transform Infrared Spectroscopy (ATR-FTIR) by detection of the typical bands of the urethane groups. C=C bonds were then crosslinked using Iracure® 2959 by BASF as the photoinitiating agent. Crosslinking was achieved by UV irradiation for the period of 120s for the PLA macromers and 30s for the PCL macromers. After these time frames, flexible, uniform and well defined films were obtained. These were then further characterized, by swelling capacity evaluation, morphologic analysis by scanning electronic microscopy (SEM), hydrolytic degradation *in vitro*, determination of surface energy by contact angle measurements as well as thermal characterization TGA and DMTA). Blood compatibility studies were performed including thrombosis and determination of haemolytic potential. Finally, biocompatibility using

human dermal fibroblasts (hFib) and antibacterial activity of the materials were evaluated *in vitro*.

## RESULTS AND DISCUSSION

PCL and PLA bioadhesives were characterized by swelling evaluation and the percentage of the materials swelling was low, indicating that volume increase *in situ* will not be significant and damage to the surrounding tissues will not occur.

The biodegradation of the samples was performed in PBS and low percentages of weight loss were registered after 6 weeks with a maximum of nearly 20%. The results obtained for surface free energies ( $\gamma_s$  PLA  $\approx$  40mN/m and  $\gamma_s$  PCL  $\approx$  30mN/m) were lower than the ones reported for skin ( $\gamma_s \approx$  38-56mN/m) and blood ( $\gamma_s \approx$  47mN/m). Therefore, we may suggest that once films are formed over any of these surfaces, they won't slough off easily since adhesion forces will be significant. Haemocompatibility studies were performed, and both thrombosis and haemolytic potential were evaluated. Thrombosis percentages obtained for PCL bioadhesives were around 90% and close to 80% for PLA bioadhesives meaning that both surfaces present thrombogenic character. The haemolytic potential of the synthesized materials was also evaluated, and results showed that it could be classified as slightly haemolytic when in direct contact with blood. However, this haemolysis was eliminated when the samples were subjected to the extraction with PBS solution (indirect contact). This result does not mean, however that this material cannot have a clinical application, since as already reported, values of haemolysis are within acceptable limits. Cell culture *in vitro* studies showed that the materials are biocompatible and in the case of PLA based materials they also present antibacterial activity.

## CONCLUSION

PLA and PCL were modified with a new compound from Lr9000 and films were obtained by UV irradiation induced crosslinking. Their overall performance during characterization indicates that they may be promising materials as bioadhesives.

### INTRODUCTION

Stem cells are spotlighted as an attractive method to replace conventional treatment method in the regenerative medicine field. Adipose-derived stem cells (ADSCs) are also a member of the pluripotent cells. Although adipose-derived stem cells have the potentials to be used for damaged tissues in various ways, few researches have dealt with the effects of ADSCs on wound healing. Absorption degree is important factors in the wound healing process. Moreover, polyurethane (PU) is frequently used wound dressings because of its good barrier properties, oxygen permeability and higher absorption degree. Therefore, in this present study, we investigated the effect and usability of adipose-derived stem cell seeded on Poly vinyl alcohol (PVA) nano web fiber and newly developed PU foam, which has high absorption degree, hybrid dressing material on wound healing.

### EXPERIMENTAL METHODS

The number of rats (Sprague-Dewley rats) used in this experiment was forty. Four round (diameter 2cm) surgical wounds were created bilaterally on the dorsum of the white rat's trunk and were assigned into 4 groups by each dressing materials: Group A, as the control group, was dressed with sterilized gauze, Group B with PVA nano web fiber-PU foam hybrid dressing material, Group C with ADSCs seeded PVA nano web fiber-PU foam hybrid dressing material, Group D with the dressing material named Medifoam™, which is commercially available. Each group was compared with gross findings at periodic times and both histological and biochemical test were conducted for each time.

### RESULTS AND DISCUSSION

In surgical wounds, Group C showed statistically higher contraction rate, higher epithelization rate and higher wound healing rate (Fig.1). In a histological aspect, on 14th day after wound formation, more thick and dense epithelial layer was observed in Group C (Fig.2). Moreover, more regular and thick alignment of collagen fibers was also observed in the same period. In Western blot, on 14th day after wound formation, the expression of TGF-β1, VEGF and Laminin α-3 was detected to be relatively strong in Group C (Fig.3).

Fig. 1. The mean percentage of the wound contraction rate (left), epithelization rate (center), healing rate (right) according to processing time of each group.

Fig. 2. Histological finding of post-wound tissues stained with hematoxylin and eosin stain (x100).

Fig 3. The expression pattern of TGF-β1, VEGF, laminin α-3 protein using western blots in the surgical wound.

### CONCLUSION

This study suggest that adipose-derived stem cell seeded on PU dressing foam which has highly absorbent degree dressing material induces stable reepithelization, angiogenesis and collagen fiber synthesis in the wound healing process. Given this, it is considered as an effective biological dressing material, as well as an innovative invention that can replace existing dressing materials with.

### INTRODUCTION

Hospital acquired infections are a major financial and societal burden with high mortality, morbidity and cost. Such infections are caused by a number of pathogenic and opportunistic bacteria, many of which are resistant to front line antibiotics. To combat their emergence and spread, new approaches have been developed such as adding biocides to wound dressings and surgical implants, but have met with limited success. We proposed an innovative technology capable of improving the clinical outcomes associated with bacterial infection of skin, deep wounds and surgical implants. This approach will exploit the ability of silver nanoparticles (NPs)<sup>1</sup> to produce antibacterial radicals and reactive compounds. To begin with, antimicrobial activity of NPs and cytotoxicity of materials were tested.

### EXPERIMENTAL METHODS

Silver nanoparticles have been synthesized using sodium borohydride reduction of silver nitrate. For the synthesis of the scaffold, silver nanoparticles were added to acrylamide and N,N'-Methylenebisacrylamide solution. The mixture was placed into a cryobath at -20°C. After 5 hours it was moved to freezer at -20°C for 12 hours.

To test antimicrobial effect, method of agar well diffusion was used. Briefly, small wells were cut in the agar medium, which was previously cultured with *Staphylococcus aureus*. Cryogel alone and cryogel with NPs were cut and placed in the wells. After incubation at 37°C for 24 hours, zone of inhibition was measured. Morphological studies were carried out using SEM. For cytotoxicity studies MTT assay was used. Cytotoxicity of cryogels, NPs, and cryogels with nanoparticles were tested. All experiments were carried in triplicates.

### RESULTS AND DISCUSSION

Polymerization of acrylamide and N,N'-methylenebisacrylamide eliminates toxicity of cryogels. Cryogels are sponge-like materials with medium to large pore sizes. The prepared cryogels were elastic, wet, and the colour was white. Upon drying, cryogel solidified and lost its properties. However, due to its property of shape memory, addition of water brought back the initial shape and characteristics. Nanoparticles were successfully incorporated into the pore walls of the cryogels according to SEM images.

Agar well diffusion method is based on the diffusion of NPs through the semi-solid agar growth medium to inhibit the growth of potentially sensitive microorganisms. The assessment of antibacterial activity of NPs within the cryogel demonstrated good inhibition zone of *S.aureus* by silver NPs within the cryogel matrix. Thus, silver NPs were not blocked by the cryogel and are available for interaction with the surrounding environment. Cytotoxicity experiments demonstrated no toxicity either by cryogels or NPs or both.

### CONCLUSION

Acrylamide cryogel and nanoparticles were successfully fabricated and fused together. The prepared novel combination demonstrated good properties for use in wound healing: good adsorption, moist environment, no toxicity, and good antimicrobial effect. Our future work will be focused on application of microwaves to NPs in a controlled regime and pulsed motion, studying effect of microwaves on antimicrobial activity of NPs and formation of free radicals.

## Design of a Functional Degradable Wound Dressing for Acute Injuries

Beren Sen, Ayse Buse Ozdabak, Alper Tunga Akarsubasi, Fatma Nese Kok

Molecular Biology-Genetics and Biotechnology Programme, Istanbul Technical University, Turkey

[sen.beren@gmail.com](mailto:sen.beren@gmail.com)

[aysebuse@hotmail.com](mailto:aysebuse@hotmail.com)

### INTRODUCTION

The aim of this study is to design a degradable wound dressing with double functionality using naturally derived polymers like chitosan and gelatin. Chitosan is chosen for its well-known superior properties in wound healing applications. Existing systems generally contain only one functionality, mostly an antimicrobial agent, and the agent was directly incorporated into the wound dressing matrix. In addition, pain management is not included in the design.

In this study, we proposed a wound dressing which is designed both to alleviate the pain of the patient during the treatment and to protect the wound from infections. For this purpose, ibuprofen and gentamicin encapsulated in type A and B gelatin microspheres will be incorporated into the chitosan matrix. Gelatin with different isoelectric points was chosen to tune the release behavior of the drugs, especially the antibiotic, at different pH conditions of a clean or infected wound.

### EXPERIMENTAL METHODS

1%, 2% and 3% (w/v) of chitosan was dissolved in 0.1 M acetic acid to prepare chitosan sponges. Chitosan solutions were frozen overnight at  $-20^{\circ}\text{C}$  or  $-80^{\circ}\text{C}$  and the samples were freeze-dried for 24 hours. Characterization of chitosan sponges was performed via scanning electron microscope (SEM). Gelatin microspheres were prepared by using water-in-oil emulsion technique adapted from the literature<sup>1</sup>.

### RESULTS AND DISCUSSION

Freezing conditions had considerable effect on the structure of chitosan sponges (Figure 1). The ones which were frozen at  $-20^{\circ}\text{C}$  had more porous structure than the others. Thickness and uniformity of the sponges, and freeze drying conditions were also optimized (data not shown).

Figure 1: SEM images of the chitosan sponges after freeze drying (left, at  $-20^{\circ}\text{C}$ ; right at  $-80^{\circ}\text{C}$ )

Before the encapsulation of the drugs, the preparation conditions were optimized by unloaded microspheres. Size distribution studies showed that although the majority of the microspheres were within  $20\text{--}30\text{ }\mu\text{m}$  for both types, size range laid between  $15\text{--}40\text{ }\mu\text{m}$  for Type B gelatin while this value was  $20\text{--}60\text{ }\mu\text{m}$  for Type A (Figure 2).

Figure 2: Size distribution of Type A and B gelatin microspheres

Swelling studies showed that Type B but not Type A gelatin microspheres swell at pH:8. Basic pH indicates infectious wound so antibiotic encapsulation will be done using those microspheres to trigger an increase in the release rate during infection.

### CONCLUSION

Swelling behavior of the Type B gelatin microspheres could be suitable to tune the release of gentamicin depending on the infectious state of the wound. Pain management drug (ibuprofen), on the other hand, should be designed not to be affected from the pH of the wound. After the optimization of the release behavior of both drugs (on-going studies), incorporation of the microspheres to the chitosan matrix will be performed.

## Design of a Functional Degradable Wound Dressing System for Effective Pain Relief

Beren Sen, Ayse Buse Ozdabak, Fatma Nese Kok

Molecular Biology-Genetics and Biotechnology Programme, Istanbul Technical University, Turkey  
[sen.beren@gmail.com](mailto:sen.beren@gmail.com)

### INTRODUCTION

In this study, we proposed a wound dressing which is designed to alleviate the pain of the patient during the treatment. For this purpose, ibuprofen encapsulated in type A gelatin microspheres will be prepared and incorporated into the chitosan sponges. Chitosan was chosen because of its superior properties in wound healing systems. Although different bioactive materials (antibiotics, growth factors, silver etc.) can be used to increase the functionality of the wound dressing systems, only one active agent is generally incorporated into the matrix for the existing systems. Additionally, pain management is not included in the design.

### EXPERIMENTAL METHODS

Gelatin microspheres were prepared by using water-in-oil emulsion technique adapted from the literature<sup>1</sup>. Ibuprofen solution (1 mg/mL) was added to gelatin solution to obtain loaded microspheres. Microspheres were crosslinked with 5% and 7.5% glutaraldehyde (GTA) solutions overnight. Release studies were carried out in pH: 4.5 and 8.0 buffers.

Chitosan (low viscosity from shrimp, medium MW) solutions were prepared at different concentrations in 0.1 M acetic acid (1%, 2% and 3% (w/v)). They were frozen overnight at -20°C and the samples were freeze-dried for 24 hours. Characterization of chitosan sponges was performed via scanning electron microscope (SEM).

### RESULTS AND DISCUSSION

Release studies showed that a burst release at the first 24 h was observed in all cases that were followed by slow release (Figure 1).

**Figure 1:** Release profiles of gelatin microspheres in pH 4.5 and 8.0 buffers

Depending on the presence/absence/stage of infection, pH of the wound would vary from normal acidic (pH=5) to basic (infectious wound, pH=8) so the system

for the pain management drug should be designed so that the release would not be affected to a great extent from the pH of the wound. For this purpose, ibuprofen was loaded into Type A gelatin microspheres with an isoelectric point of 6-9. The release study showed that microspheres crosslinked with 5% GTA had high burst release which was not depended on pH while higher crosslinking affected both rate and pH dependence of the drug release.

SEM micrographs showed that increase in the chitosan concentration resulted in more dense sponge structures (Figure 2).

**Figure 2:** SEM micrographs of the chitosan sponges with different concentrations a)1% b)2% c)3%

### CONCLUSION

Release behavior of ibuprofen from Type A gelatin microspheres in different pH conditions was found to be dependent on crosslinking degree. Further optimization will be done to obtain microcapsules with better release profile, and then the microspheres will be incorporated into the chitosan sponge for further characterization.

### INTRODUCTION:

Teeth represent the hardest tissue in most living vertebrates, including mammals, having been designed for tearing and cutting (1). Their excellent mechanical properties arise from their delicate ultrastructure, typically with highly mineralized enamel on the outside and the softer, more bone-like dentin on the inside. Mammals (including humans), amphibia and most bony fish use calcium phosphate as tooth mineral (2). The most common tooth mineral is hydroxyapatite with some carbonate substitutions on phosphate positions, the so-called dahllite (3). A notable exception are sharks which use fluoroapatite as tooth mineral (4). We have shown that teeth of recent sharks contain fluoroapatite only in enameloid but not in dentin (5). Here we report on a comprehensive study of teeth of fossilized sharks and dinosaurs where the ultrastructure and their chemical composition were analyzed in detail.

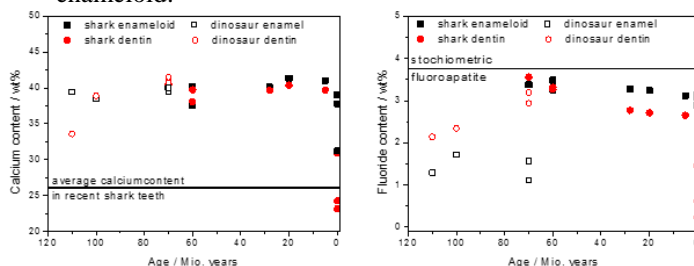

### EXPERIMENTAL METHODS:

Teeth of the extinct shark species *Squalicorax pristodontus*, *Palaeocarchorodon orientalis*, *Otodus obliquus*, *Carcharocles angustidens*, *Carcharocles megalodon*, *Isurus hastalis* as well as of the dinosaur species *Spinosaurus maroccanus*, *Carcharodontosaurus saharicus*, and the extinct marine reptiles *Plesiosaurus mauretanicus* and *Mosasaurus beaugei* were analyzed using scanning electron microscopy, X-ray powder-diffraction with Rietveld-refinement for structural analysis and elemental analysis for chemical composition. The results have been compared to the structure and chemical composition of the recent great white shark *Carcharodon carcharias*.

### RESULTS AND DISCUSSION:

The elemental analysis showed a fluoride content in all fossil shark teeth that was close to that of stoichiometric fluoroapatite, in dentin and enameloid, respectively (Fig. 1). X-ray powder-diffraction identified the crystal phase as apatite. The ultrastructure of the teeth was extraordinarily well preserved; the individual bundles and crystallites can be seen in the SEM-images (Fig. 2). In contrast to the recent shark tooth both, dentin and enameloid, were microcrystalline, whereas in *C. carcharias* only enameloid was microcrystalline, dentin was nanocrystalline. Another difference was the calcium content and with it the degree of mineralization. It was higher in dentin of the fossil teeth than in the recent great white shark. The reason is the decomposition of the organic matrix during the fossilization. The ultrastructural organization of the dinosaur teeth and plesiosaur resembles to those of crocodiles (6), but the individual crystallites in the

enameloid resemble those occurring in shark tooth enameloid.

**Fig. 1:** Correlation between calcium and fluoride content and the age of the fossilized teeth.

**Fig. 2:** SEM-images of the enameloid of *C. angustidens*.

### CONCLUSION:

We have shown that the ultrastructure of fossil shark teeth is comparable to that of recent sharks, irrespective to the age of the fossil. All fossil teeth, from sharks as well as from plesiosaurs and dinosaurs, contained high amounts of fluoride.

## Testing Stress Relaxation Process of a Pig's Skin

Aneta Liber-Kneć, Sylwia Łagan

Division of Experimental Mechanics and Biomechanics, Faculty of Mechanical Engineering,  
Cracow University of Technology, Poland  
[aliber@pk.edu.pl](mailto:aliber@pk.edu.pl)

### INTRODUCTION

The mechanical properties of a pig's skin which is used as the human skin substitute in the studies carried out in vitro are important for a number of applications, including surgery and biomechanics [1, 2]. In this study, uniaxial tensile test and stress relaxation tests were performed with swine skin samples in two different directions to study the effects of fibre direction on stress relaxation process.

### EXPERIMENTAL METHODS

The samples were taken from the dorsal region of a pig in two directions with respect to the long axis of the pig's body: parallel, perpendicular. All samples had the same dimensions: the length 100 mm and the width 10 mm. The average thickness was equal to  $2.2 \pm 0.2$  mm. The mechanical properties under static tension (modulus of elasticity, tensile strength) and relaxation tests were determined with the use of the MTS Insight 50 testing machine. The samples were mounted using flat clamps and they were extended at the speed of 5 mm/minute. The measurement base of the sample was 50 mm. With stress relaxation tests, each sample (3 for every test) was preloaded with 2 N and then loaded to different strains (5, 10, 15%) to observe its effects on stress relaxing over time.

### RESULTS AND DISCUSSION

In figures 1 and 2 stress relaxation curves for tested skin samples were shown over a 1500 second period. For the strains 5% and 10%, both for parallel and perpendicular samples the trend of relaxation curves is similar. For the strain 15% rapid relaxation can be observed at the beginning over a 500 second period and then the trend of stress relaxation become comparable to the strains 5% and 10%.

Fig. 1. Relaxation curves for perpendicular samples

For the same level of strain, the time of achieving initial stress was the same: for 5% - 30 s, for 10% - 60 s, for 15% - 90s.

Fig. 2. Relaxation curves for parallel samples

Both parallel and perpendicular samples were tested till time decreased below the value of prestress. For parallel samples both the time of relaxation and decreased below the value of prestress is lower than for perpendicular samples (Table 1).

Direction of sample	Strain [%]	Initial stress [MPa]	Time of decreasing stress below value of prestress [s]	Relaxation time [s]
perpendicular	5%	0,3	1 329,4	100
parallel	5%	0,3	849,4	95
perpendicular	10%	1,1	8 508,1	150
parallel	10%	0,4	3 823,3	110
perpendicular	15%	2,3	61 939,7	1600
parallel	15%	1,0	25 894,9	1000

Table 1. Results of stress relaxation tests

### CONCLUSION

The obtained results can be used for the modelling of stress relaxation behaviour based on QLV theory with the reduced relaxation function [3].

### INTRODUCTION

Silver alloy is one of semi-precious alloys for dental prosthesis, which has been applied remarkably in Japanese dental field. Ag-20Pd-17.7Cu-12Au alloy (G12) with Cu/Ag ratio of 0.367, which was newly developed for commercial dental silver alloy, shows a unique hardening mechanism after a simple solution treatment (ST) at relatively high temperature as well as traditionally applied Ag-20Pd-14.5Cu-12Au alloy (S12) with Cu/Ag ratio of 0.284<sup>1</sup>. However, the relationship between ST at various temperatures and the mechanical strength of G12 has not been investigated fully. Therefore, the relationship between ST and mechanical properties of G12 after ST at various temperatures was investigated systematically in this study.

### EXPERIMENTAL METHODS

Materials used in this study were hot-rolled plates of Ag-20Pd-17.7Cu-12Au alloy (G12) and Ag-20Pd-14.5Cu-12Au alloy (S12). All samples were conducted with the solution treatment (ST) at 1023~1173 K for 3.6 ks in an Ar gas atmosphere followed by water quenching (WQ). Hereafter, the samples of G12 and S12 subjected to ST were designated by using temperature. (e.g. G12/1123 K). In addition, some samples subjected to aging treatment (AT) at 673 K for 1.2 ks in a vacuum followed by air cooling after ST (G12/AT673 K).

Back-scattering electron (BSE) images from a scanning electron microscope (SEM) and elemental mapping by a wavelength dispersive X-rays spectrometer (WDS) were used for the observation of microstructures and the identification of phase constitutions. The Vickers hardness (HV) and tensile tests were performed to evaluate the mechanical strength. The corrosion potential was measured in a 3 mass% NaCl solution to evaluate the corrosion resistance.

### RESULTS AND DISCUSSION

Figure 1 shows the microstructures of G12/1173 K and G12/AT673 K. G12/1173 K is composed of three kinds of phases with Ag-rich  $\alpha_2$  phase (white area), Cu-rich  $\alpha_1$  phase (gray area) and  $\beta$  phase (black area) of Pd-Cu intermetallic compound. Although nominal melting point of G12 is around 1233 K, the high Cu concentration area like  $\alpha_1$  phase is partially dissolved and then the  $\alpha_1$  and  $\beta$  phases reprecipitate during cooling. On the other hand, the microstructure of the G12/AT673 K was composed of two kinds of phases with  $\alpha_2$  and  $\beta$  phases, which is a typical microstructure of AT after ST.

Figure 2 shows the Vickers hardness of as-received G12 and S12, and those subjected to each heat treatment.

The Vickers hardness of G12/1173 K and G12/AT673 K were almost the same value each other. It is considered that the Vickers hardness increases remarkably by the precipitation of some meta stable  $\beta'$  phases of the coherency in  $\alpha_2$  phases<sup>1</sup>. The Vickers hardness of G12 subjected to ST at relatively high temperature of 1173 K is identical to that of the same alloy subjected to typical age-hardening.

The corrosion potential of G12 changed drastically with the temperature of ST. The potential may have been increased by the decrease in the volume fraction of the  $\alpha_1$  phase with relatively high Cu content.

Fig. 1 BSE images of G12/1173 K and G12/AT673 K.

Fig. 2 Vickers hardness of as-received G12 and S12, and those subjected to each heat treatment.

### CONCLUSIONS

- 1) Microstructure of G12 subjected to ST at relatively high temperature of 1173 K was composed of three kinds of phases with  $\alpha_2$ ,  $\alpha_1$  and  $\beta$  phases, and had partially dissolved at around high Cu concentration area.
- 2) Vickers hardness of G12 subjected to ST as mentioned above was identical to that of the same alloy subjected to typical age-hardening.

## INTRODUCTION

Resin-based restorative materials are widely used in dentistry. In general, the resin part of these materials consists of a mixture of methacrylate monomers that are polymerized *in situ* with a blue light initiated free-radical polymerization mechanism. The polymerization process is never complete, and unpolymerized monomer may be released after curing. The resin composition is a parameter influencing polymerization (degree of conversion; DC), material properties and toxic potential.

2-[3-(2H-Benzotriazol-2-yl)-4-hydroxyphenyl]ethyl methacrylate (UV090) is a mono-methacrylate monomer used in several commercial materials such as contact lenses and as UV-absorbant in polymer industry. It has been used in small amounts in resin-based filling material. In this study we aimed to characterize physical properties and toxic potential of resin-based dental composites containing different amounts of the triazol-monomer.

## EXPERIMENTAL METHODS

Experimental dental composites containing 70 % inorganic filler, 12.5-15.0 % bisphenol A glycidyl methacrylate (BisGMA), 12.5-15.0 % triethylene glycol dimethacrylate (TEGDMA), 0-5 % UV090 and initiator components were prepared. The composites (2 mm thick) were cured for 20 seconds with blue light irradiation before the tests.

The degree of conversion (DC) was determined using FTIR and ATR-method directly after irradiation and at 3 h. Relation between aliphatic and aromatic double bond absorbance was used as a measurement to calculate the DC. Flexural strength was determined according to ISO 4049<sup>1</sup> with a Lloyds LRX testing machine. Leakage of unreacted monomer was measured in extracts from cured specimens incubated for 24 h in ethanol/water (75/25 vol/vol) at 37 °C using gas-chromatography.

Toxic potential of UV090 was determined by the MTT test (ISO 10993-5<sup>2</sup>). Briefly, L929 cells (a fibroblast cell line) was exposed to UV090 (0-200 µM) for 24 h. After exposure, MTT was added to the cell culture. The formation of purple coloured formazan after incubation was measured as absorbance at 570 nm and used to indicate viability.

## RESULTS AND DISCUSSION

There were no differences in DC (78 % at 3 h) with different triazol-monomer contents in the composites. This may be due to the relatively small amounts of the triazol-monomer (0-5%) in the composites. However, a decreased MPa value in flexural strength and an increase in monomer release were observed with increasing UV090-content. This suggests the formation of a less complete polymer network using the mono-methacrylate.

The MTT test showed a dose-dependent decrease of viability in the L929 cells. The MTT test yields a relative number of living cells. Hence, both cell death and decreased cell growth may be the cause of this finding. Further studies supplementing the MTT data is currently in progress and will be presented.

Results summarized:

- Addition of UV090 to the resin reduced the flexural strength of the composite
- UV090 is released from cured composites
- UV090 has a toxic potential *in vitro*

## CONCLUSION

In summary, this study showed that increased amounts of the triazol-monomer negatively influenced the measured properties of the experimental composites.

### INTRODUCTION

Alkali degradation is widely applied for elimination of N-acetylglucosamine from the reducing end of hyaluronan oligosaccharides. However, besides the main  $\beta$ -elimination reaction, there are further side and consecutive reactions proceeding, leading to formation of mixture of degradation byproducts. These byproducts could be potentially harmful similarly as the byproducts originating from acidic hydrolysis<sup>1</sup>. Thus, it is vital to identify structures and to describe basic cytotoxic characteristics of these byproducts.

### EXPERIMENTAL METHODS

The mixture after alkali degradation of HA4<sup>AN</sup> was pre-fractionated on the gel column. The later eluting band was then chromatographed on the reversed phase and degradation byproducts were isolated in milligram quantities. Structures of the purified degradation byproducts were then elucidated using NMR and MS/MS approaches.

### RESULTS AND DISCUSSION

Our results show that during alkali treatment of hyaluronan oligosaccharides, besides the major expected odd-numbered oligosaccharide and isomers of  $\Delta$ -N-acetylglucosamine described previously<sup>2</sup>, a rich mixture of further byproducts origins in a wide concentration span. These include shorter than expected

oligosaccharides, dehydrated and deacetylated oligosaccharides or several yet undescribed furan-like structures.

Some of these byproducts showed cytotoxic properties on 3T3 mouse fibroblasts and can therefore be potentially harmful. Hence, it is vital to provide satisfactory purification of all hyaluronan-based products prepared by alkali treatment and monitor the residual concentrations of these byproducts in final preparations.

### CONCLUSION

During the alkali degradation of hyaluronan oligosaccharide some yet undescribed reaction byproducts are formed, besides the expected main products. These can be comparatively nontoxic, but also strongly cytotoxic on mouse fibroblasts. Therefore it is vital to purify the coveted alkali degradation products properly and to monitor the residual levels of harmful byproducts in oligosaccharide preparations.

## INTRODUCTION

Teeth restored using composite resins are especially prone to this phenomenon due to stress generated within the tooth-restoration interface following resin contraction during polymerization, known as polymerization shrinkage. Thereby, both shrinkage and quality of the bond seem to be responsible for the degradation of marginal adaptation [1]. Microleakage is strongly controlled by marginal adaptation and is thought to be one of the major disadvantages of resin composite restorations. Amalgam surface corrosion and deposition of oxides improves marginal auto-sealing over time. In contrast to composite resins, amalgam is dimensionally stable. Sandwich technique was proposed as an effective technique as a means for pulpal protection from the acid-etch and a mechanism for sealing the cavity in the absence of good dentin adhesion. SDR<sup>®</sup>/Smart Dentine Replacement is the first bulk fill composite, simplifies the procedure for placing adhesive posterior composite fillings, even in extended class II cavities [2]. The aim of this study is to compare materials-composite resin interface characterization on nano glass ionomer, silver amalgam and dentin replacement materials in the proximal box of open sandwich combined with composite resin restorations in class II cavities by using SEM.

## EXPERIMENTAL METHODS

Cavities were prepared in 45-extracted first permanent maxillary with carbide bur. Mesio-occlusal (MO) box-like cavities (3 mm width x 1.5 mm depth) with gingival margins ended 1mm below CEJ were prepared and filled in each tooth. The teeth selected were non carious, without any restoration or cracks. The teeth were divided randomly into 3 groups of 15 teeth. The prepared cavities were filled in open sandwich technique as follows: Group I: RMGI/resin modified glass ionomer Ketac N100 nanoionomer (3M-ESPE); Group II: Silver Amalgam/ Silverfil<sup>®</sup> with Panavia F amalgam bonding (Kuraray); Group III: SDR<sup>®</sup>/Smart Dentine Replacement (Dentsply). The composite used was Filtek Z350 XT (3M-ESPE). Dental tissues were etched with 37% phosphoric acid and a Scotchbond<sup>™</sup> Universal Adhesive bonding agent (3M-ESPE) was applied and cured. The gingival increment in the open sandwich as well as the first composite increment for the composite fillings was 2 mm thick. The restored teeth were thermocycled between 5° to 55° C with 30 second dwell time for 500 cycles to stimulate the temperature changes under clinical conditions. Teeth were longitudinally broken mesio-distally. Specimens were then metalized with fine gold overlay using gold sputter machine (Leica EM SCD005, Germany).

The specimens were photographed at different sections and evaluated for gap present, if any, between base materials and resin composite/CR using SEM (FEI Quanta FEG 450) at 250 magnifications. Adaptation was evaluated at the following interfaces: Nanoionomer-composite resin (A); silver amalgam/ Silverfil<sup>®</sup>-composite resin (B) and SDR<sup>®</sup>-composite resin (C). Microleakage was evaluated by means gap between materials and CR.

## RESULTS AND DISCUSSION

The mean gap between the two materials in group A was highest 3.84µm followed by group B 2.72µm, then by group C showed least mean gap 2.05µm. At 5% probability level, mean gap of group A was higher than all the other groups, but no significant difference was observed between mean gap of group A and group B and group C.

Group	No. of samples	Mean gap (µm)	Range (µm)	S.D.
A	15	3.84*	6.84	1.43
B	15	2.72*	5.29	1.37
C	15	2.05*	4.48	1.32

Table 1 showed gap measured between test materials and composite resin.

\* Indicate no significant difference ( $p > 0.05$ ).

Although the bonding mechanism between amalgam and composite has not yet been completely explained, Silverfil<sup>®</sup>/CR interface exhibited similar microleakage gap compared with Ketac nanoionomer/CR and SDR<sup>®</sup> dentin replacement material/CR.

## CONCLUSION

Since Silverfil<sup>®</sup>/CR interface exhibited similar microleakage scores than nanoionomer/CR and SDR<sup>®</sup>/CR, sandwich restorations can be considered as a biological and aesthetic alternative to conventional Class II composite or amalgam restorations.

## Microleakage in Open-Sandwich Class II Dental Restorations

Sam'an Malik Masudi<sup>1</sup>, Ninin Sukminingrum<sup>1</sup>

<sup>1</sup>School of Dental Sciences, Universiti Sains Malaysia, 16150 Kubang Kerian, Kelantan, Malaysia  
[sam@usm.my](mailto:sam@usm.my)

### INTRODUCTION

One of the key functions of a dental restoration is to seal the exposed dentin from the oral environment, to prevent pulpal damage and further decay. Therefore, the microleakage at the tooth-restorative interface is a major concern influencing the clinical longevity of the restorations. The integrity and durability of the marginal seal has always been of prime concern in the investigation of dental restorative materials performance. In order to overcome the inherent composites disadvantages such as the polymerisation shrinkage and the weaker adhesion at the composite-dentin interfaces several solutions were proposed. The step-by-step incremental technique, transparent matrices, reflecting wedges and improved adhesive systems solved only partially these problems. The technique, so-called "Sandwich" as an effective technique for both anterior and posterior resin based restorations. The open-sandwich technique was proposed, which consists in a gingival layer of another class of material prior to resin composite insertion in class II cavities [1]. The aim of the present study is to assess the microleakage between different restorative materials and the dentine gingival margin used in the open sandwich technique in class II cavities.

### EXPERIMENTAL METHODS

Forty upper permanent premolar teeth were used and class II box-like cavities (3 mm width x 1.5 mm depth) with gingival margins ended 1mm below CEJ were prepared and filled in each tooth. The teeth were randomly divided into four groups each containing ten teeth. The prepared cavities were filled as follows: Group I: Silver Amalgam/Silverfil® with Panavia F amalgam bonding (Kuraray) + CR/composite resin; Group II: RMGI/resin modified glass ionomer Ketac N100 nanoionomer (3M-ESPE) + CR; Group III: GI/glass ionomer conventional Fuji II™ (GC Corp) + CR and Group IV: full composite filling using incremental technique. The composite used was Filtek Z350 XT (3M-ESPE). Dental tissues were etched with 37% phosphoric acid and a Scotchbond™ Universal Adhesive bonding agent (3M-ESPE) was applied and cured. The gingival increment in the open sandwich technique as well as the first composite increment for the composite fillings was 2 mm thick. The specimens were thermocycled between 5° to 55° C with 30 second dwell time for 500 cycles. The samples were then immersed in 0.5% Rhodamine B dye for 10 hours and were sectioned longitudinally. Dye penetration at the gingival margin was quantified under confocal laser scanning microscopy/CLSM (Leica, TCS SP2) at 10x magnification.

Data were analyzed using the Mann-Whitney tests and Kruskal-Wallis with a *P* value of  $\leq 0.05$  was considered statistically significant.

### RESULTS AND DISCUSSION

For the dentin-material Kruskal-Wallis test showed statistically significant differences among groups ( $p < 0.05$ ,  $\alpha = 0.0177$ ). The mean gap widths and standard deviations ( $\mu\text{m}$ ) obtained from each experimental group between dentin and the materials tested are shown in Table 1.

Group	Mean gap width ( $\mu\text{m}$ )
1. Silverfil® with Panavia F amalgam bonding + CR	$4.6 \pm 2.2^*$
2. Ketac N100 nanoionomer RMGI + CR	$5.2 \pm 2.7^*$
3. Conventional Fuji II™ GIC+ CR	$20.6 \pm 6.9$
4. Full CR Filtek Z350 XT	$3.8 \pm 2.1^*$

Table 1 show the mean gap widths and SD ( $\mu\text{m}$ ) obtained from each experimental group between dentin and the materials tested.

\* Indicate no significant difference ( $p > 0.05$ ).

The least microleakage between dentin-material interfaces was obtained using composite resin, but the results showed that there was not any statistically significant difference of microgaps in the interfaces between Z350XT® composites with Silverfil® and Ketac N100 nanoionomer (Groups 1, 2 and 4), while conventional glass ionomer (Group 3) exhibited the contrary.

### CONCLUSION

Nanohybrid composite resin Filtek Z350 XT®, Silverfil® amalgam and resin modified nanoionomer Ketac N100 restorative materials were produced similar results in microleakage between dentin-material interfaces at gingival margin of class II open-sandwich restorations. All materials used in this study were not able to totally eliminate microleakage on dentin.

## Microscopy Analysis of Cement-Enamel Junction in Teeth

Urszula Stachewicz<sup>1</sup>, Wojciech Kożuch<sup>2</sup> and Aleksandra Czyrska-Filemonowicz<sup>1</sup>

<sup>1</sup>International Centre of Electron Microscopy for Materials Science, Faculty of Metals Engineering and Industrial Computer Science, AGH University of Science and Technology, Kraków, Poland

<sup>2</sup>Dental Practise, 2Th, Kraków, Poland

[ustachew@agh.edu.pl](mailto:ustachew@agh.edu.pl)

### INTRODUCTION

Teeth sensitivity is one of great interests in clinical research, therefore cement-enamel junction in teeth has become recently a well studied area. Simply, the cement-enamel junction is the boundary between enamel on tooth crown and cement, which covers the root of the tooth. It is also called in the literature cemento-enamel junction (CEJ). Cementum is an essential mineralized dental tissue, importantly it is cementing the principal collagen fibres of periodontal ligament and enamel is a protective coating on the crown.<sup>1</sup> There are three types of CEJ, including: a) overlap, in which cementum overlaps enamel and is called coronal cementum; b) abutment, cementum butts with enamel; and (c) gap, a finite space between cementum and enamel, as shown in Figure 1.

CEJ is one of the major area where tooth external resorption can start. This process is destructive in nature and can lead to the loss of your tooth without special treatment. In case of no treatment, the tooth loss is inevitable.<sup>2</sup>

**Figure 1.** Schematic drawing of CEJ types: a) overlap, b) abutment, and (c) gap, a finite space, between cementum and enamel.

### EXPERIMENTAL METHODS

Several teeth samples were extracted from the patient with suspicion of root resorption. The sample teeth were obtained directly from the dental clinic. The carefully extracted teeth were cleaned at the final stage with dental bleaching agents. Scanning electron microscopy

(SEM, Merlin Gemini II, ZEISS) with EDX detector, Quantax 800 (Bruker) microanalysis system and EBSD detector, Quantax CrystAlign 400 (Bruker) microanalysis system was used to localize the cement-enamel junction and perform the chemical analysis.

### RESULTS AND DISCUSSION

We have demonstrated that the SEM can be used to investigate the cemento-enamel junction in tooth to image the gap between cement and enamel in teeth. Moreover, we have not observed any damaging effect of using dental bleaching agents during the samples preparation.

The empty space between the mentioned junction was observed and analyzed on the individual tooth surface. The teeth with the gap, schematically shown in Figure 1c), were cervical region where the tooth resorption process was present.

Scanning electron microscopy can be used as method to verify the resorption process on tooth for the medical diagnosis. The understanding of the teeth resorption process through the microscopy analysis allow to adjust treatment to the patient.

### SUMMARY

Scanning electron microscopy analysis of teeth resorption is able to provide depth analysis of changes at cement-enamel junction that is linked with the chemical analysis at the sub-micron level.

The thorough analysis of the early stages of resorption on teeth can be detected and lead to precise diagnosis and higher chance of successful dental treatment. Within this research we have shown that scanning electron microscopy may assist the clinician in diagnosis of the cause of teeth resorption process.

### INTRODUCTION

Hydroxyapatite [ $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$  - (HA)] exhibits chemical and crystallographic similarity to bone mineral. Due to this likeness significant research has been performed to develop preparation methods of HA. Aqueous precipitation is the most common technique used to synthesise HA since the use of low reaction temperatures ( $<100^\circ\text{C}$ ) combined with relatively cheap raw materials results in minimal operating costs. The high scalability of this methodology also makes it attractive for industrial use.

Despite much research being conducted concerning synthesis of CaPs, such as HA, relatively few authors have combined the knowledge of material properties and biological performance. Typically, it is more common to assess only the in-vitro/in-vivo performance of the end product and as such often the effects of chemical variations of the raw material are overlooked. The objective of this study is to investigate the effect of pH, temperature, solute concentration and solvent system on a range of physiochemical characteristics and to perform a number of in-vitro tests to determine any variations in biological performance. Concurrent analysis of HA substrates using a range of characterisation methods contributes to the established knowledge in this field and supported the observed differences in the viability and proliferation of MC3T3 cells assessed by live/dead and MTT assays.

### EXPERIMENTAL METHODS

HA was formed using a precipitation technique previously reported by the authors [1]. Table 1 summarises the varied precipitation conditions used.

Sample	Parameter	Parameter Value
AP01	pH	10 (adjusted)
AP02		11 (adjusted)
AP03		10 (controlled)
AP04		11 (controlled)
AP05	Solute concentration	0.1M (Ca reagent)
AP06	Temperature	$70^\circ\text{C}$
AP07	Ethanolamine	5wt%
AP08	Toluene	60%
AP09	Ethanolamine and Toluene	5wt%, 60%

Table 1: Precipitation conditions

Physiochemical properties of HA powders were characterised using XRD, FTIR, SEM, TEM, DTA-TGA, BET surface area and zeta potential. Cytocompatibility of HA substrates was assessed using a live/dead assay and the rate of MC3T3 cell proliferation was quantitatively distinguished using an MTT assay for up to 7 days.

### RESULTS AND DISCUSSION

XRD patterns for all samples were matched to HA (09-432) with no presence of secondary phases. Analysis of the molecular structure via FTIR revealed the presence of vibrations associated with  $\text{HPO}_4^{2-}$ . AP01 was also shown to exhibit bands corresponding to a PO stretch associated with DCPD. The morphology of powders visualised by SEM exposed a high degree of agglomeration that was prevalent throughout samples. Crystallites of AP01 were observed to exhibit a needle-like morphology, known to be typical of precipitated HA and synonymous with biological equivalents, with an average length and width of  $32.8 \pm 10.1\text{nm}$  and  $5.7 \pm 1.2\text{nm}$ , respectively.

Thermal studies using DTA-TGA highlighted key temperature regions associated with weight loss:  $<200^\circ\text{C}$  (all),  $200 - 300^\circ\text{C}$  (AP01 and AP03),  $250 - 700^\circ\text{C}$  (all), and  $700 - 800^\circ\text{C}$  (all except AP01 and AP06). Weight loss between these temperatures were attributed to: loss of non-bound surface water, dehydration of DCPD to DCPA, dehydration of  $\text{HPO}_4^{2-}$  to  $\text{P}_2\text{O}_7^{4-}$ , and transformation of  $\beta\text{-Ca}_2\text{P}_2\text{O}_7$  to HA and  $\beta\text{-TCP}$ , respectively. Promisingly the surface area of AP06, AP08 and AP09 powders were shown to be larger than other samples.

The zeta potential of both AP01 and AP06, measured in DI at  $25^\circ\text{C}$ , were positive compared to all other samples that exhibited varying degrees of negativity.

Interestingly, corresponding fluorescence micrographs collected up to 7 days of culture using a live/dead assay illustrated the death of the entire cell population after 1 and 3 days, respectively. MTT results further highlighted a significant variation in the proliferation of MC3T3 cells seeded onto HA substrates prepared under different synthesis conditions. Specifically the low crystallinity of powders prepared in a solvent system containing Toluene was attributed to the 200% increase in the proliferative rate of cells between 1 and 7 days compared with AP02.

### CONCLUSION

This work establishes that changes to precipitation conditions cannot be deemed trivial since they may determine the cytocompatibility of HA and the proliferative rate of cells.

## Characterisation of Bioresorbable Composite Performance for Validation of New On-Line Process Monitoring Technology

Mark Billham<sup>1</sup>, Darren Whitaker<sup>2</sup>, Marion McAfee<sup>2</sup>, Nicholas Dunne<sup>1</sup>, Fraser Buchanan<sup>1</sup>

<sup>1</sup>School of Mechanical Engineering and Aerospace, Queens University Belfast

<sup>2</sup>Centre for Precision Engineering, Materials & Manufacturing, Institute of Technology, Sligo, Ireland  
[n.dunne@qub.ac.uk](mailto:n.dunne@qub.ac.uk)

### INTRODUCTION

There is an increasing interest in the biomedical field to create implantable medical devices to provide a temporary mechanical function for use inside the human body. In many of these applications bioresorbable polymer composites using PLLA with  $\beta$ -TCP, are increasingly being used due to their biocompatibility, biodegradability and mechanical strength.<sup>1,3</sup> These medical devices can be manufactured using conventional plastics processing methods such as injection moulding and extrusion, however there is great need to understand and control the process due to a lack of knowledge on the influence of processing on material properties. With the addition of biocompatible additives there is also a requirement to be able to predict the quality and level of dispersion within the polymer matrix. On-line UV-Vis spectroscopy has been shown to monitor the quality of fillers in polymers. This can eliminate time consuming and costly post-process evaluation of additive dispersion. The aim of this work was to identify process and performance relationships of PLLA/ $\beta$ -TCP composites with respect to melt-extrusion conditions. This is part of a wider study into on-line process monitoring of bioresorbable polymers as used in the medical industry.

### EXPERIMENTAL

In this study  $\beta$ -TCP particles at 5, 15 and 30  $\mu$ m were compounded at 10, 20 & 30 wt% with poly(L,D)-lactide copolymer in a twin-screw extruder at temperatures of 200°C, 220°C and 240°C; a constant screw speed of 300rpm and constant throughput of 33g/min. The material was extruded through a strip die with an a UV-Vis probe mounted onto the die. The UV-Vis spectra in the wavelength range 290 - 990 nm were recorded through the 1mm path length and collected for each variant for evaluation of the readings. Multi-variate analysis was carried out on the spectra at each temperature and particle size. Extruded samples were collected and analysed by SEM, DSC, TGA and mechanical testing.

### RESULTS AND DISCUSSION

On-line UV-Vis spectroscopy was used to confirm the particle size and loading of the  $\beta$ -TCP filler. Multivariate analysis of the UV-Vis spectra consistently classified the data of the main principle components into particle size (fig. 1).

Figure 1. Analysis of UV-Vis spectra of 20 %-TCP/PLA shows consistency of grouping the spectral components into particle size.

The particle size and loading of the  $\beta$ -TCP influenced the rheological and tensile properties of the poly(L,D)-lactide copolymer/ $\beta$ -TCP composite. The smaller particle size of 5  $\mu$ m showed greater reduction in the tensile strain and tensile strength as the % loading increased. (fig. 2) as well as a greater increase in the modulus of the composite.

Figure 2. Tensile strain of PLLA/  $\beta$ -TCP samples.

### CONCLUSION

These results show that final properties of the PLLA/  $\beta$ -TCP composite are highly influenced by the particle size and loading. UV-Vis spectroscopy can be used on-line to monitor the final product and this can be utilised as a valuable tool for quality control in an application where consistent performance is of paramount importance.

### INTRODUCTION

Silica nanoparticles have attracted attention in biomedical fields due to their safe history, good biocompatibility and biodegradability, and easily tunable surface functionality. They have been used extensively for various applications including photothermal therapy, photodynamic therapy, magnetic resonance imaging, peptide delivery, and gene delivery<sup>1</sup>. The application of the nanoparticles is influenced by their dispersion stability in different media. Characteristics of nanoparticles may be affected by the chemistry of the surrounding and the presence of inorganic and biological moieties, so understanding of their behavior in specific environments is important<sup>2</sup>. The interaction of silica nanoparticles with proteins plays a key role in modern biotechnology and in the biomedical field.

### EXPERIMENTAL METHODS

Silica nanoparticles were synthesized by the sol-gel process using Stöber method<sup>3</sup> (SN1 and SN2) and in different way, in the water-based solution of cyclohexane and arginine (SN3). In both types of synthesis tetraethoxysilane (TEOS) or tetramethoxysilane (TMOS) were used as silica precursors. Size and stability of the silica nanoparticles in different biological media: water, bicarbonate buffering system RPMI-1640 (RPMI) and mixture of RPMI and FBS (fetal bovine serum) were examined by the dynamic light scattering (DLS) measurements (Malvern Zeta Nanosizer). The shape and size of the presented nanoparticles were also determined by transmission electron microscopy (TEM).

### RESULTS AND DISCUSSION

Obtained materials consist of silica nanoparticles with the size about 20-30 nm. TEM images of the materials are presented in the Fig. 1.

**Fig. 1.** TEM images of the silica nanoparticles: SN1, SN2 and SN3 respectively. The scale bar is 20 nm for all images.

When nanoparticles enter a biological fluid, proteins and other molecules bind to their surface leading to a formation of a dynamic protein or ion layer that defines

the biological identity of the particles. Size of the presented silica nanoparticles in different biological media are presented in the Table 1. Nanoparticles SN1 are the most resistant and show weak response to all types of biological media. The second particles SN2 show tendency to agglomeration in all researched fluids. Particles SN3 aggregate only in RPMI solution which has high ionic strength. This fact agrees with results obtained from the zeta potential measurements. Particles with small value of zeta potential are less stable and have tendency to agglomeration.

method \ probe	SN1	SN2	SN3
TEM [nm]	20	20-30	20
DLS (H <sub>2</sub> O) [nm]	46	136	41
DLS (RPMI) [nm]	50	166	490
DLS (RPMI-FBS) [nm]	87	164	95
Zeta potential (H <sub>2</sub> O)	- 45	- 45	-32
Zeta potential (NaCl)	- 28	- 28	- 6

Tab. 1. Size of the SiO<sub>2</sub> in different biological media.

We have also examined the stability of the silica nanoparticles in RPMI and RPMI+FBS versus time. SN1 and SN2 show small tendency to agglomeration in both media. After initial growth, the particle size are almost at the same level during the time of 240 minutes because of the FBS presence what stabilize nanoparticles against further agglomeration, even when the RPMI is added. SN3 nanoparticles in the RPMI agglomerate to the microparticles but they are stabilized by proteins in the RPMI+FBS fluids.

### CONCLUSION

Synthesis method, ionic strength and biological molecules can change the properties of silica nanoparticles and affect their biological effects. The proposed approach may be a useful tool in the preliminary prediction of nanoparticles behaviour in biological fluids and interpretation of toxicological results. Such knowledge is crucial for estimation of stability of the potential nanocarrier systems intended for use.

### INTRODUCTION

Hydraulic calcium silicate cements are bioactive materials showing a dynamic interaction with dentine and pulp tissue interface<sup>1</sup>. Biodentine™, Pro Root® mineral trioxide aggregate (MTA) and MedCem® MTA are three such hydraulic tricalcium silicate cements used in the field of dentistry. Materials used in endodontics should preferably be biocompatible. This is particularly desirable when they are placed in direct contact with living tissue such as in pulp capping, perforation repair or when used as a retrograde filling<sup>2</sup>. To promote healing and restoration of the function of the tooth, dental materials should either stimulate repair or be biologically neutral.

The purpose of this study was to evaluate in vitro cytotoxicity of three different commercially available dental materials (tricalcium silicate cements) using MG-63 osteoblast cells.

### EXPERIMENTAL METHODS

Biodentine™, Pro Root® MTA and MedCem® MTA were mixed according to manufacturer's instructions. Thirty disks, 5mm in diameter and 1 mm in height were made per material and allowed to set in a sterile environment. All samples were subjected to ultraviolet radiation for one hour. One half of the samples were randomly chosen and subjected to overnight extraction in medium.

Light optic profilometry, Energy dispersive x-ray analysis (EDX) and scanning electron microscopy (SEM) were used to assess surface topography, homogeneity and reproducibility of the samples used respectively.

MG63 osteoblast-like cells originally isolated from a human osteosarcoma, were used.  $1 \times 10^5$  cells were first seeded onto a 24-well plate and samples were placed on top of a monolayer cell culture. Live/death was evaluated by confocal microscopy using calcein-AM/propidium iodide staining. Cell viability and proliferation were assessed using the MTT assay. Direct contact cytotoxicity tests after 24 hours were performed with and without overnight extraction in medium.

Based on the ISO 10993-5, all tests were performed in triplicate. Statistical analysis was performed by ANOVA and post-hoc Tukey's tests. The level of significance was set at 0.05.

### RESULTS AND DISCUSSION

Biodentine™, Pro Root® MTA and MedCem® MTA showed crystalline, uneven surface topography. Surface roughness of all the three materials used were comparable.

After overnight extraction in medium, all the three materials exhibited statistically similar cell viability ( $p > 0.005$ ). Without extraction, Biodentine™ showed significant reduction in cell viability when compared to control group ( $p = 0.004$ ), Pro Root® MTA ( $p = 0.001$ ) and MedCem® MTA ( $p = 0.001$ ). Live/death assay images using calcein-AM/propidium iodide staining were in correlation with the MTT assay. In all the three cements, cell viability was increased when the samples were placed in contact with the cells after overnight extraction in medium.

Various studies report decreases in the viability of cells cultured in vitro in the presence of tricalcium silicate based biomaterials. The variation in the quantity of calcium hydroxide released may be responsible for the varying cell viability. Calcium hydroxide release may cause the denaturation of proteins in the medium and pH fluctuations which affect cell viability<sup>3</sup>.

### CONCLUSION

Our findings indicate that media conditioned with Biodentine™, Pro Root® mineral trioxide aggregate (MTA) and MedCem® MTA may modify the viability and proliferation of cells.

<sup>3</sup> Oral Biology, Dental School, Ghent University, Ghent, Belgium

[elanagai.rathinam@ugent.be](mailto:elanagai.rathinam@ugent.be)

### INTRODUCTION

Tricalcium silicate cements refer to a group of hydraulic cements with tri- and di- calcium silicates as their dominant ingredient, which react with water to form calcium silicate hydrate and calcium hydroxide. Application of these cements is abundantly being recommended for vital pulp therapy, and over the past decade, a field of research has emerged focusing on modification or development of newer tricalcium silicate cements that could overcome the shortcomings of their predecessors and increase their clinical efficiency. Signalling molecules and responding dental pulp stem cells are the two main control keys of dentin regeneration/dentinogenesis<sup>1</sup>.

The aim of this study was to present a systematic review investigating the gene expression of various dental pulp cells in response to different variants of tricalcium silicate cements. The systematic review question was: *'what are the gene or molecular expressions induced by tricalcium silicate cements when they interact with dental pulp cells?'*

### EXPERIMENTAL METHODS

A systematic search of the literature was performed by two independent reviewers followed by article selection and data extraction. The Gwets AC1 inter rater reliability coefficient for screening data was calculated as 97.35% (95% confidence interval; 0.96 – 0.99). Studies analysing all sorts of dental pulp cells (DPCs) and any variant of tri-calcium silicate cement either as the experimental or as the control group were included.

Study design, type of cells, source of cells, variant of tricalcium silicate cement, inhibitors used, techniques used for analysis, duration, staining, up-regulated/ down-regulated genes, genes and pathways expressed, molecular signalling, mineralization effect, statistics used and any significant/ non-significant results were extracted from each selected manuscript to piloted, pre-defined data extraction sheets. Evidence tables based on the included studies, provided the framework to assess data for further analysis.

### RESULTS AND DISCUSSION

A total of 39 articles were included in the review. Among the included studies, ProRoot® MTA was the most commonly used tricalcium silicate cement variant. The ERK-MAPK pathway was the most commonly activated pathway to be identified and similarly DSPP, OCN, DMP-1, ALP, BSP, OPN, COL 1 and Runx2 were the most commonly expressed genes in that order of frequency.

Biodentine™, Bioaggregate™ and MTA stimulate the osteogenic/odontogenic capacity of DPCs by proliferation, angiogenesis and biomineralization through activation of the ERK 1/2, Nuclear factor E2 related factor-2 (Nrf-2), p38, JNK MAPK, p42/p44 MAPK, NF-κB and FGFR pathways. When DPCs are placed into direct contact with tricalcium silicate cements, they show higher levels of gene activation, which in turn could translate into more effective pulpal repair and faster and more predictable formation of reparative dentin.

### CONCLUSION

Osteogenicity and dentinogenicity are highly desirable properties for any endodontic/regenerative cement. These properties have been adequately demonstrated in calcium-silicate cements in the literature. The bioactive properties of calcium-silicate cements combined with biointeractivity, biocompatibility, bioinductivity and osteoconductivity are responsible for the continuously expanding number of clinical applications of these cements in biomedical tissue engineering<sup>2</sup>.

Although tremendous progress has been made in understanding the molecular biology that controls the mechanism of action of calcium-silicate cements, the exact mechanism remains unclear and, consequently, a subject of future research.

## INTRODUCTION

Natural bone is a complex composite, mainly constituted of biological apatite and molecules of collagen. The natural composite material should combine the strength and stiffness of an inorganic compound with flexibility, toughness and resorbability of an organic phase. Osteoconductivity and load-bearing capability of a scaffold are controlled by the scaffold architecture (pore size, shape, interconnectivity) and by the biomaterial that is used in the construction. Ca-deficient hydroxyapatite (CaP) has been used as bone substitutes and bone-filling materials, due to excellent biocompatibility, osteoconductivity, bone-bonding properties. Polylactic acid (PLA) is a thermoplastic, biodegradable, biocompatible, synthetic polymer with high strength and modulus<sup>2</sup>. It can be easily processed into shapes such as screws, pins and plates for orthopedic applications, and fabricated into scaffolds for replacement and regeneration of tissues. The combination of calcium phosphate compounds and polylactide are expected to take advantages of both materials to obtain optimal scaffold for bone tissue engineering, since it possesses the fundamental characteristics such as bioactivity, biomechanical similarity, processability, and biodegradability. It also can reduce acidity of degradation products of the polylactide<sup>1</sup>.

## EXPERIMENTAL METHODS

Ca-deficient calcium phosphate was obtained via wet precipitation reaction using calcium oxide and orthophosphoric acid, as described in literature<sup>2</sup>. Biodegradable polymer and calcium phosphate composites with composition 20 wt% PLA / 80 wt% CaP and 30 wt% PLA / 70 wt% CaP were manufactured using novel liquid/solid suspension technology. Prepared CaP/PLA composite were mixed with a pore forming agent and formed into a cylinder by a pressing method. Particle size of pore forming agent was in the range from 100 µm to 300 µm. Mass proportions of all materials used in the preparation process are shown in Table 1.

Table 1. List of sample compositions

PLA/CaP composition, wt%	PLA-CaP/pore formed agent composition, wt%
20 PLA/80 CaP	60/40
	50/50
	40/60
30 PLA/70 CaP	60/40
	50/50
	40/60

Fourier-transform infrared spectroscopy (FT-IR) was used to determine the various functional groups in the

composite samples. X-ray diffractometry (XRD) was used to analyse phase composition of obtained calcium phosphates and biodegradable polymer composite samples. Archimedes method was used for the determination of samples porosity<sup>3</sup>. Compressive strength of fabricated CaP/PLA composites was measured at ambient temperature. The crosshead was run at 0.05 mm/min.

## RESULTS AND DISCUSSION

Compressive strength and open porosity of prepared samples is shown in Fig.1. For 30PLA/70 CaP porosity increases from 37% to 59%, but compressive strength decreases from 3,2 MPa to 1,2 MPa. For 20PLA/80CaP porosity increases from 39% to 61% and compressive strength decreases from 2,9 MPa to 0,3 MPa. Varying amount of pore forming agent in the range from 40 wt% to 60 wt%, open porosity increased from 37% to 60%.

Fig. 1 Compressive strength and open porosity of prepared samples

## CONCLUSION

The porosity of composite scaffold has a noticeable effect on its compressive strength. The scaffolds exhibit minimal compressive strength, with the maximal porosity. By reducing mass fraction of pore formed agent in composite for 20wt%, open porosity is decreasing for 20 % also, but compressive strength increases 3 times for 30PLA/70 CaP composite and 6 times for 20PLA/80CaP composite.

### INTRODUCTION

Neuritic plaques, the hallmark of Alzheimer's disease (AD), are primarily composed of  $\beta$ -amyloid peptides A $\beta$ (1-40) and A $\beta$ (1-42).<sup>1</sup> A $\beta$ (25-35) represents the biologically active region of A $\beta$ , as it includes the shortest fragment capable of forming large  $\beta$ -sheet aggregates.<sup>2</sup>

Extracts from the rhizome of *Curcuma longa* (Turmeric), has been used for treatment and prevention of certain pathologies, in Chinese medicine, due to its numerous biological activities including antioxidant, antiproliferative, neuroprotective and memory-enhancing activities.<sup>3-5</sup> Curcumin and curcumin derivatives were also proved to inhibit amyloid  $\beta$  peptide A $\beta$  (1-40) and A $\beta$  (1-42) fibril formation.<sup>5-8</sup>. Curcuma extract is a mixture of curcumin and its derivatives shown in Figure 1. Increasing evidence show that the single curcumin derivatives contribute in different, specific way to the final biological effect of curcuma extracts.<sup>8-9</sup>

Aim of our research is to evaluate the effect of curcumin and its derivatives **1-7** to modify the conformation of A $\beta$  (25-35). Accordingly we purified the single curcumin derivatives by HPLC and carried out an extensive spectroscopic investigation, in liposome systems composed of 1,2-Dioleoyl-sn-glycero-3-phosphocholine (DOPC), 1,2-dioleoyl-sn-glycero-3-[phospho-*rac*-(1-glycerol)] (DOPG) and DOPC/DOPG (90/10).

**Figure 1.** Structures of curcuminoids and its derivatives.

### EXPERIMENTAL METHODS

High performance liquid chromatography system (Waters 486 Tunable Absorbance Detector and Varian 9012 pump) with variable wavelength detector was used for analysis and purification of extract of *Curcuma longa*. NMR spectra for full characterization of compounds were recorded on a 300 MHz. High-resolution Mass Spectrometry (HRMS) were recorded on a high resolution mass spectrometer equipped by electrospray (ESI) and nanospray sources, and a quadrupole-time of flight hybrid analyser, coupled with capillary UPLC system (Q-TOF Premier/nanoAquity, Waters) in positive mode, and either protonated molecular ions [M+H]<sup>+</sup> were used for empirical formula confirmation, unless otherwise stated. Circular

dichroism measurements were performed on a JASCO J-810 spectropolarimeter (Jasco, Cremella, Italy) equipped with a thermostated cell holder, using a quartz cell with a 1.0-mm path length. Spectra were collected over the wavelength range from 260–190 nm with a bandwidth of 2.0 nm and a time constant of 8 s.

### RESULTS AND DISCUSSION

CD spectra of A $\beta$ (25-35) (100  $\mu$ M solution), assumes 93-94% of random coil conformation in DOPC and in DOPC/DOPG vesicles; in DOPG vesicles, the prevalence of  $\alpha$ -helix is evident. Circular dichroism spectra recorded after the addition of compounds **1-7** indicate that some of these compounds modify A $\beta$ (25-35) secondary structures. This effect is different in relation to the phospholipid content: evident conformational perturbations are observable in particular in DOPG vesicles. In these conditions the presence of the curcumin derivatives **4** and **5** induces alterations of the CD spectra corresponding to modification of the A $\beta$ (25-35) conformation. These compounds induce similar effects even in the presence of A $\beta$ (25-35) aggregates.

### CONCLUSION

Study of A $\beta$ (25-35) structure in membrane mimetic DOPC and DOPG vesicles show that the secondary structure of this peptide varies in response to the specific composition of phospholipids. In these conditions the single constituents of curcuma evidence peculiar ability to affect the secondary structure of A $\beta$ (25-35). These data suggest that the full biological activity of curcuma extracts critically depends on its composition and therefore on the conditions that favor the specific mixture of *Curcuma* extracts.

## INTRODUCTION

Caring for the environment and reducing the adverse effects of the use of common fertilizers such as soil acidification, the introduction of excessive amounts of heavy metals, salinity and over-fertilization of plants causes considerable interest in efficient fertilizers of controlled release, coated with biodegradable polymers. Polymer-coated or encapsulated controlled-release fertilizers can cause an environmental problem since undesirable residues of the coating material may accumulate in the fields. PHAs as a water-insoluble polyesters characterized by a non-toxicity and biodegradability under both aerobic and anaerobic conditions are relevant materials for coating and encapsulation of fertilizers<sup>1,2</sup>. Moreover PHAs can be produced from renewable raw materials what enables the creation of waste management systems in a closed cycle and is consistent with sustainable development<sup>3</sup>.

## EXPERIMENTAL METHODS

In the ongoing research at Cracow University of Technology using the ashes after thermal processing of sewage sludge as alternative raw material, different phosphate fertilizer were produced: liquids and solids in the form of P and NP fertilizers originating from renewable sources.

Using PHAs: poly(3-hydroxybutyrate), poly(3-hydroxyoctanoate) and their mixtures as a coating and encapsulating agent, biodegradable slow released fertilizers were produced in the form of microspheres and coated granules. The production of PHB using *B. cereus* SPV, obtained from the University of Westminster culture collection, was carried out in 20 L fermenters using modified Kannan and Rehacek medium. Medium chain length, mcl-PHA production was carried out in 72L fermenter using *P. mendocina* in MSM media.

Microstructural studies of the surface topography of the products were carried out. Microspheres and coated granules of fertilisers were investigated for nutrient release according to standard EN 13266:2001: Slow-release fertilizers. Structure, size, specific surface area and other properties of granules and microspheres were investigated.

## RESULTS AND DISCUSSION

Figure 1 show surface morphology of the calcium phosphate fertiliser (MCP) coated with mixture of P(3HB) with 10, 20, 50% of P(3HO) and microspheres

with encapsulated MCP solution with the same polyester composition.

Fig.1. (SEM) of microspheres (A-C) and coated fertiliser granules (D-F): (A) and (D) 10% P(3HO) 90% P(3HB); (B) and (E) 20% P(3HO), 80% P(3HB); (C) and (F) 50% P(3HO), 50% P(3HB);

Phosphorus release from fertilisers coated with 20% mixture of P(3HO) with P(3HB) meets EN13266:2001 standard requirements. After 72h phosphorus cumulative release was only 25%. The profile of cumulative release of phosphorus from P(3HB)/P(3HO) microspheres is seen to be bimodal, with an initial burst release followed by controlled continuous release.

## CONCLUSION

It was confirmed that PHAs as a coating for solid fertilizers or encapsulating agent for liquid one's have a very good potential in future use. Moreover, the combination of biopolymers derived from waste with the fertilizers produced from waste materials will contribute to the creation of entirely new fertilizer products in the market with potentially lower costs of production and compatible with the expectations of the European market for fertilizers.

### INTRODUCTION

Surgical sutures are used to close wounds and post-traumatic surgery. They are used to ease and speed up the healing process. Surgical sutures play a very role in the surgery, and they should have adequate physicochemical properties<sup>1</sup>.

Sutures are characterized by set of parameters that make it easier for the physician to select the appropriate suture to type, location and advance of tissue healing. Improper selection can lead to abnormal tissue adhesion and its infection. Therefore, researchers continue to develop and analyze new materials striving to ensure the best possible functionality while minimizing detrimental effects. In addition, analysis of the process of absorption of the thread makes it possible to assume that resorption will occur in a given environment

The main aim of this study was to determine mechanical properties of surgical sutures composed of bioresorbable materials in various stages of resorption and to determine speed of resorption.

### EXPERIMENTAL METHODS

The material consisted of five resorbable sutures – four of synthetic origin (Biosyn<sup>TM</sup>, Caprosyn<sup>TM</sup>, Polysorb<sup>TM</sup>, PDS<sup>TM</sup> II) and one of natural origin (Catgut<sup>TM</sup>). Sutures differed in total resorption time and the structure (monofilamentne and multifilamentne). For each type of suture at least 5 samples were prepared, each 30cm long. The material was chosen in such a way that the diameters of all suture samples were similar.

The first experiment carried out was to measure geometric parameters of each suture using a stereoscopic microscope SteREO Discovery V20 Zeiss®. For each sample we have measured the diameter in several places, calculated the average diameter and measured the weight. Afterwards samples were placed in a container of saline solution (following PN-EN ISO 10993 guidelines). Containers were then placed in a laboratory oven at 37C. For next 2 months, every 7 days one sample was removed from each container and tested. Uniaxial tension tests were carried out using a testing machine MTS Synergie 100®. Samples were mounted in the machine using dedicated holders placed 50cm apart. Tensile speed was constant and equal to 30 mm/min. Based on the experiments several mechanical parameters were estimated – breaking force, extension at break, stiffness coefficient, tensile strength strain at break and Young's modulus.

### RESULTS AND DISCUSSION

Stress-strain characteristics obtained before incubation for five types of the sutures are presented in Figure 1. Differences in shapes for each suture type can be clearly seen on this basis one can observe differences in the

shapes of the curves. They were close to the sutures Caprosyn<sup>TM</sup>, Biosyn<sup>TM</sup> and PDS<sup>TM</sup> II, Catgut. Figure 1 presents that the maximum stress values ranged from about 250MPa to 800MPa, and the maximum value of extension of the sample ranged from approximately 50 to 150%.

Fig. 1. Stress-strain characteristics obtained in the uniaxial tensile resorbable thread

Fastest resorption among analyzed sutures types was observed for Caprosyn<sup>TM</sup> and Polysorb<sup>TM</sup>. The values of all the mechanical parameters measured decreased with incubation time. The only exception was the PDS<sup>TM</sup> II for which stiffness increased with incubation time.

### CONCLUSION

Based on these results, it was possible to compare mechanical parameters of different types of surgical sutures and to determine the relationship between the parameters and bioresorption stage. This study is a source of valuable information on how bioresorption affects suture's properties, this relation is not fully known at the moment<sup>4</sup>.

## INTRODUCTION

The biological properties of polymer materials strongly depend on many factors, such as the phase composition, the structure (degree of crystallinity), the microstructure and the surface properties (roughness, wettability)<sup>1</sup>. Yet these characteristics can undergo significant changes as a result of processing of polymer materials and their composites, due to the exposure to high temperature, pressure and a solvent<sup>2</sup>. In the presented paper, the influence of the PLDLA polymer's processing and its composites with TCP on the proliferation and vitality of the cells was examined. These dependences were combined with the changes in the surface and structural properties of the tested materials as a result of their processing.

## EXPERIMENTAL METHODS

The  $\beta$ -tricalcium phosphate (TCP, Fluka, Germany) was used as the filler of the PLA matrix (PLDLA: 70% L/30% DL). Two methods of polymer processing were used: injection moulding (W) and hot compression of prepress (R). The injection moulding was performed at 160°C in a screw injection moulding machine. The hot compression methods included casting polymer films from the PLDLA or PLDLA+TCP solution in  $\text{CH}_2\text{Cl}_2$  and next cutting out the correct shape and hot compressing of the prepress (120°C, 110 kPa/cm<sup>2</sup>). The thermal stability and wettability of the samples were measured. The cytotoxicity tests were performed in Laboratory Cell, Department of Histology and Embryology, Wrocław Medical University according to PN-EN ISO 10993-5 Part 5: Tests for *in vitro* cytotoxicity'. The tests were conducted by the direct contact method on mouse fibroblasts 3T3/Balb.

## RESULTS AND DISCUSSION

In the cytotoxicity test on the samples made of polymers PLDLA „0”, PLDLA (R) and PLDLA (W), we did not state any agglutination, vacuolization, separation from the substrate or lysis of the cell membranes. The highest proliferation of the cells, at all the test times, was stated for the cultures with the non-processed polymer PLDLA „0” (Fig.1a). Both processing methods had their effect on the worsening of the cell proliferation. In all the cultures with the tested samples the percentage of dead cells was identical (Tab.1). The differences in proliferation between the non-processed polymer and that after the processing can be connected with the influence of processing on the structural and surface properties of the tested materials. Both the injection moulding and the hot compression caused a slight increase of the crystallinity degree of the polymer, as a result of the high temperature of processing, which is favourable for the ordering of the

structure and the creation of small crystalline areas. Processing also decreases the hydrophilicity of the surface, which significantly impairs cell proliferation (Tab.2).

**Fig.1.** Proliferation of mouse fibroblasts 3T3 Balb in cultures with (a) PLDLA and (b) PLDLA+TCP as compared to the control culture.

**Tab. 1.** Evaluation of cytotoxicity of biomaterials.

Culture	Time - 24 h		Time - 48 h		Time - 72 h	
	dead cells %	cyto-toxicity	dead cells %	cyto-toxicity	dead cells %	cyto-toxicity
Control culture	0	0	0	0	2	0
PLDLA „0”	0	0	0	0	2	0
PLDLA (R)	0	0	0	0	2	0
PLDLA (W)	0	0	0	0	2	0
PLDLA+TCP (R)	0	0	2	0	5	0
PLDLA+TCP (W)	0	0	3	0	5	0

**Tab. 2.** Contact angle of tested materials.

Material	PLDLA „0”	PLDLA (R)	PLDLA (W)	PLDLA+TCP (R)	PLDLA+TCP (W)
$\Phi$ [°]	54,4±3,6	82,0±1,9	84,3±1,9	59,4±4,0	79,8±4,4

For PLDLA+TCP(R) and PLDLA+TCP(W), the cell proliferation was lower than in the polymer cultures without TCP (Fig.1b). After 48 and 72h, we stated a higher percentage of dead cells, as compared to the control cultures and the polymer cultures without TCP. The worsening of these properties was more significant for PLDLA+TCP(W) with regard to PLDLA(W) than in the case of the hot-compressed samples. These changes also correlate with the hydrophilicity of materials. For PLDLA+TCP(R) the surface hydrophilicity does not undergo any significant change as compared to PLDLA „0”, although an increase of the contact angle for PLDLA+TCP(W) is clearly seen (Tab.2).

## CONCLUSION

The non-processed polymer showed better biological properties than after processing. The technique of polymer processing had only a slight influence on the cytotoxicity of the materials. A significant effect of the surface and structural properties on the cell proliferation was observed.

## INTRODUCTION

Internal fixation using miniplates is a common technique for stabilising bone fragments in maxillofacial fractures and osteotomies [1]. In this research the stability of a model fixation during uniaxial tensile test was analysed using finite element method (FEA). The comparison between FEA and actual tensile test was conducted to learn about utility of FEA in biomedical engineering and the nature of a miniplate's cracking process.

## EXPERIMENTAL METHODS

The miniplate was made of medical grade poly(L-lactide PLLA (Purasorb® PL38, Purac). Injection moulding was applied to form samples (T=200°C) (Fig.1).

Figure 1. Tested miniplate made of PL38

### Finite element method

FEA was accomplished with ABAQUS CAE software. It was used to determine how geometry of the miniplate affects its destruction. Owing to the two existing planes of symmetry the model was simplified to 1/4 of its original size to make the analysis easier and quicker (Fig.2).

Figure 2. Analysed fixation model and its simplification.

The simulation was divided in three parts, respectively:

- 1) determination of boundary conditions;
- 2) simplification of the screws tightening;
- 3) static extension of the joint.

### Tensile test

To compare and verify the results of the simulation an uniaxial tensile strength test was performed. The miniplate was attached to the base with metallic screws. Various values of the tightening torque were applied (80% and 60% of  $M_{max}$ ).

## RESULTS AND DISCUSSION

### Finite element method

FEA simulations showed the layout of stress concentration. Based on these maps, analysis of the deformation process up to decohesion were done (Fig.3a).

### Tensile test

Tensile tests revealed the influence of a tightening torque values on the deformation process of the miniplates. The best results were obtained for a 60% of  $M_{max}$ . The miniplate broke in the same spot as it was indicated by FEA (Fig.3b).

Figure 3. a) Visualisation of tensile test simulation. Progression of the necking within next three steps during elongation; b) miniplate after actual test

## CONCLUSION

The simulation and the actual tensile test were compared. It showed that simulation can help engineers to understand what happens inside of the tested sample. Investigating the mechanical aspects of resorbable miniplates used for bone fixation is a very important issue. They are more brittle than metal plates, so there is a greater possibility of their destruction during or after implantation.

## Water Loss of Surface Treated Glass-Ionomer Cements

Elizabeth Bent<sup>1</sup>, John Nicholson<sup>1</sup>.

<sup>1</sup>Applied Physics/School of Sports, Health and Applied Sciences, St Mary's University, England  
[lizzy.bent@stmarys.ac.uk](mailto:lizzy.bent@stmarys.ac.uk)

### INTRODUCTION

Glass-ionomer cements (GICs) are dental restorative materials that have a high susceptibility to water loss in the early stages of setting, as a result of the water that is used and made in the acid-base reaction<sup>1</sup>.

The water present in GICs has been found in two states: 'tightly bound' and 'loosely bound' the distinction between these types of water is whether water is removed from the GIC in a desiccating environment or with a high temperature<sup>2</sup>. 'Superficial water' is another state found in GICs which is seen 'to arise from a small loss from the surface water'<sup>3</sup>. The use of surface protection for GICs has been employed in research to understand water movement in the cement system; it was found the use of varnishes, emollients and light-activated bonding resin were effective in limiting water movement<sup>4, 5</sup>. In this research four treatments are used on GICs surfaces for 24 hours before being transferred to a desiccating environment to ascertain how surface treatment affects water loss in modern Type II.1 GICs<sup>1</sup>.

### EXPERIMENTAL METHODS

Three brands of commercial GICs; AquaCem (DENTSPLY), Fuji IX GP Extra (GC Corporation) and Ketac Molar Aplicap (3M ESPE) were used for the experiments. The first cement was hand mixed with distilled water and the remaining cements were capsules; each GIC was made by following the manufacturer's instructions then placed in a silicone rubber mould between two glass slides. The specimens were disc shaped with dimensions of 5mm in diameter by 1mm depth. Once made the specimens were transferred to an incubator for 10 minutes at 37°C to further harden. The surface treatments were applied to each brand, the treatments utilised were: desiccation over concentrated sulphuric acid, 5ml distilled water, no treatment (control) and Vaseline. Treatments were applied for 24 hours then transferred to a desiccator over concentrated sulphuric acid for six weeks; the loss in mass was recorded weekly.

### RESULTS AND DISCUSSION

Table 1 Greatest % Water Loss of surface treated GICs.  
 Key: Week 3 - a, Week 4 - b, Week 5 - c, Week 6 - d

	<i>Vaseline</i>	<i>No Treatment</i>	<i>Desiccator</i>	<i>Water</i>
AquaCem	12.99% <sub>d</sub>	15.58% <sup>a</sup>	16.36% <sub>d</sub>	14.96% <sub>c</sub>
Fuji IX GP Extra	7.04% <sup>a</sup>	8.94% <sup>c</sup>	8.96% <sup>b</sup>	8.46% <sup>c</sup>
Ketac Molar Aplicap	6.03% <sup>c</sup>	7.47% <sup>c</sup>	7.53% <sup>c</sup>	10.49% <sub>c</sub>

Table 1 show the greatest percentage water loss calculated during the six week experiment, it was found that this loss occurred at a variety times for each treatment yet was quite similar within brands. Previously GICs were found to loose between 18-28% of water under desiccation<sup>6</sup>; whilst these results have shown that even specimens under desiccation for the entire experiment lost less water than was once expected. In regards to the treatments used Vaseline offered the best protection as it had the lowest percentage water loss for each brand and Ketac Molar Aplicap lost the least amount of water and took up to five weeks to reach this loss. This data implies that there was a greater ratio of 'tightly bound' water to 'loosely bound' water in Ketac Molar Aplicap, as less water was available to be removed by desiccation over the period of the experiment.

### CONCLUSION

It was found that the treatment of Fuji IX GP Extra and Ketac Molar Aplicap with Vaseline for 24 hours was effective in reducing the amount of water lost from the material over the entire experiment. However it has yet to be found how the application of this treatment affects strength.

### INTRODUCTION

Bacterial biofilms, also known as plaque, form on teeth and dental implants, and may lead to dental caries, periodontal disease with tooth loss, serious infections or implant failure. Biofilms also mineralise, forming calculus that is removed mechanically by clinicians using the chipping action of a dental scaler.

Ultrasonic scalers are used in dentistry for plaque and calculus removal due to their efficiency and greater comfort for the patient than hand instruments. Another advantage is the generation of cavitation within the water flow over the dental tip, which increases the cleaning efficiency<sup>1</sup>. Our objective was to investigate, image and quantify the disruption of bacterial biofilms on titanium by piezoelectric dental scaler tips.

### EXPERIMENTAL METHODS

Biofilms were grown in-vitro on titanium disks in a bioreactor by *Serratia* (NCIMB40259) bacterial model system and *Streptococcus mutans* oral bacterium. *Serratia* is capable of forming biofilm on various surfaces, as well as mineralising it to calcium deficient hydroxyapatite that chemically resembles calculus<sup>2</sup>. A Satelec ultrasonic dental scaler with water irrigation of the tip was used to disrupt the dehydrated biofilms for 30 seconds at fixed power setting giving a tip displacement of 15µm. Three tips with different shape (fig. 1)

**Fig.1** Design of the tips chosen for the study. The free end of the tip is placed parallel to the biofilm during the disruption. The threaded end of the tip is attached to a handpiece.

were applied with their front side parallel to the biofilm and tip end facing down. Two positions along the tips length, the tip end (A in fig. 1) and the tip curved side

**Fig.2** Images of the disrupted biofilm, obtained by Nikon camera (left) and optical microscope (right).

(B), where previous work has demonstrated cavitation were chosen to approach the biofilms. The removal was visualised by SEM, white light interferometry, optical microscopy, high-speed camera (figs. 2 and 3) and quantified using image analysis.

**Fig.3** Disrupted biofilm imaged by white light interferometry (left) and SEM (right).

### RESULTS AND DISCUSSION

An area of disruption on both *Serratia* and *Streptococcus mutans* biofilms occurred when the tip-biofilm distance was set at 40 µm to avoid direct mechanical action of the tip (figs. 2, 3). The disruption efficacy of the cavitation decreased at a higher tip-plaque distance (1 mm). The most effective removal occurred with the thinnest tip. The effect of the disruption varied with the position of the cavitation along the tip length. SEM revealed bacteria still present in the cleaned area but not as many as before the scaling. This might be due to the roughness of the titanium surface making it difficult to be completely cleaned by the scaler as well as to the much higher adhesion, which the biofilm layer adjacent to the material surface has. High speed camera imaging reveals the detachment of large biofilm flakes while the scaler tip is vibrating within the water flow.

### CONCLUSION

We have imaged how cavitation around ultrasonic tips might be used for the non-contact disruption of biofilms. Tip shape, tip-biofilm distance and position of cavitation along the tip length have all influenced the biofilm removal with the scaler.

## Degradation Processes of Ti6Al4V Alloy by Fretting and Fretting-Corrosion

Marcin Klekotka<sup>1</sup>, Jan Ryszard Dąbrowski<sup>1</sup>

<sup>1</sup>Department of Materials and Biomedical Engineering,  
Białystok University of Technology Wiejska 45C, 15-351 Białystok, Poland  
[j.dabrowski@pb.edu.pl](mailto:j.dabrowski@pb.edu.pl)

### INTRODUCTION

High biofunctionality of titanium and its' alloys enabled it to be one of the most promising groups of metallic biomaterials used for elements of bone surgery and prosthodontics<sup>1,2</sup>. Relatively low modulus of elasticity, good corrosion resistance, high biocompatibility are characteristics undoubtedly required among modern biomaterials. Essential downside of titanium alloys is their low tribological resistance and the presence of toxic additions of aluminium and vanadium (alloys of Ti-Al-V group)<sup>3</sup>. As a result of degradation of the elements of kinematic bounds, particularly exposed to processes of fretting and fretting-corrosion, ions of aluminium and vanadium are released to the organism. They may block the regeneration of nerve cells, as well as cause many diseases, inflammations, or even, when influencing for a long period of time, carcinogenic changes<sup>4</sup>. Considering high friction and wear, their usage is limited, and incompetent adjustment to exploiting conditions may be a cause to a decrease of exploitation durability of medical constructions. Better cognition of mechanisms of destruction of biomaterials is a crucial issue, which will directly contribute to an increase of medical comfort of patients.

### EXPERIMENTAL METHODS

Titanium alloy Ti6Al4V was subjected to fretting and fretting-corrosion tests. Friction couples operated in configurations metal-metal and metal-alumina ceramic. Tests were carried out in the conditions of dry friction and simulated oral cavity environment (saliva and its substitutes based on phosphate buffer). The processes of fretting and fretting-corrosion were conducted with the use of own construction pin-on-disc fretting tester combined with potentiostat VoltaLab21. Authorial method of examination was determined by a standard PN-EN ISO 10993-15:2009. Observations of sample surfaces were carried out using a Hitachi S-3000N (SEM) scanning electron microscope and a LEXT OLS4000 confocal microscope with capability of 3D imaging. Investigations of morphology and surface structure allowed to determine volume loss of material.

### RESULTS AND DISCUSSION

Fretting and fretting-corrosion tests were started by a friction force measurement. Received figures were used to calculate friction coefficients. Positive influence of lubricants on reduction of motion resistance and wear of was observed. Natural saliva presents the most profitable tribological characteristics. Potentiodynamic tests of fretting-corrosion have shown strong influence of fraction on corrosion processes. Polarisation curves

present characteristic ragged course, which evidences constant deterioration and renovation of boundary layers. In the case of adsorption oxide layers it is an unwanted phenomenon leading to an intensification of material wear.

Fig. 1. Anode polarisation curve in the saliva environment during fretting

### CONCLUSION

The results of the studies confirmed the high susceptibility of titanium alloy Ti6Al4V to wear as a result of fretting and fretting-corrosion. A clear influence of fretting on corrosion processes was observed. Application of lubricants such as saliva and its substitutes leads to reduce friction and tribological wear in various degrees. This is caused by formation of adhesive boundary layers on the alloy surface, which were built from organic components of used lubricants. Binding energy and adhesive abilities of biofilm may determine the efficiency of its performance.

## INTRODUCTION

Enamel demineralization and gingival inflammation are common side effects during orthodontic treatment with fixed appliances<sup>1</sup>. Surface free energy (SFE) and surface roughness (SR) are important surface characteristics for biofilm formation around teeth<sup>2</sup>. The purpose of this study was to investigate the effects of surface characteristics of orthodontic adhesives on the multi-species biofilm.

## EXPERIMENTAL METHODS

Thirteen strains of bacteria (*Streptococcus mutans* ATCC 700610, *Streptococcus sanguinis* CCUG 17826, *Streptococcus sobrinus* ATCC 27607, *Streptococcus salivarius* CCUG 50207, *Lactobacillus rhamnosus* ATCC 7469, *Veillonella dispar* KCOM 1864, *Actinomyces naeslundii* KCOM 1472, *Streptococcus oralis* ATCC 9811, *Neisseria subflava* ATCC 49275, *Fusobacterium nucleatum* ATCC 10953, *Prevotella nigrescens* ATCC 33563, *Porphyromonas gingivalis* KCOM 2797, and *Aggregatibacter actinomycetemcomitans* ATCC 43718) were used to simulate biofilm formation in the oral cavity. The multi-species biofilms were grown in the CDC biofilm reactor (BioSurface Technologies, Bozeman, MT, USA). The lid of reactor supports eight independent rods which can house three removable coupons. Three orthodontic adhesives – composite (Transbond XT, TX), compomer (Transbond Plus, TP) and resin-modified glass ionomer cement (Multi-Cure, MC) (3M Unitek, Monrovia, CA, USA) – were selected to prepare coupons. Six disk-shaped coupons of each adhesive were prepared with a diameter of 12.7 mm and thickness of 3.0 mm. BMMUG medium<sup>3</sup> was used to cultivate multi-species biofilms. Three coupons of each adhesive from a reactor rod were collected at the following time points: at day 1 (T1), day 4 (T2), and day 7 (T3). Bacterial chromosomal DNAs were extracted after biofilms were detached from the coupons. Total bacteria, two cariogenic bacteria (*S. mutans* and *S. sobrinus*) and two periodontal pathogens (*P. gingivalis* and *A. actinomycetemcomitans*) were quantified using real-time PCR. Each analysis was independently repeated five times.

SR and SFE characteristics were investigated for the orthodontic adhesives using a confocal laser scanning microscopy and sessile drop method, respectively. Each analysis was repeated five times for each of three specimens.

Repeated measures analysis of variance (ANOVA) was used to determine the time-related differences in the bacterial amounts with respect to adhesive type. Kruskal-Wallis test was used to determine the differences in surface characteristics among the 3

groups. For all analyses,  $\alpha < 0.05$  was considered statistically significant.

## RESULTS AND DISCUSSION

Adhesion of total bacteria and cariogenic streptococci bacteria (*S. mutans* and *S. sobrinus*) to orthodontic adhesives significantly increased between days 1 and 4, but there was no significant difference between days 4 and 7 ( $T1 < T2 = T3$ ). Adhesion of *P. gingivalis* and *A. actinomycetemcomitans* to orthodontic adhesives significantly decreased at day 7 ( $T1 = T2 > T3$ ).

There were no significant differences in adhesion of total bacteria among adhesives ( $TX = TP = MC$ ). *S. mutans* and *S. sobrinus* adhered to MC higher than other adhesives ( $TX = TP < MC$ ). However, the amounts of *A. actinomycetemcomitans* and *P. gingivalis* did not show significant differences between the three adhesives ( $TX = TP = MC$ ).

There were significant differences in surface characteristics among the adhesives. The order of SR was, from the lowest to highest, TX, TP, and MC. However, SFE showed different trends and TP had the greatest SFE followed by MC and TX ( $TX < MC < TP$ ). Considering that MC showed the higher adhesion of cariogenic bacteria and had higher SR than other adhesives, this study suggests that the effects of SR on bacterial adhesion would be more prominent than those of SFE, specifically on cariogenic streptococci. In contrast, periodontal pathogens may not be significantly influenced by surface characteristics.

## CONCLUSION

1. Resin-modified glass ionomer cement showed higher SR than composite and compomer.
2. Adhesion of total bacteria and cariogenic bacteria to orthodontic adhesives significantly increased at T2, while that of periodontal pathogens decreased at T3.
3. Cariogenic bacteria adhered to resin-modified glass ionomer higher than to composite and compomer. However, adhesion of periodontal pathogens was not significantly influenced by the adhesive type.
4. The effects of the SR on adhesion of cariogenic streptococci may be more prominent than those of the SFE.

### INTRODUCTION

Reactive oxidative species (ROS) that damage components of cells including proteins, lipids and DNA have been linked to various diseases<sup>1</sup>. When cell membrane is attacked by radicals, lipid peroxidation products (LPOs) are formed. They are often unsaturated aldehydes of great reactivity and with potential to oxidise proteins, producing carbonylated proteins. Oxidised proteins are dysfunctional and a hypothesis is that they are an underlying cause of oxidative stress related diseases, e.g. atherosclerosis. Endogenous nucleophilic molecules such as carnosine or synthetic analogues, so-called aldehyde scavengers, have shown great potential in removing ROS or LPOs including but not limited to acrolein, and carbonyl proteins<sup>2,3</sup>.

In this paper we present hydrazide modified dextran molecules as scavengers for products of oxidative stress. They were applied to scavenge the acrolein modified BSA in buffer. The capability of protecting cells against carbonyls toxicity was also investigated.

### EXPERIMENTAL METHODS

#### Preparation of hydrazide modified dextran

Schematic chemical reaction was shown in Figure 1.

**Figure 1.** Synthesis of hydrazide modified dextran.

#### Colorimetric characterization of scavenging effects

Protein samples were treated with 2,4-dinitrophenyl hydrazine (DNPH) in dark and then precipitated by cold trichloroacetic acid buffer. The pellet was washed by ethanol/ethyl acetate before dispersing in urea-PBS buffer and observed by UV-Vis spectroscopy at 370nm.

#### Cell viability and cytotoxicity

Mouse myoblast cells (C2C12) were incubated for 24h after adding sample solutions with modified BSA with or w/o added scavenger. The cells were washed with buffer and stained by alamar blue solution. Absorbance was measured at 570nm by microplate reader.

#### Protein gel electrophoresis

All protein samples were diluted to 1 mg/ml by PBS buffer for gel electrophoresis after loading 10μl protein samples in each of wells.

### RESULTS AND DISCUSSION

Hydrazide modified dextran samples with different substitution ratio were denoted as L1 and L2 (Mw=40000, 20 and 52 hydrazide groups per 100 glucose units), H1 and H2 (Mw=100000, 17 and 57

hydrazide groups per 100 glucose units). Un-modified dextran (Mw=40000) was defined as L0.

The scavenging effects were considered for factors including different types and amount of scavengers, and different concentration of acrolein modified BSA (Figure 2A). Figure 2B described the capability of hydrazide modified dextran protecting C2C12 cells against toxicity of acrolein handled BSA. Protein gel electrophoresis was also utilized to investigate the scavenging effects (Figure 3).

**Figure 2.** Scavenging effects on acrolein handled BSA. A) UV-Vis absorbance of different acrolein concentration handled BSA after different amount or different types of dextrans. B) Cell viability of C2C12 cells after incubation for 24hs with 10mg/ml L2 (a), 3mg/ml

**Figure 3.** Gel electrophoresis of protein markers (a), fresh BSA (b), fresh BSA-10mg/ml L2 (c), 500μM acrolein handled BSA (d), and 500μM acrolein handled BSA with 10mg/ml L0 (e), 1mg/ml L2 (f), 2mg/ml L2 (g), 5mg/ml L2 (h) and 2mg/ml H2 (i).

Higher hydrazide substitution ratio and Mw of dextran with higher amounts were always equivalent with higher scavenging effects on carbonyl proteins. Hydrazide modified dextran could protect the cells against the toxicity of protein carbonyls by the reaction between hydrazide and carbonyl groups. The Mw of BSA samples was increased by the reaction between protein carbonyls and hydrazide modified dextrans leading to the darker band in the higher Mw areas.

### CONCLUSION

Hydrazide modified dextran was synthesized for scavenging carbonyl proteins in PBS buffer. It was observed that high Mw of hydrazide modified dextran with high substitution ratio could achieve best effects on scavenging carbonyl proteins and protecting cells against their toxicity. The proposed samples have the potential to be utilized as scavengers for oxidative stress.

## Preparation of Substituted Hydroxyapatite for Tooth Enamel Remineralization

Vita Zalite<sup>1</sup>, Janis Locs<sup>1</sup>

<sup>1</sup> Rudolfs Cimdins Riga Biomaterials Innovations and Development Centre, Riga Technical University, Riga, Latvia  
[vita.zalite@rtu.lv](mailto:vita.zalite@rtu.lv)

### INTRODUCTION

Hydroxyapatite (HAp) is the most frequently used mineral form for biomedical application among apatite mineral family, due to its chemical relevance to hard tissue of mammals. Chemical and structural modification of HAp have a great interest among materials scientists, practitioners of medicine and dentists. In the last decade, calcium phosphate have been studied extensively for tooth remineralization, i.e., for caries preventive purpose<sup>1</sup>. Strontium (Sr) and fluorine (F) co-substituted hydroxyapatite (SrFHAp) could be a good candidate for tooth enamel remineralization due to HAp structural similarity to mineral part of enamel, a long known anti-caries effect of fluorine<sup>2</sup> and a potential of strontium as dentin desensitising agent<sup>3</sup>. Therefore it is challenging to obtain partly co-substituted HAp with desired amount of fluorine and strontium in the apatite structure, moreover so far synthesis application of SrFHAp has not been researched for dental application.

### EXPERIMENTAL METHODS

SrFHAp powder was synthesized through a wet precipitation method. Chosen reagents ( $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ ,  $\text{Sr}(\text{NO}_3)_2$ ,  $\text{NH}_4\text{F}$  and  $(\text{NH}_4)_2\text{HPO}_4$ ) were provided by Sigma-Aldrich.  $\text{NH}_4\text{F}$  and  $(\text{NH}_4)_2\text{HPO}_4$  were dissolved in the deionized water to prepare 0.03 M solution and afterwards added dropwise into the 0.05 M solution obtained from  $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  and  $\text{Sr}(\text{NO}_3)_2$  as  $\text{Ca}^{2+}$  and  $\text{Sr}^{2+}$  ion sources. The amounts of reagents were selected to gain solution with (Ca, Sr)/P molar ratio of 1.67. Synthesis was carried out at the ambient temperature and 45°C under continuous stirring. During precipitation reaction,  $\text{NH}_4\text{OH}$  (26 wt%) was used to adjust pH of suspension between 9-9.5 till the end pH remains in the range from 9.1 to 9.5. Obtained precipitates were left overnight, afterwards centrifuged and washed threefold with deionized water, followed by drying at 105°C. Dried products were sintered in at 1000 °C for 1 h. Fourier transform infrared spectrometry (FT-IR) and X-ray diffraction (XRD) were applied for chemical and phase analyses of SrFHAp. The morphology of the powder crystallites was observed using a field emission scanning electron microscope (FE-SEM) and presence of Sr and F were confirmed by EDS analysis.

### RESULTS AND DISCUSSION

X-ray diffraction pattern of as-synthesized SrFHAp powders showed maximum at 25.8° 2θ and a set of broader peaks around the HAp characteristic regions from 31° to 34.5° 2θ, from 38.4° to 40.9° 2θ. The nature of XRD pattern indicated SrFHAp powders with low crystallinity. Figure below revealed phase composition

of SrFHAp powders after sintering at 1000°C for 1h. The peaks at 30.93° and 34.23° 2θ in black pattern indicated presence of β-tricalcium phosphate phase, which means that obtained SrFHAp synthesized at 22°C was calcium deficient HAp, while powder synthesized at 45°C (grey pattern) showed only HAp phase.

FT-IR spectra of as-synthesized SrFHAp, indicating physically attracted  $\text{H}_2\text{O}$  presence with broad absorbance bands between 3650-3200  $\text{cm}^{-1}$  and 1890-1600  $\text{cm}^{-1}$ . The characteristic bands of  $[\text{PO}_4]$  group were located at 1200-920, 600 and 570  $\text{cm}^{-1}$ , but existence of  $[\text{HPO}_4]$  group was confirmed with peak around 880  $\text{cm}^{-1}$  in SrFHAp powder obtained at 22°C, indicating calcium deficient HAp, that agrees with XRD data. Characteristic  $\text{OH}^-$  band of HAp structure existing at 3570  $\text{cm}^{-1}$  shifted to the lower wavenumber value 3546  $\text{cm}^{-1}$  due to  $\text{OH} \dots \text{F}$  bonding appearance in apatite structure in both products. EDS analysis showed 0.62±0.10 at% of Sr and 1.42±0.80 at% of F presence in the SrFHAp powder (T=22°C), and 0.85±0.07 at% of Sr and 1.81±0.43 at% of F in the SrFHAp powder (T=45°C). FE-SEM analyse revealed nanosized, rod-like morphology of obtained SrFHAp crystallites.

### CONCLUSION

SrFHAp powders were successfully obtained *via* wet precipitation synthesis method. The phase composition and element substitution level in SrFHAp powders was dependent on synthesis temperature. Future work will be devoted to evaluation *in vitro* of enamel remineralization efficiency of SrFHAp for caries preventive purpose.

### INTRODUCTION

Metallic nanoparticles (materials with at least one dimension at scales of 1-100 nm) such as gold and silver have shown promise for current and future medical applications due to their enhanced total surface area to volume ratio<sup>1</sup>, ability to penetrate tissues and cells, deliver therapeutic drugs and genes, and respond to IR and other wavelengths of light to assist in disease diagnosis. In this study, rod-shaped silver nanorods (AgNRs) and gold nanorods (AuNRs) were fabricated by electron beam physical vapor deposition (EBPVD) and their cytotoxicity towards human skin fibroblasts were assessed and compared to sphere-shaped silver nanospheres (AgNSs) and gold nanospheres (AuNSs).

### EXPERIMENTAL METHODS

**Materials.** Nanospheres of silver with a diameter of 40 nm and at a stock concentration of 0.02 mg/mL; gold with a diameter of 60 nm and at a stock concentration of 0.05 mg/mL (Sigma-Aldrich, St. Louis, MO); Dulbecco's Modified Eagle Medium (DMEM), penicillin/streptomycin (P/S), acetone, and methanol (Sigma-Aldrich), Cacodylate buffered, glutaraldehyde, cacodylate buffer, osmium tetroxide, uranyl acetate, and lead citrate; Silicon wafers (Nova Wafers, Flower Mound, TX); Primary human dermal fibroblast cells (ATTC# CCL-110); Fetal bovine serum, FBS (Hyclone, Logan, UT); Promega CellTiter 96® Aqueous Non-Radioactive Proliferation (MTS) assays (Fisher Scientific, Pittsburgh, PA). **Growth of silver and gold nanorods.** Metallic nanorods of gold and silver were produced using EBPVD<sup>2</sup>. The substrates used were silicon {100} wafers with a diameter of 76.2 mm. **Characterization and cells evaluation.** The morphology features were analysed by SEM. The absorption spectra of the nanorods and nanospheres were collected on a SpectraMax M3® spectrophotometer (Molecular Devices, Sunnyvale, CA). Nanorods and nanospheres were each mixed at 1:1 v/v with cell culture media.

### RESULTS AND DISCUSSION

The morphology of the AgNRs and AuNRs fabricated by EBPVD, and the commercially obtained AgNSs and AuNSs, were assessed by SEM and are illustrated in Fig. 1. The top view SEM images of the AgNRs and AuNRs as grown on silicon substrates confirmed the successful synthesis of rod-shaped silver and gold nanostructures using the EBPVD system.

**Figure 1.** SEM images (100 nm) of metallic nanorods grown by the electron beam physical vapor deposition system. SEM images of (a) AgNS and (b) AuNS.

### CONCLUSION

This study has demonstrated that the surface chemistry, size and shape of citrate-capped spherically shaped nanoparticles (silver and gold) and PVD grown rod-shaped nanoparticles (silver and gold) can be controlled and influenced the toxicity of fibroblast cells.

# Chitosan-Based Hydrogels Modified with Silk Fibres for Cartilage Tissue Regeneration

Magdalena Kozioł, Kinga Pielichowska, Jan Chłopek

Department of Biomaterials, Faculty of Materials Science and Ceramics, AGH University of Science and Technology, Poland  
[mkoziol@agh.edu.pl](mailto:mkoziol@agh.edu.pl)

## INTRODUCTION

Chitosan (CS) has a number of useful properties such as biocompatibility, non-toxicity and bioactivity and is often used in biomedical applications<sup>1</sup>. One of the most important features of chitosan is its ability to create hydrogels<sup>2</sup>. Despite many desired properties of natural polymers, they have also some disadvantages such as low mechanical strength<sup>3</sup>. Because of low flexibility and brittleness of the chitosan, short silk fibres (SF) have been applied<sup>4</sup>. Recently, growing interest in silk fibers biomedical applications can be observed, due to their high tensile strength, flexibility, stability to heat and humidity, biocompatibility and high permeability to oxygen<sup>5,6</sup>. Structural proteins constituting silk fibers are biocompatible and biodegradable, hence they may be used to form hydrogels based on natural polymers<sup>6</sup>.

The aim of this work was to design chitosan-based hydrogels modified with silk fibres that can be used for cartilage tissue regeneration.

## EXPERIMENTAL METHODS

Chitosan with a molecular weight of 600,000 - 800,000 and sodium tripolyphosphate (TPP) were purchased from Acros Organic. Laponite® RDS was purchased from Rockwood Additives (USA). Silk fibers were from Jedwab Polski sp. z o.o. Milanówek, Poland. Lactic acid was purchased from AVANTOR. In the first step, Laponite dispersion was made. The Laponite was dispersed in 5% lactic acid solution using magnetic stirrer for 0,5 h, and then chitosan was added. The chitosan/Laponite system was stirred for 0,5 h. In the last stage various amount (0; 0,06; 0,13; 0,17 wt. %) of short silk fibers (SF) were introduced to chitosan/Laponite system. The obtained hydrogels were poured into a Petri dish and samples were dried at room temperature for one day, and next under vacuum for seven days. In the next step, the obtained samples were characterized using differential scanning calorimetry (DSC), Fourier transform infrared spectroscopy (FT-IR) and scanning electron microscopy (SEM) methods.

## RESULTS AND DISCUSSION

Results of DSC investigations are presented in Table 1 and in Fig. 1. As it can be seen with increase of SF content in the hydrogel, the glass temperature ( $T_g$ ) of obtained composites also increases.

Table 1. Thermal properties of CS/Laponite/SF systems.

SF content [%]	$T_g$ [°C]	Delta Cp [J/g·K]
0.00	117.95	0.101
0.06	125.28	0.041
0.13	126.62	0.007
0.17	127.46	0.057

Fig. 1. DSC curves of chitosan hydrogels modified with SF.

In FTIR spectra of investigated samples, the absorption bands of amides I, II and III can be seen – Tab. 2 and Fig. 2. For CS/Laponite/SF system, some characteristic absorption bands were shifted to lower wavenumbers in comparison to the pure chitosan hydrogel that suggests changes in hydrogen interactions in obtained systems.

Table 2. Descriptions of absorption bands of CS/Laponite/SF systems.

CS/Laponite Wavenumber [cm <sup>-1</sup> ]	CS/Laponite/0.06% SF Wavenumber [cm <sup>-1</sup> ]	CS/Laponite/0.17% SF Wavenumber [cm <sup>-1</sup> ]	Absorption bands
1740	1730	1738	C=O
1616	1618	1618	N-H (amides I)
1462	1462	1462	CH <sub>2</sub> , CH <sub>3</sub>
1417	1414	1416	C-N (amides I)
1321	1319	1319	C-O
1281	1281	1279	C-O-C
1126	1126	1126	C-O-C
1092	1092	1092	Si-O-Si
1005	1005	1005	Si-O-Si
866	866	864	C-O-C
777	777	777	C-O-C
652	654	652	band characteristic for Laponite

Fig. 2. FTIR spectra of CS/Laponite/SF systems.

Also some changes in microstructure in CS/Laponite/SF systems have been observed - Fig. 3.

Fig. 3. SEM microphotographs: (A) CS/Laponite system (B) CS/Laponite system modified with 0.21% SF.

## CONCLUSIONS

Chitosan hydrogels modified with short SF were obtained. Modification of chitosan hydrogels with SF leads to increase of glass temperature of chitosan. Some changes in microstructure can be also observed.

## Stable Pluronic Gel Formation by Incorporating Graphene Oxide

Da-Ae Won, Manse Kim, Giyoong Tae

School of Materials Science and Engineering, Gwangju Institute of Science and Technology, Korea  
[gytae@gist.ac.kr](mailto:gytae@gist.ac.kr)

### INTRODUCTION

Injectable hydrogels are useful for drug delivery, tissue engineering, and other biomedical applications. Aqueous solution of Pluronic shows a thermos-sensitive sol-gel transition and can be applied as an injectable hydrogel system since it is a solution at a low temperature but quickly converted to a gel state at a body temperature<sup>1</sup>. However, since it is a lyotropic transition, the gel state is not stable in an open environment, thus it shows a very fast dissolution upon injection, which limits its practical application *in vivo*. Various reports have attempted to enhance the stability of pluronic gel *in vivo*, mostly via post-crosslinking after injection by using chemically modified pluronic<sup>2</sup>. In this study, we reported that the addition of a small amount of graphene oxide (GO) can greatly enhance the stability of pluronic hydrogel in an open environment, and demonstrated the application of this system as an injectable and stable gel *in vivo*<sup>3</sup>.

### EXPERIMENTAL METHODS

To an aqueous solution (200  $\mu$ l) of 17 wt % Pluronic F127 (PEO100 PPO65 PEO100, MW 12.6 kDa) at 4 °C, 0.04, 0.08, or 0.1 wt% carboxylated GO was added. Then, the gel was formed by increasing temperature to 37 °C. Then, 5 ml of a release buffer (PBS with 2 mM% sodium azide) was added and kept in a shaking incubator at 37°C and 100 rpm. Then, the *in vitro* degradation rates of the hydrogels were measured by measuring the remaining volume of the hydrogel daily with the exchange of the whole release buffer.

*In vivo* stability and biocompatibility of the hydrogels were studied using male BALB/c mice (8 weeks old). All animals were handled in accordance with the guidelines of the Animal Care and Use Committee of GIST. Hydrogels were prepared as a sol state by lowering temperature to 4°C and injected subcutaneously at the back of mice using a syringe with a 22G needle. The sizes of injected hydrogels were monitored at 1 day, 1 week, 2 weeks, and 8 weeks. And, histochemical staining was done to characterize the biocompatibility of the hydrogels.

### RESULTS AND DISCUSSION

As expected, hydrogel made of 17wt % of pluronic was dissolved very fast; the gel phase disappeared mostly at day 1. In contrast, by adding GO, the stability of the hydrogel was greatly improved. Also, by increasing GO from 0.04 to 0.1 wt%, the stability of gel phase was

improved systematically. So, the addition of small amounts of GO could provide the long lasting gel.

By subcutaneous injecting a sol state of the solution at 4°C, the gel was formed immediately. And, the gel with 0.1 wt % GO lasted very long; ~ 80 % of the gel was remained in one month. So, the dissolution rate of GO-containing gel was much slower *in vivo* than *in vitro*, whereas the gel formed by pluronic alone disappeared completely in 1 day. No severe inflammation was observed in all cases, supporting acceptable biocompatibility of the present system.

### CONCLUSION

A simple addition of GO could greatly enhance the stability of a physical gel system, pluronic solution, and it was possible to apply as an injectable gel *in vivo*. The present results demonstrated that the addition of GO not only increases the mechanical properties of materials, but also can enhance the thermodynamic stability of physical gel systems.

# Nanotoxicity Studies of Nanodiamond on 2D and Magnetically Bioprinted 3D Scaffold-free Liver Model

Dipesh Khanal, Dong Fu, Iqbal Ramzan, Wojciech Chrzanowski

Faculty of Pharmacy, The University of Sydney, Australia

[dipesh.khanal@sydney.edu.au](mailto:dipesh.khanal@sydney.edu.au)

## INTRODUCTION

Among classes of nanoparticles developed as drug carriers, nanodiamond (NDs) has been gaining attention owing to its biocompatibility, easy functionalization, chemical stability, high thermal conductivity, and favourable optical properties<sup>1</sup>. New classes of NDs (Ray NDs) were recently produced based on laser ablation techniques. The NDs produced by this technique have higher purity index, diamond phase content and fewer purification steps<sup>2</sup>. However, novel properties and safety of these materials and their impact on biological processes are still largely unknown and need further investigation.

Current approach for nanotoxicity study relies on the use of two-dimensional cell culture models, which have severe limitation due to lack of “biomimicry” and do not provide robust scientific evidence of nanoparticle effects *in vivo*.

3D scaffold-free magnetically bioprinted liver model mimic complexity and functionality of tissues and may serve as a platform to study effect of nanomaterials on healthy and diseased tissues<sup>3</sup>. Here we demonstrate the applicability of 3D scaffold-free liver model to interrogate toxicity of NDs.

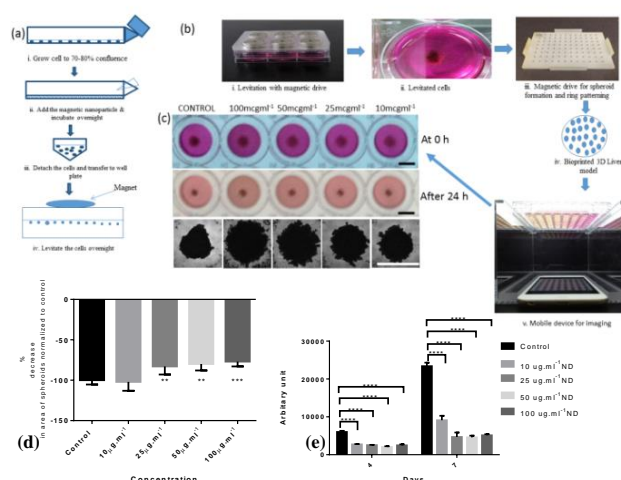

## EXPERIMENTAL METHODS

Fao Cells were used to prepare both (i) 2D monolayer cell culture model ( $2 \times 10^3$  cells per 200  $\mu$ L Dulbecco's Modified Eagle's Medium (DMEM) in a 96 well plate) and (ii) 3D scaffold-free model ( $1 \times 10^5$  cells per 300  $\mu$ L of DMEM in an ultralow adhering 96 well plate). 3D tissue model was generated by magnetic levitation (Figure 1 a and b). Nanotoxicity was assessed using real-time cell imaging up to 7 days (cell growth rate and morphology), viability (live/dead assay) on day 7, vitality assay (alamarBlue®) on day 2, 4 and 7 and 3D-spheroid ‘dot’ assay (where rate of change in area of each spheroids were monitored using a mobile based device over the period of 24 h). In both the models concentrations of NDs used were 10, 25, 50 and 100  $\mu$ g.mL<sup>-1</sup>. To examine the distribution of NDs in 2D and 3D structures and microtomed tissue sections scanning electron microscopy based on gatan back scattered electron, Lorentz contact resonance microscopy and nanoIR spectroscopy were used.

## RESULTS AND DISCUSSION

NDs was found to reduce the metabolic activity of the cells in 2D possibly associated with genotoxic effect of oxidized nanodiamonds and this effect was time-dependent (time-dependent NDs uptake) as metabolic activity of cells was seen to be significantly reduced in comparison to the control after 4 days of nanoparticle exposure. Interestingly, above a threshold concentration of 18.63  $\mu$ g.mL<sup>-1</sup>, cells had similar metabolic activity irrespective of increase in concentration (Figure 1 (e)).

It may be suggested that cells could not uptake NDs above this threshold value. On the contrary, toxic effect of NDs was observed within 24 h in the 3D model as indicated by significant differences ( $p < 0.05$ ) in rate of change in the area of spheroids, which may be related to reduced metabolic activity and cell death owing to toxic effect of NDs (Figure 1(d)). Under such condition, higher contraction of spheroid corresponds to lower toxic effect whereas dilation indicates toxicity. However, above the concentration of 25  $\mu$ g.mL<sup>-1</sup>, no significant differences ( $p > 0.05$ ) in the rate of contraction of spheroids was observed indicating uptake threshold.

**Figure 1** Toxicity studies of NDs in 2D and 3D model; (a) schematic chart for magnetization and levitation of cells; (b) magnetic levitation of the cells and bio printing of 3D Spheroids; (c) bio patterned 3D spheroids at 0 time and after 24 h of treatment with NDs, (image from mobile device; upper two panel) (scale bar = 5 mm), brightfield images of the spheroids after 24 h of treatment (lower panel) (Scale bar = 300  $\mu$ m); (d) graph showing the percentage change in area of spheroid over the treatment period; with the increase in concentration rate of change in area decreased. \*\*\* indicates significant difference from control ( $p < 0.05$ ); (e) metabolic activity results (alamarBlue® assay) on the monolayer culture treated with NDs; with the increase in concentration, metabolic activity was found to be reduced based on duration of exposure; \*\*\*\* indicates highly significant difference from control ( $p < 0.05$ ).

## CONCLUSION

Results of cell growth, viability, vitality as well as quantitative measurements of morphologic changes of 3D models after exposure to increasing concentration of NDs indicate that NDs have toxicity above the threshold concentration of  $\sim 20$   $\mu$ g.mL<sup>-1</sup>. 3D model was able to detect the toxic effect within 24 h of treatment in comparison to 2D where longer incubation (4 days) was required indicating its higher sensitivity. Thus, 3D spheroid based assay may be a useful tool for high throughput screening of nanotoxicity.

## Investigation of a Novel Bioresorbable Polymer Coated Drug-Eluting Scaffold

Tamara Mahmood<sup>1</sup>, David Scurr<sup>1</sup>, Nial Bullett<sup>2</sup>, Kadem Al-Lamee<sup>2</sup>, Morgan R. Alexander<sup>1</sup>, and Clive J. Roberts<sup>1</sup>

<sup>1</sup>Laboratory of Biophysics and Surface Analysis, School of Pharmacy, The University of Nottingham, NG7 2RD, UK, <sup>2</sup>Arterius Ltd, Bradford, BD7 1DP, UK, [Paxtm1@nottingham.ac.uk](mailto:Paxtm1@nottingham.ac.uk)

### INTRODUCTION

A stent is a medical device designed to function as a permanent or non-permanent internal scaffold to increase the diameter of the lumen of a blood vessel. Drug eluting stents have revolutionised the treatment of coronary artery disease<sup>1</sup>. Drug eluting stents have been approved for use in humans since 2002 and yet the drug release mechanism and uptake into the arterial wall are relatively poorly understood<sup>2</sup>. The first bioresorbable drug eluting scaffold (Abbott ABSORB) was introduced in 2011. In this study, a polymeric stent with novel mechanical property stent [patent W02014/045068A1] for treating coronary artery disease was characterised using Scanning electron microscopy (SEM), Atomic force microscopy (AFM) and time-of-flight secondary ion mass spectrometry (ToF-SIMS).

### EXPERIMENTAL METHODS

Using a spray-coating, sirolimus/P<sub>DLLA</sub> was coated onto the surface of a bioresorbable P<sub>L</sub>LA scaffold by Arterius Ltd. A Philips XL30 SEM and AFM FastScan (BrukerNano) were used to study the surface morphology of stents exposed to dissolution media for 0, 11 and 14 weeks. ToF-SIMS investigation was carried out on flattened luminal and abluminal sections of the scaffold. ToF-SIMS depth profiling utilised a ION-ToF-SIMS IV instrument using 10KeV Ar<sub>2500</sub><sup>+</sup> for sputtering and 10KeV Bi<sub>3</sub><sup>+</sup> for analysis.

### RESULTS AND DISCUSSION

Key functions of this device is to be a fully bioresorbable and give controlled release of a drug (sirolimus) from a polymeric coating layer. SEM (Fig.1) and AFM (Fig.2) images show that the coating layer appeared homogenous on coating (albeit with some evidence of nanoscale structures in the AFM) but became heterogeneous on dissolution. The three-dimensional distribution of sirolimus in P<sub>DLLA</sub> as a function of elution time was achieved by ToF-SIMS imaging and depth profiling (Fig.3) clearly showing the loss of drug from the coating.

Figure 1. SEM images of bioresorbable drug-polymer coated scaffolds. A drug-polymer control (top), 11 (centre) and 14(bottom) weeks eluted scaffolds.

**Figure2.** AFM images for 2x2μm area of topography (left), deformation (centre) and adhesion (right) of the abluminal side of a drug/polymer control (top), 11 (centre) and 14 (bottom) weeks eluted scaffolds.

**Figure 3.** 3D images taken from an abluminal and luminal areas of control and eluted stent. The 3D images are iso-surface overlay of Na<sup>+</sup> (red), sirolimus (green), and P<sub>DLLA</sub> (blue).

### CONCLUSIONS

The morphology and chemical composition of a novel bioresorbable drug eluting scaffold has been characterised at the nano and micro-scale. SEM and AFM revealed that the P<sub>DLLA</sub> coating presents a heterogeneous surface on dissolution. Distinctive fragments of the drug and polymers were used to monitor the spatial distribution of the drug with ToF-SIMS. Molecular depth profiling of coatings on scaffold is shown to be feasible and that 3D molecular compositional information was obtained.

### INTRODUCTION

Nowadays, scaffolds used in tissue engineering application not only have to meet the stringent requirements of biocompatibility and biodegradability but should as well stimulate natural regeneration process of the body. In the case of bone tissue regeneration, ability to trigger new blood vessel formation is essential for proper reconstruction of the tissue as the vessels provide regenerating tissues with oxygen and nutrients. It has been demonstrated that calcium ions, present in calcium phosphate glass-ceramic, exhibit angiogenic properties and help in faster and proper bone concretion process [1-5]. Therefore, comprehensive understanding of degradation process of calcium phosphate glass-ceramic is a matter of great importance.

### EXPERIMENTAL METHODS

In the present study, detailed characteristic of calcium phosphate glass-ceramic in the system of  $P_2O_5 - CaO - Na_2O - TiO_2$  was performed in order to evaluate changes occurred during degradation process of CaP glass-ceramic – ceramic scaffolds in SBF solution. Glasses with different calcinations temperatures were investigated. Morphology of tested materials in initial state and after degradation test was determined using scanning electron microscopy (SEM). Energy-dispersive X – ray spectroscopy (EDS) and Fourier transform infrared spectroscopy (FTIR) techniques were used to evaluate the changes in chemical composition of examined materials. For initial evaluation of the biocompatibility of CaP glass-ceramic, protein adsorption test was performed with Bovine Serum Albumin (BSA) as a model protein.

### RESULTS AND DISCUSSION

SEM observations revealed that the materials possess porous microstructure with round shape pores and there were no significant changes in internal architecture between glass-ceramic produced with different temperature of calcinations. After incubation in SBF solution, shapes of pores change from round to elongated. In addition, the sample surface was covered with precipitations from SBF solution in flower-like shapes. Thin film on the samples was detected as well. EDS results revealed that after degradation additional elements such as chlorine, potassium and magnesium were detected which precipitate from SBF solution. As far as FTIR results are concerned, it has been revealed that chemical composition after incubation in SBF solution changed in comparison to initial state and additional picks corresponding to the P-O and P=O bonding occurred. The picks related to phosphate

groups correlate with newly formed precipitations from SBF solution that settled on the glass-ceramic surface. Protein adsorption test revealed that BSA adsorbed to the surface of CaP glass-ceramic as pick at  $1658\text{ cm}^{-1}$  corresponding to amide I has been observed which indicate biocompatibility of this materials.

### CONCLUSION

The significant changes in morphology and chemical composition of analyzed materials after degradation test has been observed. Numerous particles in the shape of flower-like precipitation from SBF solution has been detected and identify as phosphate compounds attached to glass-ceramic surface. Preliminary biocompatibility test revealed ability to bond proteins on the surface of the tested material. Therefore, calcium phosphate glass-ceramic in the system of  $P_2O_5 - CaO - Na_2O - TiO_2$  is appeared to be promising candidate for bone tissue reconstruction supporting the natural process of regeneration.

### INTRODUCTION

Bio-inspired materials are synthetic materials whose structure, properties or function mimic those of natural materials or living matter. In this study, collagen (Coll) scaffolds reinforced by eggshell-derived nano-hydroxyapatite (nHAp) have been developed for potential use in osteochondral defects. Such defects can arise from trauma, degeneration or age-related diseases and they remain a major clinical challenge due to the limited repair capacity of the articular cartilage due to its avascularity<sup>1</sup>. Tissue engineering plays a key role in the development of improved strategies for osteochondral regeneration, providing engineered extracellular matrices that support, lead and promote new tissue regeneration<sup>2</sup>. nHAp/Coll scaffolds were characterized physicochemically to verify their chemical composition and mechanical properties. Furthermore, they were seeded with primary human mesenchymal stem cells (hMSCs) and examined for differentiation towards osteogenic and chondrogenic lineages for a period of 28 days.

### EXPERIMENTAL METHODS

**Scaffolds synthesis** Bovine type I collagen was used as a collagen source. Hydrated calcium oxide (from hen eggshell), and phosphoric acid were used for nHAp synthesis. nHAp/Coll porous scaffolds were fabricated by freeze-drying. Three different weight ratios were analysed: 0/100 (A), 30/70 (B) and 50/50 (C).

**Physicochemical analysis** X-ray diffraction and FT-IR spectroscopy were used to verify, respectively, phase and chemical composition of the composite scaffolds. Mechanical properties were evaluated by uniaxial unconfined compression tests in cell culture media.

**Biological analysis** Scaffolds were seeded with primary hMSCs. After seeding, cells were conditioned to induce terminal differentiation in osteo- or chondrogenic differentiation conditions. Cell proliferation (AlamarBlue™) and viability (Live and dead®) were analysed after 1,3,7,14,21 and 28 days. The morphology of cells on the scaffolds was evaluated using SEM analyses. Immunostaining was used to confirm terminal differentiation of cells after 28 days.

**Statistical analysis** Statistical significance was determined using One- and Two-Way ANOVA ( $p < 0.05$ , Kruskal-Wallis and Tukey's tests).

### RESULTS AND DISCUSSION

**Physicochemical properties** XRD and FT-IR analyses confirmed that scaffolds were composed of collagen and HAp, and both materials were chemically integrated with each other. Compression tests showed

improved mechanical properties with the increase of the HAp content.

**Biological response** AlamarBlue assay showed that both in osteogenic and chondrogenic conditions cell proliferation in the 30/70 and 50/50 nHAp/Coll scaffolds was significantly higher than the 0/100 (Fig. 1). Live and dead staining confirmed good cell viability for the scaffolds up to 28 days. Immunostaining showed good results both in osteo- and chondrogenic conditions after 28 days.

The scanning electron micrographs show that after 28 days in chondrogenic medium the cells had more processes compared to the cells after 28 days in osteogenic medium (Fig. 2). The cells appeared larger and more "active" and had good cell to cell interaction with adjacent cells.

**Fig. 1:** Cell proliferation in osteogenic (left) and chondrogenic (right) conditions. Statistical significance: \* 0/100 vs. 30/70, 50/50; # 30/70 vs. 50/50;  $p < 0.001$ .

**Fig. 2:** SEM images of two hMSCs after 28 days in osteogenic (left) and chondrogenic (right) condition. Scale bar 30 μm.

### CONCLUSION

nHAp/Coll scaffolds were biocompatible and were able to support stem cells and allow differentiation towards specific lineages. Scaffolds with a high HAp content showed better biological properties in the osteogenic environment. On the other hand, scaffolds with a lower HAp content showed a much better biological response in the chondrogenic environment. Further investigations are ongoing, however, these materials show potential for applications in osteochondral tissue engineering.

## Biomimetic Scaffolds Based on Biopolymers and Calcium Phosphates for Bone Tissue Engineering

Liliana Verestiuc, Florina Ivan, Maria Butnaru

Faculty of Medical Bioengineering, 'Grigore T. Popa' University of Medicine and Pharmacy, Iasi, Romania

[liliana.verestiuc@bioinginerie.ro](mailto:liliana.verestiuc@bioinginerie.ro)

### INTRODUCTION

Although the preferred treatment for restoring bone defects is autologous bones grafting some limits are associated with it: morbidity associated with the bone-graft donor site and limited quantity or quality of autologous-bone graft material [1]. An alternative therapeutic technique is tissue engineered bone [2]. Not only the combination of biomaterials but also the morphology of the scaffold, characterised by a highly interconnected, 3D pore network as well as tailored surface characteristics, determine the suitability of the scaffold. For bone tissue engineering, pore size >100  $\mu\text{m}$  are desirable, as well as high pore interconnectivity, in order to facilitate the attachment and proliferation of cells, the ingrowth of new tissue and vascularisation.

This study presents the synthesis and characterization of scaffolds based on collagen(Col), chitosan (Cs), sodium hyaluronate (Hya) and calcium phosphates (CP), obtained by using a biomimetic method. Collagen provides structural and mechanical support to tissues and organs and fulfils biomechanical functions in bone, cartilage, skin, tendon, and ligament [3]. Freeze-dried chitosan sponges have shown the ability to support osteoblast growth and deposition of mineralized matrix [4]. Hyaluronic acid has several advantages as a biomaterial like as: excellent physical properties and chemical structure that can modulate the biological interactions; the biopolymer acts locally and in combination at the fracture site to promote healing by stimulating tissue formation. The novelty of our work is represented by the biomimetic co-precipitation method of CP in the biopolymeric mixture, used to obtain calcium phosphate crystals similar to the natural process of bone formation.

### EXPERIMENTAL METHODS

By precipitation of CP from its precursors ( $\text{Ca}(\text{NO}_3)_2$  and  $\text{NaH}_2\text{PO}_4$ ) on the mixture of collagen, chitosan and hyaluronic acid, in presence of  $\text{NH}_4\text{OH}$ , biomimetic composites scaffolds were obtained. The materials were maintained at room temperature for 24 hours and than they were purified (extensively washed with distilled water) and freeze-dried. Scanning electron microscopy (SEM) and Fourier transformed infrared spectroscopy (FTIR), X-ray photoelectron spectroscopy (XPS) and X-ray diffraction (XRD) were used to characterize the structure and the morphology of the scaffolds.

The simulated fluids retention in composites was evaluated in phosphate buffer and the PBS retention degree was calculated. In vitro enzymatic degradation study was performed in the phosphate buffer solution (pH 7.2), in the presence of collagenase or lysozyme at the temperature of 37 °C.

The *in vitro* cytotoxicity studies were performed on osteoblasts and STEM cells.

### RESULTS AND DISCUSSION

FTIR, SEM(Fig.1) and XPS data confirmed the forming of CP, onto biopolymeric matrix. The results obtained indicate that the major inorganic phase is represented by hydroxyapatite and these composites present a lower enzymatic degradation which facilitates an *in vitro* degradation control.

Fig.1. SEM data of CP-Col-Cs-Hya scaffold

The scaffolds are interacting with PBS at physiological pH and the PBS retention is strictly connected with the scaffolds three-dimensional porous structure. The *in vitro* biocompatibility studies have showed that the osteoblasts and STEM cells are viable in the studied cultures.

### CONCLUSION

The obtained results confirmed that biocompatible scaffolds based on collagen, chitosan, sodium hyaluronate and calcium phosphates have been obtained using a co-precipitation biomimetic method. The chemical composition of the scaffolds, their morphology, a good interaction with simulated body fluids and the non cytotoxic effect indicate that these scaffolds are suitable for bone tissue engineering.

<sup>1</sup>\*Laboratory of Advanced Materials and Constructions, Department of Mechanical Engineering, Technological Educational Institute of Thessaly, GR 41110-Larissa, Hellas,

<sup>2</sup> Department of Materials Science, University of Patras, Rion 26500, Patras, Greece

[mouzakis@teilar.gr](mailto:mouzakis@teilar.gr)

### INTRODUCTION

Calcium phosphate (CaP) cements are used as bone substitutes and they have the advantages of injectability and in situ hardening in comparison with other implants such as ceramics. The main objective of the current study as part of an overall project for the development of new CaP bone cements is the study of calcium phosphate cements with enhanced mechanical properties. In spite the good biological properties of CaP based biocements they are usually plagued by low inherent mechanical properties. Porosity on the other hand promotes the osteoblast cell anchoring and proliferation but also reduces mechanical properties.

### EXPERIMENTAL

For the preparation of  $\alpha$ -TCP powder, equimolar quantities of calcium carbonate and calcium pyrophosphate ball milled and next the mixture was placed in alumina crucible, dried at 80 °C, placed in a furnace at 1300 °C for 12 hours and rapidly quenched on a metallic surface. The resulted material was crushed in the ball mill. The cement powder was mixed with 4 % w/v  $\text{Na}_2\text{HPO}_4$  solution in an agate mortar at a powder/liquid ratio of 0.32. Albumin and gelatin incorporated in the liquid phase of the cement were used as foaming agents. A stable foam was formed after mechanically stirring and next the powder was mixed with the foam to form the paste which was moulded in 6 mm x 12 mm cylindrical moulds. The specimens remained in 100 % humidity for 12 hours and were then removed from the mould and placed at 37 °C in a polyethylene vial containing 60 ml of Ringer solution for 14 days for hardening. Mechanical properties of these materials were determined in compressive mode at 0.5 mm/min crosshead speed. Porosity was calculated by the Ishikawa-Asaoka relation [J. Biomed. Mater. Res. 29, 1537 (1995)].

### RESULTS AND DISCUSSION

It can be seen from the compressive properties presented in Table 1 and Figure 2 below of the  $\alpha$ -TCP based porous bone cements that their mechanical properties are comparable to those of the human bones (e.g. cortical bone), making them candidates for implants in bone deficiencies.

Additive Percentage [%]	Compressive Strength [MPa]		Porosity as Calculated [%]	
	Albumin	Gelatine	Albumin	Gelatine
0	29,24	37,99	33,30	29,45
1	24,33	30,7	36,00	32,58

10	4,27	6,34	61,59	55,78

Table 1. Typical Compressive properties of the porous bone cements studied.

These properties remain high at foaming agents up to 5wt% added in solution. Representative SEM images showing the morphological characteristics of the porous hardened cements are shown below in Figure 1 below.

Figure 1. Representative SEM images from the porous calcium phosphate specimens tested as a function of albumin content.

Figure 2. Compressive Strength as a function of specimen porosity.

### CONCLUSION

It was shown that it is feasible to produce porous bone cements based on  $\alpha$ -TCP and foaming agents with satisfactory biomechanical compressive properties.

## INTRODUCTION

A promising therapy for diseases associated with increased production of reactive oxygen species (ROS), such as hypertension, ischemia, myocardial infarction and restenosis, involve the antioxidant enzymes. The efficiency of enzyme is dependent on the ability to achieve therapeutically adequate levels at the site of ROS-mediated injury [1]. Enzymes immobilization on superparamagnetic iron oxide nanoparticles (SPIONs) can increase efficiency and limit adverse effects of thermal and proteolysis degradation [2]. In this paper, with the aim to design such enzyme-immobilized SPIONs (enzySPIONs), catalase and superoxide dismutase (SOD) have been used as targeted therapeutic agents. These enzymes contain active centers with coordinated metals, which decompose superoxide anion and hydrogen peroxide, respectively, the most important reactive oxygen species [3]. For modulation the enzySPIONs efficiency the following parameters of the immobilization process were studied: the enzyme type, the ratio enzyme/SPIONs and enzyme conformation.

## EXPERIMENTAL METHODS

Functionalized SPIONs with antioxidant enzymes have been obtained by Catalase/SOD immobilization through direct reaction onto SPIONs based on magnetite, coated with functional synthetic polymer (copolymer of maleic anhydride). Briefly, 5 mg enzyme was dissolved in 20 mL phosphate buffer saline (PBS), at pH=8.00 and then poured within a suspension of SPIONs (100 mg nanoparticles dispersed in 30 mL PBS, pH=8.00, 0.05 M) and slowly mechanically stirred for 24 h. The particles have been collected from suspension through magnetic separation, purified by repeated washes with PBS (2x) and deionised water (3x) and finally freeze-dried. For modulation the enzySPIONs efficiency the immobilization parameters were studied: the enzyme type and the ratio enzyme/ SPIONs.

## RESULTS AND DISCUSSION

FT-IR data, dynamic light scattering evaluation of the zeta potential and hydrodynamic particle mean diameter confirmed the enzymes immobilization onto SPIONs. The enzySPIONs dimensions vary from 400nm for catalase immobilization to 1µm for SOD immobilization (Table 1).

The particles morphology was studied by scanning electron microscopy and suggests that the obtained enzySPIONs interact during the drying process and some clusters are formed (Figure 1).

The MTT assay revealed the citocompatibility of the enzyme-immobilized SPIONs and the hemocompatibility data indicated no interference of the enzySPIONs with blood coagulation system.

Enzymatic activity of magnetic particles has been

determined indirect by NTB-methionine-riboflavin (in the case of superoxide dismutase) and direct, with H<sub>2</sub>O<sub>2</sub> (for catalase). EnzySPIONs preserve an enzymatic activity which is dependent of the magnetic particles concentration, the enzyme nature and biological molecule conformation onto magnetic particle.

Table1. SPIONs dimension and Zeta Potential

SPIONs	Hidrodynamic diameter(nm)	Zeta Potential(mV)
Pure SPIONs	330±0.32	-20 ± 0.15
Catalase-SPIONs	432±3.12	-17 ± 0.39
SOD-SPIONs	970±0.27	-22 ± 0.32

data are presented as means ±standard deviation for n=3

Figure 1. SEM morphology of SOD-SPIONs

From the magnetization data was observed that the residual magnetization and the coercive force were zero, and there was no magnetic hysteresis loop. The lack of hysteresis is one of the criteria requirements for the identification of the particles as superparamagnetic.

## CONCLUSION

A new type of functionalized superparamagnetic nanoparticles has been obtained by SOD/catalase immobilization onto SPIONs. Functionalized SPIONs are characterized by good magnetic properties, are biocompatible and exhibits enzymatic activity which recommend them in cardiovascular applications.

## INTRODUCTION

The urethral stenosis is a disease caused by inflammatory conditions secondary by traumatic processes, infectious, iatrogenic or surgical procedures. Different therapeutic options has been used that the internal urethrotomy, terminal urethroplasty, the urethroplasty using buccal mucosa, colon, foreskin flaps and other grafts<sup>1, 2</sup>. However, the results are not always favorable. We initiated the development of a therapeutic approach using a biomaterial obtained from osseous matrix (Nukbone®) in urethral its heals the dog.

## EXPERIMENTAL METHOD

Cylindrical implants of collagen type 1 were obtained from osseous matrix (Nukbone®), with appropriate measures to replace a portion of 3 cm of the urethra in stricture induced by heat in the group 1 and three dog Sham in the group 2. between 6 and 8 years of age. The animals were sacrificed after 350, 360 and 370 days of implantation. The implanted segments were removed to perform histological studies of the regenerated tissues. The histological samples were fixed in formalin and were embedded in paraffin for cutting techniques, were used Hematoxylin-Eosin, Masson staining and Cytokeratin 7 and 20. MMP2, MMP 9, Colagenasa I and IV, were used to aid in the identification of normal and abnormal epithelial cells and residues of the Nukbone®. Also the evaluated whit uretroscopy and Magnetic Resonance (fig.1), with suitable permeability in the urethral.

## RESULTS AND DISCUSSION

In the surfaces of the urothelial implants, cell proliferation were observed for all cases, the cells were layered whose number increased with time, these were healthy urothelial cells. It was observed that the collagen cylinders were degraded the rest was healthy urethral tissue, with the permeability and low fibrosis in the Magnetic Resonance. Was maintained until complete resorption. There normal cell proliferation was proportional to the time of implantation with healthy cells. Also the form and function of the urethral stricture induced the heat.

Fig.1. Urethroscopy and permeability of the Scaffold. Arrow red. Urothelial over the implant.

## CONCLUSIONS

Collagen cylinders tested are a possible therapeutic solution for stricture the urethral in the model experimental, the use in human is the option in that diseases the urethral and ureter.

## INTRODUCTION

*In situ* nanoindentation in a scanning electron microscope (SEM) enables site specific loading and the discontinuities in the loading and unloading curves to be associated with the discrete events such as fracture onset or delamination. Here, we report on the use of *in situ* nanoindentation to study the mechanical properties of demineralised dentine and enamel after treatment with a sodium calcium phosphosilicate bioactive glass (45S5, supplied by GSK). To aid the mechanical analysis, a focused ion beam (FIB) system has been used to micromachine mechanical test structures such as coupons, bridges and cantilevers and to make site specific cross-sections to obtain sub surface information such as the depth of occlusion of the tubules.

## EXPERIMENTAL METHODS

Ten 2 mm thick tooth slices prepared from ethically acquired sound human molars were etched in 0.5% citric acid for 30 seconds. After washing the demineralised slices were cleaved in two and one half immersed in 50 ml of artificial saliva (AS) containing 10 mg of the calcium sodium phosphosilicate bioactive glass (the treated samples) and the remaining halves were immersed in only AS for 2 hours (the untreated samples). The samples were then dried and a FIB/SEM tool was used to micro machine mechanical test structures into both the dentine and the enamel and to make site specific cross sections for SEM and TEM.

## RESULTS AND DISCUSSION

EM analysis showed that a platelet hydroxyapatite-like crystalline layer occurred both on the surface and into the tubules and that the demineralised dentine zone was

Figure 1

remineralised. Figure 1, above shows a SE image of a site specific loading of a treated sample and corresponding load-displacement curves. The average hardness of the intertubular dentine of the treated samples was 1.2 GPa and the untreated samples was 0.8 GPa. The hardness and mechanical response was found to vary with distance from the bioactive glass particles that were adhered to the surface of the samples.

Site specific FIB cross-sectioning close to the indents enabled the orientation of the tubules, their degree/depth of occlusion and the degree of remineralisation to be correlated with the load curves.

Figure 2, below shows a FIB machined bridge in a treated sample during loading by a flat punch and the corresponding load-displacement curve. The FIB

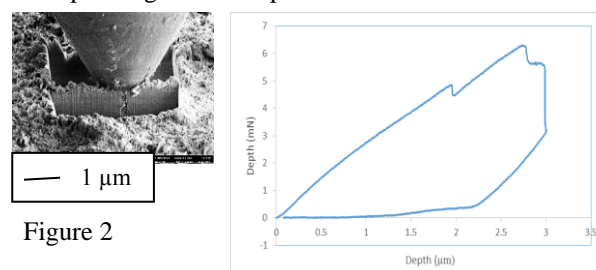

Figure 2

milling was used to select an area that contained a single occluded tubule which ran perpendicular to the surface to enable the fracturing of the formed material to be correlated to the load curves and to simplify the analysis. The fracturing was found to occur through occluding material and not at the interfaces to the peritubular dentine.

Figure 3 below shows a FIB machined enamel coupon prior to being loaded and the corresponding load-

Figure 3

displacement curves of treated and untreated enamel pillars. The untreated enamel was observed to undergo more fracturing than the treated enamel pillars. EM analysis showed that in the treated enamel the etched inter prisms regions were bridged by hydroxyapatite-like crystalline material which can partly explain the differences in mechanical response.

## CONCLUSION

The work has shown how the use of FIB micro machining, site specific FIB cross-sectioning with *in situ* nanoindentation is a very powerful combination to aid understanding the micromechanics of treated dentine and enamel.

## Effect of Crystallinity of Carbonated Hydroxyapatite on Bone Repair

### INTRODUCTION

Carbonated hydroxyapatite (CHA) is the main mineral component of bone and a potential bone substitute for orthopedic/maxillofacial surgery<sup>1,2</sup>. In this work we synthesized CHA samples (carbonate occupying phosphate sites) with different crystallinity and dissolution rate. Samples were characterized from the point of view of phase composition and stoichiometry, carbonate sites, crystallite long and short range order, crystal morphology and crystal size, surface structure, specific surface area, pore distribution and *in vitro* dissolution rate. The *in vivo* behavior of CHA samples with low, medium and high crystallinity were evaluated in order to check the inflammatory response and bone repair efficiency of each CHA.

### EXPERIMENTAL METHODS

Nanostructured CHAs containing 6-wt% CO<sub>3</sub> in phosphate sites (B type CHA) were synthesized by a wet precipitation method at 5°C (CHA5), 37°C (CH37) and 90°C (CH90) and pH=11. Samples were analyzed by X-ray diffraction (XRD), X-ray fluorescence (XRF), Fourier Transform Infrared (FTIR), Scanning and Transmission Electron Microscopy (SEM, TEM, HRTEM, XDS), thermogravimetric analysis (TGA), X-ray photoelectron spectroscopy (XPS) and Physisorption techniques. Biological evaluations were conducted using microspheres (425-600µm) of nanostructured-CHA. Subcutaneous tissue analysis, 75-Balb/C mice were randomly divided in groups of 5 animals to evaluate the local biological effects 1, 3 and 9 weeks after implantation, comparing to sham-group, according to the scoring system established in the ISO 10993-6:2007. Similarly, 72-Wistar rats (n=5, 4, 12 and 24 weeks) were used for a critical-size-calvaria-defect treated with biomaterials and cloth. These samples were processed for light microscopy and polarized light microscopy to evaluate new bone formation through histomorphometric analysis

### RESULTS AND DISCUSSION

Physico-chemical analyses showed that the decrease of the synthesis temperature induced disorder in CHA structure and decrease in the particle size, specific surface area, pore size and *in vitro* dissolution rate. Sample synthesized at 5 °C was predominantly amorphous with a high, *in vivo*, biodegradation rate while the one synthesized at 90 °C was crystalline. The inflammatory potential was also evaluated from the perspective of the capacity of the materials to attract mast cells. The CHAs did not induce a

significant increase in the number of mast cells compared to the sham group, in contrast to HA. No groups showed signs of fibrosis around the biomaterial. On the contrary, intense cellularity was observed without necrosis suggestive of the attempt to absorb the material. Together, the data obtained from the tissue response to the CHs indicates that they are biocompatible are bioabsorbable, particularly CHA5 and CHA37. In calvaria defect, CHA37 exhibited the highest resorption ( $p < 0.05$ ) and together with cHA 5°C led to greatest new bone formation (ANOVA, Kruskal-Wallis, Dunn's,  $p < 0.05$ ), Fig.1.

**Figure 3.** (A) Volume density of newly formed bone and (B) biomaterial 30, 90 and 180 days post-implantation.

### CONCLUSION

Carbonate substitution improves biological behavior of hydroxyapatite. However, crystallinity and degradation rate of CHA must be adjusted to optimize bone repair.

### INTRODUCTION

Additive manufacturing (AM) technologies allow the creation of 3D structures by direct conversion of the patient data into implantable scaffolds of a specific material system. Porous ceramic bodies obtained by this method have better mechanical strengths than porous structures obtained by other technologies as replica-SSV, foaming, etc. However, most of the AM technologies for ceramics produce a green body, which requires debinding and sintering at high temperatures in order to achieve adequate mechanical properties<sup>1</sup>.

Gypsum can be used as raw material for the production of HA<sup>2</sup>. The conversion of solid porous gypsum scaffolds on HA scaffolds<sup>3</sup> presents a great advantage due to formation of HA at temperatures of approximately 100°C, without the need of further thermal treatment. It results in a low crystalline structure considered to be bioresorbable<sup>4</sup>.

The aim of this work is the production of HA porous scaffolds with controlled porosity and high dimensional precision using hydrothermal conversion of gypsum scaffolds produced by 3D printing.

### EXPERIMENTAL METHODS

Gypsum hemihydrate powder ( $\text{CaSO}_4 \cdot 0.5\text{H}_2\text{O}$ , P.A: Merck, Germany) was granulated in a spray drier (B290 – Büchi Switzerland) using 5%-masse of PVB (B-79, Butvar, Eastman, USA) as binder. The printable granules were used to produce cylindrical structures with a diameter of 18 mm and a height of 1.9 mm in a 3D Printing machine (RX Series, Prometal, Germany).

The porous gypsum structures were submersed in 200 mL of  $(\text{NH}_4)_2\text{HPO}_4$  solution ( $0.5 \text{ mol.L}^{-1}$ ) at a temperature of 100°C at different reaction times to convert into HA. The pH of the medium was adjusted to 9 by addition of  $\text{NH}_4\text{OH}$  solution ( $6.0 \text{ mol.L}^{-1}$ ). At the end of the reaction time, the blocks were washed in deionized water until reaching neutral pH and then dried in an oven at 50°C for approximately 4 hours.

The scaffolds were characterized before and after conversion by Electron Microscopy (SEM) using Energy Dispersive Spectroscopy (EDS) and X-Ray Diffraction.

### RESULTS AND DISCUSSION

The gypsum structures produced by 3D print showed enough mechanical properties to permit their handling and conversion into HA. The produced scaffolds can be observed in Fig.1. These structures presented a geometrical density of  $0.82 \pm 0.04 \text{ g/cm}^3$  that can be related to a porosity of  $68.1 \pm 2.0 \%$ . After conversion a

slightly increase of the porosity is expected to occur due to changing of the crystal structure.

Fig. 1. Gypsum samples produced by 3D printing.

The XRD patterns before and after 12 hours conversion are showed in Fig. 2, where a total conversion of the Gypsum in HA can be verified. The maximum intensities peaks of gypsum at  $2\theta = 11.63^\circ$  and  $20.70^\circ$  are not present on the patterns of the samples after conversion.

Fig. 2. XRD Patterns of the samples before and after conversion for 12 h.

### CONCLUSION

HA scaffolds were produced by chemical conversion of 3D printed gypsum structures. A reaction time of 12 hours was enough to promote a complete formation of single phase HA.

<sup>2</sup>Department of Biomaterials, Dental School, University of Athens, Athens, Greece  
[npapaioan@med.uoa.gr](mailto:npapaioan@med.uoa.gr)

### INTRODUCTION

Accuracy and high repeatability of experimental surgical implantation technique is one of the major factors in the study of biomaterials. High repeatability allows the extraction of homogenous characteristics and secure results while reduces the sample size and the cost of the study. The aim of this study was the topographical assessment of a-TCP implantation in a femoral metaphysis rabbit model by using radiological signs and anatomic landmarks [1,2].

### EXPERIMENTAL METHODS

Twenty-four New Zealand White Rabbits were divided in two groups. All specimens underwent plain / facial radiographs and a computer-assisted topographic numeric division of each distal femur was conducted. In the first group a-tcp was implanted in the femoral metaphysis based only on anatomic landmarks. In the second group, a-tcp was implanted in the femoral metaphysis based on pre-operative radiologic evaluation combined with anatomic landmarks. Post-operative radiographic localization result of a-tcp was compared between the two groups

### RESULTS AND DISCUSSION

The second group, with the preoperative radiographic marking assistance, had higher rate of a-tcp coverage (statistically significant) of the targeted area compared with the first group. More specifically, the first group presented 80% a-tcp coverage while the second group 90% based on pre-operative planning.

The size of the rabbit as well as the presence of preoperative radiological assessment affected the direction (towards diaphysis) of the critical size defect and the distribution of the a-tcp which was injected. The second group had smaller peri-operative complications and smaller incision size .

The New Zealand White Rabbits are ideal experimental model for the study of filling bone defects. Skeletal maturation occurs in the species with the closure of the epiphyseal plates at the age of about 6 (six) months. Among experimental models, the KNZ have significant advantages such as the rate of bone turnover, the stability, the experimental reproducibility, ease hosting , small size and relative low cost [3,4,5].

The femoral metaphysis of the rabbits was chosen due to specific anatomical and cortico-cancellous characteristics which may affect the

histomorphometric analysis. The high repeatability of this anatomic site ensures these characteristics of the environment which hosts the biomaterial.

### CONCLUSION

The combination of pre-operative radiographic assessment and the anatomic landmarks provides higher rates of experimental repeatability and accuracy in the implantation of a-tcp.

## INTRODUCTION

The initial stages following contact between a bioactive glass and a biological aqueous host play a key role in starting the chain of processes ending in the dissolution of soluble species that trigger tissue regeneration and interfacial bonding. The central interaction of the glass with water results in rapid exchange between alkali ions and protons and formation of a silica-rich layer. Whereas the formation of this layer on highly bioactive glasses such as 45S5 is established<sup>1</sup>, its structural properties and mechanism of formation are less understood. A fundamental understanding of these issues can be gained through atomistic simulations.<sup>2</sup> In the past years, we have been using simulations to rationalise the behaviour of bioactive glasses at a fundamental level, from identifying new structural features of the bulk glass beyond the network connectivity that may help in predicting its bioactivity<sup>3,4</sup> to explicitly modelling the Bioglass/water interaction at the surface<sup>5</sup> and in the bulk,<sup>6</sup> to unveiling the effect of hydration on glasses for radiotherapy.<sup>7</sup> Here the target is shifted on an ion-exchanged bioactive glass, and on the effect of Na<sup>+</sup>/H<sup>+</sup> exchange on the structural features of the alkali-depleted glass.<sup>8</sup> The simulations provide a high-resolution picture of the structural evolution of the glass during this stage.

## EXPERIMENTAL METHODS

Systems of composition Na<sub>0.49-z</sub> Ca<sub>0.27</sub> P<sub>0.05</sub> Si<sub>0.46</sub> O<sub>1.56-z</sub> (OH)<sub>z</sub> with z=0, 0.1, 0.3 and 0.49 (z=0 corresponds to 45S5) were modelled, reproducing the gradual replacement of all Na<sup>+</sup> content by H<sup>+</sup> via increasing OH contents incorporated in the structure. A randomly-generated structure of ca. 3000 atoms was relaxed by thermal annealing via Molecular Dynamics (MD) simulations with a shell-model forcefield.<sup>7,8</sup> For each composition, the structural analysis was carried out on a final room-temperature MD trajectory.

## RESULTS AND DISCUSSION

The models provide a clear view of the way in which hydroxyl groups created upon alkali release are distributed and affect the glass structure. Whereas it is often assumed that the exchanged protons are found in Si-OH bonds, the simulations reveal a significant amount of OH groups not bonded to Si, but stabilised within cages of modifier (mostly Ca) ions. These “free-OH” species have been previously identified in silicate glasses and melts<sup>6,9</sup> at low hydration levels, which agrees with the present finding that their fraction decreases with increasing Na<sup>+</sup>/H<sup>+</sup> substitution (z): in Figure 1, we observe a transition from a structure with predominance of free OH at low z, to a structure where the dominant OH type is bonded to Si, at high z.

Figure 1: Free (yellow) and Si-bonded (blue) OH distribution across the Na<sup>+</sup>/H<sup>+</sup>-exchanged glass structures.

The analysis also highlights an increased connectivity of the silicate network upon gradual OH incorporation via Na<sup>+</sup>/H<sup>+</sup> exchange. This effect reflects the presence of free OH groups that preferentially attract Ca<sup>2+</sup> ions, removing them from NBOs bonded to Si atoms, which are thus led to repolymerise by forming new Si-O-Si bridges via Si-O...Si cross-linking in order to satisfy their oxygen coordination.<sup>8</sup>

## CONCLUSION

MD simulations suggest a direct, free OH-mediated mechanism for the formation of a repolymerised silica-rich network following Na<sup>+</sup>/H<sup>+</sup> exchange in 45S5 Bioglass, which can be alternative or complementary to the mechanism generally proposed. As the latter becomes more likely at higher Na<sup>+</sup>/H<sup>+</sup> exchange levels, a gradual transition between the two mechanisms could be envisaged as Na leaching proceeds and the silica gel layer is created.

## INTRODUCTION

Nowadays, scaffolds are used in several fields of tissue regeneration including dentistry. Their 3D shape stimulates growth, migration and differentiation of human cells for the reparation of the desire tissue. Successful scaffolds follow requirements, such as: possessing interconnected pores of proper size to allow the integration and vascularization of the tissue; controlled biointegration and biodegradability; surface that induces proliferation, differentiation and coupling of cells; adequate mechanical properties; and viability to be manufactured into specific shapes and sizes [1]. The aim of this study was to characterize hybrid scaffolds of  $\beta$ -TCP and collagen in their physical and mechanical properties.

## EXPERIMENTAL METHODS

The synthesis of  $\beta$ -TCP powders was based on the well-known route shown in Figure 1.

Figure 1: Route for synthesis of  $\beta$ -TCP.

After milling, a thermal treatment was performed to decompose the carbonate and nitrates, and to dehydrate the material [2]. Scaffolds were obtained by replica method, in which a sponge made of polyurethane was immersed in a ceramic suspension in order to cover its structure. Then, the pattern was compressed to remove the excess of suspension. As a result, the porous structure was covered by a uniform layer of ceramic slurry. Samples were thereafter submitted to thermal treatment in order to remove the polymer and sinter the ceramic. Collagen coating was then performed. The characterization of materials was carried out by X-ray diffraction and SEM-EDS. Scaffolds underwent compression test for mechanical assessment.

## RESULTS AND DISCUSSION

X-ray diffraction and SEM analyses revealed appropriate surface and composition of the material.

Figure 2: X-Ray diffraction of  $\beta$ -TCP.

Coated scaffolds presented better mechanical properties in comparison with non-coated samples.

Figure 3: Compression test result.

## CONCLUSION

Within the limitations of this study, it can be concluded that coating  $\beta$ -TCP scaffolds with a biodegradable polymers as collagen is an advantageous method to increase mechanical resistance in porous ceramic materials.

### INTRODUCTION

In recent years, CaO-SiO<sub>2</sub> based ceramics are categorized as bioactive ceramic materials. They have been regarded as potential candidates for artificial bone due to their excellent bone bioactivity and biocompatibility. They need only to improve their mechanical properties to use as implants under heavy loads. This paper describes the effect of magnesia in the presence of zirconia on the bioactivity, microstructure and physico-mechanical properties of calcium silicate composition adjusted at calcia/silica ratio (C/S) of 0.5.

### EXPERIMENTAL METHODS

A mixture from calcium carbonate and silica was conducted at C/S of 0.5. 20 wt. % of magnesia and 5-25wt. % of ZrO<sub>2</sub> were added. The batch with 20 wt.% MgO without ZrO<sub>2</sub> termed master batch (MB), and batches containing ZrO<sub>2</sub> termed "MBZ5", "MBZ15" and "MBZ25" for 5, 15 and 25 wt. %, respectively. Each mixture was planetary ball mill mixed in ethanol, dried, formed and fired at a temperature of 1325± 5°C. Phase composition, FE-SEM, and physico-mechanical properties in terms of apparent porosity, bulk density, linear shrinkage, Vickers hardness and fracture toughness of the fired specimens were determined and explained. The in vitro bioactivities of these specimens were investigated by analysis of their abilities to form apatite in the simulated body fluid (SBF) for a short time (7days) using SEM-EDS.

### RESULTS AND DISCUSSION

The findings indicated that the surface of the MBZ5 and MBZ15 specimens are completely covered by hydroxyapatite (HA) typical to "cauliflower"

morphology, while the MBZ25 specimens revealed the beginning of HA formation but its surface did not completely cover. The differences among the results were rationalized based on the phase composition. Vickers hardness and fracture toughness of the specimens of highly promised bioactivity are given in Table 1.

Table (1) Vickers hardness and fracture toughness of highly promised bioactivity specimens

Composition	Hardness (GPa)	Fracture toughness K <sub>IC</sub> , MPa.m <sup>1/2</sup>
MBZ5	2.32	1.8
MBZ15	2.57	1.5

### CONCLUSION

The properties of specimens of highly promised bioactivity are similar to the properties of human cortical bone. Consequently, these composites might be used as a bone implant materials.

## Lanyu Minipig is a Better Model System for Studying Wound Healing

### INTRODUCTION

Developing therapeutic approaches to treat wounds requires the selection of a suitable animal model that resembles human skin conditions. This study aimed to compare the skin wound healing features of Taiwanese Lanyu mini-pigs (TLY) with those of the domestic pig (Landrace, which is a well-known skin wound animal model) for evaluating whether TLY can be used to develop a wound healing animal model. Physiological parameters were measured, and skin growth rate was determined by measuring the changes in the size of tattoos drawn on the dorsal skin of pigs as a percentage of skin expansion of the original tattooed area. Contraction and re-epithelialization of full-thickness wounds were monitored histologically as well as by measuring the margin area and open wound area during healing.

### EXPERIMENTAL METHODS

Castrated male Taiwanese Lanyu mini-pigs (age: 7, 9, 16, and 40 weeks) from Taitung Animal Propagation Station and domestic Landrace pigs (age: 7 and 8 weeks) from the Genetic and Breeding Division of the Livestock Research Institute were used in this study. All animal care and operation procedures were performed according to the regulations of the Council of Agriculture, Executive Yuan Livestock Research Laboratory Animal review board. The skins on the dorsal side of the pigs were shaved and sterilized following anesthesia. The full-thickness excision wounds were created using a scalpel by removing the epidermis and dermis to a depth up to the subcutaneous fat layer.

### RESULTS AND DISCUSSION

The results indicated that, unlike Landrace pigs, TLY are relatively smaller in size and have a lower body weight; further, there was a linear correlation between skin growth and animal age up to maturity. Full-thickness wounds contracted remarkably during the first 5 weeks of healing in both strains irrespective of age. In >16-week-old TLY, wounds larger than 5×5 cm<sup>2</sup> showed a stable healing profile, overcoming the impact of skin growth on wound size expansion. The histological results also revealed similar healing and remodeling patterns between the two strains. Our findings suggested that 16-week-old TLY are optimally suitable for skin wound studies because they are easy to handle due to their smaller size and stable wound healing features. Skin wound model developed using TLY might be economically feasible for wound drug

screening and investigating healing profiles.

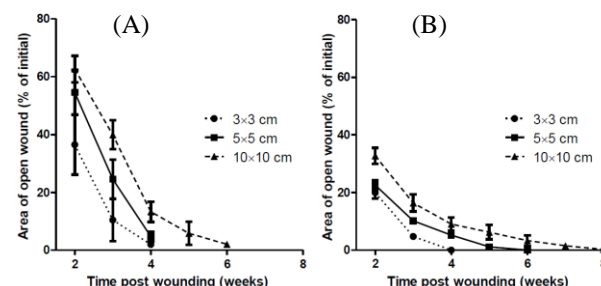

Figure 1. Profiles of wound re-epithelialization at the indicated breed and ages. Wounds were created on (A) 8-wks-old Landrace, (B) 9-wks-old TLY.

The wound healing profiles of Landrace and TLY pigs were determined at different growth stages by creating full-thickness wounds on the dorsal side of 8-week-old Landrace pigs and of 9-, 16-, and 40-week-old TLY. In TLY, the time to complete re-epithelialization did not differ according to age and wound sizes, and all smaller wounds closed within 4 to 5 weeks post wounding, whereas the larger wounds required more than 6 weeks for wound closure.

### CONCLUSION

In conclusion, compared to domestic pigs, Landrace pigs, the TLY mature earlier, have a smaller body size and bodyweight, show stable increases in physiological growth parameters, including body weight, body length, and abdominal circumference. Thus, TLY are favored for laboratory experiments. We highlight the main physiological properties of Taiwanese Lanyu mini-pig skin compared with those of domestic pig skin. The morphological features, skin growth profile, stable wound healing profile during wound contraction, re-epithelialization potential, and histological findings for the TLY obtained in this study might serve as the basis for future researches on using this breed as excision wound healing models. Taken together, our findings suggest that Taiwanese Lanyu mini-pigs can be used for developing skin wound healing animal models.

## Scanning Electron Microscope in Evaluation of Biomedical Materials – Own Experiences

Jacek Składzień, Agnieszka Wiatr, Katarzyna Zagórska-Świeży, Maciej Wiatr

Otolaryngology Department, Jagiellonian University, Poland

[jacek.skladzien@uj.edu.pl](mailto:jacek.skladzien@uj.edu.pl)

### INTRODUCTION

The limitation of development in surgery is possibility of reconstruction required after resection of pathologic tissues. Use of own patients' tissues in reconstruction is very often difficult or impossible. Therefore many studies to find alternative ways of reconstruction with artificial materials are undertaken. Biomedical materials are widely used in the surgery. They are used in organs' reconstruction (as prostheses) and in typical suturing of the surgical wounds (tapes, drainage)<sup>1</sup>. Stability in contact with patients' tissues and lack of allergic reaction with no rejection of the prostheses are of the greatest importance for biomedical materials.

### EXPERIMENTAL METHODS

Analysis of biomedical materials used in otolaryngology was performed with the scanning electron microscope (SEM). Biomedical materials obtained during surgery were compared with their sterile analogues. Changes in structure as a result of contact with patients' tissues were studied. Surgical sutures, prostheses for reconstruction of the ossicular chain in the middle ear, silastic removed from the nasal cavity that supported mucous membrane after septoplasty and latex as dressing material in the nose were taken into consideration.

### RESULTS AND DISCUSSION

Bacterial biofilm (known better than fungal one) is a three-dimensional structure that contains microcolonizations (aggregation of bacterial cells), that adheres to organic as well as inorganic surfaces (e.g. all sutures, prostheses used in reconstructions). Scanning electron microscope revealed features of biofilm on the surfaces of biomedical materials obtained from otolaryngological sites. Relationship between period of exposition and range of growth of the biofilm on analyzed surfaces was observed.

### CONCLUSION

The growth of bacterial biofilm on artificial biomedical materials is frequently observed. The stability and protection against rejection of artificial materials requires resistance to bacterial growth. This observation leads to necessity of additional modification of biomedical materials surfaces with bacteriostatic components due to decreasing or elimination of inflammation in the closest neighborhood of the used artificial prostheses or implants.

## INTRODUCTION

Mature osteoblasts are the cells responsible for bone formation and are derived from precursor osteoblasts. However, mechanisms that control this differentiation are poorly understood. In fact, unlike the majority of organs in the body, which are composed of “soft” tissues from which cells can easily be isolated and studied, the “hard” mineralized tissue of bone has made it difficult to study bone cells function. **The objective of our research program is the development of a smart and bioactive material, which can mimic the native bone extracellular matrix (ECM), and enable the understanding of their impact on the differentiation of mesenchymal stem cell (MSC).**

For this purpose, bioactive molecules were grafted onto the surface of polyethylene terephthalate (PET) in order to induce an osteogenic differentiation of MSC. Our objective is to control the spatial organization of these bioactive molecules on the surface at the micro and/or nanoscale, therefore mimicking bone ECM<sup>1</sup>.

Two different active biomolecules were used. On one hand, a RGD-containing (Arg-Gly-Asp) peptide which was selected to promote cell adhesion. On the other hand, the RKIPKASSVPTELSAISMLYL sequence from the BMP-2 (Bone Morphogenetic Protein-2), previously identified in Durrieu's group<sup>2</sup> was chosen due to its ability to promote bone differentiation while co-immobilized with RGD on PET surfaces.

## EXPERIMENTAL METHODS

In order to design the above-mentioned material, PET surfaces were modified according to the method described by Chollet et al<sup>3</sup>. First, materials were modified to generate COOH functionalities onto PET surfaces, by hydrolysis and oxidation of the material. Then, materials were immersed in a solution containing 1-Éthyl-3-(3-diméthylaminopropyl)carbodiimide (EDC) (0.2 M) + N-Hydroxysuccinimide (NHS) (0.1 M) + 4-Morpholineethanesulfonic acid (MES) (0.1 M) in order to activate the surface for peptide immobilization. Fluorescent peptides were used to characterize the homogenous functionalization of PET using fluorescence microscopy. All the samples were analysed with XPS, AFM. The amount of COOH grafted onto the film was determined using the toluidine blue-O method.

## RESULTS

Preliminary results have been obtained for homogenous surfaces by using the toluidine blue-O (TBO) method. COOH densities obtained for “PET Native”, “PET-Oxidized”, “PET-NHS” and “PET-GRGDSPC” are, respectively, 5, 32, 10, 24 pmol/mm<sup>2</sup>.

Figure 1 – (a) [COOH] densities obtained by toluidine blue staining and (b) fluorescent image of surface grafted with fluorescent peptides GRGDSK-FITC (scale bar: 25 µm).

These results show a rather low surface density of COOH moieties onto PET surfaces, while a 6-fold increase is observed after material hydrolysis and oxidation. The decrease in COOH surface concentration observed after conversion of acidic groups into activated esters and peptide immobilization confirmed successful grafting of these biomolecules. These results were further confirmed by XPS (not shown). In addition, the surface grafting of the aforementioned peptides labeled with fluorescent markers allowed measuring a steady fluorescent signal throughout the PET surface sample, therefore confirming peptide homogeneous grafting.

## CONCLUSION

Further works will focus first, on the evaluation of the impact of homogeneous bioactive surface on MSC differentiation and then on the patterning of both RGD or/and BMP-2 mimetic peptide according to predetermined micro and nanopatterns to promote the differentiation of MSC.

### INTRODUCTION

Scaffolds developed for bone tissue engineering (TE) need to facilitate and promote cell adhesion, proliferation and neo-tissue formation. They must possess specific properties to allow the new tissue to integrate with the material, without inducing any inflammatory response<sup>1</sup>. The intra-architectural scaffold geometry, porosity, scaffold material and surface area play important roles in this process<sup>2</sup>. Several polymeric systems (natural and/or synthetic) and processing methods have been proposed to develop the “ideal” scaffold for bone TE. However, so far the proposed strategies do not fulfil all the requirements for effective bone regeneration. Textile-based technologies constitute an innovative alternative for the production of 3D structures for bone TE applications, offering a superior control over scaffolds' design, manufacturing and reproducibility<sup>3</sup>. Silk fibroin (SF) derived from silkworm *Bombyx mori* has already proved to be a good biomaterial for bone TE applications<sup>4</sup>. SF-based structures offer impressive mechanical properties, biodegradability, biocompatibility and stability, which meets the basic requirements for the design of structures for bone regeneration applications<sup>5</sup>.

### EXPERIMENTAL METHODS

In this work we describe for the first time the processing of natural silk yarns into 3D scaffolds, combining standard knitting fabrics spaced by a monofilament of polyethylene terephthalate (PET). A comparative study is established using a stable polymeric system made entirely of PET. The obtained knitted spacer constructs were described in terms of morphology and mechanical properties. An *in vitro* biological assay was performed to evaluate the potential of the developed structures to support human Adipose-derived Stem Cells (hASCs) adhesion, proliferation and osteogenic differentiation. Cells were cultured over 28 days in standard basal and osteogenic conditions and evaluated through different quantitative (DNA, ALP, Calcium, RT-PCR) and qualitative (SEM, Alizarin Red, immunocytochemistry) assays. The *in vivo* biocompatibility of the textile materials was assessed by subcutaneous implantation in mice model. After 2 and 4 weeks of implantation the explants were collected and the obtained slides were stained with hematoxylin and eosin (H&E).

### RESULTS AND DISCUSSION

The cross-sections of the developed spacer textile constructs reveal a significant increase of the scaffolds three-dimensionality induced by the PET monofilament (Figure 1a). The hASCs seeded onto the spacer textile scaffolds were able to attach, spread, proliferate and differentiate, both in osteogenic and basal conditions (Figure 1b). Great evidences of ECM mineralization were observed, also penetrating and colonizing the PET monofilament (Figure 1a). The preliminary *in vivo* results revealed that the implanted scaffolds allowed tissue ingrowth, without inducing any acute inflammatory reaction (Figure 1c).

**Figure 1**—SF textile scaffolds seeded with hASCs and cultured for 28 days in osteogenic medium: (a) SEM micrographs from a cross-section and top view perspective. The red circle indicates mineralization nodules; (b) Confocal micrographs, nuclei stained in blue and Col I in green. (c) H&E staining of a SF textile scaffold in the explant, after implantation for 2 weeks.

### CONCLUSION

In this study, innovative 3D biotextile scaffolds able to support cell adhesion, proliferation and osteogenesis were successfully developed. Furthermore, these scaffolds allowed the new tissue formation and integration within the material, when subcutaneously implanted in mice. Thus, the proposed textile-based scaffolds can be promising candidates for bone TE applications such as the craniomaxillofacial complex<sup>6</sup>.

### INTRODUCTION

Nowadays, several protocols are proposed to induce the osteogenesis (new bone tissue formation) in order to regenerate or replace bone tissue when it is severely damaged. Unfortunately, producing clinically relevant volumes of bone with adequate stiffness to support load bearing functions in large defects remains the major drawback of the current approaches<sup>1</sup>. Indeed, this is mainly due to the lack of understanding of the osteogenesis mechanism *in vivo*. Accordingly, this project attempts to clarify these signalling pathways triggered during the response of stem cells to their osteoinductive microenvironment<sup>1</sup>. The original approach of this project consists in mimicking the extracellular matrix (ECM) of mesenchymal stem cells (MSCs) by grafting and micropatterning specific peptides on model biomaterial surfaces. Indeed, surface microstructuration, which somewhat mimics the ECM component organization, was demonstrated in several instances to improve cell adhesion, and even differentiation<sup>2</sup>. The peptides to be micropatterned are the RGD and BMP-2 mimetic peptides, which were selected for their ability to respectively induce the adhesion and the differentiation of MSCs into mature osteoblasts, able to synthesize a mineralized ECM<sup>3</sup>. In addition, it was shown that this combination of peptides increases the expression of RUNX2 (osteogenic marker), as opposed to the sole grafting of BMP-2 peptide<sup>3</sup>.

### EXPERIMENTAL METHODS

Glass slides were first functionalized using an amine-terminated silane. Then, the RGD and BMP-2 mimetic peptides were grafted through SMPB crosslinker. These two peptides were grafted as micropatterns by using photolithography. The designed micropatterns corresponded to square, rectangle or triangle with a constant surface area of 50  $\mu\text{m}^2$ . The surface chemistry and topography of the material were assessed using X-ray Photoelectron Spectroscopy (XPS) and Atomic Force Microscopy (AFM). Micropattern visualization and peptides surface concentration were achieved using fluorescent peptides RGD-TAMRA and BMP-2-FITC.

### RESULTS AND DISCUSSION

XPS survey analysis (Table 1) evidenced the grafting efficiency after each step of peptides grafting. On one hand, we noticed the appearance of nitrogen on aminated glass surfaces, which remains almost constant

after peptide grafting. Simultaneously, the silicon detection (substrate) decreased after each step of grafting. On the other hand, high resolution C1s XPS spectra clearly confirmed the immobilization of both peptides since the amount of amide bonds significantly increased from 1.1% on aminated glass to 7.6% and 8% on RGD and BMP-2 grafted surfaces, respectively.

Table 1: Surface composition determined by XPS

%	C	N	Si	288.4 eV : NH-C=O
SiO <sub>2</sub>	5.9	-	23.9	-
NH <sub>2</sub> -glass	58.5	8.7	8.4	1.1
RGD grafted	65.5	7.3	5.3	7.6
BMP2 grafted	62.8	8.8	5.1	8.0

The surface concentration of RGD-TAMRA and BMP FITC peptides, based on fluorescence measurements, was  $0.53 \pm 0.01$  and  $0.73 \pm 0.02$  Pmole/ $\text{mm}^2$ , respectively. Finally, peptide micropatterning was confirmed by fluorescence microscopy using fluorescent peptides. Indeed, the spatial distribution of the two peptides with the different geometries (rectangle, square, and triangles) was clearly evidenced and precisely defined (Fig. 1).

### CONCLUSION

Designing a biomimetic microenvironment onto biomaterial surfaces seems to be a promising tool to study the biological response of stem cells to their microenvironment. Indeed, understanding the mechanism of bone tissue regeneration may greatly help to induce osteogenesis by drawing relevant *in vitro* models capable to precisely direct stem cell towards specific lineages. Our preliminary surface characterization results evidenced efficient peptide grafting as well as surface microstructuring. Future works will assess the effect of peptide micropatterning on human MSCs commitment and differentiation.

### INTRODUCTION

Natural vitamin E has been frequently utilized for multiple pharmaceutical applications, demonstrating its positive effects as an emulsifier [1]. The potential health benefits of vitamin E supplementation were suggested in the 1950s [2]. An extensive attention has been paid on the antioxidant nature and free radical scavenging properties of vitamin E, due to the rapidly growing awareness of the physiological and toxic effects of free radicals in human diseases [3]. As mentioned earlier, PLGA NPs have been frequently prepared by using chemical emulsifiers such as PVA, which has showed side effects and problems. In this study, the effects of using natural vitamin E as an emulsifier for the synthesis of PLGA NPs have been studied. These combined techniques comprise three major steps as preparing an organic solvent, dispersing the organic solvent into an aqueous solution, and evaporating the volatile solvent. In addition, the cell response of the synthesized NPs has been tested by the MTT assay using osteoblast cells, as an important cell models for bone tissue engineering, in different dosages and time intervals.

### EXPERIMENTAL METHODS

The PLGA NPs were prepared by a one-step oil-in-water emulsion and solvent evaporation techniques. PLGA (50:50, Resomer-RG 503H; Boehringer Ingelheim) was dissolved in 1 mL of dichloromethane. Then, 50 mg of PLGA in dichloromethane was added into 50 mL of the dispersing phase including 0.02% sodium chloride (NaCl) and vitamin E (472.75 g/mol, Merck co.) aqueous solution (0.12%, 0.18%, 0.22% and 0.26%) under moderate magnetic stirring. The formed emulsion was then stirred on a magnetic stirrer plate at room temperature for 2 h to evaporate dichloromethane (DCM). The synthesized NPs were not necessarily required to be washed for removing the emulsifier.

### RESULTS AND DISCUSSION

Tissue engineering scaffolds can locally release biomolecules and accelerate bone ingrowth to the treated bone defects [4]. This allows for custom grafts to be designed as localized delivery systems. The homogenous distribution of the nanoparticles on the surface of porous scaffolds increases their surface area. As can be seen in the SEM micrographs provided in Fig. 1, the addition of vitamin E as the emulsifier to the PLGA nanoparticles resulted smaller particles in the

range of nanometers (ranging from 30 to 60 nanometers) for the sample containing 0.6 % vitamin E. The cellular activity of the nanoparticles showed to be nontoxic and without any sign of toxicity, suggesting that vitamin E can be used as an effective emulsifier. The main advantage of this system is that the vitamin E molecules are not required to be washed after the formation of the nanoparticles.

**Figure 4.** SEM micrographs of the synthesised samples containing NaCl and a) 0.12, b) 0.18, c) 0.22, d) 0.26 w/v % vitamin E

### CONCLUSION

In conclusion, this study suggested the use of vitamin E as an effective emulsifier in the formation of PLGA nanoparticles. It was shown that by further addition of emulsifier into the system, the nanoparticles became smaller in the range of nanometers, which is useful for incorporating in tissue engineering applications when the delivery of biological molecules and drugs is necessary in the defected sites.

## INTRODUCTION

There have been several attempts for the incorporation of bioactive nanoparticles into polymeric scaffolds to enhance the physico-chemical and biological response prior transplantation.

Among different bioactive ceramics, nanocrystalline forsterite (NF) is a crystalline form of magnesium silicate with the chemical formula  $Mg_2SiO_4$ .<sup>1</sup> The vast advantages of this material have made it interesting in a wide range of applications especially for bone tissue engineering applications.<sup>2</sup>

In this research, using ice-NF hybrid particles as porogens and coating carriers to finish the NF coating and the scaffold fabrication at a time, the porous poly (L-lactide-co- $\beta$ -malic acid) (PLMA) scaffolds with NF coating was directly fabricated by a combined technique using porogen leaching and freeze drying methods.

## EXPERIMENTAL METHODS

The ice-NF hybrid particles have been prepared according to a recently published work by Guo *et al.*<sup>3</sup> Briefly, the NF particles were milled, sieved and pre-cooled at  $-20^\circ\text{C}$ . The ice particles were separated into the desired size range (about  $300\ \mu\text{m}$ ) using standard sieves and added to the NF particles to form a mixture of ice particles and NF particles (with a ratio of 10 to 1 mg). The mixture was immersed in liquid nitrogen to fabricate ice-NF hybrid particles. The prepared particles were arranged in the mold to form a template for the porous scaffold in the next step.

## RESULTS AND DISCUSSION

It is known that by applying effective coatings on the surface of composites, a relatively higher strength and stiffness to weight ratios could be obtained. On the other hand, they could show better durability, fatigue behaviour and dimensional stability.<sup>4</sup> Fig. 1 shows the load displacement curves of the uncoated and coated scaffolds. The areas below the curves are a measure of the fracture (the energy required to fracture the sample, obtained from the area under the load-displacement curve normalized by the samples' cross-sectional area). According to this figure, the fracture energy for the coated scaffold was higher than the uncoated sample.

In addition, no significant difference was seen in LDH activity of the both PLMA and NF-coated PLMA scaffolds at three time points compared with control, indicating non-cytotoxicity effects of the scaffolds on the cells. Although spreading and expansion of the cells on the NF-coated PLMA scaffolds seems to be more

than PLMA scaffold, the cells were actively attached to the surface of both type of scaffolds. All the results obtained from *in vitro* biologic response indicated that NF coating had a promising effect on the biocompatibility of the scaffolds.

**Figure 4.** Load displacement curves of (a) the prepared uncoated, and (b) NF-coated PLMA scaffolds

## CONCLUSION

In this study, the phase-pure NF was successfully synthesized by the sol-gel low temperature process. The crystallite size of synthesized powders was in the range of 10-20 nm. Then, NF-coated porous PLMA scaffolds were fabricated by porogen leaching method combined with the pressure seepage and freeze-drying method. The obtained results confirmed the existence of the NF coating on the surface of the scaffolds, which is suitable for tissue engineering applications. The BMSCs spread and attached actively on both PLMA and NF-coated PLMA scaffolds. Furthermore, MTT and LDH specific activity tests indicated that NF coating could remarkably increase the biocompatibility *in vitro*.

### ABSTRACT

Tissue engineering has as main objective to obtain a suitable 3D scaffold; this can be obtained by decellularization organ from a donor who is functionalized by placing the patient's stem cells. The general objective of this research is to obtain 3D scaffolds by decellularization<sup>[1]</sup> of porcine organs; this implies removing total cells of the organ with the perfusion of different solutions through the vascular system in the organ, leaving intact the supporting structure called Extracellular Matrix (MEC), the main composition is collagen, elastin and other signaling proteins, preserving the essential architecture of each organ<sup>[2]</sup>. The decellularization process is performed on a device, designed and built in the laboratory specifically for this purpose named Bio-MEC, this guarantees obtaining the extracellular matrix, without damaging or changing its composition. Subsequently, this structure will provide support for the cells of the recipient patient; the future goal is to obtain a fully functional bioartificial organ.

### EXPERIMENTAL METHODS

A device was built and the appropriate parameters for optimal organ decellularization by perfusion, were determined. The key to the success of the process is the design of an air trap, this piece is critical because the presence of air in the capillaries of the organ causes inefficient decellularization. The organs are treated with a pH 7.4 saline solution to remove blood then decellularized with a detergent-based solution<sup>[3]</sup>. Scaffolds are studied with Histology, IR and SEM.

### RESULTS AND DISCUSSION

The first attempt of the decellularization process was to mimic the blood flow reported in the literature for each organ; however these values were clearly higher due to rupture of the organ. Based on that, the initial flow was decreased in 50% allowing decellularization. The time required for the decellularization is related to the intrinsic characteristics of the organ to be processed, which can range from a few hours to several days. The infrared pattern shows the presence of collagen because their characteristic bands are observed: amide A  $3290\text{cm}^{-1}$ , amide B  $2975\text{cm}^{-1}$ , amide I  $1533\text{cm}^{-1}$ , amide II  $1552\text{cm}^{-1}$ , and amide III  $1402\text{cm}^{-1}$ .

The structure of each organ is maintained after decellularization process and it is confirmed by the SEM images.

Fig. 1 The image shows a) the kidney decellularization, histological examination, Masson's trichrome, of b) native kidney, b) acellular kidney.

### CONCLUSIONS

Using the Bio-MEC device it can be obtained 3D scaffolds for organ regeneration which maintain the desirable characteristics of the extracellular matrix. This device allows the processing of any organ that has vasculature; this device may also decellularized from one to three organs at once.

# Special Sessions

## Young Scientists Forum

Sunday, 30<sup>th</sup> August

13:00 – 17:00

Hall 2

### “From Creative Thinking Towards Product Commercialization: The Complete Value Chain”

**Organizers:**

Sandra Van Vlierberghe, Lorenzo Moroni, Giuseppe Cama, Anna Finne Wistrand, Izabela Stancu

**Supported by:**

Young Scientists Forum @ ESB

The YSF workshop in Kraków, Poland will aim to cover the entire value chain ranging from idea creation towards commercialization of a developed product.

**Programme:**

- 13:00 Prof. Abhay Pandit**, National University of Ireland, Galway, Ireland  
*“Creative Thinking – How to Come up with New Ideas”*
- 13:35 Prof. Fabrizio Barberis**, University of Genoa, Italy  
*“How to Get Money to Work out your Idea”*
- 14:10 Prof. Paul Santerre**, University of Toronto, Canada  
*“You Received Funding – What’s Next – How to Survive in Research Land”*
- 14:45** Coffee break
- 15:15 Prof. Joachim Kohn**, The New Jersey Center for Biomaterials, United States  
*“How to Advance Research Results Towards the Development of a Medical Product”*
- 15:50 Dr. Lechosław F. Ciupik**, LfC-Medical, Poland  
*“R&D in Creation of Bio-Engineering Product; Researcher Responsibility”*
- 16:25 Panel discussion**

In addition to PhD students, the workshop will also focus on topics relevant for post-doctoral researchers as well as PIs. The workshop will be closed with a round table discussion during which delegates can share their opinion and exchange ideas to create an excellent networking opportunity.

## Special Fellows Session

Monday, 31<sup>st</sup> August  
16:00 – 17:45  
Hall 1

### **ICF-BSE Fellows Session, ESB-Krakow 2015**

#### **“Biomaterials education is not ready for the challenges of the future”**

**Speakers:** David Grainger, Dietmar Hutmacher, Kristi Anseth, Laura Poole-Warren,  
Kathleen Elizabeth Tanner, Lynne Jones

**Moderator:** Joachim Kohn

The “Special Fellows Session” is organized by the International College of Fellows of Biomaterials Science and Engineering (IUS-BSE). Special Fellows Sessions explore important and sometimes controversial topics. A group of six prominent Fellows will highlight the perceived strengths and weaknesses of the way most universities educate and train the next generation of biomaterials scientists. Three Fellows will argue in favor of the current status of biomaterials education, while three other Fellows will provide provocative and stimulating arguments highlighting the weaknesses of current biomaterials education. One key point of the debate will be an exploration to which extent the careers of young scientists are impacted by a lack of skills needed to translate laboratory research into products within an industrial setting. Another key point relates to the fact that current biomaterials education prioritizes breadth over depth, producing “generalists” who are not well-trained in any one field. The changing job market for biomaterials scientists (especially at the PhD level), and global challenges and perspectives will also be discussed. Together, the six presenters will provide the audience with a deep and multifaceted understanding of the strength and weaknesses of the way many young biomaterials scientists are educated and prepared for their careers. Special Fellows Sessions are designed to be interactive: the audience will have an opportunity to participate in the debate and will vote on the issues. Previous “Special Fellows Sessions” examined the utility of animal experiments (WBC Amsterdam, 2008), explored whether we will ever be able to regenerate a complete human arm (WBC Chengdu, 2012), looked at the tension between basic research and translational research (ESB Liverpool, 2014) and the competition between material science approaches and biology-based approaches in developing the next generation of regenerative therapies (US Society for Biomaterials, Charlotte NC, 2015).

---

The International College of Fellows- Biomaterials Science & Engineering (**ICF-BSE**) was established in April 1992 after the constituent biomaterials societies of the World Biomaterials Congress, now the International Union of Societies – Biomaterials Science and Engineering (**IUS-BSE**), recognized the need for the public recognition of those of their members who have gained a status of excellent professional standing and high achievements in the field of biomaterials science and engineering. The ICF-BSE is chaired by Joachim Kohn, PhD, FBSE.

## Session Agenda:

### **“Biomaterials education is not ready for the challenges of the future”**

Agree with statement- Laura Poole-Warren, Lynne Jones, Dietmar Hutmacher

Disagree with statement Kristi Anseth, David Grainger, Liz Tanner

(See the following pages for Participants' Biosketches)

### **Moderator:**

Joachim Kohn, Ph.D., FBSE

Director, the New Jersey Center for Biomaterials

Board of Governors Professor, Rutgers, the State University of New Jersey

**Joachim Kohn**, is a Board of Governors Professor at Rutgers University and honorary professor at Sichuan University, China. Professor Kohn's research interests focus on the development of new biomaterials. He pioneered the use of combinatorial and computational methods for the optimization of biomaterials for specific medical applications. He is mostly known for his seminal work on "pseudo-poly(amino acid)s"- a new class of polymers that combine the non-toxicity of individual amino acids with the strength and processability of high-quality engineering plastics. Medical devices using these materials have been implanted in more than 50,000 patients, and several new products are in pre-clinical development.

In 1997, Kohn founded the New Jersey Center for Biomaterials, which has grown into a collaborative network spanning 25 institutions, and 40 laboratories located in countries across the entire globe. He has raised about \$100M in research funding at Rutgers and helped companies to raise about \$200M in private capital for the development of his technologies. In 2008, Kohn became the Principle Investigator and Director of the Rutgers-Cleveland Clinic Consortium of the Armed Forces Institute of Regenerative Medicine (RCCC-AFIRM). In this position, Kohn oversees approximately \$60 million of funding from the Department of Defense, with the goal to develop innovative new therapies for catastrophic injuries.

## David Grainger, Ph.D, FBSE

George S. and Dolores Doré Eccles Presidential Endowed Chair in Pharmaceutics/Pharmaceutical Chemistry,  
Professor of Pharmaceutical Chemistry, Professor of Bioengineering, University of Utah

**David W. Grainger** is a *University Distinguished Professor* and *George S. and Dolores Doré Eccles Presidential Endowed Chair in Pharmaceutics and Pharmaceutical Chemistry*, and *Professor of Bioengineering* at the University of Utah, USA. Grainger's research focuses on improving drug delivery methods, implanted medical device and diagnostics performance, and nanomaterials toxicity. Grainger has published 185 research papers and 23 book chapters on biomaterials innovation in medicine and biotechnology, and novel surface and diagnostics chemistry. He has won research awards, including the *2013 Excellence in Surface Science Award* (Surfaces in Biomaterials Foundation), the *2007 Clemson Award for Basic Research* (Society for Biomaterials), and the 2005 American Pharmaceutical Research and Manufacturer's

Association's award for "*Excellence in Pharmaceutics*". Grainger served as Chair of the several of NIH's prominent review panels and also featured in the award-winning National Institutes of Health's *Center for Scientific Review Mock Study Section* professional instructional video October, 2009 (posted to <http://www.youtube.com/watch?v=HMO3HoLJuJY>). He is a co-founder of 4 biomedical start-up companies, and serves on scientific advisory board positions for several others. He advises major multi-national EU research projects and several major international interdisciplinary biomedical research centers. Grainger has won numerous teaching awards and has provided over 350 invited lectures globally.

## Kristi S. Anseth, Ph.D., FBSE

Distinguished Professor, Tisone Professor, Associate Professor of Surgery, and  
Howard Hughes Medical Institute Investigator

Kristi S. Anseth was trained in the field of chemical engineering and earned her B.S. degree from Purdue University in 1992 and her Ph.D. degree from the University of Colorado in 1994. She then conducted post-doctoral research under the guidance of Bob Langer at MIT as an NIH fellow. Dr. Anseth is presently a Howard Hughes Medical Institute Investigator and Distinguished Professor at the University of Colorado at Boulder. Her research interests lie at the interface between biology and engineering where she designs new biomaterials for applications in drug delivery and regenerative medicine. Dr. Anseth's research group has published over 280 publications in peer-reviewed journals and presented over 250 invited lectures in the fields of biomaterials and tissue engineering. She was the first engineer to be named a Howard Hughes Medical Institute Investigator. She has also received the distinguished Alan T. Waterman Award from the NSF. Dr. Anseth is an elected member of the

National Academy of Engineering (2009), the National Academy of Medicine (2009), and the National Academy of Sciences (2013). She is a dedicated teacher, who has received four University Awards related to her teaching, as well as the American Society for Engineering Education's Curtis W. McGraw Award. Dr. Anseth is a Fellow of the American Association for the Advancement of Science, the American Institute for Medical and Biological Engineering, the Materials Research Society, and was newly elected by IUSBE as fellow of Biomaterial Science and Engineering (2015). She serves on the editorial boards or as associate editor of *Biomacromolecules*, *Journal of Biomedical Materials Research — Part A*, *Acta Biomaterialia*, *Progress in Materials Science*, and *Biotechnology & Bioengineering*.

### **Dietmar W. Hutmacher, Ph.D, FBSE**

Professor and Chair of Regenerative Medicine at the Institute of Health and Biomedical Innovation (IHBI),  
Queensland University of Technology

**Dietmar W. Hutmacher** is Professor and Chair of Regenerative Medicine at the Institute of Health and Biomedical Innovation (IHBI), Queensland University of Technology, where he leads the Regenerative Medicine Group, a multidisciplinary team of researchers including engineers, cell biologists, polymer chemists, clinicians, and veterinary surgeons. His work on scaffold design and fabrication via 3D printing has created a number of new research directions and has resulted in thousands of subsequent papers, making this process one of the most commonly used in the field today. Professor Hutmacher has also pioneered a number of scaffolding approaches to engineer bone, cartilage, skin and breast tissue engineering. As a result of this unique combination of expertise and experience, he is one of the few academics to take a holistic bone-engineering concept from fundamental research to clinical application.

Importantly, this research translation has led to the treatment of a large number of patients. Professor Hutmacher has recently pioneered a highly innovative way of using tissue engineering technologies developed in his lab for cancer research. He is leading an emerging area of research in which tumours are engineered in vitro with physiological properties that can be used to study cancer biology in a highly controlled manner or test the efficacy of new drugs.

### **Laura Poole-Warren, Ph.D., UNSW, FBSE, FAIMBE**

Pro Vice-Chancellor (Research Training) and Dean of Graduate Research, The University of South Wales

**Laura Poole-Warren** is a Professor in Biomedical Engineering at The University of New South Wales (UNSW Australia). Her research group focuses on incorporating functional biological molecules into hydrogels and electroactive polymers for application to medical devices. Specific interests are in cell and drug delivery in neural and cardiovascular applications. She has published over 110 papers and has had grant funding of approximately \$4 million over the past 10 years. She has also held appointments as visiting research professor at Rutgers University in the USA and as a preclinical scientist in the biomedical industry working on development of implantable devices including wound dressings and embolic agents for cancer treatment. For 10 years up to 2012, she was a member of the Australian

Commonwealth Government statutory Advisory Committee on Medical Devices which advises the Therapeutic Goods Administration on the safety of medical devices. Laura is also the Pro-Vice Chancellor (Research Training) & Dean of Graduate Research at UNSW Australia. In these roles she has responsibility for graduate research education, researcher development and early career and postgraduate researchers. Laura is currently one of the two IUSBSE delegates for the Australasian Biomaterials and Tissue Engineering Society. Her other roles include being an Associate Editor of the journal *Biomaterials* and an advisory board member of the Bionic Vision Australia Consortium.

## **Kathleen Elizabeth (Liz) Tanner, Ph.D., FBSE, DPhil, FEAMBES, FEng, FRSE**

Professor of Biomedical Materials, University of Glasgow

**Liz Tanner** has been Professor of Biomedical Materials at the University of Glasgow since 2007, held a similar position at Queen Mary University of London (1998-2007) and was in the IRC in Biomedical Materials (1991-2001). Her research is on bioactive bone replacement and augmentation composites and bone biomechanics.

Her interests in the training of biomedical engineers and biomaterials scientists started at Queen Mary, the first university in the UK to offer degrees in Biomaterials. She started the Intercalated BSc in Clinical Materials at Queen Mary, where medical and dental students take a year out of their degree to study biomaterials and their clinical application. She developed and ran the first undergraduate degree in Biomedical Engineering in Scotland at Glasgow until July 2015. This five year enhanced undergraduate Master of Engineering degree started with 23 students in 2010, had its first MEng graduates in 2015 and now has over 150 students. Liz was one of the few non-US based academics invited to the Second Whitaker Foundation Engineering Education Summit (2005).

She was elected FBSE in 2004, a Fellow of the Royal Academy of Engineering (FEng) in 2006 and Fellow of both the Royal Society of Edinburgh (FRSE) and the European Alliance of Medical and Biological Engineering and Science (FEAMBES) in 2015.

## **Lynne C. Jones, Ph.D., M.S., FBSE**

Director, Center for Osteonecrosis Research and Education

Associate Professor of Orthopaedic Surgery, Johns Hopkins University School of Medicine

**Lynne C. Jones**, is an Associate Professor of Orthopaedic Surgery with a joint appointment in Materials Science & Engineering at the Johns Hopkins University. She serves as the Director of the JHU Clinical Research Group for Hip & Knee Surgery; the Director of Resident Research for JHU Orthopaedic Surgery; and the Director of the JHU Center for Osteonecrosis Research and Education. She is a member of numerous prestigious national and international societies including the SFB, the ORS, AAOS, the Hip Society, and the RMBS. She is the current President of ARCO-International and the Secretary-Treasurer of the National Osteonecrosis Foundation. She is a past President of the Society

For Biomaterials USA and is a current SFB representative to the ISUBSE. She has received numerous national and international recognitions including the SFB Award for Service (2015), and election as a Fellow of the International Union of Societies - Biomaterials Science and Engineering and a Fellow of the American Institute for Medical and Biological Engineering.

Dr. Jones has over 37 years of research experience in orthopaedics involving basic science and clinical science. She has published over 130 peer-reviewed publications and has been the keynote speaker at international meetings speaking on her research areas of interest – osteonecrosis, total joint arthroplasty (knee; hip), and bone grafting.

## Translational Research Symposium

Tuesday, 1<sup>st</sup> September

10:00 – 11:00

11:30 – 13:00

16:45 – 18:30

Hall 1

### **“Innovating in the Medical Device Industry – Challenges & Opportunities”**

**Organizers:**

Yves Bayon, Marc Bohner, David Eglin, Geoff Richards, Dimitrios Zeugolis

**Supported by:**

DSM Biomedical, Netherlands

Innovation and product development in the medical device industry have largely been technology driven in the last decades. Advancements have been often rapid and significant. Today’s solutions, particularly biomaterial implants, have reached high standards and state of the art treatment generally supports acceptable return to daily activities and quality of life, in the vast majority of mild cases.

Today’s product development occurs in a more complex environment, with multiple stakeholders involved. Each of these stakeholders can have different and sometimes conflicting requirements and expectations. While technological innovation may still be the driving force behind new product developments, in many cases it is not a sufficient justification.

Innovation in the medical device industry can take many forms. From an entrepreneurship perspective, it does not require inventing something completely new; it can simply involve applying an existing idea in a new way or to a new situation. Innovation includes i) Rapid cadence of market release of new devices or services, ii) Scientific communication on company’s products and key opinion leaders (KOL) support, iii) Clinical education of care providers, iv) Skilled communication channels & v) Brand equity or the value of the brand name, the five pillars of success in medical devices business.

Innovation is greatly influenced by the customer, i.e., at the same time, all major healthcare stakeholders, the patients, but also the care providers and payers, who can all influence real-world health care decision making. Putting on the market innovating products also depends on the fulfillment of regulatory requirements, guaranteeing the safety and efficacy of any market approved products. This is a crucial bottleneck for a biomaterial based device and therapy which will be specifically addressed this year though lecturers from regulatory consultants and industry describing the processes (e.g. 510K, PMA, combination product...) toward market approval. The customer and the unending changing regulatory environment represent both innovation challenges and opportunities for medical device industries.

The key driver of innovation is the value of your medical device solutions which should offer optimal efficacy, showing a proven ease of use, satisfying for users, with the greatest safety profile and at the most acceptable cost. And, innovation should also lead to, economically viable and technically feasible projects, delivering, at the end, desirable products for the customer.

For an innovative idea to reach successfully the market place, its success, the innovation process throughout its entire lifecycle should not be driven exclusively by the company, but should fully incorporate the influence of the patient needs, the clinical feedback, the regulatory and reimbursement environment and, finally, the science and technology contribution of academic partners.

The ESB 2015 Translational Research Symposium will focus on **“Innovating in the Medical Device Industry – Challenges & Opportunities”**. It will include invited lectures from the medical device innovation stakeholders, i.e. medical device industry, academic translational centres, customers and medical device regulatory experts.

The Translational Research Symposium will also offer open sessions for sharing translational research initiatives both from academia and industry.

This event will be of interest to a wide audience from large medical device producers to academics and entrepreneurs and promoters of biomaterial technologies for medical applications. The program includes significant time for networking during coffee breaks, lunch and is also synchronized with other ESB2015 sessions throughout the day allowing the delegates to view other interesting lectures during the event.

## Special Sessions

### Session 1 (10.00-11.00)

#### **Invited Speakers:**

**(TRS1) Philip Procter**, Medical Device Industry Consultant, France

*“Clinical Needs Based Biomaterial Strategy: Reducing the Risk that Innovation is “Lost in Translation” in Products for Poor Quality Bone”*

**(TRS2) Nils Reimers**, Manager R&D, Global Funding & Reimbursement, Stryker Trauma & Extremities, Germany

*“Best Practice for Registration Trials of Biodegradable Implants”*

**(TRS3) Xiang Zhang**, Lucideon Ltd., Royal Society Industry Fellow at University of Cambridge, UK

*“New Concept of Hybrid Polymer Composites for Implant Applications”*

**(TRS4) Ipsita Roy**, University of Westminster, London, UK

*“Novel Biodegradable and Biocompatible Polymers for Medical Applications”*

### Session 2 (11.30-13.00)

#### **Invited Speakers:**

**(TRS5) Jan Weber**, Sr Research Fellow, Corporate Research, Boston Scientific Corporation, USA

*“Insights into Collaboration and Innovation for Early Stage Medical Device Development”*

**(TRS6) Jens Thies**, Director Science and Innovation, DSM Biomedical, Netherlands

*“From Biomaterials Supplier to Device Development Partner – Supporting Medical Device Companies in De-Risking Medical Products”*

**(TRS7) Herbert De Breuck**, Manager R&D, Luxilon, Wijnegem, Belgium

*“Next Generation of Fibers for Medical Devices: Biopolymers and Functionalized Coatings”*

### Session 3 (16.45-18.30)

#### **Oral Presentations of Candidates for Translational Research Award:**

**(116) Antoine Alves**, NAMSA, Chasse/Rhône, France

*“FTIR Microscopy Contribution for Comprehension of Poly-L-Lactic Acid (PLA) Degradation Mechanisms”*

**(117) Mikhail Durymanov**, Institute of Gene Biology of the RAS, Russia

*“Possible Approach to Improve Systemic Gene Delivery to Tumour Using Polyplex Nanoparticles”*

**(118) Beata Butruk-Raszeja**, Warsaw University of Technology, Poland

*“Endothelialization of Polyurethanes: Immobilization of REDV Peptide”*

**(119) Inês Gonçalves**, INEB - Instituto de Engenharia Biomédica, Universidade do Porto, Portugal

*“Helicobacter Pylori-Binding Small Chitosan Microparticles that Penetrate Gastric Mucosa”*

**(120) Stephen Swioklo**, Institute for Genetic Medicine, Newcastle University, United Kingdom

*“Leaving Cells Out in the Cold: Hydrogel Encapsulation for the Improved Hypothermic Preservation of Stem Cells”*

**(121) Daniel Rodriguez**, Technical University of Catalonia (UPC-BarcelonaTECH), Barcelona, Spain

*“Antibacterial Coatings on Titanium Surfaces: a Comparison Study Between In Vitro Single-species and Multispecies Biofilm”*

**(122) Elisabeth Engel**, Institute for Bioengineering of Catalonia (IBEC), Barcelona, Spain

*“The Proangiogenic Potential of a Novel Poly(Lactic) Based Composite Membrane for Guided Bone Regeneration”*

## **Clinical Needs Based Biomaterial Strategy: Reducing the Risk that Innovation is “Lost in Translation” in Products for Poor Quality Bone**

Philip Procter

Medical Device Industry Consultant, 01220 Divonne les Bains, France  
[consultphilipprocter@gmail.com](mailto:consultphilipprocter@gmail.com)

### **INTRODUCTION**

The gap between unmet clinical needs and biomaterials qualified to meet these needs is widening. Clinicians are increasingly reluctant to use what they consider clinically unproven biomaterials products<sup>1</sup>. High end biomaterials products such as BMP's are now being phased out and the commercial resources necessary to qualify new innovative biomaterials are now scarce as there are now very few independent biomaterials makers of any significant size today. The larger medical device companies are increasingly focused on acquisition of biomaterials rather than developing their own products. The biomaterials developers are often caught in a paradox. If a biomaterial is not novel it will not attract investment, if it is novel (eg needs a new claim approval) it will also not attract investment. In any case without prospective clinical studies that prove a measurable benefit both reimbursement agencies and hospitals are increasingly reluctant to accept “novel” biomaterials. So with all these factors combining it becomes more likely that innovation does not make it through to an end product as investors/developers seek to minimise project risks. So what strategies could enable innovation in biomaterials in spite of these factors?

### **A CLINICAL NEEDS LEAD BIOMATERIALS STRATEGY**

Many biomaterials that are on sale today come from a technology lead approach. That is to say that an available technology is adapted to fit a broader and broader range of user needs, eventually risking going “off-label”. In the author’s opinion this is largely what happened with calcium phosphate cements. In the 30 years since CaP’s were introduced there have been many hundreds of CaP projects (author’s estimate) all aiming to be non-load bearing void fillers. Less than 10 of these products make up 80% of the market volume today and only two of these are available with enhanced claims (antibiotic, screw augmentation in EU markets only). Yet it is clear from the off-label use reported for CaP cements that there are clinically unmet needs. Examples are: load sharing/bearing applications, adding bone quality enhancement, or infection control measures via drugs. The author proposes the following to increase the success rate of translation of innovative biomaterials projects into clinically valued treatments.

- 1) First and foremost an evidence based approach is mandatory, starting with well-defined unmet clinical needs, ideally from prospective randomised studies.
- 2) Selection of technologies based on the unmet needs rather than making a technology fit the application.
- 3) A focus on indication specific biomaterials, as different anatomic locations and clinical conditions have different requirements.

- 4) Definition of intraoperative handling/clinical site delivery as part of the user needs
- 5) Making an assessment of the reimbursement potential at the beginning of the project.
- 6) Early determination that clinical outcome studies are needed/not needed to prove a clinical advantage.

### **ILLUSTRATIVE CASE STUDIES**

#### **1: Commercialisation of a premix CaP cement**

This project began with the unmet needs of ease of mixing and delivery together with stop start functionality. This case study shows proof of concept through to commercial realisation (CE mark) of an integrated cement mixing, delivery and implant system, iN3 (Celgentek Ltd).

#### **2: Development of an injectable cement minimising vascular impact in a bone void environment**

This unmet need resulted from the post market surveillance observation that CaP cements compromised the vascular recovery in femoral neck fractures<sup>2</sup>. The root cause was suggested to be the presence of CaP cement in the fracture line. Two approaches were pursued 1) Literature research suggested that hydrogels combined with nanoparticulate calcium and antiporotic drugs such as zoledronic acid might be effective, even when injected into the fracture line. 2) Design cement/selection of a cement that does not extrude into the fracture site or beyond. A group<sup>3</sup> has evaluated a number of cements to determine their suitability for use in the femoral neck with regard to this extrusive/intrusive behaviour. This case study reports proof of concept for both pathways.

### **CONCLUDING COMMENTS:**

The last three decades have seen many innovations in biomaterials research but few of these have succeeded in becoming mainstream as part of clinically valued treatments. Evidence based design of biomaterials is a way to change this whilst challenging to put into practice but in the author’s opinion this is essential if we are to increase the successful translation of innovative biomaterials projects into clinically valued treatments.

**Best Practice for Registration Trials of Biodegradable Implants**

Nils Reimers

Stryker Trauma GmbH, Kiel, Germany  
[Nils.Reimers@STRYKER.com](mailto:Nils.Reimers@STRYKER.com)

**SUMMARY**

Prospective clinical study shows the safety, efficacy, and resorption characteristics of an ultrasonically inserted bioresorbable pin after four years.

**INTRODUCTION**

Corrective osteotomies for treatment of Hallux Valgus are among the most prevalent procedures in foot and ankle surgery. Various treatment options have shown to be safe and effective. Bioresorbable implants may be preferred to avoid metallic implant removal and reduce the burden on the healthcare system. The aim of this study was to assess the safety, efficacy, and resorption characteristics of an ultrasonically inserted bioresorbable pin.

**PATIENTS & METHODS**

30 consecutive patients with a moderate Hallux Valgus deformity were treated with a polylactide co-polymer pin that was selectively liquefied by ultrasonic energy allowing it to flow into cancellous bone and solidifying immediately, resulting in a stable construct. Patients went through a clinical and radiographical evaluation. MRI scans were obtained at 3, 12, 24, 36, and 48 months post index procedure. Clinical outcome was measured by the EQ-5D at one year.

**RESULTS**

25 patients were included for final MRI evaluation at 48 months. All osteotomies healed without adverse reaction. The implant was still visible on MRI at 36 months in all subjects but was completely resorbed in 14 patients at 48 months, with a partially iso-intense signal detectable in the cavity that was left by the resorbed implant. The remaining patients showed advanced signs of degradation at this point in time.

**CONCLUSION**

The long-term MRI follow-up showed full degradation of the bioresorbable implant and partially to fully remodeled bone after 4 years in the majority of patients. Reducing metallic implant removal by substituting bioresorbable implants appears to be beneficial both financially and clinically.

## **New Concept of Hybrid Polymer Composites for Implant Applications**

Xiang Zhang

Lucideon Ltd. UK

Royal Society Industry Fellow at University of Cambridge

Coordinator, Reinforced Bioresorbable Biomaterials for Therapeutic Drug Eluting Stents REBIOSTENT,  
EU FP7 Project

Horizon 2020 Project

Novel Biodegradable and Biocompatible Polymers for Medical Applications

[Xiang.Zhang@lucideon.com](mailto:Xiang.Zhang@lucideon.com)

This presentation will introduce new concept on development of hybrid polymer composites for industrial applications. It will report the outcomes from a large European project involving over 14 organisations on development of new polymer hybrids, i.e. reinforced and resorbable polymer hybrids for medical applications. The presentation will cover the following points:

- New concepts of hybrid polymer composites;
- New technology for synthesis of nanoporous silica and nano phosphate bioresorbable glass for develop polymer hybrids;
- Introduction of design and development methods hybrid polymer composites i.e blends of organic and inorganic nano-materials
- Introduction of therapeutic polymer hybrids: drug-loaded bioresorbable nanoglass and polymer hybrids
- Therapeutic reinforced bioresorbable polymer hybrids for medical implants

## **Novel Biodegradable and Biocompatible Polymers for Medical Applications**

Horizon 2020 Project

[I.Roy01@westminster.ac.uk](mailto:I.Roy01@westminster.ac.uk)

This presentation will discuss the development of novel Biopolymers, both natural and synthetic with potential for application in a range of different medical applications.

Currently there is a huge need for novel and innovative polymers of medical grade for use in the fast evolving areas such as tissue engineering, controlled and targeted drug delivery, biodegradable implants including biodegradable stents and nerve conduits. These polymers need to be biocompatible, have mechanical properties suitable for the particular application, have controllable degradation rate and have suitable surface properties and microstructure to support the regeneration of tissue via optimal cell attachment, proliferation, infiltration, and vascularisation.

These wide ranging properties can be acquired by production of polymers using various synthetic routes and also efficient utilisation of a range of different known natural polymers. In addition, novel physical and chemical functionalization of the polymers can be used to make them much more effective. Finally, processing of such polymers to produce suitable microstructure in 2D and 3D constructs can be used to enhance their suitability for a wide range of medical applications.

All these aspects of the development of novel Biopolymers for use in medical applications will be elaborated in this presentation.

## Insights into Collaboration and Innovation for Early Stage Medical Device Development

David Knapp

Boston Scientific Corporation, USA

[David.Knapp@bsci.com](mailto:David.Knapp@bsci.com)

### INTRODUCTION

Large medical device companies have traditionally benefitted from internal organic growth supplemented by a healthy startup environment fueled by venture. In recent years, it has become more important than ever to innovate internally with significant changes in the funding, regulatory, reimbursement and healthcare system dynamics.

Collaboration has been a cornerstone of the culture of innovation at Boston Scientific. Taking lessons from across academia, medicine and industry, we will describe the ways in which we conduct exploratory development, collaborate internally and externally, leading to connections that are critical in this multi-disciplinary field. Over the years, we have learned that the principles that are important for creating an open and creative culture are consistent with this collaborative mindset. We will describe those key principles that we feel most reflect the culture at Boston Scientific and are critical for nurturing and translating successful early stage development to solutions that can benefit patients.

**From Biomaterials Supplier to Device Development Partner – Supporting Medical Device Companies  
in de-Risking Medical Products**

Jens C. Thies

DSM Biomedical, The Netherlands

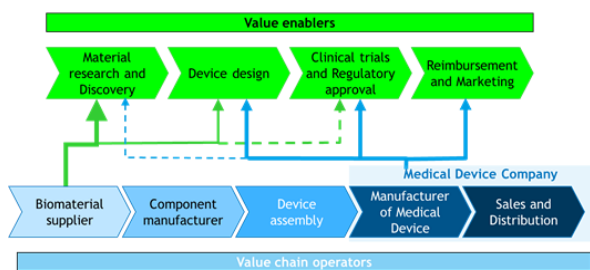

jens.thies@dsm.com

## INTRODUCTION

There are several methods and strategies by which organisation with biomaterials competences such as academic labs, small medium sized companies or large corporations can engage in the medical device industry.

The primary difference in these strategies is determined by the chosen position of the organisation in the supply (value) chain, see figure 1.

**Figure 1.** Medical device industry value chain depicting both value enablers and value chain operators.

Moving from raw (bio)material supplier to component manufacturer all the way to medical device assembler takes an organisation closer and closer to the end point of the chain which is ultimately the patient. This implies more value but also more regulatory complexity, particularly with respect to the assessment of benefit vs. risk.

In this paper we will give examples of various DSM offerings to the medical device field and show how different positions in the chain demand different levels of regulatory understanding and support of the final product. Of primary importance in all fields is the concept of risk management

## METHODS

Three product offerings are described. The first being a raw biomaterial (thermoplastic polyurethanes).

The second a medical device component (Dyneema Purity® UHMWPE fiber). The third a fully developed medical device solution (cartilage repair device). The regulatory requirements, essential biocompatibility testing as well as examples of pre-clinical translation studies and clinical studies will be discussed.

## RESULTS AND DISCUSSION

As a supplier of a raw biomaterials (thermoplastic polyurethanes), the regulatory focus is mainly with respect to biocompatibility and biostability testing and chemistry & manufacturing controls (e.g. supply chain, validations) and end product shelf life. These chapters are contained within the materials master file. Certain raw materials may also be subject to adjunct requirements such as chemical controls law.

For a medical device component (e.g. Dyneema Purity) naturally biocompatibility, biostability and CMC are still extremely relevant but here functional requirement resulting from the risk management relating to the intended use of the component become a critical aspect. These issues are the responsibility of the ‘legal’ manufacturer, i.e. the organisation who owns the regulatory approval. Therefore by effectively anticipating these risk aspects, component manufacturers can create added value for the medical device company ultimately putting the component to use.

For a fully developed medical device solution (cartilage repair device) all of the above as well as the Design Dossier detailing design history, verification and validation are critical aspects and again relate to risk management processes. For medical device development in the EU the Medical Device Directive is the leading regulatory requirement.

## CONCLUSION

Risk management is critical in mastering the regulatory requirement at various points in the business chain. This is best achieved through intimacy with the final clinical use thereby essentially mitigating risk in the final application not only for end-user (clinicians), but also for the marketing entity and most importantly for patients.

**Next Generation of Fibers for Medical Devices: Biopolymers and Functionalized Coatings**

Herbert De Breuck

Luxilon Industries NV, Vosveld 11L, B-2110 Wijnegemvidien, Belgium

[Herbert.Debreuck@luxilon.be](mailto:Herbert.Debreuck@luxilon.be)

**INTRODUCTION**

The Belgian filament manufacturer, Luxilon, is since many years a leading company in the production of specialty yarns for medical applications, such as surgical sutures for wound care and yarns for all different types of implants (hernia mesh, cardiovascular surgery, orthopaedic surgery, etc.)

In the Surgical mesh industry, there is a structural shift ongoing from completely non-absorbable mesh, via semi-absorbable, hybrid structures towards completely absorbable meshes. Compared to the non-absorbable materials, the new absorbable materials have the following benefits: improved biocompatibility, lower rejection and infection, added functions (anti-bacterial, anti-fouling, etc.). Due to the absorption, a secondary surgery is avoided, with a serious benefit, as well for the patient as for the health service costs. Materials involved are PLLA, PGA, PGLA, PCL, PLCA, etc.

On top of the development of the basic polymeric yarns, Luxilon and its partners developed a unique method to apply coatings of biomaterials on yarns and implants to give an extra benefit to polymers: better acceptance of the implant, faster / better healing and lower infection risk.

The development of all these new yarns is a multi-disciplinary cooperation between polymer suppliers, textile companies and medical device manufacturers. With a strong support of RTD centers and Universities, financing governments (EU) and controlling bodies like NAMSA, FDA,...

Luxilon participates in 3 EU funded projects for medical applications (Green Nano Mesh, Colcomp and ASCaffolds). The aim is to develop a new generation of functionalized textile based implants. Examples of products developed in these projects are anti-bacterial yarns (other than silver technology), protein and poly-saccharide coated yarns for implants and wound care, yarns for scaffolds and stem cell therapy,

As Colcomp and Green Nano Mesh come to a conclusion, the results of the project will be shown as well as a look at the further steps to industrialization. Luxilon is also working together directly with other industrial partners to develop new products. This is done in bi-lateral, strictly confidential collaboration. The presentation explains that with a good interaction, understanding and cooperation between research and industry, the EU is still on top for developing new and innovative products

The session “Surface Charge for Biomaterial Characterization” focuses on the role of zeta potential analysis as a surface sensitive technique for the characterization of biomaterial surfaces. The zeta potential is an interfacial parameter which describes the charge that a surface assumes when it gets in contact with a liquid. As the zeta potential is sensitive to the outermost surface layer, it furthermore enables time-resolved adsorption studies of biological compounds on solid surfaces. It thus combines the clear visualization of the interaction between biomaterials and their environment with the validation of the chemistry of the adsorbed layer. This enables the optimization of solid surface properties of biomaterials.

The surface charge of solid materials is best assessed by means of zeta potential analysis performed directly at the solid/water interface using the streaming potential technique. Zeta potential analysis is applicable to all classes of materials used for biomaterial applications, i.e. metals, polymers and ceramics.

The first part of the session introduces the basic principles and benefits of zeta potential analysis. The state-of-the-art instrument for zeta potential analysis on solids, SurPASS Elektrokinetic Analyzer, will be presented. Together with its wide range of measuring cells, SurPASS allows for the analysis of biomaterial samples of different shape and geometry over a wide pH range and at different electrolyte compositions.

The second part of the session focuses on recent research on modified titanium-based substrates (TiO<sub>2</sub>-coated by nanocrystals or nanotubes) used for hard tissue replacement. Influences of the topography of the surface (roughness and size of nanostructures), the substrate nature, and the material behaviour in contact with different biologically relevant electrolytic solutions on the surface charge are discussed. The information obtained by zeta potential analysis allowed for a better understanding of the behavior of such coatings in physiological conditions.

The session “Surface Charge for Biomaterial Characterization” is interesting for scientists and researchers searching for a direct method for biomaterial/environment interface analysis and a state-of-the-art technique for solid surface analysis to successfully promote the development of biomaterials.

## Zeta Potential for Biomaterial Surface Characterization

Christine Körner<sup>1</sup>, Thomas Luxbacher<sup>1</sup>

<sup>1</sup>Material Characterization, Anton Paar GmbH, Austria  
[christine.koerner@anton-paar.com](mailto:christine.koerner@anton-paar.com)

### INTRODUCTION

The present work deals with the role of zeta potential analysis as a surface sensitive technique for the characterization of biomaterial surfaces. The zeta potential is an interfacial parameter which describes the charge a surface assumes when it gets in contact with a liquid. As the zeta potential is sensitive to the outermost surface layer, it is also suited to monitor adsorption processes, thus contributing to the understanding of e.g. protein-biomaterial interaction.

Zeta potential analysis is applicable to all classes of materials used for biomaterial applications, i.e. metals, polymers and ceramics.

The work presented here focuses on titanium and adsorption of bovine serum albumin on titanium surfaces.

### EXPERIMENTAL METHODS

Zeta potential analysis of various materials was performed with SurPASS Electrokinetic Analyzer using the streaming potential technique.

If a surface is brought in contact with an aqueous electrolyte solution, charges are formed at the solid-liquid interface. Upon streaming the electrolyte solution across the sample surface, the charge compensating ions are sheared off their equilibrium position. The charge separation generates an electrical potential difference: the streaming potential.<sup>1</sup>

Fig. 1: Measuring principle of zeta potential on solid surfaces.

### RESULTS AND DISCUSSION

The zeta potential strongly depends on the parameters of the electrolyte solution, such as pH value, conductivity or additive concentration. The pH value where the zeta potential is 0 mV and a charge reversal takes place is called isoelectric point (IEP) and describes the chemistry of a surface.

Fig. 2 shows the pH dependence of zeta potential for titanium (IEP at pH 4.2) as well as a glass surface (IEP at pH 3) in phosphate buffered saline. After adsorption of albumin to the surface of the material the IEP is shifted to pH 4.7, which corresponds to the IEP of

albumin in solution<sup>2</sup>. This result implies that the material surface is completely covered with the protein.

Fig. 2: pH dependence of zeta potential for titanium (IEP 4.2) and glass (IEP 3.0) in PBS buffer, also in the presence of albumin (IEP 4.7).

Being sensitive to the outermost surface layer of a material, the zeta potential is also used to assess adsorption processes<sup>3</sup> of biological compounds in real time. The adsorption kinetics of albumin on titanium indicates an initial fast protein attachment and a subsequent slower rearrangement on the solid surface, depending on the pre-treatment of the titanium surface.

### CONCLUSION

The zeta potential serves as an indicator for surface charge at the interface of a solid and a liquid. Zeta potential analysis thus provides information on the surface chemistry of biomaterials.

Zeta potential analysis furthermore allows for the clear visualization of the interaction of biomaterials with their environment. It combines the real-time measurement of adsorption kinetics with the validation of the chemistry of the adsorbed layer. This enables the optimization of solid surface properties of biomaterials.

### INTRODUCTION

The physico-chemical properties of a biomaterial surface are considered the key factors for the design of body implants. In fact, they are responsible for the interactions with the surrounding tissues and, influencing the “race for the surface” between cells and bacteria<sup>1</sup>, they affect the following acceptance of the implant.

The most studied surface characteristics concern the wetting degree and the roughness, either at the micro- or nano-scale. Besides, the assessment of the solid surface charge becomes fundamental when the adsorption of certain ions and proteins from the body fluids and the on a body implant is considered.

Streaming potential represents a reliable method to evaluate the surface charge by determining the zeta potential (ZP) at the interface between the material and the fluid around<sup>2</sup>.

Thus, the purpose of this work was to assess measurements of zeta potential of modified titanium-based substrates used for hard tissue replacement. The surface modification concerned the synthesis of titanium dioxide (TiO<sub>2</sub>) nanostructured coatings, with the function of protecting and enhancing the properties of the bare Ti-substrate.

Several parameters were taken into consideration during the streaming potential measurements, such as the topography of the surface (roughness and size of nanostructures), the influence of the substrate nature, and the material behaviour in contact with different, biologically relevant electrolytic solutions.

### EXPERIMENTAL METHODS

A series of different nanostructured TiO<sub>2</sub>-coatings was produced. The synthesis of fully-dense and stable nanocrystalline TiO<sub>2</sub>-anatase coatings was performed by hydrothermal treatment (HT) of different Ti-based alloys for bone implants<sup>3</sup>. The formation of TiO<sub>2</sub>-nanotubes (NTs) and TiO<sub>2</sub>-nanopore structures within Ti-substrates (different diameter and length) was achieved by electrochemical anodization (EA)<sup>4</sup>.

The obtained nanostructured surfaces were analysed in terms of morphology by scanning electron microscopy (SEM), wettability by sessile drop contact angle, and roughness by atomic force microscopy (AFM).

The zeta potential of not treated (NT) and both HT and EA titanium substrates was determined by the streaming current technique, using a SurPASS electrokinetic analyzer (Anton Paar GmbH). Titration curves were carried out in potassium chloride (KCl), phosphate buffer saline (PBS) and artificial saliva, at different

ionic strengths, to determine the ZP dependence on the pH and the isoelectric point (IEP) of the materials.

### RESULTS AND DISCUSSION

The physico-chemical characterization of the TiO<sub>2</sub>-coating properties in terms of morphology, wettability and roughness was performed prior any streaming potential measurement, in order to correlate the surface properties to the surface charge.

The streaming potential analysis revealed that all the surfaces (NT, HT, EA) were negatively charged at physiological pH (7.4) in the used electrolytic solutions, even though in a different extent. In particular, significant differences were noticed when the TiO<sub>2</sub> nanostructured coatings were compared to the bare Ti-substrates. In the case of HT coatings, both the ZP values and the IEP were influenced by the morphology, nanoporosity and conductive character of the TiO<sub>2</sub> nanocrystals<sup>2,5</sup>; in the case of nanotubular structures, ZP and IEP were mostly affected by the NT diameter and the NT curvature on the top<sup>4</sup>. Such behaviour among the substrates was even more highlighted when the electrolytic solutions were switched; this was mainly due to the different ions involved and their adsorption/interaction with the surfaces.

### CONCLUSION

Streaming potential analysis represents a valuable method to evaluate the surface charge behaviour of modified-titanium surfaces (namely, TiO<sub>2</sub>-coated by nanocrystals or nanotubes). The obtained information can help to better deduce the behaviour of such coatings in physiological conditions.

Dr Ipsita Roy, *Reader, Head of Applied Biotechnology Research Group, Department of Life Sciences, Faculty of Science and Technology, University of Westminster*

Materials for medical applications take many forms, from metallic to synthetic and natural polymers, composites and materials of biological origin. The ultimate goal of an implantable device is for it to be unrecognised by the body, to allow for stable long term lifetime of the device. One strategy for this is for the devices to be bioresorbable – to disappear after their initial function is no longer needed as healing has occurred. Permanent implants may cause complications many years after initial healing has occurred and their presence in the body is no longer necessary.

Bioresorbable materials have applications in a wide range of medical indications, such as sutures, coronary and peripheral vascular scaffolds, bone pins and anchors, tissue fixation screws, drug delivery coatings and microspheres and surgical meshes and matrices. The bioresorbable materials may include polymers, metals, ceramics, glasses, composites and materials of biological origin such as natural collagen, and may allow for drug elution and delivery as well as performing a mechanical function.

Bioresorbable sutures have been available for over 40 years, yet recent innovations have expanded the market for bioresorbable implants to include cardiovascular, orthopaedic and general surgery. This has demanded increased performance from polymers, with increased strength and control over degradation being necessary.

Lead Researchers from the ReBioStent project and invited speakers will focus on novel and commercially applicable research and product development work on bioresorbable materials and medical devices.

A series of presentations will cover various aspects of materials development, product design and commercialisation.

### Programme:

#### Session 1 (9.30-11.00)

**9:30 Welcome and Introduction: Dr Xiang Zhang, Dr Ipsita Roy**

**9:50 Dr Kadem Al Lamee, Arterius Limited**

*"Commercial needs for bioresorbable materials, transfer from laboratory and barriers and gaps in the technology"*

**10:15 Prof. Oskar Hoffmann, University of Vienna**

*"Production and evaluation platforms for preclinical assessment of novel biomaterials for non-healing bone lesions"*

**10:40 Dr Ipsita Roy, University of Westminster**

*"Bioresorbable Systems: Polymers and Metals"*

## Special Sessions

### Session 2 (11.30-13.00)

- 11:30 Prof. Aldo R. Boccaccini**, University of Erlangen-Nuremberg  
*"Bioresorbable Systems: The Role of Inorganic Fillers in Composites"*
- 11:50 Dr Iban Quintana, IK4 - Tekniker**  
*"Bioresorbable Systems: The Role of Surface Functionalisation"*
- 12:10 Prof. Atul Bhaskar**, University of Southampton  
*"Bioresorbable Systems: The Role of Modelling and Simulation in Performance Assessment of Bio-Structures and Implants"*
- 12:30 Dr Gianluca Giavaresi**, Istituto Ortopedico Rizzoli, Bologna  
*"Bioresorbable Systems: The Role of Preclinical Testing"*
- 12:50 Bioresorbable Systems: Discussion**
- 13:00 Lunch including networking and posters**

### Session 3 (16:45 – 17:45)

- 16:45 Welcome back and overview of morning's proceedings: Dr Xiang Zhang, Dr Ipsita Roy**
- 16:55 Elena Boccardi**, University of Erlangen-Nuremberg  
**Zein Azhari**, Cambridge University  
*"Research into Bioresorbable Systems"*
- 17:15 Panel discussion and overview of proceedings with speakers from the Bioresorbable System Session**

---

#### **Keynote 1:**

**Commercial needs for bioresorbable materials, transfer from laboratory and barriers and gaps in the technology.**

**Dr Kadem Al Lamee, Arterius Limited**

A variety of bioresorbable materials exist for medical applications, including polymers and metals. The real-world commercial requirements for these include sufficient mechanical strength, degradation period, biocompatibility and safe degradation products. In addition, regulatory and quality requirements demand careful control of the raw materials and a high burden of proof for bench testing, biocompatibility, pre-clinical and clinical evidence.

#### **Keynote 2:**

**Production and evaluation platforms for preclinical assessment of novel biomaterials for non-healing bone lesions.**

**Prof. Oskar Hoffmann, University of Vienna**

Development and transfer from laboratory to commercial application from the perspective of InnovaBone, which is focussed on optimally performing bio-inspired biomaterials mimicking the natural physiological processes underlying bone repair of non-healing bone lesions

#### **Polymers and Metals.**

**Dr Ipsita Roy, University of Westminster**

Biodegradable polymers and metals are core materials essential for the development of resorbable medical structures and devices. The currently available biodegradable polymers and metals include both synthetic polymers (e.g. PLA, PLLA, PLGA, PCL) and natural polymers, including bacteria derived polymers (e.g. collagen, gelatin, alginate, polyhydroxyalkanoates and  $\gamma$ -polyglutamic acid) and Magnesium. The availability of such a wide range of polymers and metals has widened the possible areas of medical applications, heralding an exciting new era of innovative smart functional materials.

#### **The role of inorganic fillers in composites.**

**Prof Aldo R. Boccaccini, University of Erlangen-Nuremberg**

Inorganic fillers in composite materials for biomedical applications cover a broad range of bioactive ceramics, e.g. CaP and HA particles, bioactive glasses (BG), bioinert oxides, e.g. TiO<sub>2</sub>, as well as antibacterial components, e.g. Ag, ZnO, and functional inclusions, e.g. carbon nanotubes. In addition, inorganic fillers exhibiting mesoporous structure, e.g. silicate BG, can enhance the biological performance of the composite by imparting controlled drug delivery properties.

#### **The role of surface functionalisation.**

**Dr Iban Quintana, IK4 - Tekniker**

Rapid re-endothelialization of the arterial wall and the inner surface of the stent are critical for the prevention of the main causes of in-stent restenosis or thrombosis. In combination with biochemical modifications, physical modifications of this surface can be applied to recruit endothelial cells (ECs), to support their adhesion, proliferation and migration. In this talk, physical and biochemical technologies used during the RebioStent project will be described, as well as the results obtained in terms of ECs behavior.

### **The role of modelling and simulation in performance assessment of bio-structures and implants.**

**Professor Atul Bhaskar, University of Southampton**

The prediction of the performance of implants and bio-structures under mechanical stress is required in a wide range of applications such as scaffolds, orthopedic implants, and stents—before carrying out expensive laboratory as well as in-vivo tests, which may or may not involve animals and humans. This is particularly critical for bioresorbable implants and structures. With advances in computational stress analysis, such as the Finite Element Analysis, it is now possible to assess the stiffness and strength of such structures in-silico with increased confidence. Examples of lattice bio-structures and expandable stents will be taken up to illustrate the methodology.

### **The Role of Preclinical Testing.**

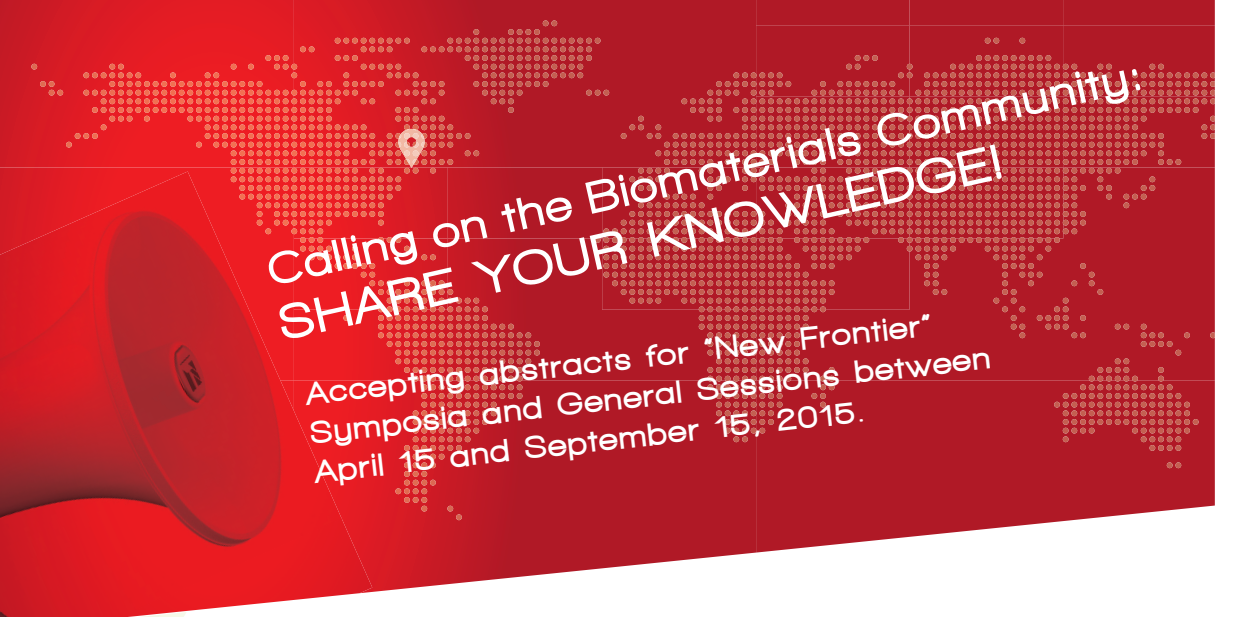

**Dr Gianluca Giavaresi, Istituto Ortopedico Rizzoli, Bologna**

As stated in ISO 10993-1, the selection and evaluation of any material or device intended for use in humans requires a structured programme of assessment that is an extend evaluation of different physico-chemical and biological aspects, such as biocompatibility, toxicology, degradation and mechanical function, giving assurance that the final product will perform as intended and be safe for human use. Preclinical in vitro and in vivo testing is part of this structured programme with the aim to evaluate the biological response of tested material or device.

### **Research into Bioresorbable Systems:**

- **Elena Boccardi, University of Erlangen-Nuremberg**
  - Mesoporous silica particles as drug carriers in drug delivery systems have been explored for the better controlled release of drugs due to their high surface areas, well-defined pore structures and tuneable pore sizes. In this study, bioresorbable mesoporous silica particles have been used as inorganic filler into biodegradable polymers to develop biocomposites which could improve the surface hydrophilicity, mechanical stability and drug delivery capability.
- **Zein Azhari, Cambridge University**
  - This work investigates novel di-block copolymers consisting of Poly-Ethylene Glycol (PEG) and a larger PLLA block of constant molecular weight. The study focuses on the degradation behaviour of the materials and how varying the molecular weight of the PEG component could regulate this to suit certain applications.

The event will be of interest to a wide audience of biomaterials scientists and engineers, including medical device manufacturers and academics. The programme will include a discussion and Q&A panel.

Calling on the Biomaterials Community:  
**SHARE YOUR KNOWLEDGE!**

Accepting abstracts for "New Frontier"  
Symposia and General Sessions between  
April 15 and September 15, 2015.

The WBC 2016 will host the worldwide biomaterials community to define the next phase of biomaterials development between May 17-22, 2016 in Montréal, Canada.

We seek innovative biomaterials, new paradigms and emerging methodological approaches to chart the future of biomaterials science and engineering. We are providing a stimulating cosmopolitan venue for multidisciplinary research to germinate breakthrough ideas and share the translational activity in clinical and industrial development. Engage the biomaterials community with your scientific and engineering endeavours to make an impact!

**Submit Your Abstracts at: [WBC2016.org](http://WBC2016.org)**

#### GENERAL SESSIONS:

Biomaterials and Host Response

Biomaterials in Therapeutic and  
Diagnostic Delivery

Building Blocks

Functional Biomaterials

Innovation in Fabrication

Mechanics and Modelling

Regenerative Medicine

Surfaces and Interfaces

Tissue Engineering

#### NEW FRONTIER SYMPOSIA:

The final list of "New Frontier" Symposia is available at [WBC2016.org](http://WBC2016.org).

10<sup>th</sup> World Biomaterials Congress  
May 17-22, 2016 | Montréal, Canada
