# Welcome Address

On behalf of the Organizing Committee, I would like to warmly welcome all of you to the 27<sup>th</sup> European Conference on Biomaterials. It is also my great pleasure to welcome you to the Royal Capital City of Kraków.

Kraków is often considered as one of the most beautiful cities in the Eastern Europe, and a historic and cultural heart of Poland. The unique places are the Main Market Square, Cloth Hall, St. Mary's Basilica and Wawel Castle - the seat of Polish kings from 11<sup>th</sup> to the early 17<sup>th</sup> century. Nowadays, Kraków is a modern city with increasing number of conference and congress centres hosting world's most prestigious scientific and cultural events. Our conference is organized in newly opened Congress Centre ICE, localized nearby Old Town with beautiful view of Royal Wawel Castle.

The ESB2015 is in many ways a very special Conference. It is the first time when we all gather in the middle east of Europe, in a unique city filled not only with proud history and tradition but also with modern spirit. Kraków is well known for its great universities like the Jagiellonian University and my home university - AGH University of Science and Technology. I am sure that the academic spirit of the city will support scientific discussions.

The main motto of the ESB2015 conference is: *"Balancing the needs for basic research and translation in a time of limited resources"*. The theme of our conference covers variety of different topics, in which we bring up traditional biomaterials issues, novel manufacturing and modification techniques, most current research on stem cells, cell instructive materials, angio- and vasculogenesis, and many more. In addition to our exciting scientific programme, we are pleased to host also some special sessions like e.g. Young Scientist Forum or Special Fellows Session.

We are extremely grateful to the European Society for Biomaterials for giving us this wonderful opportunity to organize the ESB conference. We appreciate all those who have helped us during almost two years of preparation. We would like to thank our Honorary Patronage and Partners, and the Conference Sponsors and Exhibitors.

Once more I would like to express our warmest welcome to participants from all over the world, to experienced and young researchers, to industrial partners - thank you all for coming. I hope that after those few days, you will leave Kraków feeling inspired by the scientific atmosphere of the Conference and delighted by the cultural beauty of our Royal City.

**Jan Chłopek**

*Chair of the ESB2015 Organizing Committee*

*President of the Polish Society for Biomaterials*

# ESB President's Address

Dear Members and Friends of the ESB,

During the last few months our Secretary, Prof Marc Bonher and his team have gone through the hard work of digitalisation of the vast, 40 years-old archive of the ESB. Noticeably, the very first paper of this archive is a letter of intent drafted by the founders of our Society and dated 3<sup>rd</sup> October 1975, a year before the establishment of the ESB.

It is a concise letter that powerfully encapsulates their great vision, a vision that is still at the core of our mission today after so many years. A sentence in this letter is particularly meaningful today:

*"All the gentlemen being present at this meeting will undertake a promotional work and try to find potential new members in their own countries, also raising the interest of institutions in the matter".*

I am sure that our founders would be very proud to see that after 40 years the ESB is still holding that vision and determination.

On 30<sup>th</sup> August 2015 Eastern Europe will open, for the first time, its doors to the ESB through the excellent work of our colleagues of the Polish community and in particular through the leadership of the conference chairman Prof Jan Chlopek, the co-chair Prof Elzbieta Pamula and the whole local organising committee.

The ESB Council and I are very grateful to them for their professional approach to the organisation. Throughout the time of preparation they have meticulously looked at all the aspects of the conference giving demonstration of a true collaborative spirit and passionate dedication to the cause of the ESB. The choice of a beautiful venue, the finesse with which the scientific programme has been articulated and the care for the legacy of this conference has been exemplar.

Prof Chlopek and his team will open the doors with generous hospitality, but also with a decisive statement that concerns us all:

*"Balancing the needs for basic research and translation in a time of limited resources".*

This hospitality and this statement echo the vision set for our Society 40 years ago; we are invited to look at new outreaches and at the interest of all parties involved in biomaterial R&D and we are asked to do so at a time of limited financial resources. Indeed, balancing the needs of researchers, industry, clinicians and patients is more than ever a shared effort where all the stakeholders involved have to have their voice and input. While we are challenged by a shortage of financial resources, we are growing stronger and stronger in our human capital and it is our duty to nourish it, particularly valuing the contribution of our Young Scientist Forum. To this end, in the last 12 months the ESB has been pursuing concerted actions in collaboration with the Presidents of the national societies and the European Commission; we will present this initiative to you all at the General Assembly.

In this occasion we will also give our farewell to three friends who will be ending their mandate as ESB Council members, Prof Lucy Di Silvio, Prof Michael Doser and Prof Pedro Granja. They have been pillars of our Council for many years contributing to the launch of the YSF, to the strengthening of our links with industry and to the re-organisation of the ESB administration. They leave behind a strong legacy that will not be forgotten and we count on their advice and support for the years to come. At the same time, we will welcome the new elected members of the Council. Their names will also be announced at the General Assembly and a new exciting page of our long history will be written through the integration of their talents.

Beside all that, when attending the oral and poster sessions of this exciting programme, let us stand proud for the value of the knowledge we are capable of generating and let us earnestly assess the costs and benefits that our work bring to our society. Above all, let us ponder for a while on the views of those who may not be attending the conference, in particular let us look at things with the eyes of our patients.

It is an invitation to us all, but it is a particular exhortation for our young scientists. The ability of balancing pure scientific knowledge with societal responsibility will define the future; that is their future.

**Matteo Santin**

*President of the European Society for Biomaterials*

# General Information

## CONFERENCE VENUE

The conference is being held at the ICE Kraków Congress Centre, 17 Marii Konopnickiej Street. This modern centre was designed to meet the highest, world class requirements and it was opened less than a year ago. Excellent location of the venue, its contemporary interiors and finest technical solutions make it a perfect setting for the organization of international conferences, as well as prestigious cultural and social events.

Password-free **Wi-Fi** is available for the Conference Delegates. However, because of the large number of users, Wi-Fi should not be used for large file exchanges.

## TRANSPORT INFORMATION

The Conference venue is located close to the City Center - it is only a 15-min walk.

It is also possible to use different forms of public and private transportation to get to the venue, e.g. bus, tram or taxi.

ICE Kraków Congress Centre Access Information can be found here:

**<http://www.icekrakow.com/information/access>**

Public transport connections can be found here:

**<http://krakow.jakdojade.pl/?locale=en>**

To avoid overcharging and for safety reasons, Delegates are advised to use only licensed taxis (there are over dozen of licensed taxi companies in Kraków) - full list of those is available here:

**<http://cracow.travel>**

## REGISTRATION DESK

The Registration Desk is located in Main Foyer on Level 0.

Opening times are as follows:

Sunday, 30 <sup>th</sup> August	12:00 - 20:00
Monday, 31 <sup>st</sup> August	07:30 - 18:00
Tuesday, 1 <sup>st</sup> September	08:00 - 19:30
Wednesday, 2 <sup>nd</sup> September	08:00 - 18:00
Thursday, 3 <sup>rd</sup> September	08:00 - 15:00

Social event and optional tours tickets can be bought at the Registration Desk. The Staff will be also happy to give extra tourist information and make travel or transport arrangements.

## BADGES

Name badges will be issued to all delegates upon registration. **Attendees must wear the official conference badge at all times and present it to enter the Conference venue and all ESB2015 social events.**

## ORGANIZING COMMITTEE INFORMATION DESK

Organizing Committee members can be found at the Information Desk on Level 0. Please do not hesitate to contact us with all the enquiries.

## CLOAKROOMS

Cloakrooms are located on Level 0 (on the left from the main entrance) and are free of charge. It is also possible to leave travel luggage there.

Opening times are as follows:

Sunday, 30 <sup>th</sup> August	12:00 - 20:30
Monday, 31 <sup>st</sup> August	08:00 - 19:00
Tuesday, 1 <sup>st</sup> September	08:00 - 20:00
Wednesday, 2 <sup>nd</sup> September	08:00 - 18:00
Thursday, 3 <sup>rd</sup> September	08:00 - 15:00

## CONFERENCE HALLS

There will be six parallel sessions in Halls: 1, 2, 3A, 3B, 4A, 4B.

Hall 1 can be entered from level 0 and 1.

Hall 2 can be entered from level 0 and 1.

Halls 3A, 3B, 4A, 4B are located on level 3.

Please refer to the Conference venue levels maps for the exact locations of the halls.

## POSTER AREA

Poster Area is located on Level -1. Either lifts or staircases might be used to get there. Please note that the lifts close to Halls 3A, 3B, 4A, 4B can be used only to get to the Poster & Lunch Area (other levels are not available). The lifts in the Foyer go to each level.

In case of any troubles with finding the right way, please ask Technical Support or Organizing Committee members for help.

## EXHIBITION AREA

The Exhibition is located on Level 0 and Level 1 (Sponsor). Please refer to exhibition map for names and exact location of the Exhibitors' booths.

## COFFEE BREAKS

Coffee together with other refreshments and sweet pastries will be served on Levels 0 and 1 and will be a perfect opportunity to join the Exhibition.

Please note: On Sunday, 30<sup>th</sup> August coffee break for Delegates participating in the Young Scientists Forum Workshop and IUSBSE Committee Meeting will be held on Level 2.

## LUNCH AREA

Lunch will be served on Level -1. Either lifts or staircases might be used to get there. Please note that the lifts close to Halls 3A, 3B, 4A, 4B can be used only to get to the Poster & Lunch Area (other levels are not available). The lifts in the Foyer go to each level.

In case of any troubles with finding the right way, please ask Technical Support or Organizing Committee members for help.

## SPEAKER READY ROOM

**All presentations (.ppt or .pptx) should be brought to the Speaker Ready Room (level 0, near the Registration Desk) no later than 16:00 on the day prior to presentation.**

Speakers are advised to check with technicians if the presentation or embedded videos run properly. The system is PC-based, thus Mac users should also ensure PowerPoint compatibility of their presentation.

Speaker Ready Room hours:

Sunday, 30 <sup>th</sup> August	12:00 - 17:45
Monday, 31 <sup>st</sup> August	07:30 - 18:00
Tuesday, 1 <sup>st</sup> September	08:00 - 18:00
Wednesday, 2 <sup>nd</sup> September	08:00 - 16:30
Thursday, 3 <sup>rd</sup> September	08:00 - 11:00

## ORAL PRESENTATIONS

To ensure that all the sessions run smoothly, Oral Presenters are kindly requested to read the following instructions.

- Speakers should check the conference programme carefully for the scheduled session time and presentation order.
- Use of personal laptops to run the presentation will not be possible. Speakers must upload their presentations (.ppt or .pptx) in the Speaker Ready Room no later than 16:00 on the day prior to their allocated session.
- Speakers should arrive to their assigned session hall 5 minutes before the start of their session in order to introduce themselves to the Session Chairs and familiarize with the hall arrangement.
- In each hall, there is a speaker podium with two microphones and a slide changer/laser pointer for use in the presentation.
- Oral presentations should last no longer than 12 min, and then there should be 3 min for discussion. With six parallel sessions it is crucial to keep strictly to the timetable; it is also a sign of respect to Session Chairs, other Speakers and fellow Delegates. All Oral Presenters are kindly requested not to exceed their time, otherwise their presentation will be interrupted by the Chair, whose responsibility is to keep the session on schedule.
- Technical support and audiovisual operators are ready to attend any problem during presentations. In case of such an event, Speakers should continue their presentation; the problem will be fixed as quickly as possible.

## DISCUSSION

After each presentation there should be enough time for longer or shorter discussion.

Numbered microphone stands have been prepared in Hall 1 and Hall 2. Delegates wishing to ask a question or make a comment, should stand next to the closest microphone stand (queue if necessary) and wait for the permission from the Session Chair.

In all the other halls (Hall 3A, Hall 3B, Hall 4A, Hall 4B), there will be a Technical Support person ready to hand the microphone, so one should just raise a hand or stand up to make a clear sign that is willing to take part in the discussion.

Delegates are kindly asked not to speak without the microphone, since it might be hard for the presenter or the audience to hear.

## RAPID FIRE PRESENTATIONS

There are three Rapid Fire Sessions planned - each of them during the Poster Session and lunch time. Special Rapid Fire Area was arranged on Level -1, next to the Poster Area. Rapid Fire Presentations start at 13:30 on Monday, Tuesday and Wednesday.

Rapid Fire Presenters are kindly requested to read the following instructions.

- Speakers should check in the Final Programme time and order of the presentation.
- Use of personal computers will not be possible. All Rapid Fire Presentations (maximum 4-5 slides, .ppt or .pptx) should be uploaded in the Speaker Ready Room no later than 16:00 on the day prior to scheduled presentation.
- Speakers should arrive to the Rapid Fire area 5 minutes before the start of their session.
- Rapid Fire Presentation must not exceed 4 minutes. The timing should be kept strictly.
- Speakers will be provided with a wireless microphone and a slide changer/laser pointer for use in the presentation.

## POSTER SESSIONS

Poster Presenters are kindly requested to attach their poster (1189 mm (tall) x 841 mm (wide), Portrait style (A0 Size)) to their assigned poster panel on Sunday, 30<sup>th</sup> August (12:00 - 17:45) or on Monday morning, 31<sup>st</sup> August. Posters will be arranged numerically and organized by topics. Please check the Final Programme for the assigned poster number.

Poster Sessions will be held on the Level -1 next to the Lunch Area. All posters will be exposed during the whole Conference. Poster Presenters are encouraged to be present at their posters on:

Monday, 31 <sup>st</sup> August	13:15 - 14:45
Tuesday, 1 <sup>st</sup> September	13:00 - 14:30
Wednesday, 2 <sup>nd</sup> September	13:00 - 14:30

Posters must be removed until 18:00 on Wednesday, 2<sup>nd</sup> September. After that time, all the remaining posters will be taken off and gathered at the Organizing Committee Information Desk, where it would be possible to collect them. Any posters not collected by 14:00 on Thursday, 3<sup>rd</sup> September will be discarded.

# Plenary Speakers

## Joachim KOHN

*The New Jersey Center for Biomaterials  
UNITED STATES*

### L1

**Title: “Bioactive Materials for the Treatment of Major Injuries: Opportunities and Challenges”**

**Monday, 31<sup>st</sup> August  
9:00 - 9:45, Hall 1**

Joachim Kohn, PhD, Board of Governors, Professor of Chemistry and Chemical Biology at Rutgers University, is a research entrepreneur, a multi-disciplinary translational scientist, and a national leader in the development of polymeric biomaterials for drug delivery, tissue engineering, and regenerative medicine. In 1997, Kohn founded the New Jersey Center for Biomaterials, which has grown into a collaborative network spanning 25 institutions and 40 laboratories. As a translational scientist, Kohn has 58 issued US Patents on novel biomaterials and seven companies have licensed his technologies. He has raised about \$100M in research funding at Rutgers and helped four licensees to raise about \$200M in private capital.

In 2014, Professor Kohn was inducted into the National Academy of Inventors. He is the recipient of numerous awards and honors, including the prestigious Thomas Alva Edison Patent Award for best patent in New Jersey in the category of medical research, and the Clemson Award from the Society for Biomaterials. He is a Fellow of AIMBE and serves as the Chair of the International College of Fellows of Biomaterials Science and Engineering. Since 2008, he is the Director and Principal Investigator of the Rutgers-Cleveland Clinic Consortium of the Armed Forces Institute of Regenerative Medicine, a \$60 Million research project funded by the Department of Defense.

Professor Kohn’s scientific expertise ranges from synthetic polymer chemistry and materials science to drug delivery, cell biology, tissue engineering, and regenerative medicine. He pioneered the use of combinatorial and computational methods for the optimization of biomaterials for specific medical applications. He discovered „pseudo-poly(amino acid)s” - a new class of polymers that combine the non-toxicity of individual amino acids with the strength and processability of high-quality engineering plastics. Medical devices using these materials are being developed by several companies, have been approved in the USA and Canada, and have been implanted in more than 50,000 patients.

## **Maria SIEMIONOW**

*University of Illinois at Chicago  
Department of Orthopaedics  
UNITED STATES*

### **L2**

**Title: “Regenerative Transplantation -  
from Experimental Laboratory to Clinical Applications”**

**Monday, 31<sup>st</sup> August  
9:45 - 10:30, Hall 1**

Dr. Siemionow, a world-renowned scientist and microsurgeon, is Professor of Orthopedics and Director of Microsurgery Research at The University of Illinois at Chicago. She earned her medical degree from Poznan Medical Academy in her native Poland. Prior to her UIC appointment, she was Director of Plastic Surgery Research and Head of Microsurgical Training for Cleveland Clinic’s Department of Plastic Surgery. She specializes in microsurgery, hand surgery, peripheral nerve surgery, transplantation, and microsurgery research. She is pioneering development of new technology for minimal immunosuppression in transplantation and enhancement of nerve regeneration.

Currently President of the American Society for Reconstructive Transplantation, Dr. Siemionow is Past President of the International Hand and Composite Tissue Allotransplantation Society and the American Society for Peripheral Nerve. Additionally, she is a member of the academic-industry team, Warrior Restoration Consortium, focusing on development of clinical therapies and new treatments for wounded soldiers as part of the second phase of the Armed Forces Institute for Regenerative Medicine (AFIRM II).

She has received numerous honors, including high praise as Principal Investigator for the world’s first, her Composite Facial Allograft Transplantation protocol; in 2008, she led the team that performed the first near-total face transplantation in the United States.

Author of more than 330 scientific publications, she twice has been honored with the James Barrett Brown Award for the best publication in a plastic surgery journal, and earned the Folkert Belzer Award in Transplantation for her work on transplantation and tolerance. Dr. Siemionow also received Outstanding Achievement in Clinical Research Award from the Plastic Surgery Educational Foundation (2010); the 2011 American Society of Plastic Surgeons’ Board of Trustees Special Achievement Award and in 2013 Casimir Funk National Science Award and the Honoris Causa Doctorat awarded by Poznan University of Medical Sciences. In 2014, Dr Siemionow received the Great Immigrants Award from the Carnegie Foundation of New York.

## **C. James KIRKPATRICK**

*Institute of Pathology, University Medical Center  
Johannes Gutenberg University of Mainz  
GERMANY*

### **L3**

**Title: “In vitro Models & Nanobiointerfaces:  
A Multidisciplinary Challenge”**

**Monday, 31<sup>st</sup> August  
14:45 - 15:30, Hall 1**

C. James Kirkpatrick has a triple doctorate in science and medicine (MD, PhD, DSc) from the Queen’s University of Belfast (N. Ireland) and since 1993 is Professor and Chairman of Pathology at the Johannes Gutenberg University (JGU) in Mainz, Germany. He has a special interest in human cell culture techniques to study cell-biomaterial interactions, and has pioneered complex co-culture systems in three-dimensions. His “REPAIR-lab”, is a member of the European Institute of Excellence on Tissue Engineering and Regenerative Medicine. He is a former President of both the German and the European Society for Biomaterials and was the latter’s recipient of the George Winter Award in 2008. In 2010 he was awarded the Chapman Medal from the Institute of Materials, Minerals & Mining, London, UK for “Distinguished research in the field of biomedical materials”. Since 2013 he is an Honorary Member of the German Society for Biomaterials, and in 2014 he received the TERMIS-EU Career Achievement Award (awarded in Genova, Italy). He also holds visiting professorships in China, Singapore and Sweden.

He is author/coauthor of 486 publications in peer-reviewed journals and has an h-index of 54 (Web of Science). He is a former Associate Editor of the Journal of Pathology (2001-2006) and a current Associate Editor of Biomaterials (since 2002) as well as a member of the Editorial Advisory Board of several journals in the biomaterials and regenerative medicine fields. He is a member of the Scientific Advisory Board of a number of research institutes, centres of excellence and companies in biomaterials and regenerative medicine in Europe, as well as the German Federal Institute for Drugs & Medical Devices (BfArM) (since 2007).

Current research is on nanoparticle interactions with the air-blood and blood-brain barriers, as well as on adult stem cells and inflammatory processes in vascularization of tissue engineered constructs.

## **Geoff RICHARDS**

AO Research Institute Davos  
SWITZERLAND

### **L4**

**Title: “Medical Translational Research:  
A Different Route to Fundamental Research”**

**Tuesday, 1<sup>st</sup> September  
9:00 - 9:45, Hall 1**

Since 1991 Prof Richards has been based at the AO Research Institute Davos performing R&D of fracture fixation devices. In 2009, Prof Richards became Director of the Institute. Currently he holds an honorary Professorship at Cardiff University, Wales and also one at Aberystwyth University, Wales. He has been a member of European Society of Biomaterials since 1993 and co-organised ESB2009 in Lausanne, Switzerland (with Marc Böhner and Christine Wandrey). 1201 attendees participated (highest ESB registration at that time). Prof Richards holds a Life Honorary Member Swiss Society for Biomaterials after being in many functions including president. He was involved in helping set up statutes of the Romanian Society for Biomaterials and helped them (and later) the Polish Society for Biomaterials affiliate to ESB. In 2004 he was awarded the ESB Jean Leray Award. He is a Fellow of Biomaterials Science and Engineering (FBSE).

In 1999 Prof Richards co-founded eCM journal ([www.ecmjournal.org](http://www.ecmjournal.org)), one of the first online open access journals in the world (before “open access” was used). He is Editor-in-Chief, webmaster and webeditor. eCM initiated the first transparent review process in 1999 (now known as open peer review) including a transparent route to becoming a member of the eCM International Review Panel. He has organised annual eCM conferences since 1999. Prof Richards is an executive Committee member European Orthopaedic Research Society (organised EORS2010 in Davos) and an elected member European & World Council for Tissue Engineering & Regenerative Medicine International Society (TERMIS). He will organise TERMIS-EU in 2017 in Davos. In 2014 after helping set up the charter of International Combined Orthopaedic Research Societies (ICORS), he became a Member of the executive committee. He is author on 120 peer reviewed papers, 4 patents, more than 400 abstracts and 11 book chapters. He has supervised 10 PhD's, 15 masters thesis's, 4 medical thesis's and 2 diplomas.

## **Michael V. SEFTON**

*Institute of Biomaterials and Biomedical Engineering  
University of Toronto  
CANADA*

### **L5**

**Title: “Vascularization in Tissue Engineering:  
Alternative Foreign Body Responses”**

**Tuesday, 1<sup>st</sup> September  
15:30 - 16:15, Hall 1**

Michael V. Sefton is University Professor and Michael E. Charles Professor in the Department of Chemical Engineering and Applied Chemistry and the Institute of Biomaterials and Biomedical Engineering, University of Toronto. He was Director of the Institute of Biomaterials and Biomedical Engineering at the University of Toronto from 1999-2005 and President of the US Society for Biomaterials in 2006.

He received the Albright and Wilson Americas Award of the Canadian Society for Chemical Engineering (CSChE) in 1988, named University Professor in 2003 and elected a Fellow of the Royal Society of Canada in 2005. He has also received the Founders Award of the US Society for Biomaterials and the Killam Prize in Engineering of the Canada Council. In 2011 he received the Acta Biomaterialia Gold award and more recently received the RS Jane Award of the CSChE (2012), the Professional Engineers Ontario Gold Medal (2013) and the Canadian Council of Professional Engineering Gold Medal in 2014.

He has been active in the preparation of blood compatible materials through heparinization, the microencapsulation of mammalian cells in synthetic polymers and various strategies for vascularizing tissue constructs.

## **Kazunori KATAOKA**

*Department of Materials Engineering  
University of Tokyo  
JAPAN*

### **L6**

***Title: “Targeted Chemo- and Molecular-therapy  
by Self-assembled Supramolecular Nanosystems”***

***Wednesday, 2<sup>nd</sup> September  
8:30 - 9:15, Hall 1***

Kazunori Kataoka, Ph.D. is Professor of Biomaterials at Graduate School of Engineering, the University of Tokyo, Japan. He has been appointed joint position since 2004 from Graduate School of Medicine, the University of Tokyo as Professor of Clinical Biotechnology at Center of Disease Biology and Integrative Medicine. He received B.Eng. (1974) and Ph.D. (1979) from the University of Tokyo.

Dr. Kataoka received several awards, including the Society Award from the Japanese Society for Biomaterials (1993), the Society Award from the Society of Polymer Science, Japan (2000), Clemson Award from the Society for Biomaterials USA (2005), Founder’s Award from the Controlled Release Society (2008), the Science and Technology Prize awarded by the Minister of Education, Culture, Sports, Science and Technology, Japan (2010), Humboldt Research Award (2012), Leo Esaki Prize (2012) and Lif-time Achievement Award for Journal of Drug Targeting.

He served as a president of the Society of Polymer Science, Japan (2010-12), and a president of the Controlled Release Society (2012-13). He has been elected as a Fellow of the American Institute of Medical and Biological Engineering (AIMBE) (1999-), and a Fellow of the International Union of Societies for Biomaterials Science and Engineering (IUSBSE) (2004-). He has been on the editorial board of twelve international journals, including Journal of Biomaterials Science, Polymer Edition (Editor) and Biomaterials (Associate Editor).

His current major research interest is supramolecular materials for nanobiotechnology, particularly focusing on drug and gene targeting, and has published more than 500 papers with h-index: 108.

## Małgorzata LEWANDOWSKA-SZUMIEŁ

Center for Biostructure Research  
Medical University of Warsaw  
POLAND

**L7**

**Title: "Cell-made or Man-made Materials for Bone Reconstruction?"**

**Wednesday, 2<sup>nd</sup> September**

**15:30 - 16:15, Hall 1**

Małgorzata Lewandowska-Szumieł PhD, DSc - professor and a Head of the Tissue Engineering Laboratory, Department of Histology and Embryology, Centre for Preclinical Research and Technology (CePT), Medical University of Warsaw, Poland.

Her major scientific Interest is focused on: tissue engineering, adult stem cells in regenerative medicine, biomaterials and scaffolds for cell transplantation, cell behavior in contact with implantable materials (biocompatibility in vitro), cell response toward physical factors.

She was graduated from the Warsaw University of Technology, Department of Materials Science and Engineering (M.Sc., Eng.) and her further education and scientific career was connected with the Medical University of Warsaw (Ph.D. in medicine with honors, thesis: "Aluminium releasing from alumina based bioceramics under in vivo conditions", Post-doctoral degree (habilitation) in medicine, thesis: "Potential of in vitro systems in biocompatibility studies of implantable materials for bone reconstruction".

She holds the honorary status of „Fellow, Biomaterials Science and Engineering” (FBSE) from International Union of Societies of Biomaterials Science and Engineering and was awarded by the Polish Academy of Sciences for a series of works on the interaction of cells with implantable materials.

She is an author and co-author of over 50 papers published in peer-review journals and five patents (at various stages of the patent process) concerning original systems for cell culture and cell-based systems for bone reconstruction. She served as a Polish expert for the EU negotiations on the Regulation of The European Parliament and of the Council on advanced therapy medicinal products.

## **Abhay PANDIT**

*Network of Excellence for Functional Biomaterials  
National University of Ireland, Galway  
IRELAND*

### **L8**

**Title: “Biological-basis for Designing Biomaterials for the Injured and Degenerated Host - Examples in the Neural Space”**

**Thursday, 3<sup>rd</sup> September  
9:00 - 9:45, Hall 1**

Prof Abhay Pandit is the Director of the newly formed Center for Research in Medical Devices (CURAM) that is funded by Science Foundation Ireland. Prior to this he founded and directed the Network of Functional Biomaterials (NFB), a Science Foundation Ireland funded Strategic Research Cluster at the National University of Ireland, Galway. Prof Pandit has over twenty-five years of experience in the field of biomaterials. After a seven-year stint in industry he began working in academia. His research programme at the National University of Ireland, Galway hosts several patented technology platforms associated with the development of bioinspired materials, which are responsive to their environment and trigger the smart release of the biomolecule at the desired target site. These platforms have been developed for musculoskeletal, cardiovascular, soft tissue repair and neural targets with a number of others targets currently under investigation. He is the author of 4 granted patents with 18 patent applications pending. He has published 165-refereed journals and has authored 484 papers at both national and international conferences. He is an Associate Editor of Biomaterials journal and also serves on the editorial board of 13 journals, a referee for 77 journals, a Grant Panellist for 8 funding agencies, and an expert Grant Reviewer for 37 funding agencies.

Prof Pandit hosted the Tissue Engineering Regenerative Medicine International Society Conference – EU Meeting in 2010 and hosted The European Society for Biomaterials Conference in 2011 – the first group to host these prestigious conferences in consecutive years. In recognition of his services to the research community Prof Pandit was inducted as an International Fellow in Biomaterials Science and Engineering by the International Union of Societies for Biomaterials Science and Engineering (IUSBSE)-the first Irish academic to be inducted as a fellow. He has been elected as a Council Member of the Tissue Engineering and Regenerative Medicine (2010-2013) and as a Council Member of the International Society and European Society for Biomaterials (2013-2017).

# Keynote Speakers

## **Matthias EPPLÉ**

*Institute of Inorganic Chemistry  
University of Duisburg-Essen  
GERMANY*

### **K1**

**Title: “Antimicrobial Effects of Biomaterials:  
Silver Ions, Silver Nanoparticles and Antimicrobial Peptides”**

**Monday, 31<sup>st</sup> August  
16:00 - 16:30, Hall 3B**

Matthias Epplé is a Professor of Inorganic Chemistry at the University of Duisburg-Essen (Germany). After completion of his PhD at the Technical University of Braunschweig, he did research at the University of Washington (Seattle, USA), the University of Hamburg (Germany), and the Royal Institution (London, U.K.). In 2000, he became Professor at the University of Bochum and in 2003, he moved to the University of Duisburg-Essen. His research interests are concentrated on the chemistry of solid biomaterials, e.g. the properties of calcium phosphate ceramics and their composites, inorganic and polymeric nanoparticles for drug and gene delivery, and the synthesis of metallic nanoparticles and their biological actions. He is the past President of the German Society for Biomaterials.

## **Zhongwei GU**

*National Engineering Research Center for Biomaterials  
Sichuan University  
CHINA*

### **K2**

**Title: “Bioinspired Design of Dynamic Macromolecular  
for Gene Delivery”**

**Monday, 31<sup>st</sup> August  
16:00 - 16:30, Hall 4A**

Professor Zhongwei Gu has thrice being the chief scientist of the National Basic Research Program of China (the 973 program) since 1999, director of the National Engineering Research Center for Biomaterials at Sichuan University, vice-chairman of the Chinese Society for Biomaterials (CSBM), executive member of the council of the Chinese Materials Research Society(C-MRS) and Chinese Society for Biomedical Engineering (CSBME) and is a Fellow of international Biomaterials Science and Engineering (FBSE). His current research activities focus on the molecular design and controlled preparation of novel biomedical polymers, self-assembled biomaterials and nano-biomaterials, polymeric carriers and controlled drug/gene delivery systems, and biomaterials for molecular diagnosis. He has published more than 280 papers and received ~25 patents, composes/ translates ~14 books and chapters, and is the invited speaker in many international and domestic conferences.

## **Satoru KIDOAKI**

*Institute for Materials Chemistry and Engineering  
Kyushu University  
JAPAN*

### **K3**

**Title: “Manipulation of Cell Mechanotaxis by Designing Curvature of the Elasticity Boundary on Hydrogel Matrix”**

**Monday, 31<sup>st</sup> August  
16:00 - 16:30, Hall 4B**

Satoru Kidoaki, Ph.D, a professor of Laboratory of Biomedical and Biophysical Chemistry, Institute for Materials Chemistry and Engineering (IMCE), Kyushu University, Japan. He graduated from Nagoya University, Japan in 1998, and earned his Ph.D. degree on physical chemistry on first-order phase transition of giant duplex DNAs. From 1998 to 2000, he worked at National Cardiovascular Research Center in Japan as a post-doc researcher, where he investigated direct measurement of molecular and surface forces acting on the biomedical devices. After another one-year pos-doc position, he was employed in 2001 as an associate professor of Division of Biomedical Engineering, Graduate School of Medicine, Kyushu University, Japan. He started the researches on mechanics of biomolecules, biosurfaces, and cells and tissues for development of tissue engineering devices and regenerative medicine. Since 2006, he has been in the present position, and promoting the studies on mechanobio-materials to manipulate cell behaviors.

## **Yasuhiko TABATA**

*Institute for Frontier Medical Sciences  
Kyoto University  
JAPAN*

### **K4**

**Title: “Dual Release of a Macrophages Recruitment Agent and Growth Factor for Bone Regeneration”**

**Tuesday, 1<sup>st</sup> September  
11:30 - 12:00, Hall 2**

Dr. Yasuhiko Tabata is the Professor and Chairman of the Department of Biomaterials at the Institute for Frontier Medical Sciences, Kyoto University and serves as adjunctive professor at 14 different universities. He received his BD in Polymer Chemistry (1981), Ph.D. (1988) in Technology, D.Med. Sc. (2002), and D.Pharm. (2003) all at Kyoto University. He received the Young Investigator Award (1990), the Scientific Award from the Japanese Society for Biomaterials (2002), the Scientific Award from the Japan Society of Drug Delivery System (2011), and several awards. He has published 1,280 scientific papers including 120 book chapters and review articles, and has 130 patents. Dr. Tabata is the Board Governor of 5 Japanese Academic Societies or an associate member of the Science Council of Japan, Cabinet Office and the Editorial Board of 7 scientific journals. Specific research interests include biomaterials, drug delivery system (DDS), tissue engineering, stem cell technology, and medical diagnostics.

## Véronique MIGONNEY

Laboratory of Biomaterials and Specialty Polymers  
Université Paris 13  
FRANCE

### K5

**Title: "Contributions of Adhesive Proteins to the Cell Response to Bioactive Polymers and Surfaces"**

**Tuesday, 1<sup>st</sup> September**  
**11:30 - 12:00, Hall 3B**

Véronique Migonney is Professor of Chemistry and Biomaterials at the Institut Galilée, University Paris 13, France. She has been appointed as Director of the research laboratory Chemistry, Structures and Properties of Biomaterials and Therapeutic Agents by the CNRS. She received Materials Eng. Diploma (1981) and Ph.D. (1986). She served as associated director of the Institut Galilée (1998-2004), director of the Master Degree in Biomaterials (2004-), president and past-president of the French Society of Biomedical Engineering (2011-) and vice-president of the Alliance for Biomedical Engineering (2014-). She has been elected as Fellow of the International Union of Societies for Biomaterials Science and Engineering (IUSBSE) (2012). She has been Editor in chief and on the editorial board of IRBM, JBSMM. Her major research interest is the synthesis and grafting of bioactive polymers onto biomaterials surfaces to control the host response. She has published > 90 papers and 22 patents.

## Dieter SCHARNWEBER

Max Bergmann Center of Biomaterials  
Technische Universität Dresden  
GERMANY

### K6

**Title: "Glycosaminoglycan Derivatives – Promising Candidates for the Design of Functional Biomaterials"**

**Tuesday, 1<sup>st</sup> September**  
**11:30 - 12:00, Hall 4A**

Prof. Scharnweber is head of the group „Biomaterial-Development“ at the Max Bergmann Center of Biomaterials at the Institute of Materials Science, Technische Universität Dresden (TU Dresden). He is local speaker of the DFG-Transregio 67 „Functional biomaterials for controlling healing processes in bone and skin – from material science to clinical application“. His major scientific interests are on biomaterials focusing on (i) composition-structure-property relationships of oxide layers on titanium-based materials, (ii) techniques for surface-engineering of biomaterials, (iii) matrix-engineering, i.e. the design of artificial extracellular matrices mimicking the native cellular microenvironment, and (iv) the design and combination of defined biochemical and physical microenvironments for applications in tissue engineering and regenerative therapies. Dieter Scharnweber has studied chemistry at the TU Dresden with a PhD in physical chemistry. After a habilitation on biomaterials in 2002 he is professor at the TU Dresden since 2008.

## **Rui L. REIS**

*3B's Research Group - Biomaterials, Biodegradables and Biomimetics*  
*University of Minho*  
 PORTUGAL

**K7**

**Title: „Hydrogels and Scaffolds of Natural Origin as Support for Stem Cells in the Regeneration of Different Tissues”**

**Tuesday, 1<sup>st</sup> September**  
**16:45 - 17:15, Hall 2**

Professor Rui L. Reis, PhD, DSc, Hon. Causa MD, 48 years old, is the Vice-Rector for R&D of University of Minho (UMinho) in Portugal, Director of the 3B's Research Group on Biomaterials, Biodegradables and Biomimetics ([www.3bs.uminho.pt](http://www.3bs.uminho.pt)) and of the ICVS/3B's Associate Laboratory (around 430 researchers), of UMinho. He is the CEO of the European Institute of Excellence on Tissue Engineering and Regenerative Medicine (TERM), the President and CSO of the company Stematters, the President-elect of Global TERMIS and the editor-in-chief of the Journal of Tissue Engineering and Regenerative Medicine. He is co-author of 870 ISI listed publications (710 full papers in scientific journals), around 210 book chapters, 30 patents and 6 books. He has around 1650 communications in international conferences. He is PI of projects totalizing around 30 MEuros, including the very prestigious ERC Advanced Grant and an ERA Chairs. He runs a research group of around 175 researchers with more than 70 PhD holders. He was been awarded several major national and international scientific and innovation awards in Europe and the USA, including the Jean Leray and George Winter awards from ESB and the Clemson Award for Contributions to the Literature from SFB.

## **Wojciech CHRZANOWSKI**

*Faculty of Pharmacy*  
*The University of Sydney*  
 AUSTRALIA

**K8**

**Title: “Bionano Characterization - Beyond Imaging with Scanning Probe Microscopy”**

**Tuesday, 1<sup>st</sup> September**  
**16:45 - 17:15, Hall 4A**

Dr Wojciech Chrzanowski joined the University of Sydney in 2010 and he has established the Bio-interface group and Bio-nano-characterisation laboratory within the Faculty of Pharmacy. His research is balanced between basic and translation science and it develops new examination approaches to interrogate biological responses at nano level to inform the design of new biologically active materials for implantable devices and drug delivery. For a series of publications describing significant advances in nanobiomedical sciences and biointerfaces he was invited to present over 50 seminars, and lectures at Universities in the USA, Japan, Australia, UK, and Korea. He received two invitational fellowships to Tokyo University and Chubu University funded by Japan Society of Promotion of Science. Dr Chrzanowski published excess of 100 peer-reviewed publications (last 10 years). His publications attracted 1100 citations and his h-index is 20. He is also an inventor on 4 patents.

## Lucie BACAKOVA

Institute of Physiology  
Academy of Sciences of the Czech Republic  
CZECH REPUBLIC

**K9**

**Title: "Endothelial Cells on Biofunctionalized Polymeric Materials for Vascular Tissue Engineering"**

**Wednesday, 2<sup>nd</sup> September**

**9:30 - 10:00, Hall 3A**

Lucie Bacakova, MD, PhD, Assoc. Prof. graduated from the Charles University, Faculty of General Medicine, Prague, Czech Republic, and received the PhD degree in Physiology and Pathophysiology of Humans and Animals in 1992. Then she did research at the Institute of Physiology, Academy of Sciences of the Czech Republic. In 1996, she was a Research Fellow at the University of Washington, Department of Vascular Biology and Pathology, Seattle, WA, U.S.A. (Prof. S.M. Schwarz), and in 2000-2001, at the University of Pennsylvania, Biophysical Engineering & NanoBio-Polymers Lab, Philadelphia, PA, U.S.A. (Prof. D.E. Discher). Since 2005, she is the Head of the Department of Biomaterials and Tissue Engineering at the Institute of Physiology, Acad. Sci. CR. In 2013, she became Associated Professor at the 2<sup>nd</sup> Medical Faculty, Charles University, Prague, CR. She has published about 150 papers in international impacted journals (h-index 26). Her main interests include the cell-material interaction *in vitro* and engineering of bone, vascular and skin tissue.

## Sandra VAN VLIERBERGHE

Polymer Chemistry & Biomaterials Group  
Ghent University  
BELGIUM

**K10**

**Title: "3D Printing of Crosslinkable Gelatins: Overcoming the Mechanical Boundaries"**

**Wednesday, 2<sup>nd</sup> September**

**9:30 - 10:00, Hall 4A**

Prof. Sandra Van Vlierberghe is active within the Polymer Chemistry & Biomaterials Group (PBM) at Ghent University (UGent, Belgium) and holds a 10% professorship at the Faculty of Engineering of the Vrije Universiteit Brussel (VUB, Belgium). She has acquired expertise related to the synthesis, the modification and the processing of (bio)polymers including polyesters, proteins and polysaccharides for a plethora of applications in the fields of regenerative medicine and optical applications. She received her PhD in Sciences in 2008 at Ghent University. She authored more than 65 Web of Science Core Collection cited papers and she is promoter of 11 PhD's, edited a book, authored 5 chapters in books and was invited speaker at several international conferences. She currently is spokesperson of the 'Young Scientists Forum (YSF)' and editorial board member of the Biomaterials Network. Finally, she also holds a 10% professorship at the University of Antwerp (Belgium) for teaching polymer-related courses.

## **Neil CAMERON**

*Department of Materials Science and Engineering  
Monash University  
AUSTRALIA*

### **K11**

**Title: “Polypeptide Nanoparticles for Ocular Drug Delivery”**

**Wednesday, 2<sup>nd</sup> September**

**11:30 - 12:00, Hall 1**

Prof. Neil Cameron is the Monash Warwick Alliance Professor of Polymer Materials, based at Monash University. His research is focused on novel polymeric biomaterials, in particular scaffolds for 3D cell culture and tissue engineering, self-assembling polypeptides and sugar-containing polymers (glycopolymers). His research to date has led to >125 papers and he has given >130 invited lectures. He was awarded a DTI SMART Award (2001), the Macro Group UK Young Researcher’s Medal (2003), an ICI Strategic Fund Award (2004), a Durham University Christopherson/Knott Fellowship (2008) and he was a member of the team that won the RSC’s Rita and John Cornforth award (2011). He serves/has served on the Scientific Advisory Boards of the Centre of Excellence in Polymeric Materials (PoliMat) and Reinnervate Ltd, the Editorial Board of the journal Polymer Chemistry and the Editorial Advisory Board of the journal Polymer. He is currently Chairman of the Macro Group UK.

## **Laura POOLE-WARREN**

*Graduate School of Biomedical Engineering  
University of New South Wales  
AUSTRALIA*

### **K12**

**Title: “Tissue-engineered Electrodes for Neural and Cardiovascular Applications”**

**Wednesday, 2<sup>nd</sup> September**

**11:30 - 12:00, Hall 3B**

Laura Poole-Warren is a Professor in Biomedical Engineering at the University of New South Wales (UNSW Australia). Her research group focuses on incorporating functional biological molecules into hydrogels and electroactive polymers for application to medical devices. Specific interests are in cell and drug delivery in neural and cardiovascular applications. She has published over 100 papers and has had grant funding of approximately \$4 million over the past 10 years. She has also held appointments as visiting research professor at Rutgers University in the USA and as a preclinical scientist in the biomedical industry working on development of implantable devices including wound dressings and embolic agents for cancer treatment. For 10 years up to 2012, she was a member of the Australian Commonwealth Government statutory Advisory Committee on Medical Devices which is concerned with advising the Therapeutic Goods Administration on the safety of medical devices.

## **Che CONNON**

*Institute of Genetic Medicine  
Newcastle University  
UNITED KINGDOM*

### **K13**

**Title:** „*Bio-fabrication and Physiological Self-release of Tissue Equivalents using Smart Peptide Amphiphile Templates*”

**Wednesday, 2<sup>nd</sup> September**

**11:30 - 12:00, Hall 4A**

Che Connon obtained a PhD in Biophysics from the Open University Oxford Research Unit in 2000, during which time he investigated corneal wound healing and transparency. He subsequently obtained a JSPS post-doctoral fellowship to work in Kyoto, Japan for two years studying corneal stem cell transplantation. Upon his return to the UK he was awarded a Royal Society Fellowship to investigate the nanostructure of amniotic membrane used in ocular therapeutics. Since 2013 he has held the position of Professor of Tissue Engineering at Newcastle University.

Professor Connon's research team seeks to engineer functional replacement and temporary 'bridge' tissues using a modular approach while also developing model systems to study physiological and pathophysiological corneal tissue formation. Of current interest is the application of self-assembling peptide amphiphiles to control cell behavior and direct tissue formation.

## **Roberto DE SANTIS**

*Institute of Polymers, Composites and Biomaterials  
National Research Council of Italy  
ITALY*

### **K14**

**Title:** “*3D Fiber Deposition and Stereolithography Techniques for the design of Multifunctional Nanocomposite Magnetic Scaffolds*”

**Thursday, 3<sup>rd</sup> September**

**11:30 - 12:00, Hall 1**

Roberto De Santis was born in Naples, Italy, in 1966. He received the mechanical engineering degree in 1994, the PhD in Biotechnology of Dental Materials in 1997 and the Master in Biomaterials in 2001. He is researcher at the Institute of Polymers, Composites and Biomaterials of the Italian National Research Council from 2001. He is adjunct professor of Science and Technology of Dental Materials at the School of Dentistry, Faculty of Medicine of Naples “Federico II”. He is leader of the “Biomaterials and Tissue Engineering” unit of the Department of Chemical Science and Materials Technology. He is part of the board member of the SIB Italian Society of Biomaterials and of the SIBOT Italian Society of Biomechanics in Orthopadics and Traumatology. He is author of more than 70 papers published on international and national journals, 10 book chapters, 5 patents, 1 trade mark, and more than 100 international congress presentations.

## **Lorenzo MORONI**

Maastricht University, MERLN Institute  
Department of Complex Tissue Regeneration  
THE NETHERLANDS

### **K15**

**Title: “Polymer Brush-Assisted Fabrication of Protein Gradients inside of 3D Microporous Scaffolds”**

**Thursday, 3<sup>rd</sup> September**  
**11:30 - 12:00, Hall 2**

Dr. Moroni studied Biomedical Engineering at Polytechnic University of Milan, Italy, and Nanoscale Sciences at Chalmers Technical University, Sweden. He received his Ph.D. cum laude in 2006 at University of Twente on 3D scaffolds for osteochondral regeneration, for which he was awarded the European Doctorate Award. In 2007, he worked at Johns Hopkins University as a post-doctoral fellow in the Elisseeff lab, focusing on hydrogels and stem cells. In 2008, he was appointed the R&D director of the Musculoskeletal Tissue Bank of Rizzoli Orthopedic Institute, where he investigated the use of stem cells from alternative sources for cell banking, and the development of novel bioactive scaffolds for skeletal regeneration. From 2009 till 2014, he joined again University of Twente, where he worked in the Tissue Regeneration Dept. Since 2014, he holds an associate professor position at the MERLN Institute. His research group interests aim at developing biofabrication technologies to generate libraries of 3D scaffolds able to control cell fate. In 2014, he received the prestigious Jean Lera Award for outstanding young principal investigators from the ESB and the ERC starting grant.

## **Mirosława EL FRAY**

Division of Biomaterials and Microbiological Technologies  
Polymer Institute, West Pomeranian University of Technology  
POLAND

### **K16**

**Title: “Elastomeric Materials of Enhanced Mechanical Performance for Implantable Artificial Heart”**

**Thursday, 3<sup>rd</sup> September**  
**11:30 - 12:00, Hall 3A**

Head of the Division of Biomaterials and Microbiological Technologies and director of the Nanotechnology Centre for Education and Research, and director of Polymer Institute. She graduated from Szczecin University of Technology, where she also received her PhD in 1996. She was a post-doc at the Technical University Hamburg-Harburg, and scientific researcher at the University Bayreuth, Germany (2000-2003). She received her habilitation (DSc) at the Warsaw University of Technology in 2004. She received the Royal Society fellowship in 2005 at the Imperial College London, UK. She is an author and co-author of over 250 scientific papers. Her scientific background is on the polymer synthesis and characterization, biodegradation and modification towards specific biomedical applications (including polymers for artificial heart, heart patches, elastomeric and photocurable networks, and nanocomposites). Currently, she is employed as full professor at the West Pomeranian University of Technology, Szczecin, contributing to research and education in the field of polymer chemistry, nanotechnology, including nanocomposites, and polymeric biomaterials.

# Awards Winners

## International Award

### **Nicholas A. PEPPAS**

*Biomedical Engineering Department  
The University of Texas at Austin  
UNITED STATES*

***Tuesday, 1<sup>st</sup> September  
8:30 - 9:00, Hall 1***

Nicholas A. Peppas is the Cockrell Family Distinguished Chaired Professor in the Departments of Chemical, Biomedical Engineering and Pharmacy, and Chairman of the Department of Biomedical Engineering of the University of Texas at Austin. His work in biomaterials, polymer physics, drug delivery and bionanotechnology follows a multidisciplinary approach by blending modern molecular and cellular biology with engineering principles to design the next-generation of medical systems and devices for patient treatment. Over the past 40 years he has set the fundamentals and rational design of biomedical hydrogels and drug delivery systems and developed models of drug and protein diffusion in controlled release devices and biological tissues.

In 2012 he received the Founders Award of the National Academy of Engineering, the highest recognition of the Academy, for these contributions to the field. In 2008, AIChE named him one of the One Hundred Chemical Engineers of the Modern Era. Peppas is a member of the National Academy of Engineering, the National Academy of Medicine, the National Academy of Inventors, the National Academy of France, the Royal Academy of Spain, the Academy of Athens and the Academy of Texas. He has been recognized with awards from AIChE (Founders Award, William Walker Award, Institute Lecture, Jay Bailey Award, Bioengineering Award, Materials Award), the Biomedical Engineering Society (Distinguished Scientist Award), the American Institute of Medical and Biological Engineering (Galletti Award), the Society for Biomaterials (Founders, Clemson and Hall Awards), the Controlled Release Society (Founders, Heller and Eurand Awards) and other societies.

He is President of the International Union of Societies of Biomaterials Science and Engineering, and Past-Chair of the Engineering Section of the American Association for the Advancement of Science, and the Council of BME Chairs. Previously, he served as President of SFB and the Controlled Release Society. He has supervised the research of 100 PhDs and about 180 postdocs and visiting scientists. Peppas holds a Dipl. Eng. from the NTU of Athens (1971), a Sc.D. from MIT (1973), honorary doctorates from the Universities of Ghent, Parma, Athens, Patras and Ljubljana, and an Honorary Professorship from Sichuan University.

## Jean Leray Award

### **Joaquim Miguel OLIVEIRA**

*3B's Research Group - Biomaterials, Biodegradables and Biomimetics  
University of Minho  
PORTUGAL*

**Wednesday, 2<sup>nd</sup> September**

**14:30 - 15:00, Hall 1**

J. Miguel Oliveira BSc, PhD (Portuguese, M, 37 years old) is a Principal Investigator “Investigador FCT 2012” at the PT Government Associate Laboratory ICVS/3B's (<http://www.3bs.uminho.pt/users/migueloliveira>). He is the Director of Pre-Clinical Research at the FIFA MEDICAL CENTER, Estádio do Dragão, Porto, PT since Feb. 2013. Currently, he is a Lecturer in Doctoral Program in Tissue Engineering, Regenerative Medicine and Stem Cells (TERM&SC) at UMinho, PT (since Dec. 2013). He is also an Invited lecturer at the Faculty of Medicine, U. Porto (since Sept. 2013) and Dept. of Polymer Eng., UM, PT (2009-present). Along the years he has focused his work on the field of biomaterials for tissue engineering, nanomedicine, stem cells and cell/drug delivery. More recently, he set-up a new research line within the ICVS/3B's on 3D in vitro models for cancer research. As result of his proficiency, he has published so far more than 100 scientific contributions in scientific journals with referee, being 3 of those review papers produced under invitation.

Miguel Oliveira was approved 7 patents, published 2 books, 1 special issue in scientific journals, and more than 40 book chapters in books with international circulation. He has participated in more than 140 communications in national/international conferences and has been invited/keynote speaker in more than 30 plenary sessions. He has an h-index of 20, i10 of 35 and received more than 1800 citations. He has been the responsible for developing and licensing a patent on gellan gum-based polysaccharides (Mimsys® G) to Stematters, the first product commercialized by this spin-off of 3B's. He has been awarded several prizes and he is very active on the elaboration and scientific coordination of several PT and international funded projects.

In addition, he is member of the advisory board of the Journal of Materials Science: Materials in Medicine, International Journal of Tissue Engineering, Journal ISRN Biomaterials, The Journal of Experimental Orthopaedics, Journal “Recent Patents on Corrosion Science”, and referee in more than 30 international journals.

# George Winter Award

## Luigi AMBROSIO

*Chemical Sciences & Materials Technology Department  
National Research Council  
ITALY*

**Thursday, 3<sup>rd</sup> September  
8:30 - 9:00, Hall 1**

Luigi Ambrosio is Director of Chemical Sciences & Materials Technology Department, National Research Council of Italy.

He received the doctoral degree in Chemical Engineering (1982) from University of Naples "Federico II". He was Research Associate at University of Naples (1983-1985), Research Associate at University of Connecticut, USA (1985-1986), and Visiting Scientist at Kontron Medical Inc., USA (1986- 1988). Adjunct Professor of University of Connecticut, USA (1997-2003) and of University of Naples "Federico II" (1997-2010). Director of Institute of Composites and Biomedical Materials, National Research Council of Italy (2008-2012). Visiting Professor at Instituto de Química/UFRGS, Porto Alegre, Brazil (since 2012). Distinguished Professor at Nanjing Normal University, China (since 2013).

He is member of Advisory Board and Guest Editor of International and National Scientific Journals, Vice-President of the Italian Society of Biomaterials (2006-2013), and President of the European Society for Biomaterials (2006-2013), Past President since 2013.

Board Committee Member of: - IMAST Scarl., (2002-2008), CRdC - Campania Region (since 2004), IBEC, Barcelona, Spain (2007-2013), ALS srl (2006-2015). CIRA S.C.p.A (2012-2014), CNCCS Scarl (since 2012), Dhitec Scarl (Since July 2014), INAIL (Since July 2014).

He has been nominated Fellow of the American Institute for Medical and Biological Engineering (March 2001), and Fellow of Biomaterials Science and Engineering (May 2004) and APA Distinguished Award (2014).

Member of the European Commission Advisory Group of the FP7-NMP (2006-2008) and Member of High Level Group - *Key Enabling Technologies* - European Commission (since 2009).

Research interests include design and characterisation of polymers and composites for medical applications and tissue engineering, rheology of biological fluids, structural properties of natural tissue, properties and processing of polymers and composites and nanostructures, hydrogels and biodegradable polymers.

Publications include over 300 papers on international scientific journals and book, 18 patents, over 500 presentations at international and national conferences and over 100 invited lectures.

## Other Awards

### Translational Award

This award is established to recognise, encourage and stimulate outstanding translational research contributions to the field of biomaterials. The award is attributed to a postdoctoral scientist presenting the best contribution in translational research at the Biomaterials conference of the Society. Among the numerous applications for the Translational Award 7 candidates were selected. Their oral presentations are scheduled on Tuesday, 1<sup>st</sup> September, at 16:45 – 18:30 during Translational Research Symposium. The winner announcement will take place during the Closing Ceremony on Thursday, 3<sup>rd</sup> September, at 13:15.

### European Doctoral Award

This award is established to recognise, encourage and stimulate outstanding translational research contributions to the field of biomaterials. The candidate applies for and completes his/her Ph.D. according with the rules of his/her own country and university. This award demonstrate that the winners have all received high standard research education and training at a European level in the fields of Biomaterials and Tissue Engineering, and that they are also able to produce scientific results deserving recognition by being published and accepted in high quality journals and conferences. The EDA awardees are: Ana Puga, Andrada Serafim, Cristina Gonzalez Garcia, Israel Gonzalez de Torre, Jose Ballester, Małgorzata Krok, Martina Lorenzetti, Michael Monaghan, Riccardo Levato, Shane Browne and Tiziano Serra. EDA awardees presentation will be during Young Scientists Forum on Wednesday, 2<sup>nd</sup> September, at 15:00.

### Rudolf Cimdins Scholarship Awards (Travel Awards)

The ESB supports student participation at the ESB Annual conference through the travel award scheme. Candidates apply to the ESB Council and the award covers a contribution to registration and travel. The winners still need to pay their registration etc, but they will get the money reimbursed by the ESB Treasurer after the conference. It should be noted that the awards are normally given to candidates who would not otherwise be able to attend the ESB conference as they come a long way/ come from a poorly funded country/group. Recipients will be announced at the Closing Ceremony on Thursday, 3<sup>rd</sup> September, at 13:15.

### Best Student Oral/Poster Presentations

All candidates must be students, must have an accepted abstract as presenting author and should have indicated on the registration form their desire to be considered for these awards. Oral presentations and posters will be assessed by the Conference Award Committee. Winners will be announced during the Closing Ceremony on Thursday, 3<sup>rd</sup> September, at 13:15.

### Best Rapid Fire Presentations

Springer, international publisher specialising in science, technology and medicine, is awarding two Best Rapid Fire Presentation Prizes. The winners will receive Springer book voucher worth 250 €.

# Special Sessions

## Young Scientists Forum

Sunday, 30<sup>th</sup> August  
13:00 - 17:00, Hall 2

### “From Creative Thinking Towards Product Commercialization: The Complete Value Chain”

#### Organizers:

Sandra Van Vlierberghe, Lorenzo Moroni, Giuseppe Cama, Anna Finne Wistrand, Izabela Stancu

#### Supported by:

Young Scientists Forum @ ESB

The YSF workshop in Kraków, Poland will aim to cover the entire value chain ranging from idea creation towards commercialization of a developed product.

#### Programme:

- 13:00**    **Prof. Abhay Pandit**, National University of Ireland, Galway, Ireland  
*“Creative Thinking – How to Come up with New Ideas”*
- 13:35**    **Prof. Fabrizio Barberis**, University of Genoa, Italy  
*“How to Get Money to Work out your Idea”*
- 14:10**    **Prof. Paul Santerre**, University of Toronto, Canada  
*“You Received Funding – What’s Next – How to Survive in Research Land”*
- 14:45**    Coffee break
- 15:15**    **Prof. Joachim Kohn**, The New Jersey Center for Biomaterials, United States  
*“How to Advance Research Results Towards the Development of a Medical Product”*
- 15:50**    **Dr. Lechosław F. Ciupik**, LfC-Medical, Poland  
*“R&D in Creation of Bio-Engineering Product; Researcher Responsibility”*
- 16:25**    **Panel discussion**

In addition to PhD students, the workshop will also focus on topics relevant for post-doctoral researchers as well as PIs.

The workshop will be closed with a round table discussion during which delegates can share their opinion and exchange ideas to create an excellent networking opportunity.

# Special Fellows Session

Monday, 31<sup>st</sup> August  
16:00 - 17:45, Hall 1

## “Biomaterials Education is not Ready for the Challenges of the Future”

### Session Chair and Organizer:

**Joachim Kohn**, PhD, FBSE

*Chair, International College of Fellows*

*Board of Governors Professor and Director, New Jersey Center for Biomaterials*

*Rutgers - The State University of New Jersey, USA*

The “Special Fellows Session” is organized by the International College of Fellows of Biomaterials Science and Engineering (IUS-BSE). Special Fellows Sessions explore important and sometimes controversial topics. A group of six prominent Fellows will highlight the perceived strengths and weaknesses of the way most universities educate and train the next generation of biomaterials scientists. Three Fellows will argue in favor of the current status of biomaterials education, while three other Fellows will provide provocative and stimulating arguments highlighting the weaknesses of current biomaterials education. One key point of the debate will be an exploration to which extent the careers of young scientists are impacted by a lack of skills needed to translate laboratory research into products within an industrial setting. Another key point relates to the fact that current biomaterials education prioritizes breadth over depth, producing “generalists” who are not well-trained in any one field. The changing job market for biomaterials scientists (especially at the PhD level), and global challenges and perspectives will also be discussed. Together, the six presenters will provide the audience with a deep and multifaceted understanding of the strength and weaknesses of the way many young biomaterials scientists are educated and prepared for their careers. Special Fellows Sessions are designed to be interactive: the audience will have an opportunity to participate in the debate and will vote on the issues.

Previous “Special Fellows Sessions” examined the utility of animal experiments (WBC Amsterdam, 2008), explored whether we will ever be able to regenerate a complete human arm (WBC Chengdu, 2012), looked at the tension between basic research and translational research (ESB Liverpool, 2014) and the competition between material science approaches and biology-based approaches in developing the next generation of regenerative therapies (US Society for Biomaterials, Charlotte NC, 2015).

## Speakers:

### **Kristi S. Anseth, PhD**

*Distinguished Professor, Tisone Professor, Associate Professor of Surgery,  
and Howard Hughes Medical Institute Investigator*

Chemical and Biological Engineering

University of Colorado, Boulder, USA

### **David W. Grainger, PhD, FBSE**

*University Distinguished Professor and George S. & Dolores Doré Eccles  
Presidential Endowed Chair of Pharmaceutics and Pharmaceutical Chemistry*

Department of Bioengineering

University of Utah, USA

### **Dietmar Hutmacher, PhD, FBSE**

*Professor, Science and Engineering Faculty,*

Queensland University of Technology, Brisbane, Australia

### **Lynne C. Jones, M.S., PhD, FBSE**

*Director, Center for Osteonecrosis Research and Education*

*Associate Professor of Orthopaedic Surgery*

Johns Hopkins University

Baltimore, MD, USA

### **Laura Poole-Warren, PhD, FBSE**

*Professor and Pro Vice-Chancellor for Research Training, Dean of Graduate Research  
Graduate School of Biomedical Engineering,*

University of New South Wales

Sydney, Australia

### **Elizabeth Tanner, PhD, FBSE**

*Professor of Biomedical Materials*

*Department of Biomedical Engineering*

University of Glasgow, Scotland, UK

# Translational Research Symposium

Tuesday, 1<sup>st</sup> September

10:00 - 11:00

11:30 - 13:00

16:45 - 18:30

Hall 1

## “Innovating in the Medical Device Industry – Challenges & Opportunities”

### Organizers:

Yves Bayon, Marc Bohner, David Eglin, Geoff Richards, Dimitrios Zeugolis

### Supported by:

DSM Biomedical, Netherlands

The ESB 2015 Translational Research Symposium will focus on **“Innovating in the Medical Device Industry – Challenges & Opportunities”**. It will include invited lectures from the medical device innovation stakeholders, i.e. medical device industry, academic translational centres, customers and medical device regulatory experts. The Translational Research Symposium will also offer open sessions for sharing translational research initiatives both from academia and industry. This event will be of interest to a wide audience from large medical device producers to academics and entrepreneurs and promoters of biomaterial technologies for medical applications. The program includes significant time for networking during coffee breaks, lunch and is also synchronized with other ESB2015 sessions throughout the day allowing the delegates to view other interesting lectures during the event.

### Session 1 (10.00-11.00)

#### Invited Speakers:

**Philip Procter**, Medical Device Industry Consultant, France

*“Clinical Needs Based Biomaterial Strategy: Reducing the Risk that Innovation is “Lost in Translation” in Products for Poor Quality Bone”*

**Nils Reimers**, Manager R&D, Global Funding & Reimbursement,  
Stryker Trauma & Extremities, Germany

*“Best Practice for Registration Trials of Biodegradable Implants”*

**Xiang Zhang**, Lucideon Ltd., Royal Society Industry Fellow at University of Cambridge, UK

*“New Concept of Hybrid Polymer Composites for Implant Applications”*

**Ipsita Roy**, University of Westminster, London, UK

*“Novel Biodegradable and Biocompatible Polymers for Medical Applications”*

## Session 2 (11.30-13.00)

### **Invited Speakers:**

**Jan Weber**, Sr Research Fellow, Corporate Research, Boston Scientific Corporation, USA  
*"Insights into Collaboration and Innovation for Early Stage Medical Device Development"*

**Jens Thies**, Director Science and Innovation, DSM Biomedical, Netherlands  
*"From Biomaterials Supplier to Device Development Partner – Supporting Medical Device Companies in De-Risking Medical Products"*

**Herbert De Breuck**, Manager R&D, Luxilon, Wijnegem, Belgium  
*"Next Generation of Fibers for Medical Devices: Biopolymers and Functionalized Coatings"*

## Session 3 (16.45-18.30)

### **Oral presentations of Candidates for Translational Research Award:**

**Antoine Alves**, NAMSA, Chasse/Rhône, France  
*"FTIR Microscopy Contribution for Comprehension of Poly-L-Lactic Acid (PLA) Degradation Mechanisms"*

**Mikhail Durymanov**, Institute of Gene Biology of the RAS, Russia  
*"Possible Approach to Improve Systemic Gene Delivery to Tumour Using Polyplex Nanoparticles"*

**Beata Butruk-Raszeja**, Warsaw University of Technology, Poland  
*"Endothelialization of Polyurethanes: Immobilization of REDV Peptide"*

**Inês Gonçalves**, INEB - Instituto de Engenharia Biomédica, Universidade do Porto, Portugal  
*"Helicobacter Pylori-Binding Small Chitosan Microparticles that Penetrate Gastric Mucosa"*

**Stephen Swioklo**, Institute for Genetic Medicine, Newcastle University, United Kingdom  
*"Leaving Cells Out in the Cold: Hydrogel Encapsulation for the Improved Hypothermic Preservation of Stem Cells"*

**Daniel Rodriguez**, Technical University of Catalonia (UPC-BarcelonaTECH), Barcelona, Spain  
*"Antibacterial Coatings on Titanium Surfaces: a Comparison Study Between In Vitro Single-species and Multispecies Biofilm"*

**Elisabeth Engel**, Institute for Bioengineering of Catalonia (IBEC), Barcelona, Spain  
*"The Proangiogenic Potential of a Novel Poly(Lactic) Based Composite Membrane for Guided Bone Regeneration"*

# Surface Charge for Biomaterial Characterization

Tuesday, 1<sup>st</sup> September  
11:30 - 13:00  
Hall 4B

## Speakers:

Dr. Christine Körner, Anton Paar GmbH, Graz, Austria

Dr. Martina Lorenzetti, Jožef Stefan Institute, Ljubljana, Slovenia

## Sponsored by:

Anton Paar, Austria

The session “Surface Charge for Biomaterial Characterization” focuses on the role of zeta potential analysis as a surface sensitive technique for the characterization of biomaterial surfaces. The zeta potential is an interfacial parameter which describes the charge that a surface assumes when it gets in contact with a liquid. As the zeta potential is sensitive to the outermost surface layer, it furthermore enables time-resolved adsorption studies of biological compounds on solid surfaces. It thus combines the clear visualization of the interaction between biomaterials and their environment with the validation of the chemistry of the adsorbed layer. This enables the optimization of solid surface properties of biomaterials.

The surface charge of solid materials is best assessed by means of zeta potential analysis performed directly at the solid/water interface using the streaming potential technique. Zeta potential analysis is applicable to all classes of materials used for biomaterial applications, i.e. metals, polymers and ceramics.

The first part of the session introduces the basic principles and benefits of zeta potential analysis. The state-of-the-art instrument for zeta potential analysis on solids, SurPASS Elektrokinetic Analyzer, will be presented. Together with its wide range of measuring cells, SurPASS allows for the analysis of biomaterial samples of different shape and geometry over a wide pH range and at different electrolyte compositions.

The second part of the session focuses on recent research on modified titanium-based substrates (TiO<sub>2</sub>-coated by nanocrystals or nanotubes) used for hard tissue replacement. Influences of the topography of the surface (roughness and size of nanostructures), the substrate nature, and the material behaviour in contact with different biologically relevant electrolytic solutions on the surface charge are discussed. The information obtained by zeta potential analysis allowed for a better understanding of the behavior of such coatings in physiological conditions.

The session “Surface Charge for Biomaterial Characterization” is interesting for scientists and researchers searching for a direct method for biomaterial/environment interface analysis and a state-of-the-art technique for solid surface analysis to successfully promote the development of biomaterials.

# Science for Industry: Bioresorbable Materials for Medical Applications

Wednesday, 2<sup>nd</sup> September

9:30 - 11:00

11:30 - 13:00

16:45 - 17:45

Hall 4B

**ReBioStent**

Reinforced Bioresorbable Biomaterials for Therapeutic Drug Eluting Stents

## Organizers:

Xiang Zhang, Ipsita Roy, Kadem Al-Lamee, Stuart Maclachlan, Maria Joao Barros, Nial Bullett, Mark Taylor

## Supported by:

- ReBioStent project, grant agreement n° 604251 from the European Union's Seventh Programme for research, technological development and demonstration (FP7)
- ARTERIUS, United Kingdom

## Chairs:

Dr Xiang Zhang, *Principal Consultant, Lucideon Limited, and Royal Society Industry Fellow at University of Cambridge*

Dr Ipsita Roy, *Reader, Head of Applied Biotechnology Research Group, Department of Life Sciences, Faculty of Science and Technology, University of Westminster*

Materials for medical applications take many forms, from metallic to synthetic and natural polymers, composites and materials of biological origin. The ultimate goal of an implantable device is for it to be unrecognised by the body, to allow for stable long term lifetime of the device. One strategy for this is for the devices to be bioresorbable – to disappear after their initial function is no longer needed as healing has occurred. Permanent implants may cause complications many years after initial healing has occurred and their presence in the body is no longer necessary.

Bioresorbable materials have applications in a wide range of medical indications, such as sutures, coronary and peripheral vascular scaffolds, bone pins and anchors, tissue fixation screws, drug delivery coatings and microspheres and surgical meshes and matrices. The bioresorbable materials may include polymers, metals, ceramics, glasses, composites and materials of biological origin such as natural collagen, and may allow for drug elution and delivery as well as performing a mechanical function.

Bioresorbable sutures have been available for over 40 years, yet recent innovations have expanded the market for bioresorbable implants to include cardiovascular, orthopaedic and general surgery. This has demanded increased performance from polymers, with increased strength and control over degradation being necessary.

### Session 1 (9.30-11.00)

- 9:30** **Welcome and Introduction: Dr Xiang Zhang, Dr Ipsita Roy**
- 9:50** **Dr Kadem Al Lamee, Arterius Limited**  
*"Commercial needs for bioresorbable materials, transfer from laboratory and barriers and gaps in the technology"*
- 10:15** **Prof. Oskar Hoffmann, University of Vienna**  
*"Production and Evaluation Platforms for Preclinical Assessment of Novel Biomaterials for Non-Healing Bone Lesions"*
- 10:40** **Dr Ipsita Roy, University of Westminster**  
*"Bioresorbable Systems: Polymers and Metals"*

### Session 2 (11.30-13.00)

- 11:30** **Prof. Aldo R. Boccaccini, University of Erlangen-Nuremberg**  
*"Bioresorbable Systems: The Role of Inorganic Fillers in Composites"*
- 11:50** **Dr Iban Quintana, IK4 - Tekniker**  
*"Bioresorbable Systems: The Role of Surface Functionalisation"*
- 12:10** **Prof. Atul Bhaskar, University of Southampton**  
*"Bioresorbable Systems: The Role of Modelling and Simulation in Performance Assessment of Bio-Structures and Implants"*
- 12:30** **Dr Gianluca Giavaresi, Istituto Ortopedico Rizzoli, Bologna**  
*"Bioresorbable Systems: The Role of Preclinical Testing"*
- 12:50** **Bioresorbable Systems: Discussion**
- 13:00** **Lunch including networking and posters**

### Session 3 (16:45 – 17:45)

- 16:45** **Welcome back and overview of morning's proceedings: Dr Xiang Zhang, Dr Ipsita Roy**
- 16:55** **Elena Boccardi, University of Erlangen-Nuremberg**  
**Zein Azhari, Cambridge University**  
*"Research into Bioresorbable Systems"*
- 17:15** **Panel discussion and overview of proceedings with speakers from the Bioresorbable System Session**

# Additional Meetings

## **IUSBSE Committee Meeting**

**The Annual Meeting of the Delegates to the International Union of Societies for Biomaterials Science and Engineering**

**Sunday, 30<sup>th</sup> August**

**12:00 - 17.00**

**Hall 4C, Level 3**

**(14:45 – 15:15 Coffee break, Level 2)**

## **ESB Council and Presidents of the National Societies for Biomaterials Meeting**

**Monday, 31<sup>st</sup> August**

**17:45 - 18:45**

**ESB Lounge, Level 0**

## **Fellows Business Meeting and Lunch**

**(FBSE - “Fellow, Biomaterials Science and Engineering”)**

**Tuesday, 1<sup>st</sup> September**

**13:00 - 14:30**

**Hall 4C, Level 3**

## **Editorial Board Meeting and Lunch**

**Journal of Materials Science: Materials in Medicine**

**Wednesday, 2<sup>nd</sup> September**

**13:00 - 14:30**

**ESB Lounge, Level 0**

# Social Events

## Welcome Reception

**ICE Congress Centre, Level 3**

**Sunday, 30<sup>th</sup> August**

**18:00 - 20:00**

Begin your ESB2015 journey at the appealing Welcome Reception! Say hello to your biomaterials community friends and meet new ones. Get exclusive opportunity to experience traditional Polish song and dance performance of “Małe Słowianki” group. Enjoy delicious food and drinks and get a first taste of famous Polish hospitality.

## Concert

**St. Mary’s Basilica, Main Market Square - Rynek Główny**

**Monday, 31<sup>st</sup> August**

**19:30 - 20:15**

After a day filled with a scientific programme, come to the St. Mary’s Basilica, magnificent gothic church, famous for its wooden altarpiece carved by Wit Stwosz, for the soothing and relaxing classical music concert.

## Keynotes & Chairpersons Dinner *(by invitation only)*

**Cloth Hall - National Museum, Main Market Square - Rynek Główny**

**Monday, 31<sup>st</sup> August**

**20:30 - 22:00**

To show our appreciation to all those who have helped us with the ESB2015 Conference organization. The Keynotes&Chairpersons Dinner is an exclusive event and the Cloth Hall is truly a unique place, perfectly tailored to this occasion.

## YSF Social Event

*(Limited number of tickets – on a first come first served basis!)*

**The Club “Under the Lizards” – “Pod Jaszczurami”, Main Market Square - Rynek Główny**

**Monday, 31<sup>st</sup> August**

**20:30 - 03:00**

**Ticket: 30€/person**

**Haven’t bought the ticket, yet? Do this ASAP at the Registration Desk.**

The exciting YSF Social Event in one of the oldest students club in Kraków, the Club “Under the Lizards”, for all those feeling young at heart. The unique atmosphere, the exceptional climate, great music, food and drinks - Under the Lizards has it all. Let’s have fun and get to know each other better!

## Acta Biomaterialia Anniversary Reception

ICE Congress Centre, Level 1  
Tuesday, 1<sup>st</sup> September  
18:30 - 19:30

*Acta* BIOMATERIALIA

Do not miss the opportunity to celebrate wonderful 10<sup>th</sup> anniversary of Acta Biomaterialia, the Elsevier Journal! Feel welcomed by the Acta Bio Editor-in-Chief, prof. William R. Wagner and enjoy food and drinks. Remember to toast for Acta Biomaterialia superb achievements!

### Gala Dinner

*(Limited number of tickets – on a first come first served basis!)*

**Wieliczka Salt Mine - 125 m underground!**

**Wednesday, 2<sup>nd</sup> September**

**18:00 - 21:00**

**Ticket: 100€/person, available also at the Registration Desk**

The Wieliczka Salt Mine is one of the most valuable monuments of material and spiritual culture in Poland. Each year it is visited by more than one million tourists from all over the world. It is also a world class monument, featuring among twelve objects on the UNESCO's World Cultural and Natural Heritage List.

The ESB2015 Conference Gala Dinner will be organized in the chamber "Warszawa", located 125 m underground.

For the Gala Dinner Participants, transport from the Conference Venue to the Wieliczka Salt Mine will be provided. Bus will depart at 18:00 from a parking located in front of the ICE Congress Centre. The journey to Wieliczka will take about half an hour. Before the Dinner, a sightseeing tour in the underground part of the museum is planned. The tour begins with a walk down exactly 380 wooden steps, and thus appropriate walking shoes are recommended (after the Dinner, the way upward will be with the lift). Also, please note that the air temperature in the salt mine chambers is only about 14-16°C (57-61°F).

# **DETAILED SCIENTIFIC PROGRAMME**

# Oral presentations

Sunday, 30<sup>th</sup> August

Sunday, 30<sup>th</sup> Aug

<b>Hall 2</b>	<b>Young Scientists Forum Workshop (1)</b> Organizers: Sandra Van Vlierberghe, Lorenzo Moroni, Giuseppe Cama, Anna Finne Wistrand, Izabela Stancu
13:00	<b>Creative Thinking – How to Come up with New Ideas</b> <u>Prof. Abhay Pandit</u> <i>National University of Ireland, Galway, Ireland</i>
13:35	<b>How to Get Money to Work out your Idea</b> <u>Prof. Fabrizio Barberis</u> <i>University of Genoa, Italy</i>
14:10	<b>You Received Funding – What’s Next – How to Survive in Research Land</b> <u>Prof. Paul Santerre</u> <i>University of Toronto, Canada</i>

<b>Hall 2</b>	<b>Young Scientists Forum Workshop (2)</b> Organizers: Sandra Van Vlierberghe, Lorenzo Moroni, Giuseppe Cama, Anna Finne Wistrand, Izabela Stancu
15:15	<b>How to Advance Research Results Towards the Development of a Medical Product</b> <u>Prof. Joachim Kohn</u> <i>The New Jersey Center for Biomaterials, United States</i>
15:50	<b>R&amp;D in Creation of Bio-Engineering Product; Researcher Responsibility</b> <u>Lechosław F. Ciupik</u> <i>LfC-Medical, Poland</i>
16:25	<b>Panel Discussion</b>

Hall 1	Plenary Lecture 1	
9:00	L1	<b>Bioactive Materials for the Treatment of Major Injuries: Opportunities and Challenges</b> <u>Joachim Kohn</u> <i>The New Jersey Center for Biomaterials, United States</i>  Chairs: Elżbieta Pamuła, AGH University of Science and Technology, Poland Jan Chłopek, AGH University of Science and Technology, Poland Matteo Santin, University of Brighton, United Kingdom

Hall 1	Plenary Lecture 2	
9:45	L2	<b>Regenerative Transplantation - from Experimental Laboratory to Clinical Applications</b> <u>Maria Siemionow</u> <i>University of Illinois at Chicago, Department of Orthopaedics, United States</i>  Chairs: Elżbieta Pamuła, AGH University of Science and Technology, Poland Jan Chłopek, AGH University of Science and Technology, Poland Matteo Santin, University of Brighton, United Kingdom

Session 1	Bone Tissue Engineering 1	
Hall 1	Chairs: Despina Deligianni, University of Patras, Greece Zhongwei Gu, Sichuan University, China Gifty Tetteh, University of Sheffield, United Kingdom (YSF Chair)	
11:00	1	<b>Osteocyte Function in Regulating Osteoclast Differentiation on Ceramic Biomaterials</b> <u>Miho Nakamura</u> , Teuvo Hentunen, Jukka Salonen, Naoko Hori, Kimihiro Yamashita <i>Tokyo Medical and Dental University, Japan</i>
11:15	2	<b>Pannexin 1 and Pannexin 3 Regulated Osteoblastic Differentiation of Human Bone Marrow Mesenchymal Stem Cells in a Three Dimensional Macroporous Scaffold</b> <u>Julien Guerrero</u> , Hugo Oliveira, Rachida Aid, Reine Bareille, Didier Letourneur, Yong Mao, Joachim Kohn, Joelle Amedee <i>INSERM U1026, France</i>
11:30	3	<b>Hydrolysis of Octacalcium Phosphate Co-Precipitated Gelatin Composite and Osteoblastic Cell Response</b> Yushi Ezoe, Takahisa Anada, Hajime Yamazaki, Tetsu Takahashi, <u>Osamu Suzuki</u> <i>Tohoku University, Japan</i>
11:45	4	<b>Novel Bioactive Hydrogel-Nanosilica Hybrid Materials as a Potential Injectable Scaffold for Bone Tissue Engineering</b> <u>Joanna Lewandowska-Łańcucka</u> , Sylwia Fiejdasz, Łucja Rodzik, Marcin Koziół, Maria Nowakowska <i>Jagiellonian University, Poland</i>

## Session 2 Hall 2

Chairs: Lucy Di Silvio, *King's College London Guy's Hospital, United Kingdom*  
Dietmar Hutmacher, *Queensland University of Technology, Australia*  
Christoph Tondera, *Helmholtz-Zentrum Dresden-Rossendorf, Germany* (YSF Chair)

11:00	5	<b>Anisotropic Bilayered Alginate Hydrogels with Channel-Like Pores for Osteochondral Regeneration</b> Kathleen Schütz, Florian Despang, Giuseppe Filardo, Alice Roffi, Annapaola Parilli, Maria Sartori, Francesca Salamanna, Elizaveta Kon, <u>Michael Gelinsky</u> <i>TU Dresden, Germany</i>
11:15	6	<b>Induction of Mesenchymal Stem Cell Differentiation and Cartilage Formation by Cross-Linker-Free Collagen Microspheres</b> <u>Emmanuel Belamie</u> , Marc Mathieu, Sylvain Vigier, Marie-Noëlle Labour, Christian Jorgensen, Danièle Noël <i>Institut Charles Gerhardt Montpellier, France</i>
11:30	7	<b>Biodegradable Glues for Meniscus Repair in a Full-Thickness Explant Model</b> <u>Agnieszka Bochynska</u> , Gerjon Hannink, Tony van Tienen, Dirk Grijpma, Pieter Buma <i>Radboud UMC / University of Twente, Netherlands</i>
11:45	8	<b>A Bioactive Bacterial Exopolysaccharide from Deep-Sea Environment: Modification, Characterization and Chondrogenic Potential for Cartilage Regenerative Medicine</b> <u>Agata Zykwińska</u> , Nathalie Chopin, Corinne Sinquin, Jacqueline Ratiskol, Jean Le Bideau, Boris Halgand, Claire Vinatier, Jérôme Guicheux, Pierre Weiss, Sylvia Collic-Jouault <i>Ifremer, France</i>

## Session 3 Hall 3A

Chairs: Nicholas Peppas, *The University of Texas, United States*  
Wojciech Chrzanowski, *The University of Sydney, Australia*  
Katarzyna Krukiewicz, *Silesian University of Technology, Poland* (YSF Chair)

11:00	9	<b>Functionalized Poly(Vinyl Alcohol) Membranes for the Thermal and Photochemical Nitric Oxide Delivery</b> Sarah Lourenço, <u>Marcelo G. de Oliveira</u> <i>University of Campinas, Brazil</i>
11:15	10	<b>Smart Polymer Nanoparticles for Triggered Drug Releases</b> Christian Tolle, Jan Riedel, Dagmar Wirth, Henning Menzel <i>Braunschweig University of Technology, Germany</i>
11:30	11	<b>Polymer Coatings with Liposomal Drug Deposits towards Substrate-Mediated Drug Delivery</b> <u>Martin E. Lyngé</u> , Marie Baekgaard Laursen, Marina Fernandez-Medina, Brigitte Städler <i>Aarhus University, Denmark</i>
11:45	12	<b>PLGA/Calcium Phosphate Composite Nanoparticles as Efficient Carriers of Hydrophilic Drugs (Nucleic Acids, Proteins)</b> <u>Jens Nelsen</u> , Gregor Dördelmann, Diana Kozlova, Sarah Karczewski, Rosario Lizio, Silko Grimm, Jessica Mueller-Albers, Shirley Knauer, Matthias Eppler <i>University Duisburg-Essen, Germany</i>

## Session 4 Hall 3B

### Surface Modification 1

Chairs: Iulian Antoniac, *University Politehnica of Bucharest, Romania*  
Veronique Larreta Garde, *University of Cergy Pontoise, France*  
Yi-Shiang Huang, *University of Liege, Belgium* (YSF Chair)

- |       |    |  |

| 11:45 | 20 | <b>Tailoring of DMTMM Conjugated Ha-Tyr Allows Precise Control of Cellular Environment</b><br><u>Claudia Loebel</u> , Tino Stauber, Matteo D'Este, Mauro Alini, Marcy Zenobi-Wong, David Eglin<br><i>AO Research Institute, Switzerland</i>   |

## Session 6 Hall 4B

### Advanced Manufacturing 1

Chairs: Sandra Van Vlierberghe, *Ghent University, Belgium*  
Dimitrios Stamatialis, *University of Twente, Netherlands*  
Artur Pinto, *LEPABE and INEB, Portugal (YSF Chair)*

- |       |    |  |
|-------|----|--|
| 11:00 | 21 | <b>Jet-Sprayed Hybrid Nanofibrillar Matrices with Controlled Deposition and Delivery of Nanoparticles</b><br>Nermin Keloglu, Bernard Verrier, Dominique Sigaudou-Roussel, Thomas Trimaille, <u>Jerome Sohier</u><br><i>UMR CNRS 5305, France</i>                               |
| 11:15 | 22 | <b>Microstereolithography &amp; Plasma Polymerisation Coating of Nerve Guidance Conduits</b><br>James Clarke, Adam Harding, Fiona Boissonade, John Haycock, Frederik Claeysens<br><i>The University of Sheffield, United Kingdom</i>   |
| 11:30 | 23 | <b>Smart Biomaterials from Extruded Biopolymer Nanofibres</b><br>Mohammad Raoufi, Neda Aslankoochi, Sarah Young, Joachim P. Spatz, <u>Dorothea Brüggemann</u><br><i>MPI for Intelligent Systems, Germany</i>   |
| 11:45 | 24 | <b>Borophosphate Glasses/Fibers and their In-Vitro Properties</b><br><u>Jonathan Massera</u> , Yaroslav Shpotyuk, Thierry Jouan, Catherine Boussard-Plédel, Bruno Bureau, Laeticia Petit, Miina Ojansivu, Susanna Mietinen<br><i>Tampere University of Technology, Finland</i> |

## Session 7 Hall 1

### Osteointegration 1

Chairs: Pamela Habibovic, *Maastricht University, Netherlands*  
Tomasz Ciach, *Warsaw University of Technology, Poland*  
Caitlin Langford, *Monash University, Australia (YSF Chair)*

- |       |    |  |
|-------|----|--|
| 12:15 | 25 | <b>In Vivo Study on the Biodegradation Behaviour of Mg-Based Alloys for Orthopaedic Application</b><br>Sau Shun Wong, <u>Wing Yuk Ip</u> , Luen Chow Chan, Chi Ping Lai<br><i>The University of Hong Kong, Hong Kong</i>   |
| 12:30 | 26 | <b>A Comparative Tribocorrosion Study Between TiN- and DLC- Coated Titanium for Loading Bearing Biomedical Applications</b><br><u>Guohua Zhao</u> , Nuria Espallargas, Ragnhild E. Aune<br><i>KTH Royal Institute of Technology, Sweden</i>  |
| 12:45 | 27 | <b>In vitro Biological Studies of Porous Titanium Obtained by Two Different Powder Metallurgy (PM) Techniques: Loose Sintering and Space Holder</b><br><u>Juan Pavón</u> , Ana Civantos, Viviana Ramos, Jose A Rodriguez, Yadir Torres, Jose Lopez-Lacomba<br><i>University of Antioquia, Colombia</i> |
| 13:00 | 28 | <b>"Bridging of Spine" – Comparison of Titanium and Dynamic Polymer Stabilization</b><br>Lechosław Ciupik, Agnieszka Kierzkowska, Jacek Sterna, Edward Słoiński, <u>Monika Cieřlik-Górna</u><br><i>Institute of Bioengineering and Medical Technologies, Poland</i>                                    |

## Session 8 Hall 2

### Neural Regeneration 1

Chairs: Yuichi Ohya, *Kansai University, Japan*

Michael Doser, *Institute for Textile Research and Process Engineering, Germany*

Chaoyu Liu, *The University of Hong Kong, Hong Kong (YSF Chair)*

- 
- |       |    |   |
|-------|----|---|
| 12:15 | 29 | <b>Interfacing 3D Graphene Oxide Scaffolds with the Injured Rat Spinal Cord</b><br>Ankor González-Mayorga, Elisa López-Dolado, Jorge E. Collazos-Castro, María Luisa Ferrer, Francisco del Monte, María Concepción Gutiérrez, <u>María Concepción Serrano</u><br><i>Hospital Nacional de Paraplégicos, Spain</i>  |
| <hr/> |    |   |
| 12:30 | 30 | <b>Dual Peptide Functionalised Intraluminal Collagen Fibre Conduits Regulates Neurite Outgrowth of Primary Neurons</b><br><u>Sahana Ganesh</u> , William Daly, Abhay Pandit<br><i>National University of Ireland, Galway, Ireland</i>   |
| <hr/> |    |   |
| 12:45 | 31 | <b>Characterization of Polyurethane/Poly lactide Blends in Terms of their Applicability as Biomaterials Supporting Nerve Regeneration</b><br><u>Jadwiga Laska</u> , Paulina Bednarz, Anna Lis, Jakub Grzesiak, Krzysztof Marycz, Dariusz Szarek<br><i>AGH University of Science and Technology, Poland</i>  |
| <hr/> |    |   |
| 13:00 | 32 | <b>Spinal Cord Injury Recovery of Rhesus Monkey Implanted with PPy/I Plasma Polymer</b><br>Ayayacatl Morales-Guadarrama, Hermelinda Salgado-Ceballos, Israel Grijalva, Juan Morales-Corona, Camilo Rios, Guillermo J. Cruz, Araceli Diaz-Ruiz, Maria-Guadalupe Olayo, Laura Alvarez-Mejia, Rodrigo Mondragón-Lozano, Alejandra Ibáñez-Contreras, Braulio Hernández-Godínez, Omar Fabela-Sánchez, Stephanie Sánchez-Torres, <u>Roberto Olayo</u><br><i>Instituto Nacional de Investigaciones Nucleares, Mexico</i> |
- 

## Session 9 Hall 3A

### Drug Delivery 2

Chairs: Anna Karewicz, *Jagiellonian University, Poland*

David Grainger, *University of Utah, United States*

María Rosa Aguilar, *Spanish National Research Council, Spain (YSF Chair)*

- 
- |       |    |   |
|-------|----|---|
| 12:15 | 33 | <b>Cell Membrane Capsules for Encapsulation of Chemotherapeutic and Cancer Cell Targeting <i>in Vivo</i></b><br><u>Zhengwei Mao</u> , Yuanhong Zhang, Lihua Peng, Jianqing Gao<br><i>Zhejiang Univeristy, China</i>   |
| <hr/> |    |   |
| 12:30 | 34 | <b>Electrospun Triclosan-Loaded Chitosan Nanofibres for Potential Drug Delivery Application</b><br><u>Safa Ouerghemmi</u> , Stéphanie Degoutin, Nicolas Tabary, Frédéric Cazaux, Ludovic Janus, Nicolas Blanchemain, Bernard Martel<br><i>UMET, France</i>  |
| <hr/> |    |   |
| 12:45 | 35 | <b>Dual Release and Antibacterial Effects of Chlorhexidine and Silver Released from Electrospun Chitosan/Poly(Ethylene Oxide) Nanofibres</b><br><u>Jiankang Song</u> , Stefan S. Remmers, Carla J.M. Bartels, Jinlong Shao, Eva Kolwijck, Sander C.G. Leeuwenburgh, John A. Jansen, Fang Yang<br><i>Radboud University Medical Centre, Netherlands</i>    |
| <hr/> |    |   |
| 13:00 | 36 | <b>Collagen/Hyaluronic Acid-Based Hydrogels for Brain Applications: the Role of Hyaluronic Acid Molecular Weight</b><br>Marta Tunesi, Armando Chierchia, Luca Barbieri, <u>Teresa Russo</u> , Lucia Boeri, Annalisa Grimaldi, Roberto De Santis, Luigi Ambrosio, Antonio Gloria, Diego Albani, Carmen Giordano<br><i>National Research Council, Italy</i> |
- 

## Session 10 Hall 3B

### Surface Modification 2

Chairs: Triantafillos Papadopoulos, *University of Athens, Greece*  
Stanisław Błażewicz, *AGH University of Science and Technology, Poland*  
Elena Diana Giol, *Ghent University, Belgium* (YSF Chair)

- |       |    |  |
|-------|----|--|
| 12:15 | 37 | <b>Endothelialisation of Titanium Dioxide Coated Gas Exchange Membranes for the Development of a Bioartificial Lung</b><br><u>Michael Pflaum</u> , Marina Kauffeldt, Bettina Wiegmann, Sabrina Schmeckebeier, Daniele Dipresa, Sotirios Korossis, Jochen Schein, Axel Haverich<br><i>Hannover Medical School, Germany</i>      |
| 12:30 | 38 | <b>Orthopaedic Bio-activation of PEEK using Plasma Immersion Ion Implantation</b><br><u>Edgar Wakelin</u> , Giselle Yeo, Alexey Kondyurin, Michael Davies, David McKenzie, Anthony Weiss, Marcela Bilek<br><i>University of Sydney, Australia</i>  |
| 12:45 | 39 | <b>Alginate Hydrogels, Coated with Calcium Phosphate Nanoparticles by an Electrophoretic Deposition Method</b><br><u>Sabrina Daumann</u> , Katrin Wallat, Michael Gepp, Ronan Le Harzic, Heiko Zimmermann, Frank Stracke, Matthias Eppler<br><i>University of Duisburg-Essen, Germany</i>                                      |
| 13:00 | 40 | <b>Calcium- and Phosphorus-Rich Oxide Coatings on Tantalum Obtained by Plasma Electrolytic Oxidation</b><br><u>Maciej Sowa</u> , Maja Woszczak, Grzegorz Dercz, Andrey I. Kukharensky, Danila M. Korotin, Ernst Z. Kurmaev, Seif O. Cholak, Wojciech Simka, Marcin Basiaga<br><i>Silesian University of Technology, Poland</i> |

## Session 11 Hall 4A

### Cell Instructive Materials 2

Chairs: Sander Leeuwenburgh, *Radboudumc Biomaterials, Netherlands*  
Rachel Williams, *University of Liverpool, United Kingdom*  
Anna Diez-Escudero, *Technical University of Catalonia (UPC), Spain* (YSF Chair)

- |       |    |   |
|-------|----|---|
| 12:15 | 41 | <b>Human E-Cadherin Fusion Protein Matrix Improving the Proliferation and Hepatic Differentiation of Human Mesenchymal Stem Cells</b><br><u>Jun Yang</u> , Jinbin Xu, Yan Zhang, Toshihiro Akaike<br><i>Nankai University, China</i>  |
| 12:30 | 42 | <b>Silk-Collagen Inspired Artificial Proteins for 3D Cell Culture Study</b><br><u>Małgorzata Włodarczyk-Biegun</u> , Kambiz Farbod, Marc Werten, Frits de Wolf, Jeroen van den Beucken, Sander Leeuwenburgh, Marleen Kamperman, Martien Cohen Stuart<br><i>Wageningen UR, Netherlands</i> |
| 12:45 | 43 | <b>Fluorescent Hydrogel for Improved Traceability of Biomedical Devices In Vivo</b><br><u>Arturo Ibáñez-Fonseca</u> , Francisco Javier Arias, José Carlos Rodríguez-Cabello<br><i>Bioforge Group, Universidad de Valladolid, Spain</i>  |
| 13:00 | 44 | <b>Self-Gelling Elastin and Silk-Elastin Recombinamers for Ophthalmic Applications</b><br>Alicia Fernández-Colino, Daniela Quinteros, José Bermúdez, Santiago De Palma, José Carlos Rodríguez-Cabello, <u>Francisco Javier Arias</u><br><i>University of Valladolid, Spain</i>            |

**Session 12**  
**Hall 4B**

**Cell Encapsulation and Delivery 1**

Chairs: Pedro Granja, *University of Porto, Portugal*  
Elżbieta Pamuła, *AGH University of Science and Technology, Poland*  
Juhi Samal, *National University of Ireland, Galway, Ireland (YSF Chair)*

- |       |    |  |
|-------|----|--|
| 12:15 | 45 | <b>A Functional Macromolecular Gradient Hydrogel System as a Platform to Model Tissue-to-Tissue Interfaces</b><br>Diana Pereira, Joaquim Oliveira, Rui Reis, Abhay Pandit<br><i>3B's Research Group, Portugal</i>  |
| 12:30 | 46 | <b>Cell-Laden Microparticles for Microtissue Assembling: a Bottom-Up Approach for Bone Tissue Engineering</b><br>Irene Cano-Torres, Riccardo Levato, Miguel A. Mateos-Timoneda, Elisabeth Engel<br><i>Institute for Bioengineering of Catalonia, Spain</i>                             |
| 12:45 | 47 | <b>Enhanced <math>\beta</math>-cell Pancreatic Islet Formation Using Carboxybetaine-Functionalised Chitosan Nanobeads</b><br>Mark Best, Valeria Perugini, Gary Phillips, Anna Guildford, Adrian Bone, Wendy MacFarlane, Matteo Santin<br><i>University of Brighton, United Kingdom</i> |
| 13:00 | 48 | <b>Assessing the Potential of Fucoidan-Based Microparticles for Biomedical Application</b><br>Lara L. Reys, Simone S. Silva, Nuno Oliveira, Diana Soares da Costa, João F. Mano, Tiago H. Silva, Rui L. Reis<br><i>3B's Research Group, Portugal</i>                                   |

**Hall 1**  
**Plenary Lecture 3**

- |       |    |   |
|-------|----|---|
| 14:45 | L3 | <b>In Vitro Models &amp; Nanobiointerfaces: a Multidisciplinary Challenge</b><br>C. James Kirkpatrick<br><i>Institute of Pathology, University Medical Center, Johannes Gutenberg University of Mainz, Germany</i><br><br>Chairs: Michael Doser, <i>Institute for Textile Research and Process Engineering, Germany</i><br>Pedro Granja, <i>University of Porto, Portugal</i> |
|-------|----|---|

**Hall 1**  
**Special Fellows Session**  
**"Biomaterials Education is not Ready for the Challenges of the Future"**

Chair: Joachim Kohn, *The New Jersey Center for Biomaterials, United States*

- |       |  |
|-------|--|
| 16:00 | <b>Speakers:</b><br>Kristi S. Anseth, <i>University of Colorado, United States</i><br>David W. Grainger, <i>University of Utah, United States</i><br>Dietmar Hutmacher, <i>Queensland University of Technology, Brisbane, Australia</i><br>Lynne C. Jones, <i>Johns Hopkins University, United States</i><br>Laura Poole-Warren, <i>University of New South Wales, Sydney, Australia</i><br>Elizabeth Tanner, <i>University of Glasgow, Scotland, United Kingdom</i> |
|-------|--|

## Session 13      Bioactive Materials

### Hall 2

Chairs: Guy Daculsi, *INSERM LIOAD UMR 791, France*  
 Hasan Uludag, *University of Alberta, Canada*  
 Andrada Serafim, *University Politehnica of Bucharest, Romania (YSF Chair)*

16:00	49	<b>Influence of Calcium Salt Addition on Bioactive Glass Nanospheres</b> Kai Zheng, Qiang Chen, Nicola Taccardi, V. R. Reddy Marthala, Martin Hartmann, <u>Aldo Boccaccini</u> <i>University of Erlangen-Nuremberg, Germany</i>
16:15	50	<b>Bioactive Ti Metal Able to Release Ga Ions: Preparation by Chemical and Heat Treatments</b> <u>Seiji Yamaguchi</u> , Shekhar Nath, Yoko Sugawara, Tomiharu Matsushita, Tadashi Kokubo <i>Chubu University, Japan</i>
16:30	51	<b>High Strength <math>\beta</math>-TCP-Fe-Ag Nanocomposites and Porous Scaffolds for Bone Repair</b> <u>Elazar Gutmanas</u> , Sanyaja Kumar Swain, Irena Gotman <i>Technion, Israel</i>
16:45	52	<b>Tailoring the Bioactivity of Mesoporous Bioglasses: the Role of the Structure Directing Agents</b> Natividad Gómez-Cerezo, Isabel Izquierdo-Barba, <u>Daniel Arcos</u> , María Vallet-Regí <i>Universidad Complutense de Madrid, Spain</i>
17:00	53	<b>Novel Bioactive Glass Composites for Soft Tissue Applications</b> <u>Owen Clarkin</u> , Dermot F. Brougham, Bing Wu, Catriona Lally <i>Dublin City University, Ireland</i>
17:15	54	<b>Thermal and In Vitro Properties of SrO and ZnO Containing Bioactive Glasses</b> Johan Sangder, Susanne Fagerlund, <u>Leena Hupa</u> <i>Åbo Akademi University, Finland</i>
17:30	55	<b>Bioresorbable Chitosan- Bioglass Nanocomposite Scaffolds for Drug Delivery Applications</b> <u>Emad El-Meliigy</u> , Sara Ali <i>National Research Centre, Egypt</i>

# Session 14 Hall 3A

Chairs: Maria Siemionow, *University of Illinois at Chicago, United States*  
Joaquim Miguel Oliveira, *3B's Research Group - University of Minho, Portugal*  
Minkle Jain, *Japan Advanced Institute of Science and Technology, Japan (YSF Chair)*

- |       |    |   |
|-------|----|---|
| 16:00 | 56 | <b>Generation of Limbal Epithelial Cell Progenitors by Two Methods: by Differentiation form iPS Cells and by Direct Trans-differentiation form Human Dermal Fibroblasts</b><br>Artur Cieřlar-Pobude, Viktoria Knořlach, Saeid Ghavami, <u>Marek Łos</u><br><i>Linköping University, Sweden</i>  |
| 16:15 | 57 | <b>A Multifactorial Approach Towards Enhanced Extracellular Matrix Deposition and Maintenance of Mesenchymal Stem Cell Phenotype Using Macromolecular Crowding and Low Oxygen Tension</b><br>Diana Gaspar, Daniela Cigognini, Pramod Kumar, Abhigyan Satyam, Senthil Alagesan, Clara Sanz-Noguéz, Matthew Griffin, Timothy O'Brien, Abhay Pandit, Dimitrios Zeugolis<br><i>National University of Ireland, Galway, Ireland</i>                      |
| 16:30 | 58 | <b>Cryptic Cell Cycle Stasis of Human Pluripotent Stem Cells Revealed by Culture in a Biocompatible Thermoresponsive Copolymer Gel</b><br>Irene Canton, Nicholas J. Warren, Richard Weightman, Andrew Wood, Harry Moore, Steve P. Armes<br><i>University of Sheffield, United Kingdom</i>   |
| 16:45 | 59 | <b>Co-Transplantation of VEGF-Transfected Adipose Derived Stromal Cells to Enhance Bone Regeneration and Neovascularization from Bone Marrow Stromal Cells</b><br>Mi Lan Kang, Ji Eun Kim, <u>Gun-Il Im</u><br><i>Dongguk University Ilsan Hospital, Republic of Korea</i>  |
| 17:00 | 60 | <b>Effect of Mechanical Stimulation on Osteogenesis of Self-Assembled Collagen-Cell Seeded Microspheres</b><br><u>Maryam Shariatzadeh</u> , Cecile Perrault, Damien Lacroix<br><i>University of Sheffield, United Kingdom</i>   |
| 17:15 | 61 | <b>5-Azacytidine Mediated hMSC Behaviour On Electrospun Scaffolds to Induce Myogenesis</b><br>Ines Fasolino, <u>Vincenzo Guarino</u> , Valentina Cirillo, Marica Marrese, Luigi Ambrosio<br><i>Institute of Polymers, Composites and Biomaterials, CNR, Italy</i>   |
| 17:30 | 62 | <b>Microvesicles Derived from Stem Cells as a Novel Effective Tool for Transferring of Bioactive Molecules to Mature Primary Cells - Future Implications for Tissue Regeneration</b><br>Sylwia Bobis-Wozowicz, Katarzyna Kmiotek, Małgorzata Sekula, Sylwia Kedracka-Krok, Elżbieta Kamycka, Urszula Jankowska, Jacek Kolcz, Dariusz Boruczkowski, Buddhadeb Dawn, Zbigniew Madeja, <u>Ewa Zuba-Surma</u><br><i>Jagiellonian University, Poland</i> |

## Session 15 Hall 3B

## Antimicrobial Surfaces and Materials 1

Chairs: Dieter Scharnweber, *Technische Universität Dresden, Germany*  
Mirosława El Fray, *West Pomeranian University of Technology, Poland*  
Hanna Tiainen, *University of Oslo, Norway* (YSF Chair)

16:00	K1	<b>Keynote</b> <b>Antimicrobial Effects of Biomaterials: Silver Ions</b> <u>Matthias Epple</u> , Svitlana Chernousova, Kateryna Loza, Oleg Prymak, Maria A. Surmeneva, Roman Surmenev <i>University of Duisburg-Essen, Germany</i>
16:30	63	<b>Influences of the pH on the Adsorption Properties of an Antimicrobial Peptide on Titanium Surfaces</b> Yendry Corrales-Ureña, Linda Wittig, Matheus Vieira Nascimento, Juliano Faccioni, <u>Paulo Lisboa-Filho</u> , Klaus Rischka <i>São Paulo State University (UNESP), Brazil</i>
16:45	64	<b>Titanium Modified with Silver Nanoparticles for Oral Implantology</b> <u>Rafał Pokrowiecki</u> , Barbara Szaraniec, Tomasz Zaręba, Tomasz Szponder, Krzysztof Pałka, Jan Chłopek, Stefan Tyski <i>Jagiellonian Medical University, Poland</i>
17:00	65	<b>Bio-Inspired Antimicrobial Surfaces for Titanium Implant</b> Ting Dju, Terje Sjöström, Leanne Fisher, Angela Nobbs, Howrad Jenkinson, Max Ryadnov, Monica Tsimbouri, Matt Dalby, <u>Bo Su</u> <i>University of Bristol, United Kingdom</i>
17:15	66	<b>Antimicrobial Titanium Surfaces</b> <u>Zuzanna Trzcińska</u> , Fabien Brouillet, David Grossin, Cedric Charvilat, Anna Peacock, Artemis Stamboulis <i>University of Birmingham, United Kingdom</i>
17:30	67	<b>Novel Biosensor for Detecting and Preventing Periodontal Disease</b> M. Hoyos-Nogués, S. Brosel-Oliu, N. Abramova, A. Bratov, <u>C. Mas-Moruno</u> , F.J. Gil <i>Technical University of Catalonia, Spain</i>

Monday, 31<sup>st</sup> Aug

# Session 16 Hall 4A

Chairs: Neil Cameron, *Monash University, Australia*  
 Henning Menzel, *University of Technology Braunschweig, Germany*  
 Bernhard Neuhaus, *Universität Duisburg-Essen, Germany (YSF Chair)*

16:00	K2	<b>Keynote</b> <b>Biointspired Design of Dynamic Macromolecular for Gene Delivery</b> <u>Zhongwei Gu</u> <i>Sichuan University, China</i>
16:30	68	<b>Biostable Gold-Installed Nanocomplexes as siRNA Carriers for Improved In Vivo Tumor Targeting</b> <u>Roun Heo</u> , Jueun Jeon, Jae Hyung Park <i>Sungkyunkwan University, Korea</i>
16:45	69	<b>ELR Devices for Breast Cancer Gene Delivery</b> <u>Maria Jesus Piña</u> , Alessandra Girotti, Mercedes Santos, Jose Carlos Rodríguez-Cabello, Francisco Javier Arias <i>Universidad Valladolid, Spain</i>
17:00	70	<b>Ion-Doped Hydroxyapatite Nanoparticles as Potential Vectors in Gene Therapy</b> <u>Zhitong Zhao</u> , Montserrat Espanol, Maria-Pau Ginebra <i>Universitat Politècnica de Catalunya, Spain</i>
17:15	71	<b>Tuning Transfection Efficiency by Modulating the Biodegradation Rate of Trimethyl Chitosan Nanoparticles</b> <u>Carla Gomes</u> , Aida Varela-Moreira, Maria Gomez-Lazaro, Pedro Moreno, Ana Pêgo <i>INEB - Instituto Engenharia Biomédica, Portugal</i>
17:30	72	<b>Cell-Penetrating Peptide Mediated Gene Delivery via Polymeric Microneedles; A Platform for DNA Vaccination</b> <u>Helen McCarthy</u> , Ahlam Ali, Joanne McCaffrey, John McBride, Adrien Kissenpfennig, Ryan Donnelly <i>Queen's University Belfast, United Kingdom</i>

## Session 17 Hall 4B

### Biointerfaces 1

Chairs: Dimitrios Zeugolis, *National University of Ireland, Galway, Ireland*  
Krzysztof Szczubiałka, *Jagiellonian University, Poland*  
Rongquan Duan, *University of Twente, Netherlands (YSF Chair)*

16:00	K3	<b>Keynote</b> <b>Manipulation of Cell Mechanotaxis by Designing Curvature of the Elasticity Boundary on Hydrogel Matrix</b> <u>Satoru Kidoaki</u> , Ayaka Ueki <i>Kyushu University, Japan</i>
16:30	73	<b>Nanotemplated and Fibronectin Based-Polyelectrolytes Films as Bioactive Delivery Systems</b> Adeline Gand, Coline Chat, Mathilde Hindie, Paul Van Tassel, <u>Emmanuel Pauthe</u> <i>University of Cergy-Pontoise, France</i>
16:45	74	<b>Mapping Interactions between MMP1 and Collagen Substrate: from Crystal Structure to Molecular Dynamics with Meta-Dynamics</b> Anthony Nash, Laurent Bozec, Helen Birch, Nora de Leeuw <i>University College London, United Kingdom</i>
17:00	75	<b>Protein-Adsorption and Blood-Interaction Studies on Nanotopography Gradients</b> <u>Rebecca Huber</u> , Katharina Maniura, Nicholas Spencer <i>ETH Zürich/ EMPA St.Gallen, Switzerland</i>
17:15	76	<b>Heterogeneous Polymer Surfaces with Organized Collagen Layers Influence Preosteoblasts Behavior</b> Emilienne Zuyderhoff, <u>Christine Dupont-Gillain</u> <i>Université Catholique de Louvain, Belgium</i>
17:30	77	<b>Nanoroughness and Oxygen Functional Groups on Parylene C Coating: Towards Anti-Infective and Biocompatible Implants Surface</b> <u>Monika Gołda-Cepa</u> , Monika Brzychczy-Włoch, Minna Hakkarainen, Klas Engvall, Andrzej Kotarba <i>Jagiellonian University, Poland</i>

Hall 1      Plenary Lecture 4

9:00      L4      **Medical Translational Research: A Different Route to Fundamental Research**  
Geoff Richards  
AO Research Institute Davos, Switzerland

**Chairs:** Joelle Amedee, INSERM, U1026, France  
Marc Bohner, RMS Foundation, Switzerland

Hall 1      Translational Research Symposium (1)

Organizers: Yves Bayon, Marc Bohner, David Eglin, Geoff Richards, Dimitrios Zeugolis

- 10:00      TRS1      **Clinical Needs Based Biomaterial Strategy: Reducing the Risk that Innovation is “Lost in Translation” in Products for Poor Quality Bone**  
Philip Procter  
Medical Device Industry Consultant, France
- 10:20      TRS2      **Best Practice for Registration Trials of Biodegradable Implants**  
Nils Reimers  
Manager R&D, Global Funding & Reimbursement, Stryker Trauma & Extremities, Germany
- 10:40      TRS3      **New Concept of Hybrid Polymer Composites for Implant Applications**  
Xiang Zhang  
Lucideon Ltd., Royal Society Industry Fellow at University of Cambridge, United Kingdom
- TRS4      **Novel Biodegradable and Biocompatible Polymers for Medical Applications**  
Ipsita Roy  
University of Westminster, London, United Kingdom

Session 18      Smart Biomaterials 1  
Hall 2

**Chairs:** Che Connon, Newcastle University, United Kingdom  
Pedro Granja, INEB - University of Porto, Portugal  
Giuseppe Cama, University of Ghent, Belgium (YSF Chair)

- 10:00      78      **Overcoming Transport Limitation in 3D Cell Culture by Using a New Class of Oxygen Delivery Systems**  
Antonio Paciello, Giuseppe Amalfitano, Alessandro Garziano, Francesco Urciuolo, Paolo Antonio Netti  
Istituto Italiano di Tecnologia, Italy
- 10:15      79      **Tunable Biodegradable Polyurethane with Thermal Activation Cues at Human Body Temperature**  
Maziar Matloubigharagozloo, V. Prasad Shastri  
Hermann Staudinger Institute of Macromolecular Chemistry, Germany
- 10:30      80      **Mixed Matrix Membranes for Removal of Protein-Bound Toxins from Human Plasma**  
Esmee van Geffen, Denys Pavlenko, Karin Gerritsen, Dimitrios Stamatiadis  
University of Twente, Netherlands
- 10:45      81      **Glucose Delivery System Based-Hydrogel Composite Scaffold for Enhancing MSC Survival**  
Julie Boisselier, Joseph Paquet, Laurent Bidault, Michael Deschepper, Elodie Lefebvre, Charline Gossart, Julie Dubois, Adeline Gand, Delphine Logeart-Avramaglou, Veronique Larreta Garde, Emmanuel Pauthe, Hervé Petite  
University of Cergy-Pontoise, France

## Session 19 Hall 3A

### Wound Healing 1

Chairs: Julio San Roman, *Institute of Polymer Science and Technology, CSIC, Spain*  
Miriam V. Flores-Merino, *Autonomous University of The State of Mexico, Mexico*  
Peter Duckworth, *University of Bristol, United Kingdom (YSF Chair)*

- |       |    |   |
|-------|----|---|
| 10:00 | 82 | <b>In Situ Skin Regeneration by the Gene-Activated Materials</b><br><u>Lie Ma</u> , Luyan Li, Xing Liu, Rui Guo, Changyou Gao<br><i>Zhejiang University, China</i>  |
| 10:15 | 83 | <b>Modulation of Inflammatory Macrophage Activation by StarPEG–Heparin Based Hydrogels to Improve Impaired Wound Healing</b><br>Nadine Lohmann, Wandel Elke, Inka Forstreuter, Lucas Schirmer, Uwe Freudenberg, Carsten Werner, Jan Simon, <u>Sandra Franz</u><br><i>University Leipzig, Germany</i>                      |
| 10:30 | 84 | <b>Nano-Microfibrous Scaffold for Burn-Wound Healing</b><br><u>Pallabi Pal</u> , Pavan Srivas, Prabhash Dadhich, Bodhisatwa Das, Santanu Dhara, Arun Achar<br><i>Indian Institute of Technology, India</i>  |
| 10:45 | 85 | <b>Expression Pattern of Tissue Transglutaminase in the Response to Gelatin based Hydrogels <i>In Vitro</i> and <i>In Vivo</i></b><br><u>Sandra Ullm</u> , Christoph Tondera, Robert Wodtke, Tim Gebauer, Axel Neffe, Andreas Lendlein, Reik Löser, Jens Pietzsch<br><i>Helmholtz-Zentrum Dresden-Rossendorf, Germany</i> |

## Session 20 Hall 3B

### Surface Modification 3

Chairs: Håvard Haugen, *University of Oslo, Norway*  
Véronique Migonney, *Université Paris 13, France*  
Catalina Vallejo Giraldo, *National University of Ireland, Galway, Ireland (YSF Chair)*

- |       |    |  |
|-------|----|--|
| 10:00 | 86 | <b>Functionalization of Scaffold Surfaces: Role of Ce Valence States of Cerium Oxide Nanoparticles in Control of Cell Proliferation</b><br><u>Tamaki Naganuma</u><br><i>National Institute for Materials Science (NIMS), Japan</i>                             |
| 10:15 | 87 | <b>Antibacterial Jet Bioactive Surfaces</b><br><u>Irina Sukhorukova</u> , Alexander Sheveyko, Philipp Kiryukhantsev-Korneev, Natalya Gloushankova, Sergey Ignatov, Dmitry Shtansky<br><i>National University of Science and Technology, Russian Federation</i> |
| 10:30 | 88 | <b>Differential Response of Human Bone Marrow Cells on Aligned vs Randomly Oriented Carbon Nanotubes</b><br>Anthoula Kroustalli, <u>Despina Deligianni</u><br><i>University of Patras, Greece</i>  |
| 10:45 | 89 | <b>Bioinspired Thin Films Materials for Direct Blood Contact</b><br><u>Klaudia Trembecka-Wojciga</u> , Roman Major, Juergen M. Lackner, Hanna Plutecka, Boguslaw Major<br><i>Institute of Metallurgy and Materials Science PAS, Poland</i>                     |

## Session 21 Hall 4A

### Cartilage Tissue Engineering 2

Chairs: Michael Gelinsky, *Technische Universität Dresden, Germany*

Yasuhiko Tabata, *Kyoto University, Japan*

Judith Hahner, *Leibniz-Institute für Polymerforschung Dresden, Germany (YSF Chair)*

- 
- |       |    |  |
|-------|----|--|
| 10:00 | 90 | <b>Mechanical &amp; Degradation Characterisation of AZ31 Magnesium (Mg) for Use in Paediatric Tracheal Stents</b><br><u>Isaiah Adekanmbi</u> , K. Elizabeth Tanner, Haytham Kubba, Helen Lu<br><i>Glasgow University, United Kingdom</i>         |
| <hr/> |    |  |
| 10:15 | 91 | <b>Superior Lubrication Ability of Artificial Hydrogel Cartilage</b><br><u>Teruo Murakami</u> , Seido Yarimitsu, Kazuhiro Nakashima, Tetsuo Yamaguchi, Yoshinori Sawae, Nobuo Sakai, Atsushi Suzuki<br><i>Kyushu University, Japan</i>           |
| <hr/> |    |  |
| 10:30 | 92 | <b>Sr- and Zn-Substituted Calcium Phosphates-Based Composites for Osteochondral Tissue Engineering Scaffolding</b><br><u>Sandra Pina</u> , Joaquim M. Oliveira, Rui L. Reis<br><i>University of Minho, Portugal</i>                              |
| <hr/> |    |  |
| 10:45 | 93 | <b>Si-HPMC and Si-Chitosan Hydrogel for Cartilage Tissue Engineering</b><br><u>Gildas Réthoré</u> , Cécile Boyer, Amadou Touré, Fabienne Jordana, Olivier Gauthier, Jérôme Guicheux, Pierre Weiss<br><i>LIOAD - Université de Nantes, France</i> |
- 

## Session 22 Hall 4B

### Cell Encapsulation and Delivery 2

Chairs: Mariacristina Tanzi, *Politecnico di Milano, Italy*

Roman Major, *Institute of Metallurgy and Materials Science PAS, Poland*

Solène Passemard, *Ecole Polytechnique Fédérale de Lausanne, Switzerland (YSF Chair)*

- 
- |       |    |  |
|-------|----|--|
| 10:00 | 94 | <b>Response of Human Macrophages to Cytokine Induction under Three-Dimensional (3D) Artificial Extracellular Matrix (ECM) Mimicking Conditions</b><br><u>Marta Evangelista</u> , Alexandru Gudima, Vladimir Riabov, Martin Pravda, Julia Kzhyskowska, Nihal Engin Vrana<br><i>PROTIP MEDICAL, France</i> |
| <hr/> |    |  |
| 10:15 | 95 | <b>2D Cell Monolayer and 3D Cell Construct Cryopreservation by Slow Vitrification</b><br><u>Kazuaki Matsumura</u> , Keiko Kawamoto, Suong-Hyu Hyon<br><i>Japan Advanced Institute of Science and Technology, Japan</i>   |
| <hr/> |    |  |
| 10:30 | 96 | <b>Interaction of Sub-Compartmentalized Microreactors with Hepatocytes</b><br><u>Yan Zhang</u> , Brigitte Städler<br><i>Aarhus University, Denmark</i>   |
| <hr/> |    |  |
| 10:45 | 97 | <b>Macrophage-Laden 3D Fibrin Gels: Effect of Fibrinogen Concentration on Inflammation</b><br><u>Katharina Maniura</u> , Arie Bruinink, <u>Vera Malheiro</u><br><i>EMPA, Switzerland</i>   |
- 

## Hall 1 Translational Research Symposium (2)

Organizers: Yves Bayon, Marc Bohner, David Eglin, Geoff Richards, Dimitrios Zeugolis

11:30	TR55	<b>Insights into Collaboration and Innovation for Early Stage Medical Device Development</b> <u>Jan Weber</u> <i>Sr Research Fellow, Corporate Research, Boston Scientific Corporation, United States</i>
12:00	TR56	<b>From Biomaterials Supplier to Device Development Partner – Supporting Medical Device Companies in de-Risking Medical Products</b> <u>Jend Thies</u> <i>Director Science and Innovation, DSM Biomedical, Netherlands</i>
12:30	TR57	<b>Next Generation of Fibers for Medical Devices: Biopolymers and Functionalized Coatings</b> <u>Herbert De Breuck</u> <i>Manager R&amp;D, Luxilon, Wijnegem, Belgium</i>

## Session 23 Hall 2 Bone Tissue Engineering 2

Chairs: Pamela Habibovic, Maastricht University, Netherlands

William Wagner, University of Pittsburgh McGowan, United States

Christy Thomas, University of Westminster, United Kingdom (YSF Chair)

11:30	K4	<b>Keynote</b> <b>Dual Release of a Macrophages Recruitment Agent and Growth Factor for Bone Regeneration</b> Yang-hee Kim, <u>Yasuhiro Tabata</u> <i>Institute for Frontier Medical Sciences, Kyoto University, Japan</i>
12:00	98	<b>Fabrication and Characterization of Clinoptilolite/PCL-PEG-PCL Composite Scaffolds for Bone Tissue Engineering</b> <u>Ahmet Engin Pazarçeviren</u> , Ayşen Tezcaner, Özge Erdemli <i>Middle East Technical University, Turkey</i>
12:15	99	<b>Osteoinductive Dental Ring for Vertical Bone Regeneration with Simultaneous Introduction of Dental Implants</b> <u>Anna Chróścicka</u> , Piotr Wychowński, Ewa Jankowska-Steifer, Marek Kujawa, Małgorzata Lewandowska-Szumieł <i>Medical University of Warsaw, Poland</i>
12:30	100	<b>Novel N-(2-Carboxybenzyl)Chitosan Bionanocomposites for Tissue Scaffolding Applications</b> Maria Nerantzaki, Zoi Terzopoulou, Maria Anastasopoulou, Michalis Karakassides, Iro Koliakou, Aldo Boccaccini, Dimitrios Bikiaris <i>Aristotle University of Thessaloniki, Greece</i>
12:45	101	<b>BMP-2 stimulation Affects Structure and Mechanical Properties of Newly Synthesized ECM In Vitro</b> <u>Erik Brauer</u> , Aaron Herrera, Petra Knaus, Georg Duda, Ansgar Petersen <i>Julius Wolff Institute, Germany</i>

## Session 24 Hall 3A

## Stem Cells 2

Chairs: Josep A. Planell, *Universitat Oberta de Catalunya, Spain*

Ewa Zuba-Surma, *Jagiellonian University, Poland*

Maryam Shariatzadeh, *University of Sheffield, United Kingdom (YSF Chair)*

- |       |     |   |
|-------|-----|---|
| 11:30 | 102 | <b>Aging Reduces Osteogenic and Increases Adipogenic Potential of Mesenchymal Stem Cells Grown on Titanium</b><br>Rodrigo Abuna, Camila Stringhetta-Garcia, Rita Dornelles, Adalberto Rosa, <u>Marcio Beloti</u><br><i>University of Sao Paulo, Brazil</i>  |
| 11:45 | 103 | <b>Controlled Release of Amorphous Calcium Phosphate from Titania Nanostructures Induces Osteoblastic Differentiation in Human Mesenchymal Stem Cells</b><br><u>Robert McLister</u> , Mura McCafferty, George Burke, Brian J. Meenan<br><i>Ulster University, United Kingdom</i>  |
| 12:00 | 104 | <b>Chondrogenesis of Umbilical Cord Mesenchymal Stem Cells in a Porous Asymmetric Scaffold of Poly(Lactic Acid) Functionalized with Hyaluronan: Deposition of a Hyaline Cartilaginous Matrix</b><br>Elias Al Tawil, Alexandre Monnier, Quang Trong Nguyen, Jean-Pierre Vannier, Brigitte Deschrevel<br><i>University of Rouen, France</i> |
| 12:15 | 105 | <b>Characterization of In Vitro-Spheroids from Human Mesenchymal Stem Cells under Osteogenic and Adipogenic Differentiation</b><br>Geneviève Schmid, Heike Paape, Ellen Schmuhl, Stefanie Adam, Nicole Herzmann, Juliane Meyer, Achim Salamon, Susanne Meyer, <u>Kirsten Peters</u><br><i>Rostock University Medical Center, Germany</i>  |
| 12:30 | 106 | <b>Investigation of the Effect of Different Velocities and Surface Treatments on hMSCs Seeding Efficiency and Mechanical Characterization of 3D Insert PCL Scaffolds Undergoing Compression Loading</b><br><u>Marzia Brunelli</u> , Cecile M. Perrault, Damien Lacroix<br><i>University of Sheffield, United Kingdom</i>                  |
| 12:45 | 107 | <b>Osteogenic Effects of Short, Steady Media Perfusion in hBMSC 3D Cultures Depend on Cell Culture and Cell Differentiation Stage and a Scaffold Type</b><br><u>Joanna Filipowska</u> , Justyna Pawlik, Katarzyna Cholewa-Kowalska, Maria Laczka, Anna M. Osyczka<br><i>Jagiellonian University, Poland</i>                               |

## Session 25 Hall 3B

### Surface Modification 4

Chairs: Christine Dupont-Gillain, *Université Catholique de Louvain, Belgium*  
Dorota Bociąga, *Lodz University of Technology, Poland*,  
Luis Rojo, *King's College London, United Kingdom* (YSF Chair)

11:30	K5	<b>Keynote</b> <b>Contributions of Adhesive Proteins to the Cell Response to Bioactive Polymers and Surfaces</b> Helena Felgueiras, Meg Evans, <u>Véronique Migonney</u> <i>Université Paris 13, France</i>
12:00	108	<b>Prebiotic Chemistry Inspired Coatings for Biomedical Applications</b> Helmut Thissen, Mario Salwiczek, Christopher D. Easton, Aylin Koegler, Richard A. Evans <i>CSIRO Manufacturing Flagship, Australia</i>
12:15	109	<b>Grafting of Bioactive Molecules on PET to Recruit Endothelial Progenitors Cells and Enhance Adhesion of Endothelial Cells</b> <u>Caroline Royer</u> , Laurent Plawinski, Gaétan Laroche, Marie-Christine Durrieu <i>Hôpital Saint-François d'Assise, France</i>
12:30	110	<b>Functionalization of Biomedical Surfaces by Peptide Aptamers</b> Gabriela Melo Rodriguez, James Bowen, Artemis Stamboulis <i>University of Birmingham, United Kingdom</i>
12:45	111	<b>Nanoporous Anodic Titanium Dioxide Layers as Scaffolds for Cell Growth</b> <u>Magdalena Jarosz</u> , Anna Pawlik, Justyna Syguda-Cholewińska, Tomasz Sawoszczuk, Danuta Jarocho, Marcin Majka, Grzegorz D. Sulka, Marian Jaskuła <i>Jagiellonian University, Poland</i>

## Session 26 Hall 4A

### Cell Instructive Materials 3

Chairs: John Jansen, *Radboud University, Netherlands*

Timothy Douglas, *Ghent University, Belgium*

Jennifer Ashworth, *University of Cambridge, United Kingdom (YSF Chair)*

11:30	K6	<b>Keynote</b> <b>Glycosaminoglycan Derivatives – Promising Candidates for the Design of Functional Biomaterials</b> <u>Dieter Scharnweber</u> , Linda Hübner, Sandra Rother, Ute Hempel, Ulf Anderegg, Sergey A. Samsonov, M. Teresa Pisabarro, Lorenz Hofbauer, Matthias Schnabelrauch, Sandra Franz, Jan C. Simon, Vera Hintze <i>TU Dresden, Germany</i>
12:00	112	<b>Glycosaminoglycan Mimicking Surfaces Trigger Distinct Response of Stem Cells via Fibronectin Adsorption</b> <u>Ana Rodrigues Araujo</u> , D. Soares da Costa, S. Amorim, RL Reis, RA Pires, I. Pashkuleva <i>3B's Research Group, Portugal</i>
12:15	113	<b>Collagen-GAGs Based Interpenetrating Polymer Networks (IPNs) as Tissue Engineered Heart Valve (TEHV)</b> <u>Rabia Nazir</u> , Arne Bruyneel, Carolyn Carr, Jan Czernuszka <i>Oxford University, United Kingdom</i>
12:30	114	<b>Biofunctional Microassemblies Based on Renewable Resources - Microfluidic Generation and Release Applications</b> <u>Mélanie Marquis</u> , Agata Zykawska, Corinne Sinquin, Jacqueline Ratiskol, Stéphane Cuenot, Bernard Cathala, Denis Renard, Sylvia Collic-Jouault <i>INRA, France</i>
12:45	115	<b>Glycosaminoglycans as Biomaterials, Drugs and Pathogens</b> Kamil Kamiński, Bartłomiej Kałaska, Anna Mikulska, Joanna Filipowska, Anna Osyczka, Shin-Ichi Yusa, Małgorzata Kajta, Andrzej Mogielnicki, Maria Nowakowska, <u>Krzysztof Szczubiatka</u> <i>Jagiellonian University, Poland</i>

## Hall 4B

### Surface Charge for Biomaterial Characterization

Sponsored by: Anton Paar

11:30	SCh1	<b>Zeta Potential for Biomaterial Surface Characterization</b> <u>Christine Körner</u> , Thomas Luxbacher <i>Anton Paar GmbH, Graz, Austria</i>
12:15	SCh2	<b>TiO<sub>2</sub>-Coated Ti-Alloys for Body Implants &amp; Surface Charge: Expectations on the Bio-Response</b> <u>Martina Lorenzetti</u> , Mukta Kulkarni, Aleš Iglič, Thomas Luxbacher, Spomenka Kobe, Saša Novak <i>Jožef Stefan Institute, Ljubljana, Slovenia</i>

## Hall 1 Plenary Lecture 5

- 15:30 L5 Vascularization in Tissue Engineering: Alternative Foreign Body Responses**  
Michael V. Sefton  
*Institute of Biomaterials and Biomedical Engineering, University of Toronto, Canada*
- Chairs:** Abhay Pandit, *National University of Ireland, Galway, Ireland*  
 Małgorzata Lewandowska-Szumieł, *Medical University of Warsaw, Poland*

## Hall 1 Translational Research Symposium (3)

Organizers: Yves Bayon, Marc Bohner, David Eglin, Geoff Richards, Dimitrios Zeugolis

- 16:45 116 FTIR Microscopy Contribution for Comprehension of Poly-L-Lactic Acid (PLA) Degradation Mechanisms**  
 Yves Bayon, Antoine Alves, Carol Grossiord, Céline Brunon  
*NAMSA, Chasse/Rhône, France*
- 17:00 117 Possible Approach to Improve Systemic Gene Delivery to Tumour Using Polyplex Nanoparticles**  
Mikhail Durymanov, Alexei Yartukin, Andrey Rosenkranz, Alexander Sobolev  
*Institute of Gene Biology of the RAS, Russia*
- 17:15 118 Endothelialization of Polyurethanes: Immobilization of REDV Peptide**  
Beata Butruk-Raszeja, Magdalena Dresler, Aleksandra Kuźmińska, Tomasz Ciach  
*Warsaw University of Technology, Poland*
- 17:30 119 Helicobacter pylori-Binding Small Chitosan Microparticles that Penetrate Gastric Mucosa**  
 Patrícia C. Henriques, Paula Sampaio, Maria Lázaro, André Maia, António Gouveia, José Manuel Lopes, Ana Magalhães, Celso A. Reis, M. Cristina L. Martins, Paulo Costa, Inês C. Gonçalves  
*Universidade do Porto, Portugal*
- 17:45 120 Leaving Cells Out in the Cold: Hydrogel Encapsulation for the Improved Hypothermic Preservation of Stem Cells**  
 Stephen Swiokło, Che Connon  
*Newcastle University, United Kingdom*
- 18:00 121 Antibacterial Coatings on Titanium Surfaces: a Comparison Study Between In Vitro Single-Species and Multispecies Biofilm**  
 Maria Godoy-Gallardo, Zhejun Wang, Ya Shen, José M. Manero, F. Javier Gil, Carlos Mas-Morun, Daniel Rodríguez, Markus Haapasalo  
*Technical University of Catalonia, Spain*
- 18:15 122 The Proangiogenic Potential of a Novel Poly(lactic) Based Composite Membrane for Guided Bone Regeneration**  
 Hugo Oliveira, Nadège Sachot, Sylvain Catros, Sylvie Rey, Joan Martí, Oscar Castano, Joëlle Amedee, Elisabeth Engel  
*Institute for Bioengineering of Catalonia (IBEC), Spain*

## Session 27 Hall 2

### Bone Tissue Engineering 3

Chairs: Joelle Amedee, *INSERM, U1026, France*

Małgorzata Lewandowska-Szumieł, *Medical University of Warsaw, Poland*

Claudia Loebel, *AO Research Institute Davos, Switzerland (YSF Chair)*

- |       |     |  |
|-------|-----|--|
| 16:45 | K7  | <b>Keynote</b><br><b>Hydrogels and Scaffolds of Natural Origin as Support for Stem Cells in the Regeneration of Different Tissues</b><br><u>Rui Reis</u><br><i>3B's Research Group - University of Minho, Portugal</i>   |
| 17:15 | 123 | <b>Organic and Inorganic Bioactive Signals to Prepare Biomimetic Chitosan Based Scaffolds for Bone Tissue Regeneration</b><br><u>Maria Grazia Raucci</u> , Daniela Giugliano, Antonella Giuri, Vincenzo De Benedictis, Christian Demitri, Alessandro Sannino, Luigi Ambrosio<br><i>National Research Council of Italy, Italy</i> |
| 17:30 | 124 | <b>Polyvinyl Alcohol/Alginate Dual Network Hydrogels for Tissue Engineering</b><br><u>Shathani Nkhwa</u> , Sanjukta Deb<br><i>King's College London Dental Institute, United Kingdom</i>   |
| 17:45 | 125 | <b>Analysis of Integrin-Binding Dependent Cell Attachment on Collagen-Based Scaffolds</b><br>Carlos Schuster, Richard Farndale, Samir Hamaia, Serena Best, Ruth Cameron,<br><u>Natalia Davidenko</u><br><i>Cambridge University, United Kingdom</i>  |
| 18:00 | 126 | <b>A Novel Biological Polyester Based Wet Spun Scaffold for Bone Tissue Engineering</b><br><u>Ayse Selcen Alagoz</u> , Jose Carlos Rodriguez-Cabello, Nesrin Hasirci, Vasif Hasirci<br><i>BIOMATEN METU Center of Excellence in Biomaterials and Tissue Engineering, Turkey</i>  |
| 18:15 | 127 | <b>Resorption of Calcium Phosphate Bone Substitutes: an In Vitro Study</b><br><u>Marta Gallo</u> , Solène Tadier, Sylvain Meille, Marc Bohner, Aldo Boccaccini, Rainer Detsch, Jérôme Chevalier<br><i>INSA, France</i>   |

## Session 28 Hall 3A

## Angio- and Vasculogenesis

Chairs: Abhay Pandit, *National University of Ireland, Galway, Ireland*

Michael Sefton, *University of Toronto, Canada*

Sonia Zia, *Hannover Medical School, Germany (YSF Chair)*

16:45	128	<b>Induction of Endothelial Cell Sprouting by Poly (<math>\epsilon</math>-Lysine) Dendron Tethered with an Angiopoietin-1-mimicking Peptide</b> <i>Maria Elena Verdenelli, Steven Meikle, Gary Phillips, Matteo Santin</i> <i>University of Brighton, United Kingdom</i>
17:00	129	<b>Sustained Release of Adipose-Derived Stem Cells by Thermosensitive Chitosan-Gelatin Hydrogel for Therapeutic Angiogenesis</b> <i>Nai-Chen Cheng, Tai-Horng Young</i> <i>National Taiwan University Hospital, Taiwan</i>
17:15	130	<b>Cobalt Doped Proangiogenic Hydroxyapatite for Bone Tissue Engineering Application</b> <i>Senthilguru Kulanthaivel, Krishna Pramanik, Indranil Banerjee</i> <i>National Institute of Technology, India</i>
17:30	131	<b>Development of a Synthetic Pseudovascular Network to Investigate Neovascularisation for Tissue Engineering Applications</b> <i>Lindsey Dew, Ilida Ortega, Adam Kelly, Frederik Claeysens, Sheila MacNeil</i> <i>University of Sheffield, United Kingdom</i>
17:45	132	<b>Angiogenic Response on Chitosan-Graft-Poly (<math>\epsilon</math>-Caprolactone) Copolymer in vitro, enhanced by Wharton's Jelly-derived Mesenchymal Stromal Cells</b> <i>Evi Mygdali, Maria Kaliva, Maria Vamvakaki, Charalampos Pontikoglou, Maria Chatzinikolaidou</i> <i>University of Crete, Greece</i>
18:00	133	<b>Vasculogenesis and Accelerated Healing through the Emergent Design of an Hierarchically Structured Scaffold</b> <i>Julian F Dye, Giuseppe Scionti, Elizabeth A Wahl, Tomas Egana, Maroun Khoury</i> <i>Dept LHCS, The Open University, United Kingdom</i>
18:15	134	<b>Repair of "Burr Holes" Using Chitosan-Siloxane Porous Hybrids</b> <i>Yuki Shirotsaki, Motomasa Furuse, Takuji Asano, Yoshihiko Kinoshita, Toshiki Miyazaki, Satoshi Hayakawa, Akiyoshi Osaka, Toshihiko Kuroiwa</i> <i>Kyushu Institute of Technology, Japan</i>

## Session 29 Hall 3B

## Antimicrobial Surfaces and Materials 2

Chairs: Matthias Epple, *University of Duisburg-Essen, Germany*  
Barbara Szaraniec, *AGH University of Science and Technology, Poland*  
Riccardo Levato, *Institute for Bioengineering of Catalonia (IBEC), Spain* (YSF Chair)

- |       |     |   |
|-------|-----|---|
| 16:45 | 135 | <b>A Nanocomposite Wound Dressing with Potential to Sustain Active Chlorhexidine on a Wound Bed</b><br><u>Peter Duckworth</u> , Sarah Maddocks, Gareth Robinson, Sameer Rahatekar, Michele Barbour<br><i>University of Bristol, United Kingdom</i>  |
| 17:00 | 136 | <b>Enrichment of Enzymatically Mineralized Gellan Gum Hydrogels with Polyphenol-Rich Ecklonia Cava Extract Seanol® to Endow Antibacterial Properties</b><br><u>Timothy Douglas</u> , Gilles Brackman, Katarzyna Reczynska, Agnieszka Dokupil, Krzysztof Pietryga, Peter Dubrue, Tom Coenye, Elzbieta Pamula<br><i>Ghent University, Belgium</i> |
| 17:15 | 137 | <b>Development of an Antibacterial Hybrid Sponge (Chitosan/Hydroxyapatite) for Bone Regeneration</b><br><u>Claudia Flores</u> , Jean Christophe Hornez, Feng Chai, Gwenael Raoul, Nicolas Tabary, Frédéric Cazaux, Joel Ferri, Hartmunt F. Hildebrand, Bernard Martel, Nicolas Blanchemain<br><i>University of Lille, France</i>                |
| 17:30 | 138 | <b>Antimicrobial Properties of a Novel Hydrogel Bandage Lens Material</b><br><u>Andrew Gallagher</u> , Mal Horsburgh, Jamal Alorabi, Don Wellings, Rachel Williams<br><i>University of Liverpool, United Kingdom</i>  |
| 17:45 | 139 | <b>Ephemeral Biogels to Control Anti-Biofilm Agent Delivery</b><br><u>Véronique Larreta Garde</u> , Elodie Lefebvre, Damien Seyer<br><i>University of Cergy Pontoise, France</i>  |
| 18:00 | 140 | <b>Broad-Spectrum Antimicrobial Polycarbonate Hydrogels for Wound Dressing Applications</b><br><u>Haritz Sardon</u> , Ana Pascual, Jeremy Tan, James Hedrick, Yi YanYang<br><i>University of the Basque Country, Spain</i>  |
| 18:15 | 141 | <b>Injectable Gellan Gum-Based Nanoparticle-Loaded System for the Local Delivery of Vancomycin in Osteomyelitis Treatment</b><br><u>Urszula Posadowska</u> , Monika Brzychczy-Włoch, Elzbieta Pamula<br><i>AGH University of Science and Technology, Poland</i>   |

## Session 30 Hall 4A

## Bioimaging and Biosensing

Chairs: Didier Letourneur, *Inserm U1148 Cardiovascular Bioengineering, France*

Tomasz Ciach, *Warsaw University of Technology, Poland*

Magdalena Ziabka, *AGH University of Science and Technology, Poland (YSF Chair)*

16:45	K8	<b>Keynote</b> <b>Bionano Characterization - Beyond Imaging with Scanning Probe Microscopy</b> <u>Wojciech Chrzanowski</u> <i>The University of Sydney, Australia</i>
17:15	142	<b>Long-Term and Bioinert Labeling of Mesenchymal Stem Cells with Polymeric-Gd Conjugates and MRI Monitoring of the Cell Behaviour in Ischemic Rats</b> <u>Tetsuji Yamaoka</u> , Yoichi Tachibana <i>National Cerebral and Cardiovascular Center Research Institute, Japan</i>
17:30	143	<b>Nile Blue-Based Nano-Sized pH Sensors for Simultaneous Far-Red and Near-Infrared Live</b> <u>Jeppe Madsen</u> , Irene Canton, Nicholas J. Warren, Efrosyni Themistou, Adam Blanz, Burcin Ustbas, Xiaohu Tian, Russell Pearson, Giuseppe Battaglia, Andrew L. Lewis, Steven P. Armes <i>University of Sheffield, United Kingdom</i>
17:45	144	<b>Phenotypic and Functional Sensing of Cell Microvesicles Using an Immobilized Chemosensor</b> Catherine Belle, Sylvain Nlate, Marie-Christine Durrieu, Eduardo Angles-Cano, <u>Laurent Plawinski</u> UMR 5248, CNRS, Bordeaux University, <i>France</i>
18:00	145	<b>Mass Transport Study with Fluorescent Dextran Molecules in Gellan Gum Hydrogel</b> Ana M. Soto, <u>Janne Koivisto</u> , Jenny E. Parraga, Jari Hyttinen, Minna Kellomäki, Edite Figueiras <i>University of Tampere, Finland</i>
18:15	146	<b>The Effect of Biomolecular Interaction and Chondrocyte Adhesion to Surface Grafted Hyaluronan Layers</b> <u>Erik Nilebäck</u> , Noomi Altgärde, Angelika Kunze, Lars Enochson, Laura de Battice, Iva Pashkuleva, Jana Becher, Stephanie Möller, Matthias Schnabelrauch, Rui L. Reis, Anders Lindahl, Sofia Svedhem <i>Biolin Scientific, Sweden</i>

## Session 31 Hall 4B

## Biointerfaces 2

Chairs: Yannis Missirlis, *University of Patras, Greece*  
Alina Sionkowska, *Nicolaus Copernicus University, Poland*  
Judit Buxadera Palomero, *Technical University of Catalonia, Spain* (YSF Chair)

- |       |     |  |
|-------|-----|--|
| 16:45 | 147 | <b>Surface Topography: Is It Clinically Relevant?</b><br>Andrew English, Ayesha Azeem, Manus Biggs, Abhay Pandit, <u>Dimitrios Zeugolis</u><br><i>National University of Ireland, Galway, Ireland</i>  |
| 17:00 | 148 | <b>Cell-Material Interaction Enhanced by Hybrid Covalent Coated Nanofibers</b><br>Joan Marti, Nadege Sachot, <u>Oscar Castano</u> , Miguel Mateos-Timoneda, Aldrik Velders, Malgorzata Lewandoska, Josep A. Planell, Elisabeth Engel<br><i>Institute for Bioengineering of Catalonia (IBEC), Spain</i>         |
| 17:15 | 149 | <b>Fibronectin Based Thin Films: Description of a Novel Growth Mechanism and Influence on Cell Behavior</b><br><u>Adeline Gand</u> , Coline Chat, Alysée Barraux, Guy Ladam, Paul R Van Tassel, Emmanuel Pauthe<br><i>University of Cergy-Pontoise, France</i>   |
| 17:30 | 150 | <b>Primary Macrophage Phenotype Control by IL-4 Releasing, Self-Crosslinking PLL/HA-Aldehyde Derivative Multilayer Coatings</b><br><u>Helena Knopf-Marques</u> , Sonali Singh, Lucie Wolfowa, Vladimir Velebny, Pierre Schaaf, Amir Ghaemmaghami, Nihal Engin Vrana, Philippe Lavalle<br><i>INSERM, France</i> |
| 17:45 | 151 | <b>Biointerfaces through Continuous Electrojet-Writing</b><br><u>Zhaoying Li</u> , Yan Yan Shery Huang, Xia Li<br><i>University of Cambridge, United Kingdom</i>   |
| 18:00 | 152 | <b>Bioactive Helical Nanomaterials and their Influence on Stem Cell Differentiation</b><br><u>Gregor Kemper</u> , Laurent Plawinski, Emilie Pouget, Shawn Wettig, Reiko Oda, Marie-Christine Durrieu<br><i>CBMN UMR 5248, CNRS, Bordeaux University, France</i>  |
| 18:15 | 153 | <b>Case Study of a Retrieved Trans-Femoral Bone Anchored Amputation Prosthesis</b><br><u>Anders Palmquist</u> , Sara Windahl, Birgitta Norlindh, Rickard Brånemark, Peter Thomsen<br><i>University of Gothenburg, Sweden</i>   |

Hall 1		Plenary Lecture 6
8:30	L6	<b>Targeted Chemo- and Molecular-Therapy by Self-Assembled Supramolecular Nanosystems</b> <u>Kazunori Kataoka</u> <i>Department of Materials Engineering, University of Tokyo, Japan</i>  <b>Chairs:</b> Maria Siemionow, <i>University of Illinois at Chicago, United States</i> Michael Sefton, <i>University of Toronto, Canada</i>

Session 32 Hall 1		Cancer Therapy
		<b>Chairs:</b> Kazunori Kataoka, <i>University of Tokyo, Japan</i> Hasan Uludag, <i>University of Alberta, Canada</i> Joana Silva-Correia, <i>3B's Research Group, University of Minho, Portugal (YSF Chair)</i>
9:30	154	<b>Multitargeting Theranostic Nanoparticles for the Treatment of HER2-Positive Breast Cancer</b> Raquel Palao-Suay, <u>Maria Rosa Aguilar</u> , Francisco Parra-Ruiz, Susan N. Thomas, Nathan Rohner, Samarendra Maji, Richard Hoogenboom, Julio San Roman <i>ICTP-CSIC, Spain</i>
9:45	155	<b>ROS-Generating Titanium Oxide-Based Nanoparticles for Non-Invasive Cancer Surgery</b> <u>Dong Gil You</u> , V.G. Deepagan, Wooram Um, Sangmin Jeon, Ich Chan Kwon, Kwangmeyung Kim, Jae Hyung Park <i>Sungkyunkwan University, Korea</i>
10:00	156	<b>Investigation of Dendrimer-Based Nanoparticles Cellular Uptake and Cell Tracking in a Semi-Automated Microfluidic Platform</b> <u>Mariana Carvalho</u> , Fátima Maia, Rui Reis, Miguel Oliveira <i>3B's Research Group, Portugal</i>
10:15	157	<b>Effects of SPION Loaded Hyaluronan Polymeric Micelles on Gene Expression in Normal and Cancer Cells</b> <u>Kristina Nešporová</u> , Vojtěch Pavlík, Daniela Šmejkalová, Vladimír Velebný <i>Contipro Biotech, Czech Republic</i>
10:30	158	<b>Molecular Weight of Surface Immobilized Hyaluronic Acid Influences CD44-Mediated Adhesion of Gastric Cancer Cells</b> <u>Sara Amorim</u> , Diana Soares da Costa, Daniela Freitas, Ana Magalhães, Celso Reis, Rui Reis, Iva Pashkuleva, Ricardo Pires <i>3B's Research Group - University of Minho, Portugal</i>
10:45	159	<b>Novel Halogenated Phthalocyanines as Photosensitizers for Photodynamic Therapy for Cancer</b> <u>Łukasz Łapok</u> , Arkadiusz Gut, Małgorzata Cyza, Mariusz Kępczyński, Dorota Jamróż, Grzegorz Szewczyk, Tadeusz Sarna, Alexandr Gorski, Jędrzej Solarski, Tadeusz Waluk, Maria Nowakowska <i>Jagiellonian University, Poland</i>

## Session 33 Hall 2

## Soft Tissue Engineering

Chairs: Julia Babensee, *Georgia Institute of Technology, United States*  
Lorenzo Moroni, *Maastricht University, Netherlands*  
Andrew Gallagher, *University of Liverpool, United Kingdom (YSF Chair)*

- |       |     |  |
|-------|-----|--|
| 9:30  | 160 | <b>The Role of Electrical Stimulation in Tendon Maintenance and Repair: Electrospun PVDF-TrFE/Boron Nitride Nanotubes as Bioactive Scaffold for Promoting Tendon Regeneration</b><br><u>Marc Fernandez</u> , Gemma Orpella, Ghazal Tadayyon, Matteo Palma, Abhay Pandit, Dimitrios Zeugolis, Manus Biggs<br><i>National University of Ireland, Galway, Ireland</i> |
| 9:45  | 161 | <b>Patterned Thermoresponsive pNIPAM-pHEMA Hydrogels for Corneal Repair</b><br><u>Cemile Bektas</u> , Vasif Hasirci<br><i>Middle East Technical University, Turkey</i>   |
| 10:00 | 162 | <b>Macromolecular Crowding in Corneal Fibroblasts Culture Accelerates the Production of Extracellular Matrix-rich Supramolecular Assemblies</b><br>Pramod Kumar, Abhigyan Satyam, <u>Kyriakos Spanoudes</u> , Abhay Pandit, Dimitrios Zeugolis<br><i>National University of Ireland, Galway, Ireland</i>   |
| 10:15 | 163 | <b>Elaboration and Evaluation of Alginate Foam Scaffolds for Soft Tissue Engineering</b><br><u>Raya Bushkalova</u> , Caroline Ceccaldi, Christophe Tenailleau, Benjamin Duployer, Philippe Bourin, Daniel Cussac, Angelo Parini, Brigitte Sallerin, Sophie Girod-Fullana<br><i>INSERM UMR 1048, France</i>   |
| 10:30 | 164 | <b>Polyhydroxyalkanoates, a Family of Natural Polymers and Their Application in Cardiac Tissue Engineering</b><br><u>Ipsita Roy</u> , Andrea Bagdadi, Prachi Dubey, Ranjana Rai, Jonathan Knowles, Aldo R. Boccaccini, Mohan Edirisinghe, Sian Harding<br><i>University of Westminster, United Kingdom</i>   |
| 10:45 | 165 | <b>Fabrication of a Biosynthetic Hydrogel Scaffold for Skin Repair</b><br>Mario Flores-Reyes, Jaime Flores-Estrada, Ma. Victoria Dominguez-García, <u>Miriam V. Flores-Merino</u><br><i>Research Center in Medical Sciences, Uaem, Mexico</i>  |

## Session 34 Hall 3A

## Cardiovascular Applications 1

Chairs: Ana Paula Pego, *INEB - Instituto de Engenharia Biomédica, Portugal*  
Mirosława El Fray, *West Pomeranian University of Technology, Poland*  
Lindsey Dew, *University of Sheffield, United Kingdom (YSF Chair)*

- |       |     |   |
|-------|-----|---|
| 9:30  | K9  | <b>Keynote</b><br><b>Endothelial Cells on Biofunctionalized Polymeric Materials for Vascular Tissue Engineering</b><br><u>Lucie Bacakova</u> , Jaroslav Chlupac, Elena Filova, Jana Musilkova, Katarina Novotna, Tomas Riedel, Vladimir Proks, Ilya Kotelnikov, Ognen Pop-Georgievski, Eduard Brynda, Frantisek Rypacek, Laurence Bordenave<br><i>Academy of Sciences of the Czech Republic, Czech Republic</i> |
| 10:00 | 166 | <b>Evaluation of a Pro-Healing Polydopamine-Coated Stent on In-Stent Restenosis Using a Rat Model</b><br><u>Adrien Hertault</u> , Blandine Maurel, Feng Chai, Mickael Maton, Joël Lyskawa, Jonathan Sobocinski, Stephan Haulon, Nicolas Blanchemain<br><i>INSERM U1008, Research Group on Biomaterials, France</i>  |
| 10:15 | 167 | <b>Anti-Thrombogenic Effects Of Bioactive CoCr Surfaces for Cardiovascular Applications</b><br>Maria Isabel Castellanos, Jordi Guillem-Martí, Carlos Mas-Moruno, Maribel Díaz-Ricart, Ginés Escolar, Francisco Javier Gil, José María Manero, <u>Marta Pegueroles</u><br><i>Technical University of Catalonia (UPC), Spain</i>  |
| 10:30 | 168 | <b>Improving the Biocompatibility of Intravascular Devices</b><br><u>Guillaume Le Saux</u> , Laurent Plawinski, Sylvain Nlate, Marie-Christine Durrieu<br><i>CBMN, France</i>   |
| 10:45 | 169 | <b>Nanomaterials for Cardiovascular Applications: Quo Vadimus?</b><br><u>Iwona Cicha</u> , Christoph D. Garlich, Christoph Alexiou<br><i>University Hospital Erlangen, Germany</i>  |

**Session 35**  
**Hall 3B**

**Antimicrobial Surfaces and Materials 3**

Chairs: Nicolas Blanchemain, *Université de Lille, France*

Fabrizio Barberis, *Università di Genova, Italy*

Zuzanna Trzcńska, *University of Birmingham, United Kingdom* (YSF Chair)

9:30	170	<b>High Throughput Methods for the Discovery of Materials that Resist Bacterial Adhesion</b> <u>Andrew Hook</u> <i>University of Nottingham, United Kingdom</i>
9:45	171	<b>Physicochemical Properties and Cell-Biological Action of Alloyed Silver-Gold Nanoparticles</b> <u>Oleg Prymak</u> , Simon Ristig, Svitlana Chernousova, Wolfgang Meyer-Zaika, Matthias Epple <i>University of Duisburg-Essen, Germany</i>
10:00	172	<b>Enzymatic Disassembly of Biofilm Extracellular Matrix by Smart Nanoparticles to Eradicate Bacterial Infections</b> <u>Riccardo Levato</u> , Aida Baelo, Esther Julian, Joan Gavalda, Elisabeth Engel, Eduard Torrents, Miguel Angel Mateos-Timoneda, Anna Crespo <i>Institute for Bioengineering of Catalonia, Spain</i>
10:15	173	<b>Anti-Helicobacter Pylori Activity of Nanoparticles Loaded with a Polyunsaturated Fatty Acid</b> <u>Catarina L. Seabra</u> , Cláudia Nunes, Marta Correia, José C. Machado, Celso A. Reis, Inês C. Gonçalves, Salette Reis, M. Cristina L. Martins <i>Universidade do Porto, Portugal</i>
10:30	174	<b>Antifouling Coatings as a Platform for Antimicrobial Peptide Immobilization</b> <u>Judit Buxadera-Palomero</u> , Patricia Carrasco, Cristina Canal, Carles Mas-Moruno, F. Xavier Gil, Daniel Rodríguez <i>Technical University of Catalonia, Spain</i>
10:45	175	<b>Modified PVC Urinary Catheters to Prevent Bacterial Adhesion</b> <u>Luisa Islas</u> , Guillermina Burillo, Carmen Alvarez-Lorenzo, Angel Concheiro <i>Universidad Nacional Autonoma de Mexico, Mexico</i>

## Session 36 Hall 4A

## Advanced Manufacturing 2

Chairs: Roberto De Santis, *National Research Council of Italy, Italy*  
Karol Gryń, *AGH University of Science and Technology, Poland*  
Robin Rajan, *Japan Advanced Institute of Science and Technology, Japan (YSF Chair)*

9:30	K10	<b>Keynote</b> <b>3D Printing of Crosslinkable Gelatins: Overcoming the Mechanical Boundaries</b> Jasper Van Hoorick, Heidi Declercq, Maria Cornelissen, Hugo Thienpont, Aleksandr Ovsianikov, Peter Dubrue, <u>Sandra Van Vlierberghe</u> <i>Ghent University, Belgium</i>
10:00	176	<b>3D Bioprinting of Functional Fibrin-Based Skin Equivalents</b> Nieves Cubo, Marta García, Diego Velasco, Juan Cañizo, Jose Luis Jorcano <i>Universidad Carlos III, Spain</i>
10:15	177	<b>A New Laser-Based Approach for Native Silk Structuring</b> Anastasia Brif, Chris Holland, Frederik Claeysens <i>University of Sheffield, United Kingdom</i>
10:30	178	<b>Development of Porous PLLA Micro-Cylinders for Tissue Engineering Applications</b> Antonio Castro, John Jansen, Jeroen van den Beucken, Fang Yang <i>RadboudUMC, Netherlands</i>
10:45	179	<b>Cell Proliferation Controlled by Selective Laser Melting (SLM) Process Parameters</b> Bartłomiej Wysocki, Joanna Idaszek, Wojciech Świążkowski, Krzysztof Kurzydłowski <i>Warsaw University of Technology, Poland</i>

## Hall 4B

## Science for Industry (1)

## Bioresorbable Materials for Medical Applications

Organizers: Xiang Zhang, Ipsita Roy, Kadem Al-Lamee, Stuart MacLachlan, Maria Joao Barros, Nial Bullett, Mark Taylor

9:30	<b>Welcome and Introduction</b> Xiang Zhang, Ipsita Roy
9:50	<b>Commercial Needs for Bioresorbable Materials, Transfer from Laboratory and Barriers and Gaps in the Technology</b> Kadem Al-Lamee <i>Arterius Limited, United Kingdom</i>
10:15	<b>Production and Evaluation Platforms for Preclinical Assessment of Novel Biomaterials for Non-Healing Bone Lesions</b> Oskar Hoffmann <i>University of Vienna, Austria</i>
10:40	<b>Bioresorbable Systems: Polymers and Metals</b> Ipsita Roy <i>University of Westminster, United Kingdom</i>

## Session 37 Hall 1

### Drug Delivery 3

Chairs: Wojciech Chrzanowski, *The University of Sydney, Australia*  
Izabela-Cristina Stancu, *University Politehnica Bucharest, Romania*  
Martin Lynge, *Aarhus University, Denmark (YSF Chair)*

11:30	K11	<b>Keynote</b> <b>Polypeptide Nanoparticles for Ocular Drug Delivery</b> <u>Neil Cameron</u> <i>Monash University, Australia</i>
12:00	180	<b>Micro and Nano Hydrogel Carrier Systems for Controlled Drug Delivery of Therapeutic Proteins</b> Henning Menzel, Andreas Bertz, Nils Poth, Wibke Dempwolf, Jan-Erik Ehlers, Karl-Heinz Gericke, Peter P. Müller, Gerhard Gross, Stefanie Wöhl-Bruhn, Heike Bunjes <i>University of Technology, Germany</i>
12:15	181	<b>Peptide Binding Dendrimer Decorated Injectable Hyaluronan Hydrogels Modulate the Controlled Release of BMP-2 and TGF-<math>\beta</math>1</b> Ryan Seelbach, Peter Fransen, Miriam Royo, Fernando Albericio, Mauro Alini, Alvaro Mata, <u>David Eglin</u> <i>AO Research Institute Davos, Switzerland</i>
12:30	182	<b>Co-Deliver of Glucagon-Like Peptide-1 and Dipeptidyl Peptidase 4 Inhibitor for Treatment of Type 2 Diabetes</b> <u>Francisca Araújo</u> , Neha Shrestha, Mohammad-Ali Shahbazi, Dongfei Liu, Bárbara Herranz-Blanco, Ermei Mäkilä, Jarno Salonen, Jouni Hirvonen, Pedro L. Granja, Bruno Sarmento, Hélder A. Santos <i>INEB, Portugal</i>
12:45	183	<b>Controlled Release of Platinum-Bisphosphonate Complexes from Injectable Calcium Phosphate Cements for Treatment of Bone Tumors</b> Kemal Sariibrahimoglu, <u>Kambiz Farbod</u> , Astghik Hayrapetyan, Jan N. W. Hakvoort, Michele Iafisco, Nicola Margiotta, Joop G. C. Wolke, Jeroen J. J. P. van den Beucken, John A. Jansen, Sander C. G. Leeuwenburgh <i>Radboud University Medical Center, Netherlands</i>

## Session 38 Hall 2

## Composite Scaffolds

Chairs: Luigi Ambrosio, *National Research Council, Italy*

Ki Dong Park, *Ajou University, Korea*

Sungho Lee, *Nagoya Institute of Technology, Japan* (YSF Chair)

11:30	184	<b>Structurally-Graded Collagen Biomaterials for Osteotendinous Repair</b> Laura Mozdzen, William Grier, Ashley Moy, Steven Caliari, <u>Brendan Harley</u> <i>University of Illinois, United States</i>
11:45	185	<b>Biomaterialized Cellulose-PEGDA Scaffolds for Bone Tissue Regeneration</b> <u>Christian Demitri</u> , Maria Grazia Raucci, Antonella Giuri, Vincenzo Maria De Benedictis, Daniela Giugliano, Alessandro Sannino, Luigi Ambrosio <i>University of Salento, Italy</i>
12:00	186	<b>Preparation and Characterization of Silicone Elastomer Composites for Biomedical Prosthetic Applications</b> <u>Petroula Tarantili</u> <i>National Technical University of Athens, Greece</i>
12:15	187	<b>High-Resolution Synchrotron X-Ray Analysis of Bioglass-Enriched Hydrogels</b> <u>Svetlana Gorodzha</u> , Timothy Douglas, Sangram Samal, Katarzyna Cholewa-Kowalska, Kevin Braeckmans, Andre Skirtach, Venera Weinhardt, Tilo Baumbach, Maria Surmeneva, Roman Surmenev <i>National Research Tomsk Polytechnic University, Russian Federation</i>
12:30	188	<b>Computational and Experimental Study of the Degradation Behaviour of CaCO<sub>3</sub>-PLGA Composites</b> <u>Ismael Moreno Gomez</u> , Xiang Zhang, Serena Best, Ruth Cameron <i>University of Cambridge, United Kingdom</i>
12:45	189	<b>Development of Nanostructured Composites Based on ε-Polylysine and Apatite</b> <u>Kristine Salma-Ancane</u> , Liga Stipniece, Inga Narkevica <i>Rudolfs Cimdins Riga Biomaterials Innovation and Development Centre, Latvia</i>

## Session 39 Hall 3A

## Cardiovascular Applications 2

Chairs: Elisabeth Engel, *Institut for Bioengineering of Catalonia, Spain*

Paul Santerre, *University of Toronto, Canada*

Agnieszka Piegat, *West Pomeranian University of Technology, Poland (YSF Chair)*

11:30	190	<b>Chitosan Based Hydrogels for Vascular Applications: In Vitro and In Vivo Hemocompatibility Evaluation</b> <u>Audrey Ausseil</u> , Xavier Berard, Sandro Cornet, Vincenzo Brizzi, Marlène Durand, Alexandra Montembault, Laurent David, Rachida Aid, Didier Letourneur, Laurence Bordenave <i>INSERM U1026, France</i>
11:45	191	<b>Enriched Decellularized Matrices for Tissue Engineering: Effects of Des-Acyl Ghrelin on Vascular Cells</b> <u>Francesca Boccafroschi</u> , Margherita Botta, Luca Fusaro, Martina Ramella, Francesco Copes, Mario Cannas <i>University of Piemonte Orientale, Italy</i>
12:00	192	<b>Biomimetic Strategy to Improve Haemo- and Biocompatibility of PET</b> <u>E. Diana Giol</u> , Ronald Unger, Sandra van Vlierberghe, C. James Kirkpatrick, Peter Dubruel <i>Ghent University, Belgium</i>
12:15	193	<b>Synthesis of Porous Polyhydroxyalkanoate (PHA) Fibres by Pressurized Gyration Process and their Evaluation as Tissue Engineering Scaffolds</b> <u>Pooja Basnett</u> , Suntharavathanan Mahalingam, Barbara Lukasiewicz, Sian Harding, Mohan Edirisinghe, Ipsita Roy <i>University of Westminster, United Kingdom</i>
12:30	194	<b>Enhanced Interfacial Strength of Surgical Sealants Composed of Hydrophobically Modified, Cod-Derived Gelatins with Different Hydrocarbon Chain Length</b> <u>Ryo Mizuta</u> , Temmei Ito, Keiko Yoshizawa, Toshimasa Akiyama, Katsuhiro Kamiya, Tetsushi Taguchi <i>National Institute for Materials Science, Japan</i>
12:45	195	<b>Athrombogenic Diffusive Layers as the Biomaterial for Blood Contact Applications in the Dynamic High Shear Stresses Conditions</b> <u>Małgorzata Gonsior</u> , Tadeusz Wierzchoń, Roman Kustosz, Maciej Darlak, Magdalena Kościelniak-Ziemniak <i>Foundation for Cardiac Surgery Development, Poland</i>

**Session 40**  
**Hall 3B**

**Neural Regeneration 2**

Chairs: Michael Doser, *Institute for Textile Research and Process Engineering, Germany*  
Leonora Buzanska, *Mossakowski Medical Research Centre PAS, Poland*  
Sahana Ganesh, *National University of Ireland, Galway, Ireland (YSF Chair)*

11:30	K12	<b>Keynote</b> <b>Tissue-Engineered Electrodes for Neural and Cardiovascular Applications</b> <u>Laura Poole-Warren</u> , Josef Goding, Ulises Aregueta-Robles, Alexander Patton, Penny Martens, Rylie Green <i>University of New South Wales, Sydney, Australia</i>
12:00	196	<b>Delivery of Neurotrophic Factors to the Brain Using Fibrin-Based Hollow Microsphere Reservoirs</b> <u>Juhi Samal</u> , Deirdre Hoban, Carol Naughton, Ruth Concannon, Eilis Dowd, Abhay Pandit <i>National University of Ireland, Galway, Ireland</i>
12:15	197	<b>Amine-Functionalized Oligomer-Cross-Linked Gelatin-Based Conduits for Nerve Regeneration</b> <u>Caroline Kohn</u> , Julia M. Mehnert, Christian Kascholke, Michaela Schulz-Siegmund, Matthias Brandenburger, Michael C. Hacker <i>University of Leipzig, Germany</i>
12:30	198	<b>A Dual-Layered Microfluidic System for the Controlled In Situ Delivery of Anti-inflammatory Factors in Chronic Neural Implants</b> <u>Laura Frey</u> , Su Ryon Shin, Kevin O'Kelly, Ali Khademhosseini <i>Harvard Medical School, United States</i>
12:45	199	<b>Schwann Cell Behavior in Degradable PVA-Tyramine Hydrogels</b> <u>Ulises Aregueta Robles</u> , Khoon Lim, Penny Martens, Laura Poole-Warren, Nigel Lovell, Rylie Green <i>University of New South Wales, Sydney, Australia</i>

## Session 41 Hall 4A

### Cell Instructive Materials 4

Chairs: Guy Daculsi, *INSERM LIOAD UMR 791, France*

Maria Chatzinikolaidou, *University of Crete, Greece*

Ana Rita Rodrigues Araújo, *3B's Research Group - University of Minho, Portugal (YSF Chair)*

11:30	K13	<b>Keynote</b> <b>Bio-Fabrication and Physiological Self-Release of Tissue Equivalents Using Smart Peptide Amphiphile Templates</b> <u>Che Connon</u> , Ricardo Gouveia, Valeria Castelletto, Ian Hamely <i>Newcastle University, United Kingdom</i>
12:00	200	<b>Cellular Alignment in Response to Direct Laser Interference Patterning on Polyurethane Surfaces</b> <u>Lucas Cortella</u> , Denise Langheinrich, Idágene Cestari, Andrés Lasagni, Ismar Cestari <i>University of São Paulo, Brazil</i>
12:15	201	<b>Correlation of Mechanical Properties of Bio-Imitating Coatings with the Life Processes of Human Cells</b> <u>Roman Major</u> , Juergen M. Lackner <i>Institute of Metallurgy and Materials Science PAS, Poland</i>
12:30	202	<b>Effect of Osteogenic Growth of Adipose Derived Stem Cells And Human Osteoblasts on the Mechanical Properties of Protein Based Films with Microchannels</b> <u>Esen Sayin</u> , Rosti Hama Rashid, Ahmed Elsheikh, José Carlos Rodríguez-Cabello, Erkan Türker Baran, Vasif Hasirci <i>Center of Excellence in Biomaterials and Tissue Engineering, Turkey</i>
12:45	203	<b>Vasculogenesis by a Maleimide Cross-Linked PEG Hydrogel Containing Calcium Phosphate Glass Particles</b> <u>Claudia Navarro</u> , Jessica Weaver, Óscar Castaño, Amy Clark, Jose Garcia, Soledad Pérez-Amodio, Dennis Zhou, Douglas Clift, Andres J. García, Elisabeth Engel <i>Institute for Bioengineering of Catalonia, Spain</i>

## Hall 4B

### Science for Industry (2)

#### Bioresorbable Materials for Medical Applications

Organizers: Xiang Zhang, Ipsita Roy, Kadem Al-Lamee, Stuart MacLachlan, Maria Joao Barros, Nial Bullett, Mark Taylor

11:30	<b>Bioresorbable Systems: The Role of Inorganic Fillers in Composites</b> <u>Aldo R. Boccaccini</u> <i>University of Erlangen-Nuremberg, Germany</i>
11:50	<b>Bioresorbable Systems: The Role of Surface Functionalisation</b> <u>Iban Quintana</u> <i>IK4-TEKNIKER Ultra - Precision Processes Unit, Spain</i>
12:10	<b>Bioresorbable Systems: The Role of Modelling and Simulation in Performance Assessment of Bio-Structures and Implants</b> <u>Atul Bhaskar</u> <i>University of Southampton, United Kingdom</i>
12:30	<b>Bioresorbable Systems: The Role of Preclinical Testing</b> <u>Gianluca Giavaresi</u> <i>Istituto Ortopedico Rizzoli, Italy</i>
12:50	<b>Bioresorbable Systems: Discussion</b>

## Hall 1

## Plenary Lecture 7

- 15:30 L7 **Cell-Made or Man-Made Materials for Bone Reconstruction?**  
Małgorzata Lewandowska-Szumieł  
*Center for Biostructure Research, Medical University of Warsaw, Poland*
- Chairs:** Kazunori Kataoka, *University of Tokyo, Japan*  
Peter Dubruel, *Ghent University, Belgium*

## Session 42 Hall 1

### Bone Tissue Engineering 4

**Chairs:** Michael Gelinsky, *Technische Universität Dresden, Germany*  
Peter Dubruel, *Ghent University, Belgium*  
Marianne Sommer, *ETH Zurich Complex Materials, Switzerland (YSF Chair)*

- 16:45 204 **Ectopic Bone Formation by Commercial Calcium Phosphate Bone Graft Substitutes**  
Rongquan Duan, Davide Barbieri, Xiaoman Luo, Joost de Bruijn, Huipin Yuan  
*Xpand Biotechnology BV, Netherlands*
- 17:00 205 **In Vivo and In Vitro Characterization of Porous Polyurethane-Hydroxyapatite Scaffolds as a Bone Substitute**  
Gifty Tetteh, Maksym Pogorielov, Ihtesham U. Rehman, Gwendolen C. Reilly  
*University of Sheffield, United Kingdom*
- 17:15 206 **Preparation and Bioactivity of Nanocomposite Scaffolds Based on Biodegradable Polyurethane Foams and Bioactive Glass Nanoparticles**  
Cristian Covarrubias, Amaru Aguero, Monserrat Cádiz, Mario Díaz, Mehrdad Yazdani-Pedram, Juan Pablo Rodríguez, Carla Urra, Juan Cahuich, Juan M. Cervantes  
*University of Chile, Chile*
- 17:30 207 **Influence of Hydroxyapatite on Degradation Behaviour of PLA Fibres Scaffold**  
Nancy Vargas-Becerril, Lucia Téllez-Jurado, Octavio Álvarez-Fregoso, Manuel Hipólito-García, Luis María Rodríguez-Lorenzo, José Arturo Fernández-Pedrero, Marco Antonio Álvarez-Pérez  
*Autonome National University of Mexico, Mexico*

## Session 43 Hall 2

## Cellular Response

Chairs: Ana Paula Pego, *INEB - Instituto de Engenharia Biomédica, Portugal*  
Lucy Di Silvio, *King's College London Guy's Hospital, United Kingdom*  
Małgorzata Krok-Borkowicz, *AGH University of Science and Technology, Poland (YSF Chair)*

- |       |     |   |
|-------|-----|---|
| 16:45 | 208 | <b>Biomaterial Systems for Delivery or Education of Immunosuppressive Dendritic Cells to Ameliorate Multiple Sclerosis in a Murine Model</b><br>Aline Thomas, Sangeetha Srinivasan, Jennifer Blanchfield, Aaron M. Rosado, Andres Garcia, Brian Evavold, <u>Julia Babensee</u><br><i>Georgia Institute of Technology, United States</i> |
| 17:00 | 209 | <b>Microdialysis and Proteomics – New Approaches to Analyse the Early Stages of Fracture Repair in Bone Defects</b><br><u>Yvonne Förster</u> , Johannes Schmidt, Sven Baumann, Ute Hempel, Martin von Bergen, Stefan Kalkhof, Stefan Rammelt<br><i>Technische Universität Dresden, Germany</i>  |
| 17:15 | 210 | <b>Cellular Recognition of Collagen Based Scaffolds</b><br><u>Daniel Bax</u> , Natalia Davidenko, Richard Farndale, Ruth Cameron, Serena Best<br><i>University of Cambridge, United Kingdom</i>   |
| 17:30 | 211 | <b>Multicellular Spheroids and 3D Scaffold Cultures Up-Regulate Different Events in Osteogenic Differentiation of Adipose-Derived Mesenchymal Stem Cells</b><br><u>Sławomir Rumiński</u> , Adam Zalewski, Małgorzata Lewandowska-Szumiel<br><i>Medical University of Warsaw, Poland</i>   |

## Session 44 Hall 3A

## Wound Healing 2

Chairs: Antonio Merolli, *The Catholic University Gemelli Medical School, Italy*  
Marc Bohner, *RMS Foundation, Switzerland*  
Patrycja Domalik-Pyzik, *AGH University of Science and Technology, Poland (YSF Chair)*

- |       |     |   |
|-------|-----|---|
| 16:45 | 212 | <b>Balancing Fibroblast Differentiation in a Biomimetic Wound Healing Model</b><br>Jiranuwat Sapudom, Michael Ansorge, Marina Chkolnikov, Katja Franke, Ulf Anderegg, <u>Tilo Pompe</u><br><i>Universität Leipzig, Germany</i>  |
| 17:00 | 213 | <b>New Bilayered Biodegradable Polymeric Systems. A Feasible Approach for Skin Lesions</b><br>Noemi Santurce, Álvaro González-Gómez, Raul Rosales, Marcela Martin del Campo-Fierro, Blanca Vazquez, <u>Julio San Roman</u><br><i>Institute of Polymers CSIC and CIBER-BBN, Spain</i>  |
| 17:15 | 214 | <b>Fluorescent Activated Cell Sorting (FACS) as a Tool to Quantify the Immune Cell Response to Intramuscular Implanted Materials in Rats</b><br>Tanja Schmidt, Zienab Kronbach, Marie Heinze, Susann Krummsdorf, Marcel Geilling, <u>Frank Witte</u><br><i>Berlin-Brandenburg Center For Regenerative Medicine, Germany</i> |
| 17:30 | 215 | <b>Endogenous Human Dermal Equivalent in Vitro Model to Study Wound Healing Process</b><br><u>Bernadette Lombardi</u> , Costantino Casale, Giorgia Imparato, Francesco Urciuolo, Paolo Netti<br><i>Istituto Italiano di Tecnologia, Italy</i>   |

## Session 45 Hall 3B

### Bone Cements

Chairs: Heinz Redl, *Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, Austria*  
Zbigniew Jaegermann, *Institute of Ceramics and Building Materials, Poland*  
Anton Goncharenko, *V.N. Karazin Kharkiv National University, Ukraine (YSF Chair)*

- |       |     |  |
|-------|-----|--|
| 16:45 | 216 | <b>Modification of Calcium Phosphate Bone Cements with Biologically Active Metal Ions: In Vitro and In Vivo Characterization</b><br><i>Anja Lode, Anne Bernhardt, Barbe Rentsch, Claudia Rentsch, Martha Geffers, Mandy Quade, Stefan Rammelt, Uwe Gbureck, Michael Gelinsky</i><br><i>Technische Universität Dresden, Germany</i> |
| 17:00 | 217 | <b>Development of Novel Implants with Embedded Therapeutics</b><br><i>Sophie Cox, Hany Hassanin, Moataz Attallah, Duncan Shepherd, Owen Addison, Uwe Gbureck, Liam Grover</i><br><i>University of Birmingham, United Kingdom</i>   |
| 17:15 | 218 | <b>The Influence of Phase Change Materials Based on Poly(Ethylene Glycol) on the Properties of Acrylic Bone Cements</b><br><i>Kinga Pielichowska, Katarzyna Filipek</i><br><i>AGH University of Science and Technology, Poland</i>   |
| 17:30 | 219 | <b>Marine Collagen Reinforcement of Calcium Phosphate Bone Cements: A Biological Assessment</b><br><i>Iwan Palmer, John Nelson, Wolfgang Schatton, Nicholas Dunne, Fraser Buchanan, Susan Clarke</i><br><i>Queen's University, United Kingdom</i>  |

## Session 46 Hall 4A

### Nanoparticles

Chairs: Josep A. Planell, *Universitat Oberta de Catalunya, Spain*  
Aneta Frączek-Szczypta, *AGH University of Science and Technology, Poland*  
Hyeyoun Chang, *Korea University of Science and Technology, Korea (YSF Chair)*

- |       |     |   |
|-------|-----|---|
| 16:45 | 220 | <b>Cellular Uptake and Degradation of Poly(Lactide-co-Glycolide) Nanoparticles and its Influences on Cell Functions</b><br><i>Dahai Yu, Pengfei Jiang, Zhengwei Mao, Changyou Gao</i><br><i>Zhejiang University, China</i>  |
| 17:00 | 221 | <b>Evaluation of Biological Effects of Nanomaterials on Human Cell Line, EA.hy926</b><br><i>Małgorzata Siatkowska, Tomasz Wasiak, Paulina Sokołowska, Joanna Rywaniak, Katarzyna Działoszyńska, Sylwia Kotarba, Kinga Kądzioła, Nina Bartoszek, Marta Kamińska, Agnieszka Kołodziejczyk, Piotr Komorowski, Krzysztof Makowski, Bogdan Walkowiak</i><br><i>Lodz University of Technology, Poland</i> |
| 17:15 | 222 | <b>Gellan-Gum Coated Gold Nanorods as Intracellular Drug Release System for Osteogenic differentiation</b><br><i>Stephanie Vial, Silvia Vieira, Fatima Maia, Mariana Carvalho, Rui Reis, Pedro Granja, Joaquim Oliveira</i><br><i>3Bs Research Group, Portugal</i>  |
| 17:30 | 223 | <b>On the Influence of Various Physiochemical Properties of the CNTs Layers on the Cell's Reaction In Vitro</b><br><i>Aleksandra Benko, Elzbieta Menaszek, Marek Nocurń, Marta Błażewicz, Aneta Frączek-Szczypta</i><br><i>AGH University of Science and Technology, Poland</i>   |

Science for Industry (3)  
Bioresorbable Materials for Medical Applications

Organizers: Xiang Zhang, Ipsita Roy, Kadem Al-Lamee, Stuart Maclachlan, Maria Joao Barros,  
Nial Bullett, Mark Taylor

16:45	<b>Welcome back and overview of morning's proceedings</b> Xiang Zhang, Ipsita Roy
16:55	<b>Research into Bioresorbable Systems</b> <u>Elena Boccardi</u> , <i>University of Erlangen-Nuremberg, Germany</i> <u>Zein Azhari</u> , <i>Cambridge University, United Kingdom</i>
17:15	<b>Panel discussion and overview of proceedings with speakers from the Bioresorbable System Session</b>

Hall 1		Plenary Lecture 8
9:00	L8	<b>Biological-Basis for Designing Biomaterials for the Injured and Degenerated Host - Examples in the Neural Space</b> <u>Abhay Pandit</u> <i>Network of Excellence for Functional Biomaterials, National University of Ireland, Galway, Ireland</i>  <b>Chairs:</b> Laura Poole-Warren, <i>University of New South Wales, Sydney, Australia</i> Jadwiga Laska, <i>AGH University of Science and Technology, Poland</i>

Session 47 Hall 1		Neural Regeneration 3
		<b>Chairs:</b> Jadwiga Laska, <i>AGH University of Science and Technology, Poland</i> Serena Best, <i>University of Cambridge, United Kingdom</i> Caroline Kohn, <i>Universität Leipzig, Germany</i> (YSF Chair)
10:00	224	<b>Novel Collagen Type I-Hyaluronic Acid Bi-Phasic Conduit for Peripheral Nerve Repair: an In Vivo Study</b> <u>Tijna Alekseeva</u> , Phoebe E. Roche, Amos Matsiko, Amro Widaa, William A. Lackington, Alan Ryan, Alan J. Hibbitts, Garry Duffy, Fergal J. O'Brien <i>Royal College of Surgeons in Ireland, Ireland</i>
10:15	225	<b>Sustained Biochemical Signalling and Contact Guidance Provided by Electrospun Bicomponent Scaffolds for Enhancing Nerve Regeneration</b> <u>Chaoyu Liu</u> , Min Wang <i>The University of Hong Kong, Hong Kong</i>
10:30	226	<b>The “Micro” and “Macro”- Scale Approach in Building Up Neural Stem Cell Microenvironments for Developmental and Toxicity Studies</b> <u>Leonora Buzanska</u> , Marzena Zychowicz, Krystyna Pietrucha, Martyna Podobinska, Jose Luis Gerardo Nava, Gary Brook <i>Mossakowski Medical Research Centre PAS, Poland</i>
10:45	227	<b>Pre-Clinical Investigation of a Novel Biodegradable Polymer Based Medical Device for Peripheral Nerve Regeneration</b> <u>Atefeh Mobasser</u> i, Giorgio Terenghi, Adam Reid, Julie Gough, David Richards <i>University of Manchester, United Kingdom</i>

## Session 48 Hall 2

### Bone Tissue Engineering 5

Chairs: Aldo Boccaccini, *University of Erlangen-Nuremberg, Germany*  
Rui Reis, *3B's Research Group - University of Minho, Portugal*  
Thomas Paterson, *University of Sheffield, United Kingdom (YSF Chair)*

10:00	228	<b>Decrease of MRI Artifact in Spinal Instruments of Zirconium Alloy</b> <u>Takao Hanawa</u> , Naoyuki Nomura, Maki Ashida, Yusuke Tsutsumi, Hisashi Doi, Peng Chen, Manabu Itoh <i>Tokyo Medical and Dental University, Japan</i>
10:15	229	<b>Investigation of Degradation Behavior and Corrosion of Magnesium Alloys for Orthopedic Implants</b> <u>Iulian Antoniac</u> , Ana Blajan, Aurora Antoniac <i>University Politehnica of Bucharest, Romania</i>
10:30	230	<b>Polyurethane-Ceramic Matrices as Orbital Implants</b> Semih Sahan, Pezhman Hosseinian, Deniz Ozdil, Mustafa Turk, <u>Halil Murat Aydin</u> <i>Hacettepe University, Turkey</i>
10:45	231	<b>Bioresorbable Multifunctional Composite Devices – Practical Aspects of Miniplates for Osteosynthesis</b> <u>Karol Gryń</u> , Barbara Szaraniec, Maja Kuś, Kamil Dudziński, Jan Chłopek <i>AGH University of Science and Technology, Poland</i>

## Session 49 Hall 3A

### Clinical Trials

Chairs: Dimosthenis Mavrilas, *University of Patras, Greece*  
Ryszard Uklejewski, *Casimir the Great University, Poland*  
Shahram Ghanaati, *Medical Center of the Goethe University Frankfurt, Germany (YSF Chair)*

10:00	232	<b>Clinically Used Dextran Coated Iron Oxide Nanoparticles and Their Induced Macrophage Autophagy</b> Rongrong Jin, Jiuju Du, James Anderson, <u>Hua Ai</u> <i>Sichuan University, China</i>
10:15	233	<b>Radiodensitometric Assessment Long Time after Dental Periimplantitis Defect Filled with “Pure” Synthetic HAp Bioceramics</b> <u>Vadims Klimecs</u> , Girts Salms, Andrejs Skagers, Aleksandrs Grishulonoks, Laura Neimane, Liga Berzina-Cimdina, <i>Institute of Stomatology, Latvia</i>
10:30	234	<b>Debris of a Carbon-Fibre-Reinforced Polymers (CFRP) Wrist Plate Led to a Destructive Synovitis in Human</b> <u>Antonio Merolli</u> , Lorenzo Rocchi, Alessandro Morini, Luigi Mingarelli, Paolo Scialabba D'Amico, Francesco Fanfani <i>The Catholic University of Rome, Italy</i>
10:45	235	<b>Clinical Performance of Moldable Bioceramic for Bone Regeneration in Maxillofacial Surgery</b> <u>Guy Daculsi</u> , Thomas Miramond, Pascal Borget, Elodie Seris <i>Inserm UMRS 791 Lioad, France</i>

## Session 50 Hall 3B

### Antimicrobial Surfaces and Materials 4

Chairs: Pentti Tengvall, *University of Gothenburg, Sweden*

Lukasz Major, *Institute of Metallurgy and Materials Science PAS, Poland*

Bora Onat, *Middle East Technical University, Turkey (YSF Chair)*

- 
- |       |     |   |
|-------|-----|---|
| 10:00 | 236 | <b>Antibacterial Effect of Bioactive Starch-Based Scaffolds Functionalized with Silanol Groups</b><br><u>Ana Rodrigues</u> , Albina Franco, Fernando Rodrigues, António Castro, Isabel Leonor, Rui Reis<br><i>3Bs Research Group, Portugal</i>                        |
| <hr/> |     |   |
| 10:15 | 237 | <b>Bioactive Orthopaedic Devices Preventing Biofilm Formation and Local Infection</b><br>Loïc Pichavant, Hélène Carrié, Laurent Plawinski, Jocelyne Caillon, Gilles Amador,<br>Valérie Héroguez, <u>Marie-Christine Durrieu</u><br><i>Université Bordeaux, France</i> |
| <hr/> |     |   |
| 10:30 | 238 | <b>Anti-Bacterial Borosilicate Glass Formulations for Bone Tissue Engineering Applications</b><br><u>João S. Fernandes</u> , Margarida Martins, Nuno N. Neves, Ricardo A. Pires, Rui L. Reis<br><i>3Bs Research Group, Portugal</i>                                   |
| <hr/> |     |   |
| 10:45 | 239 | <b>Alginate/Chitosan-Based Materials with Bioactive Functionalities</b><br><u>Agnieszka Kyzioł</u> , Anna Regiel-Futyr, Aleksandra Mazgala, Justyna Michna,<br>Małgorzata Kus-Liśkiewicz, Silvia Irueta<br><i>Jagiellonian Univeristy, Poland</i>                     |
- 

## Session 51 Hall 4A

### Biomimetic Materials

Chairs: Sanjukta Deb, *King's College, United Kingdom*

Anna Ślósarczyk, *AGH University of Science and Technology, Poland*

Nina Henry, *INSERM, France (YSF Chair)*

- 
- |       |     |  |
|-------|-----|--|
| 10:00 | 240 | <b>First Principles Modelling to Establish the Thermodynamically Most Favourable Form and Position of Silicon in Bone Mineral</b><br><u>Helen Chappell</u> , Ravin Jugdaohsingh, Jonathan Powell<br><i>MRC Human Nutrition Research, United Kingdom</i>  |
| <hr/> |     |  |
| 10:15 | 241 | <b>Modification of Living Diatom, <i>Thalassiosira weissflogii</i> by Calcium Precursor as a Sacrificial Template for Development of Next Generation of Structural Biomaterials</b><br><u>Asrizal Abdul Rahman</u> , Syed Ansar Md. Tofail, Abhay Pandit<br><i>National University of Ireland, Galway, Ireland</i>   |
| <hr/> |     |  |
| 10:30 | 242 | <b>Fabrication and Histological Evaluation of Carbonate Apatite Coated Calcite</b><br><u>Kunio Ishikawa</u> , Kanji Tsuru, Masako Kobayashi, Youji Miyamoto<br><i>Kyushu University, Japan</i>   |
| <hr/> |     |  |
| 10:45 | 243 | <b>Crystallization and Thermal Evolution of Pyrophosphate Polymorphs and Prospective Biomaterials with a Metastable <math>\alpha</math>1-Calcium Pyrophosphate from Amorphous Calcium Phosphates with an Initial CaP Ratio of 1:1</b><br>Zoltan Zyman, Matthias Epple, Anton Goncharenko, Dmytro Rokhmistrov<br><i>V.N. Karazin Kharkiv National University, Ukraine</i> |
- 

## Session 52 Hall 4B

### Osteointegration 2

Chairs: Jerome Guicheux, *INSERM U791 LIOAD, France*  
Helmut Thissen, *CSIRO Manufacturing Flagship, Australia*  
Monika Golda-Cępa, *Jagiellonian University, Poland (YSF Chair)*

- |       |     |  |
|-------|-----|--|
| 10:15 | 244 | <b>Functionally Graded Hybrid Scaffolds for Osteo-Chondral Defect Repair: Scaffold Design</b><br>Serena Bertoldi, Masoumeh Meskinfam, Paola Petrini, Alessandro Cerri, Nicolò Albanese, MariaCristina Tanzi, <u>Silvia Farè</u><br><i>Politecnico di Milano, Italy</i>                                       |
| 10:30 | 245 | <b>Formation of Hybrid Materials Based on Calcium Phosphate Deposit on Carbon Fiber Scaffold</b><br>Quentin Picard, <u>Lise Guichaoua</u> , Sandrine Delpoux, Nathalie Rochet, Jérôme Chancolon, Franck Fayon, Fabienne Warmont, Sylvie Bonnamy<br><i>Université d'Orléans, France</i>                       |
| 11:00 | 246 | <b>Emulsion Templating: a Versatile Route to the Preparation of Biodegradable and Biocompatible Scaffolds for Tissue Engineering</b><br>Caitlin Langford, David Johnson, Neil Cameron<br><i>Monash University, Australia</i>   |
| 11:15 | 247 | <b>Cross-Linked, Macroporous Hybrid Glass Implants of Defined Architecture for Bone Regeneration</b><br><u>Stephan Hendrixx</u> , Christian Kascholke, Tobias Flath, Christian Raack, Mathias Gressenbuch, Peter Schulze, Michael C. Hacker, Michaela Schulz-Siegmund<br><i>Universität Leipzig, Germany</i> |

## Session 53 Hall 1

### Advanced Manufacturing 3

Chairs: Jérôme Sohier, *CNRS Institute of Biology and Chemistry of Proteins, France*  
Tomasz Goryczka, *University of Silesia, Poland*  
Barbara Lukasiewicz, *University of Westminster, United Kingdom (YSF Chair)*

- |       |     |   |
|-------|-----|---|
| 11:30 | K14 | <b>Keynote</b><br><b>3D Fiber Deposition and Stereolithography Techniques for the Design of Multifunctional Nanocomposite Magnetic Scaffolds</b><br><u>Roberto De Santis</u> , Ugo D'Amora, Teresa Russo, Alfredo Ronca, Antonio Gloria, Luigi Ambrosio<br><i>IPCB-CNR Institute of Polymers, Composites and Biomaterials – Naples, Italy</i> |
| 12:00 | 248 | <b>Tailoring Porosity from the Nano- to the Macroscale of Low-Temperature Consolidated Robocasted Scaffolds</b><br><u>Edgar B. Montufar</u> , Yassine Maazouz, Borja Gonzalez, Ladislav Celko, Jozef Kaiser, Maria-Pau Ginebra<br><i>Technical University of Catalonia, Spain</i>   |
| 12:15 | 249 | <b>Development of Bioactive and Antimicrobial 3D Plotted PCL Scaffolds for Bone Tissue Engineering</b><br>Giuseppe Cama, Myriam Gomez Tardajos, Peter Dubruel<br><i>Ghent University, Belgium</i>   |
| 12:30 | 250 | <b>Two-Photon Polymerization ofOrmocomp® 3D Structures Doped with Piezoelectric Barium Titanate Nanoparticles</b><br>Attilio Marino, Jonathan Barsotti, Massimiliano Labardi, Barbara Mazzolai, Virgilio Mattoli, Gianni Ciofani<br><i>Italian Institute of Technology, Italy</i>   |
| 12:45 | 251 | <b>Additive Manufacturing of Poly-High Internal Phase Emulsion Scaffolds with Tuneable Mechanical Properties for Bone Tissue Engineering</b><br>Robert Owen, Colin Sherborne, Gwendolen Reilly, <u>Frederik Claeysens</u><br><i>The University of Sheffield, United Kingdom</i>   |

## Session 54 Hall 2

### Bone Tissue Engineering 6

Chairs: Elizabeth Tanner, *University of Glasgow School of Engineering, United Kingdom*  
Serena Best, *University of Cambridge, United Kingdom*  
Anna Donesz-Sikorska, *Wrocław University of Technology, Poland (YSF Chair)*

- |       |     |  |
|-------|-----|--|
| 11:30 | K15 | <b>Keynote</b><br><b>Polymer Brush-Assisted Fabrication of Protein Gradients Inside of 3D Microporous Scaffolds</b><br>Andrea Di Luca, Michel Klein Gunnewiek, Hermen Bollemaat, Clemens van Blitterswijk, Julius Vancso, Edmondo Benetti, <u>Lorenzo Moroni</u><br><i>University of Maastricht, Netherlands</i>                                 |
| 12:00 | 252 | <b>Osteogenic Potential of Self-Assembling Bioceramic Nanoparticles</b><br><u>Michelle O'Doherty</u> , Sreekanth Pentlavalli, Philip Chambers, Marine Chalanqui, Helen McCarthy, Nicholas Dunne<br><i>Queen's University Belfast, United Kingdom</i>   |
| 12:15 | 253 | <b>Results of Pilot Experimental Studies in 10 Animals on Prototype of the Multispiked Connecting Scaffold with Thermo-Electrochemically Ca-P Modified Surface for Non-Cemented Biofixation of RA Endoprostheses</b><br>Ryszard Uklejewski, Piotr Rogala, Mariusz Winiecki, Wanda Stryła<br><i>Casimir the Great University, Poland</i>          |
| 12:30 | 254 | <b>Analysis of Osteoinductive Properties of Combinations of Macroporous Ceramic (MBCP+™), Simvastatin, rhBMP-2, and BMSC in a Femoral Critical Size Induced Membrane Model in Rats</b><br><u>Erwan de Mones</u> , Silke Schlaubitz, Reine Bareille, Lionel Couraud, Jean-Christophe Fricain<br><i>INSERM U1026, France</i>                       |
| 12:45 | 255 | <b>The Influence of Calcium Phosphate Microparticle Incorporation in Highly Orientated Macroporous Collagen Scaffolds on the Mechanism of Bone Defect Healing</b><br><u>Ansgar Petersen</u> , Hans Leemhuis, Andreas Hoess, Agnes Ellinghaus, Berthold Nies, Ingo Heschel, Georg N. Duda<br><i>Charité – Universitätsmedizin Berlin, Germany</i> |

## Session 55 Hall 3A

### Cardiovascular Applications 3

Chairs: Lucie Bacakova, *Academy of Sciences of the Czech Republic, Czech Republic*  
Kinga Pielichowska, *AGH University of Science and Technology, Poland*  
Claudia Navarro, *Institute for Bioengineering of Catalonia, Spain (YSF Chair)*

- |       |     |   |
|-------|-----|---|
| 11:30 | K16 | <b>Keynote</b><br><b>Elastomeric Materials of Enhanced Mechanical Performance for Implantable Artificial Heart</b><br>Agnieszka Piegat, <u>Mirosława El Fray</u><br><i>West Pomeranian University of Technology, Szczecin, Poland</i>   |
| 12:00 | 256 | <b>Preparation of a Small Diameter Decellularized Blood Vessel Covered with SPU Fibers by Electrospinning</b><br><u>Tsuyoshi Kimura</u> , Hiroko Morita, Pingli Wu, Naoko Nakamura, Kwangwoo Nam, Toshiya Fujisato, Akio Kishida<br><i>Tokyo Medical and Dental University, Japan</i>   |
| 12:15 | 257 | <b>Blend Electrospinning of Biodegradable Chitosan/Polycaprolactone Fibers as a Process to Create Scaffolds for Cardiovascular Tissue Engineering</b><br>Alexandros Repanas, Birgit Glasmacher, Alexandra Theodoropoulou, <u>Dimosthenis Mavrilas</u><br><i>University of Patras, Greece</i>  |
| 12:30 | 258 | <b>Designing Novel Polymeric Endovascular Devices</b><br>Daniel Cohn, Randa Abbas, Fany Widlan, Matthew Zarek, Ram Malal, Allan Bloom<br><i>The Hebrew University of Jerusalem, Israel</i>  |
| 12:45 | 259 | <b>Mechanical Characterization of Small Diameter Grafts Made of Segmented Polyurethanes Based on Alkaline Aminoacids</b><br>Omar Castillo-Cruz, Francis Aviles, Rossana F. Vargas-Coronado, Jose Manuel Cervantes-Uc, <u>Juan Valerio Cauich-Rodriguez</u> , Lerma Hannaiy Chan-Chan<br><i>Centro de Investigación Científica de Yucatán, Mérida, Yucatán, Mexico</i> |

**Session 56**  
**Hall 3B**

**Surface Modification 5**

Chairs: Kunio Ishikawa, *Kyushu University, Japan*

Tomasz Moskaiewicz, *AGH University of Science and Technology, Poland*

Aleksandra Benko, *AGH University of Science and Technology, Poland (YSF Chair)*

11:30	260	<b>Patterning of Neuron Adhesion and Differentiation on Diamond-Like Carbon by Pulsed Laser Ablation</b> <u>James Dugan</u> , Frederik Claeysens <i>University of Sheffield, United Kingdom</i>
11:45	261	<b>Electrochemically Assisted Deposition of Strontium Modified Magnesium Phosphate on Titanium Surfaces</b> Markus Meininger, Julia Zerweck, Cornelia Wolf-Brandstetter, Uwe Gbureck, Jürgen Groll, <u>Claus Moseke</u> <i>University of Würzburg, Germany</i>
12:00	262	<b>Hydrothermally-Treated Nano-Crystalline TiO<sub>2</sub> Coatings Boost the "Race for the Surface" Towards Osteogenesis rather than Bacterial Adhesion</b> <u>Martina Lorenzetti</u> , Iztok Dogša, David Stopar, Katrin Susanne Lips, Reinhard Schnettler, Mitjan Kalin, Spomenka Kobe, Saša Novak <i>Jožef Stefan Institute, Slovenia</i>
12:15	263	<b>Covalent Attached Fibronectin Fragment-PLDLLA Nanofibers on Titanium for Guiding Osteoblast Behaviour</b> <u>Jordi Guillem-Marti</u> , Gerard Boix-Lemonche, Dencho Gugutkov, George Altankov, Francisco Javier Gil, Jose Maria Manero <i>Technical University of Catalonia (UPC), Spain</i>
12:30	264	<b>Morphometric Examination of Local Tissue Reactions following Implantation of Ti<sub>6</sub>Al<sub>4</sub>V Plates Coated with Anti-Adhesive Plasma-Fluorocarbon-Polymer Films in Rats</b> <u>Andreas Hoene</u> , Birgit Finke, Holger Testrich, Silke Lucke, Uwe Walschus, Karsten Schröder, Jürgen Meichsner, Maciej Patrzyk, Michael Schlosser <i>University Medical Center Greifswald, Germany</i>
12:45	265	<b>Evaluation of Biological Response of Implants Modified by Carbon Coatings with Si (Si-DLC)</b> <u>Dorota Bociaga</u> , Jacek Grabarczyk, Joanna Piasecka-Zelga, Jan Skowroński, Piotr Niedzielski <i>Lodz University of Technology, Poland</i>

**Session 57**  
**Hall 4A**

**Smart Biomaterials 2**

Chairs: Manus Biggs, *National University of Ireland, Galway, Ireland*

Helen Chappell, *MRC Human Nutrition Research Biominerals Research, United Kingdom*

Valentina Bonfrate, *University of Salento, Italy (YSF Chair)*

11:30	266	<b>Biodegradable Semiconductor Hydrogels for the Photothermal Control of Growth Factor Bioavailability</b> <u>Francisco Martín-Saavedra</u> , Martín Prieto, Manuel Arruebo, Jesús Santamaría, Nuria Vilaboa <i>La Paz University Hospital-IdiPAZ, Spain</i>
11:45	267	<b>Nanoporous Bead and Monolith Adsorbents for Haemoperfusion Applications</b> Yishan Zheng, Susan Sandeman, Ganesh Ingavle, Carol Howell, Sandeep Kumar, Matthew Pope, Michal Kowalski, Kolitha Basnayake, Steve Tension, Sergey Mikhailovsky <i>University of Brighton, United Kingdom</i>
12:00	268	<b>Biodegradable Temperature-Responsive Injectable Polymer Formulation Convenient at Clinical Scene</b> <u>Yuichi Ohya</u> , Yasuyuki Yoshida, Akihiro Takahashi, Akinori Kuzuya <i>Kansai University, Japan</i>
12:15	269	<b>Mechanical and Cytotoxic Evaluation of a Novel Hydrogel with Potential to Deliver Bioceramic Nanoparticles</b> <u>Sreekanth Pentlavalli</u> , Michelle O'Doherty, Philip Chambers, Marine Chalanqui, Helen McCarthy, Nicholas Dunne <i>Queen's University, United Kingdom</i>
12:30	270	<b>Thermally Modulated Mesenchymal Stem Cell Separation Using Thermoresponsive Cationic Copolymer Brush</b> <u>Kenichi Nagase</u> , Yuri Hatakeyama, Tatsuya Shimizu, Katsuhisa Matsuura, Masayuki Yamato, Naoya Takeda, Teruo Okano <i>Tokyo Women's Medical University, Japan</i>
12:45	271	<b>Biopolymer Mediated Uptake of Sugar Molecules for Cell Preservation and Therapy</b> <u>Rongjun Chen</u> , Andrew Lynch, Liwei Wu, Zhenlu Hu, Nigel Slater <i>Imperial College London, United Kingdom</i>

**Session 58  
Hall 4B**

**Drug Delivery 4**

Chairs: David Eglin, *AO Research Institute Davos, Switzerland*  
Henning Menzel, *University of Technology Braunschweig, Germany*  
Jiankang Song, *Radboud University, Netherlands (YSF Chair)*

11:30	272	<b>Lipid Nanoparticles Loaded into Biopolymer-Based Hydrogels; Materials for Controlled Rate of Drug Delivery</b> Lisa Racine, Rachel Auzély-Velty, <u>Isabelle Texier</u> <i>Université Grenoble Alpes, CEA/DTBS, France</i>
11:45	273	<b>Selective In Vitro Anticancer Effect of Hyaluronan Polymeric Micelles Loaded with SPIONs</b> Daniela Smejkalova, Kristina Nesporova, Gloria Huerta-Angeles, Jakub Syrovatka, Andrea Galisova, Daniel Jirak, Vladimir Velebny <i>Contipro Pharma, Czech Republic</i>
12:00	274	<b>Injectable Hydrogel Based on a Novel Amphiphilic Hyaluronic Acid Derivative for Controlled Drug Release</b> Assunta Borzacchiello, Luisa Russo, Fabio Salvatore Palumbo, Stefano Agnello, Giovanna Pitarresi, Gaetano Giammona, Luigi Ambrosio <i>Institute for Composite and Biomedical Materials IMCB-CNR, Italy</i>
12:15	275	<b>Polysaccharide-Based Nanomicrosystems for Controlled Delivery of Anti-Inflammatory Agents</b> <u>Anna Krawiec</u> , Agnieszka Rojewska, Marta Baster, Elena Iruin Amatriain, Michał Rączy, Maria Nowakowska <i>Jagiellonian University, Poland</i>
12:30	276	<b>Combination of Different BMP2- Peptide Release Mechanisms from Natural Polymeric Systems</b> <u>Daniela Giugliano</u> , Maria Grazia Raucci, Luigi Ovaleo Pandolfo, Alessandra Sorinte, Luigi Ambrosio <i>Institute of Polymers, Composites and Biomaterials – National Research Council of Italy, Italy</i>
12:45	277	<b>Mesoporous Bioactive Glass/CaP Bone Cement Composites for the Delivery of the Growth Factor BDNF</b> <u>Matthias Schumacher</u> , Katrin S. Lips, Michael Gelinsky <i>Technische Universität Dresden, Germany</i>

# Rapid Fire Presentations (1)

Monday, 31<sup>st</sup> August (start at 13:30)

278	<b>Development of Novel Bioresorbable Iron-silver Materials and their in vitro Degradation Behavior</b> <u>Sanjaya K. Swain</u> , David Starosvetsky, Irena Gotman, Elazar Y. Gutmanas <i>Israel</i>
279	<b>Dissolution Behaviours of MgO-P<sub>2</sub>O<sub>5</sub>-TiO<sub>2</sub>/Nb<sub>2</sub>O<sub>5</sub> Glasses in MgO-rich Region</b> <u>Sungho Lee</u> , Hiroataka Maeda, Akiko Obata, Kyosuke Ueda, Takayuki Narushima, Toshihiro Kasuga <i>Japan</i>
280	<b>Development of Structurally Analogous Cryoprotective Synthetic Polyampholytes and Elucidation of Mechanism</b> <u>Robin Rajan</u> , Kazuaki Matsumura <i>Japan</i>
281	<b>Shear- Thinning Soft Bionanocomposites Based on Laponite and Poly-L-Lysine for Cell Delivery Purposes</b> <u>Minkle Jain</u> , Kazuaki Matsumura <i>Japan</i>
282	<b>Viscoelastic Behaviour of Embroidered Scaffolds for the Tissue Engineering of Ligaments</b> <u>Judith Hahner</u> , Claudia Hinüber, Annette Breier, Gert Heinrich <i>Germany</i>
283	<b>Exploring the Limits of Scaffold Interconnectivity for Cell Type Specific Invasion</b> <u>Jennifer Ashworth</u> , Marco Mehr, Paul Buxton, Serena Best, Ruth Cameron <i>United Kingdom</i>
284	<b>The Impact of Thrombocytes on the Cell Proliferation within the 3D Scaffolds</b> <u>Kateřina Pilařová</u> , Věra Jenčová, Jana Horáková, Jakub Erben, Jiří Chvojka, David Lukáš <i>Czech Republic</i>
285	<b>Development of a Valved Conduit for Venal Reconstruction</b> <u>Sonia Zia</u> , Lucrezia Morticelli, Karsten Grote, Igor Tudorache, Sergei Cebotari, Andres Hilfiker, Birgit Glasmacher, Axel Haverich, Sotirios Korossis <i>Germany</i>
286	<b>Biocompatible Collagen Paramagnetic Scaffold for Controlled Drug Release</b> <u>Valentina Bonfrate</u> , Simona Bettini, Luca Salvatore, Marta Madaghiele, Ludovico Valli, Gabriele Giancane, Alessandro Sannino <i>Italy</i>
287	<b>Uptake of Nanoparticles by Macrophage Cell Line Predicts In Vivo Clearance by Reticuloendothelial System</b> <u>Hyeoun Chang</u> , Ick Chan Kwon, Kwangmeyung Kim <i>Republic of Korea</i>
288	<b>Development of Novel Biomaterials, Natural Polymers, Polyhydroxyalkanoates (PHAs), for Biomedical Applications</b> <u>Barbara Lukasiwicz</u> , Pooja Basnett, Ipsita Roy <i>United Kingdom</i>
289	<b>Does Ascorbic Acid Modified Polyurethanes May be Suitable Candidates for Soft Tissue Engineering?</b> <u>Iga Gubanska</u> , Justyna Kucinska-Lipka, Marta Pokrywczynska, Tomasz Drewa, Helena Janik <i>Poland</i>
290	<b>Thermal Crystallization and Phase Evolution in the Amorphous Calcium Phosphate Powders with a Ca/P Ratio of 1:1</b> <u>Anton Goncharenko</u> , Matthias Eppler, Zoltan Zyman, Dmytro Rokhmistrov <i>Ukraine</i>

# Rapid Fire Presentations (2)

Tuesday, 1<sup>st</sup> September (start at 13:30)

291	<b>Methodological Evaluation of Quantitative <i>in Vivo</i> MRI Volume Measurements of Hydrogels by <i>ex Vivo</i> CT Imaging</b> <u>Christoph Tondera</u> , Sandra Ullm, Sebastian Meister, Tim P. Gebauer, Axel T. Neffe, Andreas Lendlein, Jens Pietzsch <i>Germany</i>
292	<b>Intraocular Lenses with Surfaces Functionalized by Biomolecules in Relation with Lens Epithelial Cell Adhesion</b> <u>Yi-Shiang Huang</u> , Virginie Bertrand, Dimitriya Bozukova, Christophe Pagnoulle, Edwin De Pauw, Marie-Claire De Pauw-Gillet, Marie-Christine Durrieu <i>Belgium</i>
293	<b>Introducing Controlled Nano-Roughness in 3D Silk Fibroin Scaffolds for Bone Tissue Engineering</b> <u>Marianne R. Sommer</u> , Ralph Müller, Sandra Hofmann, André R. Studart <i>Switzerland</i>
294	<b>Effect of Calcium Phosphate Ceramic Substrate Geometry on Cell Organization and Behaviour</b> <u>A. Hayrapetyan</u> , E.R. Urquia Edreira, J.G.C. Wolke, J.A. Jansen, J.J.J.P. van den Beucken <i>Netherlands</i>
295	<b>Novel Approach Towards Osseointegration: Surface Functionalization on Zirconia</b> <u>Carlos Caravaca</u> , Liu Shi, Sandra Balvay, Pascaline Rivory, Emmanuelle Laurenceau, Yann Chevolot, Daniel Hartmann, Laurent Gremillard, Jérôme Chevalier <i>France</i>
296	<b>Novel Enzymatically Cross-linked Silk Fibroin Hydrogel with Potential Applications as Suppressor of Angiogenesis and Tumor Progression</b> Viviana Ribeiro, <u>Joana Silva-Correia</u> , Vera Miranda-Gonçalves, Le-Ping Yan, Ana L. Oliveira, Rui M. Reis, Rui L. Reis, Joaquim M. Oliveira <i>Portugal</i>
297	<b>Electrophoretic Deposition of Composite Coatings Based on ZnO Nanoparticles on Ti6Al7Nb Alloy</b> <u>Joanna Karbowniczek</u> , Luis Cordero-Arias, Aleksandra Czyrska-Filemonowicz, Aldo R. Boccacini <i>Poland</i>
298	<b>Bioactivation of SiO<sub>2</sub> Sol-gel Coatings as a Modification Method of Metallic Implants</b> <u>Anna Donesz-Sikorska</u> , Justyna Krzak, Jerzy Kaleta, Małgorzata Krok-Borkowicz, Elżbieta Pamuła <i>Poland</i>
299	<b>Multimodal Image Registration for Assessment of Bone Formation in Porous Metal Implants</b> <u>Hua Geng</u> , Taek Bo Kim, Aine Devlin, Naomi Todd, Kamel Madi, Julian R. Jones, Christopher Mitchell, Chris Sutcliffe, Sarah Cartmell, Peter D. Lee <i>United Kingdom</i>
300	<b>Injectable Hydroxyapatite Enriched Hyaluronate Gels for Versatile Tissue Engineering Applications</b> <u>Cecilia De León</u> , Elvira Estella, L. Téllez-Jurado, M.A. Álvarez-Pérez, Julio San Román, Luis M. Rodríguez-Lorenzo <i>Spain</i>
301	<b>Bone Induction by Surface Modified Calcium Phosphate Ceramics</b> <u>Rongquan Duan</u> , Davide Barbieri, Xiaoman Luo, Florence de Groot, Huipin Yuan, Joost D. de Bruijn <i>Netherlands</i>
302	<b>Optical Coherence Tomography as a Complementary Method to X-ray Computed Tomography in Dental Diagnosis</b> Marcin Strąkowski, Milena Supernak-Marczewska, <u>Paulina Strąkowska</u> , Ewa Kowalska, Maciej Kraszewski, Małgorzata Ryniec-Wilczyńska, Michał Trojanowski, Violetta Szyzik <i>Poland</i>
303	<b>Molecular Basis of the Gp36 MPER Fusogenic Activity</b> <u>Anna Maria D'Ursi</u> , Agostino Bruno, Mario Scrima, Manuela Grimaldi, Grazia Della Sala, Vittorio Limongelli <i>Italy</i>

# Rapid Fire Presentations (3)

Wednesday, 2<sup>nd</sup> September (start at 13:30)

304	<b>Engineering PEGylated Alginate Hydrogels for Cell Microencapsulation</b> <u>Solène Passemard</u> , François Noverraz, Virginia Crivelli, Redouan Mahou, Françoise Borcard, Sandrine Gerber-Lemaire, Christine Wandrey <i>Switzerland</i>
305	<b>Study of Biodegradation Impact on PLA/Graphene-Nanoplatelets Biocomposites Mechanical and Biological Properties</b> <u>Artur M. Pinto</u> , Carolina Gonçalves, Inês C. Gonçalves, Fernão D. Magalhães <i>Portugal</i>
306	<b>Osteoinductive and Antibacterial Coatings for Dental Implants</b> <u>Beatriz Palla</u> , Francisco Javier Romero, Mar Fernández, Julio Suay, Mariló Gurruchaga, Isabel Goñi <i>Spain</i>
307	<b>On-Demand Release of Dexamethasone from Conjugated Polymer Matrix</b> <u>Katarzyna Krukiewicz</u> , Artur P. Herman, Sławomir Boncel, Jerzy K. Żak <i>Poland</i>
308	<b>Mesoporous Silica Nanofibers as Drug Delivery Systems for Intervertebral Disc Regenerative Medicine: Analysis of Protein-Silica Interactions</b> <u>Nina Henry</u> , Johann Clouet, Catherine Le Visage, Eric Gautron, Bernard Humbert, Jérôme Guicheux, Jean Le Bideau <i>France</i>
309	<b>Regulation of Inflammatory Gene Expression by Functionalized Calcium Phosphate Nanoparticles with Different Delivery Strategies to the Gut</b> <u>Bernhard Neuhaus</u> , Annika Frede, Astrid Westendorf, Matthias Eppe <i>Germany</i>
310	<b>How the Interfacial Shear Strength in PLGA Fibre-Reinforced Brushite Cements Affects the Composites Mechanical Properties</b> <u>Stefan Maenz</u> , Max Hennig, Mike Mühlstädt, Elke Kunisch, Raimund W. Kinne, Frank Plöger, Jörg Bossert, Klaus D. Jandt <i>Germany</i>
311	<b>Heparinization of Calcium Phosphates: Towards Enhancing Biological Performance</b> <u>Anna Díez-Escudero</u> , Montserrat Espanol, Maria-Pau Ginebra <i>Spain</i>
312	<b>Intercellular Delivery of Self-Assembling Osteogenic Nanoparticles: Fate and Effect</b> <u>Philip Chambers</u> , Sreekanth Pentlavalli, Michelle O'Doherty, Marine Chalanqui, Helen O. McCarthy, Nicholas Dunne <i>Northern Ireland</i>
313	<b>Porous Particles as Cell Delivery Vehicles for Bone Tissue Engineering</b> <u>Thomas Paterson</u> , James Dugan, Colin Sherborne, Chia-Cheng Chen, Nicola Green, Gwendolen Reilly, Frederik Claeyssens <i>United Kingdom</i>
314	<b>Biodegradable SCL-PHA Composite Scaffolds for Bone Tissue Engineering</b> <u>Christy Thomas</u> , Aldo. R. Boccaccini, Ipsita Roy <i>United Kingdom</i>
315	<b>Multifunctional Anti-Adhesive Films Prepared by Layer-by-Layer Formation of Zwitterionic Micelles</b> <u>Bora Onat</u> , Vural Bütün, Sreeparna Banerjee, İrem Erel-Göktepe <i>Turkey</i>

# Poster Presentations

316	<b>Production of Spray Dried Calcium Phosphate-Gelatin Composite and The Impact of Cross-linking Agent on Composite Structure and Bioactivity in Simulated Body Fluid</b> <u>Tugba Basargan Ozsagioglu</u> , Gülhayat Nasun Saygili <i>Turkey</i>
317	<b>Preparation of Polycaprolactone-Polyethylene Glycol-Casein Bioblends using Spray Dryer</b> <u>Erhan Ozsagioglu</u> , Yuksel Avcibasi Guvenilir <i>Turkey</i>
318	<b>3D-Powder-Printing of Strontium Modified Magnesium Phosphate Cements for Bone Augmentation</b> Emilie März, Claus Moseke, Uwe Gbureck, Jürgen Groll, <u>Elke Vorndran</u> <i>Germany</i>
319	<b>Selection and Optimization of Hydroxyapatite and Chlorapatite Powders for 3D-printing</b> Zeinab Salary, Parastoo Parastoo Jamshidi, <u>Zuzanna Trzcíńska</u> , David Grossin, Ghislaine Bertrand, Olivier Marsan, Cédric Charvillat, Imane Demnati, Moataz Moataz Attallah, Artemis Stamboulis <i>United Kingdom</i>
320	<b>Zirconia-Ceria Hydroxide Sol-Gel Synthesis: Colloid Processing and Powders Preparation for Potential Biomedical Application</b> <u>Damian Nakonieczny</u> , Zbigniew Paszenda, Tomasz Radko <i>Poland</i>
321	<b>Influence of the Colloid System pH for the Phase Composition and Morphology of Cerium Oxide Doped Zirconia Powders – Properties Evaluation</b> <u>Damian Nakonieczny</u> , Zbigniew Paszenda, Sabina Drewniak, Tomasz Radko <i>Poland</i>
322	<b>Synthesis of MTA Powder by Spray-Pyrolysis</b> Jeong-Cheol Lee, Seung-Hoon Um, Bong Kyu Choi, <u>Sang-Hoon Rhee</u> <i>Republic of Korea</i>
323	<b>Direct Fabrication of Porous Titanium Implant via 3D Printing</b> <u>Pavan Kumar Srivas</u> , Kausik Kapat, Prabhash Dadhich, Pallabi Pal Pal, Bodhisatwa Das, Santanu Dhara <i>India</i>
324	<b>Preparation of Electroconductive Titania Scaffolds for Bone Tissue Regeneration</b> <u>Inga Narkevica</u> , Jurijs Ozolins <i>Latvia</i>
325	<b>A Novel Model of Nonalcoholic Fatty Liver Disease in a 3D Liver-on-Chip Device</b> <u>Manuele Gori</u> , Maria Chiara Simonelli, Luca Businaro, Marcella Trombetta, Alberto Rainer <i>Italy</i>
326	<b>Stainless Steels Alloyed with Molybden for Medical Applications</b> <u>Victor Geanta</u> , Ionelia Voiculescu <i>Romania</i>
327	<b>New Titanium Alloys for Medical Applications</b> <u>Ionelia Voiculescu</u> , Victor Geanta <i>Romania</i>
328	<b>A Novel Pluronic/Alginate Scaffold for 3D Liver Cell Culture</b> <u>Manuele Gori</u> , Sara Maria Giannitelli, Pamela Mozetic, Marcella Trombetta, Alberto Rainer <i>Italy</i>
329	<b>As-cast Biodegradable MgCa Alloys –Structure, Mechanical and Corrosion Properties</b> <u>Sonia Boczkal</u> , Michał Karaś, Anna Kozik, Dawid Kapinos, Marzena Lech-Grega <i>Poland</i>
330	<b>Bone Tissue Engineering Using Combined Additive Manufacturing and Microtomography with FEM Verification</b> <u>Jakub Kamiński</u> , Maciej Śniechowski, Sebastian Wroński, Janusz Malinowski, Jacek Tarasiuk <i>Poland</i>

331	<b>Investigating Neovascularization in Rat Decellularized Intestine - an in vitro Platform for Studying Angiogenesis</b> <u>Lindsey Dew</u> , Giulia Gigliobianco, Chuh Chong, Sheila MacNeil <i>United Kingdom</i>
332	<b>Development of a Bioengineered Vascular Niche for the Treatment of Type 1 Diabetes Mellitus</b> Valeria Perugini, <u>Mark Best</u> , Anna Guildford, Gary Phillips, Wendy Macfarlane, Adrian Bone, Matteo Santin <i>United Kingdom</i>
333	<b>Capture Antibodies to Biofunctionalize Vascular Prosthesis</b> Sven Liebler, Fritz Grunert, John Thompson, <u>Burkhard Schlosshauer</u> <i>Germany</i>
334	<b>Utilization of Biocompatible and Biodegradable Polymers in Stem Cell Research and Biomedical Applications</b> Malgorzata Sekula, <u>Patrycja Domalik-Pyzik</u> , Anna Morawska-Chochół, Jakub Czuchnowski, Zbigniew Madeja, Ewa Zuba-Surma, Jan Chłopek <i>Poland</i>
335	<b>High Throughput Materials Discovery of Polymers Resistant to Staphylococcus Epidermidis</b> <u>Andrew Hook</u> <i>United Kingdom</i>
336	<b>Fabrication of Antibacterial Multi-function Materials on Bioactive Micro Arc Oxidized TiO<sub>2</sub></b> Tzer-Min Lee, Yu-Pu Chu, Yen-Ting Liu <i>Taiwan, Province of China</i>
337	<b>Silver-Containing Bioceramics Based on Hydroxyapatite</b> <u>Zoltan Zyman</u> , Mykola Tkachenko, Tatiana Babkina <i>Ukraine</i>
338	<b>Antimicrobial and Toxicological Studies of Novel Chlorhexidine-Hexametaphosphate Nanoparticles for Coating Central Venous Catheters</b> Helena Grady, Sarah Maddocks, Margaret Saunders, Andrew Collins, Michele Barbour <i>United Kingdom</i>
339	<b>Anti-Biofilm Effects of Poly-epsilon-Lysine Dendrons and their Interactions with Bacterial Membranes</b> <u>Orode Aniejurengho</u> , Mariagemiliana Dessi, Steve Meikle, Matteo Santin <i>United Kingdom</i>
340	<b>Influence of Silver Additive on the Physicochemical Properties of the New Cement Type Biomaterials</b> <u>Dominika Siek</u> , Joanna Czechowska, Aneta Zima, Anna Ślósarczyk <i>Poland</i>
341	<b>In vitro Studies of Antibacterial Activity of Sol-Gel Bioglasses Containing Mg, Sr and Au</b> <u>Lidia Ciolek</u> , Andrzej Olszyna, Ewa Zaczyńska, Anna Czarny <i>Poland</i>
342	<b>Bone Allograft with Antibacterial Coating for Therapeutic Application</b> <u>István Hornyák</u> , Edit Madácsi, Pálma Kalugyer, Zsombor Lacza <i>Austria</i>
343	<b>Antimicrobial Efficiency and Bacterial Damage on Copper Surfaces</b> <u>Claudia Hahn</u> , Michael Hans, Frank Muecklich, Ralf Moeller, Reinhard Wirth, Guenther Reitz, Petra Rettberg <i>Germany</i>
344	<b>Antibacterial Sol-Gel Coating of Ceramic TiO<sub>2</sub> Scaffolds for Bone Regeneration</b> <u>David Wiedmer</u> , Cedric Bossard, Hanna Tiainen, Håvard Haugen <i>Norway</i>
345	<b>Metallic Copper as an Antimicrobial Agent for Infection Prevention</b> <u>Michael Hans</u> , Claudia Hahn, Marc Solioz, Ralf Möller, Frank Muecklich <i>Germany</i>
346	<b>Interaction and Miscibility of Biodegradable Polymers with Biologically Active Molecules</b> <u>Eva Sanchez-Rexach</u> , Inger Martínez de Arenaza, Emilio Meaurio, Jose-Ramon Sarasua <i>Spain</i>

347	<b>Bactericidal Behaviour of a New Biodegradable and Biocompatible PLDA/Mg Composite</b> Miguel Ángel Pacha-Olivenza, Juan Pablo Fernández-Hernán, Amparo María Gallardo-Moreno, José Luis González-Carrasco, Sandra Carolina Cifuentes, <u>María Luisa González-Martín</u> <i>Spain</i>
348	<b>Development and in vitro Testing of Gelatin-Based Antibacterial Burn Wound Dressings</b> Birgit Stubbe, <u>Sandra Van Vlierberghe</u> , Gilles Brackman, Mohaddeseh Amiri Aref, Henk Hoeksema, Stan Monstrey, Frank Vanhaecke, Piet Van Espen, Karolien Dewael, Tom Coenye, Peter Dubruel <i>Belgium</i>

764	<b>Physical Properties and Toxic Potential of Dental Composites Containing a Triazol-Monomer</b> Torbjørn Knarvang, Jan T. Samuelsen, Hilde Kopperud <i>Norway</i>
765	<b>Structures of Chosen Degradation Byproducts Originating from Alkali Treatment of Hyaluronan Oligosaccharides</b> <u>Ondrej Kotland</u> , Kristina Nesporova, Radovan Buffa, Petra Liskova, Daniela Smejkalova, Martina Hermannova, Marek Kuzma, Vladimir Velebný, Tereza Silova <i>Czech Republic</i>
766	<b>SEM Evaluation on Adaptation of Various Materials Interface under Composite Sandwich Restorations</b> <u>Sam'an Malik Masudi</u> , Ninin Sukminingrum <i>Malaysia</i>
767	<b>Microleakage in Open-Sandwich Class II Dental Restorations</b> <u>Sam'an Malik Masudi</u> , Ninin Sukminingrum <i>Malaysia</i>
768	<b>Microscopy Analysis of Cement-Enamel Junction in Teeth</b> <u>Urszula Stachewicz</u> , Wojciech Kożuch, Aleksandra Czyrska-Filemonowicz <i>Poland</i>
769	<b>Influence of Precipitation Conditions on Cytocompatibility of Hydroxyapatite Substrates</b> <u>Sophie Cox</u> , Parastoo Jamshidi, Richard Williams, Liam Grover, Kajal Mallick <i>United Kingdom</i>
770	<b>Characterisation of Bioresorbable Composite Performance for Validation of New On-Line Process Monitoring Technology</b> Mark Billham, Darren Whitaker, Marion McAfee, <u>Nicholas Dunne</u> , Fraser Buchanan <i>Ireland</i>
771	<b>Silica Nanoparticles Stability in Model Biological Media</b> <u>Beata Borak</u> , Błażej Poźniak, Rafał Wiglus, Robert Pązik <i>Poland</i>
772	<b>Direct Contact Cytotoxicity Evaluation of Three Different Tricalcium Silicate Cements Used in Dentistry – An in vitro Study</b> <u>Sivaprakash Rajasekharan</u> , Heidi Declercq, David Schaubroeck, Peter De Coster, Luc Martens <i>Belgium</i>
773	<b>Gene Expression Profiling and Molecular Signalling of Dental Pulp Cells in Response to Tricalcium Silicate Cements: A Systematic Review</b> <u>Elanagai Rathinam</u> , Sivaprakash Rajasekharan, Ravi Teja Chitturi, Luc Martens, Peter De Coster <i>Belgium</i>

774	<b>Porous Ca-Deficient Hydroxyapatite/Biodegradable Polymer Composites</b> <u>Marina Sokolova</u> , Janis Locs, Aleksandrs Mirošnikovs <i>Latvia</i>
775	<b>Modulation of A<math>\beta</math>(25-35) Conformation: Curcumin and Curcumin Derivatives Effects</b> <u>Anna Maria D'Ursi</u> , Manuela Rodriguez, Maria Carrano, Manuela Grimaldi, Rosario Randino <i>Italy</i>
776	<b>Novel Environmental Use of Polyhydroxyalkanoates – Controlled Release Fertilizers</b> <u>Katarzyna Gorazda</u> , Ipsita Roy, Agnieszka Makara <i>Poland</i>
777	<b>Comparative Study of Mechanical Properties of the Selected Bioresorbable Thread Used in Orthopedics</b> <u>Magdalena Tomanik</u> , Sylwia Szotek, Anna Nikodem <i>Poland</i>
778	<b>Influence of Processing Methods on Biological Behaviour of Polylactide and Its Composites</b> <u>Anna Morawska-Chochół</u> , Jan Chłopek, Danuta Paluch <i>Poland</i>
779	<b>Analysis of the Biodegradable Miniplates Deformation. Finite Elements Method vs. Uniaxial Tensile Test</b> <u>Kamil Dudziński</u> , Robert Karńtoch, Karol Gryń <i>Poland</i>
780	<b>Water Loss of Surface Treated Glass-Ionomer Cements</b> <u>Elizabeth Bent</u> , John Nicholson <i>United Kingdom</i>
781	<b>Imaging of in-vitro Plaque Removed From Titanium Using Cavitation</b> <u>Emilia Pecheva</u> , Nina Vyas, Judith Brown, Gareth Price, Rachel Sammons, Damien Walmsley <i>United Kingdom</i>
782	<b>Degradation Processes of Ti6Al4V Alloy by Fretting and Fretting-Corrosion</b> Marcin Klekotka, <u>Jan Ryszard Dąbrowski</u> <i>Poland</i>
783	<b>Effects of Surface Characteristics of Orthodontic Adhesives on Multi-Species Biofilm</b> <u>Jung-Sub An</u> , Kyung Sun Kim, So Ha Jo, Sug-Joon Ahn <i>Republic of Korea</i>
784	<b>Hydrazide Modified Dextran as Scavengers for Carbonylated Proteins</b> <u>Ming Gao</u> , Tobias Larsson, Tim Bowden <i>Sweden</i>
785	<b>Preparation of Substituted Hydroxyapatite for Tooth Enamel Remineralization</b> <u>Vita Zalite</u> , Janis Locs <i>Latvia</i>
786	<b>Shape and Surface Chemistry Effects on the Cytotoxicity and Cellular Uptake of Metallic Nanorods and Nanospheres</b> Pelagie Favi, Mariana Morales, Paul Elliot, Alejandro Restrepo, Ming Gao, Hanchen Huang, <u>Juan Pavon</u> , Thomas Webster <i>Colombia</i>
787	<b>Chitosan-Based Hydrogels Modified with Silk Fibres for Cartilage Tissue Regeneration</b> <u>Magdalena Koziol</u> , Kinga Pielichowska, Jan Chłopek <i>Poland</i>
788	<b>Stable Pluronic Gel Formation by Incorporating Graphene Oxide</b> Da-Ae Won, Manse Kim, <u>Giyoong Tae</u> <i>Republic of Korea</i>
789	<b>Nanotoxicity Studies of Nanodiamond on 2D and Magnetically Bioprinted 3D Scaffold-Free Liver Model</b> <u>Dipesh Khana</u> , Dong Fu, Iqbal Ramzan, Wojciech Chrzanowski <i>Australia</i>
790	<b>Investigation of a Novel Bioresorbable Polymer Coated Drug-Eluting Scaffold</b> <u>Tamara Mahmood</u> , David Scurr, Nial Bullett, Kadem Al-Lamee, Morgan R. Alexander, Clive J. Roberts <i>United Kingdom</i>

791	<b><i>In vitro</i> Degradation Study of Calcium Phosphate Glass-Ceramic Exhibiting Angiogenic Properties</b> <u>Anna Matras</u> , Agata Roguska, Małgorzata Lewandowska, Marc Batista, Elisabeth Engel, Oscar Castano <i>Poland</i>
792	<b>Potential for Bio-Inspired Eggshell-derived Hydroxyapatite/Collagen Scaffolds for Osteochondral Tissue Engineering</b> <u>Cristian Parisi</u> , Luca Salvatore, Neelam Gurav, Sanosh Kunjalukkal Padmanabhan, Francesca Gervaso, Marta Madaghiele, Antonio Licciulli, Alessandro Sannino, Lucy Di Silvio <i>United Kingdom</i>
793	<b>Biomimetic Scaffolds Based on Biopolymers and Calcium Phosphates for Bone Tissue Engineering</b> <u>Liliana Verestiuc</u> , Florina Ivan, Maria Butnaru <i>Romania</i>
794	<b>Porosity Related Mechanical Response of Calcium Phosphate Bone Cements</b> <u>Dionysios Mouzakis</u> , Stefanos Zaoutsos, Stamatia Rokidi, Nikolaos Bouropoulos <i>Greece</i>
795	<b>Antioxidant Enzymes Immobilized on Biocompatible SPIONs for Cardiovascular Applications</b> <u>Liliana Verestiuc</u> , Lacramioara Lungoci, Vera Balan, Maria Butnaru, Ovidiu Bredetean <i>Romania</i>
796	<b>Regeneration the Urethral with Collagen Scaffold in Stricture Urethral Induced the Heat</b> Christian Acevedo-García, Jorge Jaspersen, Guillermo Soria, Jorge García, Saulo Mendoza, Luis Molina, Jaime Sanchez, Benjamin León, Cristina Piña, Gabriela Gutierrez-Reyes <i>Mexico</i>
797	<b>Insitu Nanoindentation of Dentine and Enamel Treated with 45S5 Bioactive Glass</b> <u>Richard Langford</u> , Jonathan Earl, John J. Melcholsky <i>United Kingdom</i>
798	<b>Effect of Crystallinity of Carbonated Hydroxyapatite on Bone Repair</b> Suelen Sartoretto, Marcelo Uzeda, Adriana Alves, Rodrigo Resende, José Calasans-Maia, Mônica Calasans-Maia, <u>Alexandre Rossi</u> , José Mauro Granjeiro <i>Brazil</i>
799	<b>Production of HA Scaffolds via Conversion of 3D Printed Gypsum Structures</b> <u>Alan Dantas</u> , Andrea Ferraz, Amanda Barbosa, Debora Scalabrin, Márcio Fredel, Jens Günster, Cynthia Gomes <i>Germany</i>
800	<b>Repeatability of Surgical Implantation of Biomaterials. Radiological Analysis of a-TCP Localization in Critical Sized Femoral Metaphysis Defect in Rabbits</b> Nikolaos Papaioannou, Triantafillos Papadopoulos, <u>Christos Zafeiris</u> , Nikitas Schizas, Aikaterini – Anna Neri, Cleopatra Nacopoulos, Ismini Donta <i>Greece</i>
801	<b>Formation and Structure of Silica-Rich Gel Layer in Na/H-exchanged 45S5 Bioglass: MD Models</b> <u>Antonio Tilocca</u> <i>United Kingdom</i>
802	<b>Physical and Mechanical Characterization of Hybrid Scaffolds Based on b-TCP and Collagen</b> Isadora Deschamps, Gabriel Magrin, Aguedo Aragonés, Cesar Benfatti, Ricardo Magini, <u>Júlio Souza</u> , Márcio Fredel <i>Brazil</i>
803	<b>Combined Effect of Magnesia and Zirconia on the Bioactivity of Calcium Silicate Ceramics at C/S ratio Less Than Unity</b> <u>Emad Ewais</u> , Amira Amine, Yasser Ahmed, Eman Ashor, Ulrike Hess, Kursch Rezwan <i>Egypt</i>
804	<b>Lanyu Minipig is a Better Model System for Studying Wound Healing</b> Ting-Yung Kuo, Ming-Jen Lin, Lih-Ren Chen, <u>Lynn L.H. Huang</u> <i>Taiwan, Province of China</i>
805	<b>Scanning Electron Microscope in Evaluation of Biomedical Materials – Own Experiences</b> Jacek Składzień, Agnieszka Wiatr, Katarzyna Zagórska-Swieży, <u>Maciej Wiatr</u> <i>Poland</i>

806	<b>Stem Cells Differentiation in Osteoblasts Lineage Using Bioactive Surfaces Mimicking Bone Microenvironment</b> Laurence Padiolleau, <a href="#">Laurent Plawinski</a> , Gaëtan Laroche, Marie-Christine Durrieu <i>France</i>
807	<b>Textile-Based Silk Scaffolds for Bone Tissue Engineering Applications</b> Viviana Ribeiro, Alain Morais, Vítor Correlo, Alexandra Marques, Ana Ribeiro, Carla Silva, Nuno Durães, Graça Bonifácio, Rui Sousa, Joaquim Oliveira, Rui Reis, <a href="#">Ana Oliveira</a> <i>Portugal</i>
808	<b>Impact of the Micro-scale Distribution of RGD/BMP-2 Peptides on hMSCs Osteogenesis</b> Ibrahim Bilem, Pascale Chevallier, Laurent Plawinski, Eli Sone, <a href="#">Marie-Christine Durrieu</a> , Gaëtan Laroche <i>France</i>
809	<b>Controllable Synthesis and Characterization of Multifunctional Poly(Lactic-co-Glycolic Acid) Nanoparticles for Tissue Engineering Applications</b> <a href="#">Masoud Mozafari</a> , Katayoun Nazemi, Fathollah Moztarzadeh <i>Iran</i>
810	<b>Tissue-engineered Poly (L-lactide-co-<math>\beta</math>-malic acid) Bone Scaffolds Functionalized with Forsterite Nanoparticles</b> Sina Moztarzadeh, Fuzhan Rahmadian, Fathollah Moztarzadeh, <a href="#">Masoud Mozafari</a> <i>Iran</i>
811	<b>Organ Decellularization: Design and Construction of a Device for Obtaining 3D Scaffolds, The Beginning of Bioartificial Organs in México</b> Héctor Martínez-Hernández, Benjamín León Mancilla, <a href="#">María-Cristina Piña-Barba</a> <i>Universidad Nacional Autónoma de México, Mexico</i>

## BRONZE SPONSOR - Level 1

### IME Technologies

[www.imetechnologies.nl](http://www.imetechnologies.nl)

IME Technologies is a successful electrospinning OEM that develops, manufactures and sells state-of-the-art electrospinning equipment. IME Technologies specifically serves academic institutes and innovative customers in the biomedical industry all over the world. With our products and supporting services we help our customers to improve the efficiency of their electrospinning research, product development and manufacturing, thereby shortening their time-to-market for new nanofiber applications.

## Stand 1

### SHIM-POL A.M. BORZYMOWSKI

[www.shim-pol.pl](http://www.shim-pol.pl)

SHIM-POL A. M. BORZYMOWSKI is an exclusive representative of a SHIMADZU-KRATOS corporation and a service centre for Poland. We offer UHPC, HPLC and GC chromatographs; MS systems: GC-MS(MS), LC-MS(MS), LCMS-IT-TOF, MALDI-TOF-TOF; UV-VIS, FTIR spectrophotometers; TOC analysers; ESCA-XPS, SIMS, ISS and Auger spectrometers, and fluorescence analysers (EDX); additional equipment: PHENOMENEX, CHROMACOL, generators, PIKE - accessories, HORIZON TECHNOLOGY.

## Stand 2

### Taylor & Francis Group

[www.taylorandfrancisgroup.com](http://www.taylorandfrancisgroup.com)

**Taylor & Francis Group**  
an informa business

Taylor & Francis partners with world-class authors, from leading scientists and researchers, to scholars and professionals operating at the top of their fields. Together, we publish in all areas of the Humanities, Social Sciences, Behavioural Sciences, Science, Technology and Medicine sectors. We are one of the world's leading publishers of scholarly journals, books, eBooks, text books and reference works.

### Stand 3

**Anton Paar**

[www.anton-paar.com](http://www.anton-paar.com)

Anton Paar develops, produces and distributes highly accurate laboratory instruments and process measuring systems, and provides custom-tailored automation and robotic solutions. It is the world leader in the measurement of density, concentration and CO<sub>2</sub> and in the field of rheometry. Anton Paar GmbH is owned by the charitable Santner Foundation.

### Stand 4

**Oxford University Press**

[global.oup.com](http://global.oup.com)

Oxford University Press is a department of the University of Oxford. It furthers the University's objective of excellence in research, scholarship, and education by publishing worldwide. We publish in many countries, in more than 40 languages, and in a variety of formats - print and digital. Our products cover an extremely broad academic and educational spectrum, and we aim to make our content available to our users in whichever format suits them best.

### Stand 5

**EBERS Medical Technology SL**

[www.ebersmedical.com](http://www.ebersmedical.com)

EBERS Medical Technology SL designs, manufactures and commercializes of tissue engineering bioreactors, mechanical testing machines for biological samples and biomaterials, microfluidic devices for cell culture under physiological conditions and oxygen sensors.

## Stand 6

**IOP Publishing**

[www.ioppublishing.org](http://www.ioppublishing.org)

**IOP Publishing**

IOP Publishing provides a range of journals, magazines, websites, books and services that enable researchers to reach the widest possible audience for their research.

Visit our stand at ESB to find out what IOP Publishing can offer to our authors.

## Stand 7

**Springer**

[www.springer.com](http://www.springer.com)

Our business is publishing. With more than 2,900 journals and 200,000 books, Springer offers many opportunities for authors, customers and partners. Throughout the world, we provide scientific and professional communities with superior specialist information – produced by authors and colleagues across cultures in a nurtured collegial atmosphere of which we are justifiably proud.

## Stand 8

**BINDER GmbH**

[www.binder-world.com](http://www.binder-world.com)

**Best conditions for your success**

BINDER is the world's largest specialist in simulation chambers for the scientific and industrial laboratory. More than 22,000 units leave our plant in Tuttlingen, Germany annually. Our products: CO<sub>2</sub> incubators, incubators, growth chambers, ultra-low temperature freezers, drying/heating ovens, temperature test chambers, vacuum drying ovens, safety drying ovens, and climate chambers.

## Stand 9

### Royal Society Publishing

[www.royalsocietypublishing.org](http://www.royalsocietypublishing.org)

## THE ROYAL SOCIETY PUBLISHING

J R Soc Interface and Interface Focus regularly publish high quality content in the area of biomaterials. For more information about the scope and editorial procedures of our journals, please come and have a chat with our representative Dr Tim Holt at the Royal Society's booth.

## Stand 10

### JPK Instruments AG

[www.jpk.com](http://www.jpk.com)

JPK Instruments, is a world-leading manufacturer of Atomic Force Microscopes and optical tweezers systems. From the beginning applying AFM technology, JPK has recognized the opportunities within nanotechnology for life sciences and soft matter research. This led to JPK's success in uniting the worlds of nanotechnology tools and life science applications.

## Stand 11

### Plasma Biototal Ltd

[www.plasma-biototal.com](http://www.plasma-biototal.com)

Manufacturer of Calcium Hydroxylapatite (Captal® Grades) and Beta TriCalcium Orthophosphate powders for use in manufacturing orthopaedic composites, ceramic products and coatings. Provision of coating services to orthopaedic device manufacturers on a global basis. Company holds relevant ISO quality management accreditations and FDA compliant Masterfiles for products.

## Stand 12

### BRUKER microCT

[www.bruker-microct.com](http://www.bruker-microct.com)

Bruker microCT formerly known as SkyScan develops and manufactures microtomography and nanotomography systems for non-destructive 3D imaging. The company provides the leading imaging and analytical X – ray microCT.

## Stand 13

### Biolin Scientific

[www.biolinscientific.com](http://www.biolinscientific.com)

Biolin Scientific is a leading Nordic instrumentation company with roots in Sweden, Denmark and Finland. Our customers include companies working with pharmaceuticals, energy, chemicals, and advanced materials, as well as academic and governmental research institutes. Our precision instruments help discover better drugs faster, develop better solutions for energy and materials, and perform research at the frontiers of science and technology. Biolin Scientific proprietary systems are based on nanotechnology and advanced measurement techniques. They have earned leadership in several industries through our commitment to scientific excellence and continuous product development. Today, Biolin Scientific provides products and services in more than 70 countries around the world.

## Stand 14

### CAM Bioceramics B.V.

[www.cambioceramics.com](http://www.cambioceramics.com)

CAM Bioceramics is a contract manufacturer of orthobiologic ceramics. We use our experience and production capabilities to enable orthopedic and dental OEMs develop and manufacture a wide range of bioceramics. CAM develops orthobiologic ceramics and manufactures them in compliance with the industry quality standards.

## Stand 15

**SCANCO Medical AG**

[www.scanco.ch](http://www.scanco.ch)

**SCANCO**  
MEDICAL

SCANCO Medical is a Swiss company that specializes in the development of state-of-the-art micro-computed tomography systems. These systems integrate high-quality imaging with powerful 3D analysis tools. We provide long-term support to our customers that includes technical assistance, maintenance, updates and training. Leading academic, industrial and healthcare institutions worldwide employ SCANCO Medical microCT systems in a wide range of applications.

## Stand 16

**UNI-EXPORT INSTRUMENTS**

[www.uni-export.com.pl](http://www.uni-export.com.pl)

**UNI-EXPORT**  
Instruments Polska

UNI-EXPORT INSTRUMENTS Polska operates on a market of specialized research and measurement equipment for more than 10 years. We are an authorised (and in most cases exclusive) distributor of some leading equipment manufacturers from the USA and Europe.

## Stand 17

**nLab sp. z o.o.**

[www.nlab.pl](http://www.nlab.pl)

 **nLab**  
Spółka z o.o.

Since 1998 nLab delivers advanced research instrumentation. We specialize in the field of electrochemistry, corrosion research, electrochemical energy sources, tensiometry, studies of surface properties, surface plasmon resonance (SPR and L-SPR), scanning electrochemical microscopy (SECM), physico-chemical and analytical studies. We are the exclusive representative in Poland of well-known brands: Metrohm-Autolab, KSV-NIMA, Attension, Biolin Scientific, BioNavis, KEInstruments, Sensolytics, Insplorion. For all these products we also provide the service.

## Stand 18

**TA/ElectroForce**

[www.bose-electroforce.com](http://www.bose-electroforce.com)

Your success is our mission at TA/ElectroForce®. We provide mechanical testing, characterization, and tissue growth solutions to researchers worldwide. Our ElectroForce® zero-friction motor technology provides exceptional performance and simplicity for sterile and non-sterile applications. Visit our booth to learn more about our biomedical instruments, including the NEW 3DCulturePro™ bioreactor.

## Bioactive Materials for the Treatment of Major Injuries: Opportunities and Challenges

Joachim Kohn, PhD.

Distinguished Professor and Director  
The New Jersey Center for Biomaterials  
Rutgers, the State University of New Jersey  
[kohn@dls.rutgers.edu](mailto:kohn@dls.rutgers.edu)

### HISTORIC PERSPECTIVE

This presentation addresses recent advances in the treatment of major tissue evulsions, stemming from trauma, disease, or aging. In the USA and Europe, the large number of war veterans returning from the recent military conflicts in Afghanistan and Iraq heightened the willingness of the Government to invest in regenerative medicine. The goal of this effort is the development of fundamentally new therapies that can restore “form and function” to patients who suffered very significant injuries, including devastating injuries to the face, massive 3<sup>rd</sup> degree burns, and loss of limbs due to blast injuries. As these new therapies are perfected, they will undoubtedly revolutionize the treatment of major injuries and will benefit not only military personnel but the civilian population as well. Biomaterials science in combination with cell-based therapies and new bioactives is at the center of these research efforts.

### BIOACTIVE MATERIALS – A NEW FRONTIER

There is a strong and growing emphasis on using synthetic biomaterials in combination with cells (in particular stem cells). Recently, the profound influence of biology on the development of biomaterials became evident with the search for bioactive materials, e.g., materials that can be used to direct the cellular response toward predictable and desirable outcomes. Achieving “bioactivity” by a synthetic, engineering approach has been an elusive goal. Nobody has so far been able to create an engineered construct that mimics all the functions of natural extracellular matrix (ECM) perfectly. To develop materials with ECM-like properties, two approaches are being explored concurrently: The “engineering approach” starts from simple, but readily available (usually synthetic) materials that can be decorated with various biologically active signaling moieties in such a way that key cellular responses such as attachment, migration, proliferation, and differentiation can be driven towards a desired outcome. In contrast, the “biological approach” starts from living tissue. The main goal of the biological approach is to simplify the tremendous complexity of natural tissues by removing most cellular components and their associated antigens without destroying the fine structure of ECM and without significant damage to the many sensitive signaling moieties that give ECM its characteristic biological activity. Since these two approaches come from opposite directions, it is very likely that the next generation of synthetic, bioactive scaffolds will compete with ECM-derived allograft products or products derived from de-cellularized tissues.

### BIOMATERIALS-ENABLED THERAPIES

Major injuries can be treated in three ways: By replacing lost limbs or tissues with prosthetic devices (examples: artificial legs, arms, total hip replacement), by replacing lost tissue with allografts (example: face transplant, organ transplant), or by regenerative approaches where bioactive scaffolds and cells are used to generate the lost tissue de novo. The quest to regenerate a living human ear is an illustrative example for a biomaterials-enabled therapy. The first attempt at creating a living human ear replacement goes back to the early 1990's when a crudely shaped scaffold seeded with chondrocytes was implanted under the skin of nude mice. This research concept was recently developed further, using the latest techniques in biomaterials science and biology, resulting for the first time in a promising prototype that may be useful in the clinic. Another example is the development of nerve conduits for regeneration of large gaps in peripheral nerves, using a bioactive polymer that intrinsically supports neurite growth better than other synthetic materials. Recent work on the first bioactive scaffolds for the regeneration of the osteochondral interface of major joints represents yet another example of a biomaterials-enabled cell therapy.

### CURRENT LIMITATIONS AND CHALLENGES

In spite of significant progress, the field of biomaterials science still faces significant challenges that are best presented in three distinct groups:

*Fundamental science challenges* include (1) our inability to overcome mass transfer limitations (nutrient transport) in tissues sized for human patients; (2) our inability to generate innervated tissues, mostly muscle; (3) our inability to engineer micro-vascular beds and fully vascularized tissue; (4) the lack of regenerative approaches to treat traumatic brain injury or degenerative brain disorders. *Technology challenges* include our bottlenecks around (1) cell sourcing, (2) problems relating to the scale up of production, sterilization, shelf life, and (3) the lack of an efficient FDA regulatory approval processes. Finally, a major challenge relates to the *assembly of complex tissue constructs*. While we can grow muscle, bone, tendons, and ligaments separately in the lab, we cannot grow a fully assembled joint, and we cannot regenerate whole limbs or whole organs (other than skin and bladder). This specific challenge is due to our inability to recapitulate in the lab the natural processes that occur during embryonic development.

### ACKNOWLEDGMENTS

This is an overview based on the work of the entire biomaterials research community. The author acknowledges the countless scientists who contributed to the research advances described in this lecture.

## Regenerative Transplantation - from Experimental Laboratory to Clinical Applications

Maria Siemionow

Department of Orthopaedics, University of Illinois at Chicago, USA  
[siemiom@hotmail.com](mailto:siemiom@hotmail.com)

### **Introduction**

The presentation will outline cellular therapies which are currently developed in the Microsurgery Laboratory at University of Illinois at Chicago. These therapies represent four different regenerative medicine approaches of combining naturally occurring nerve scaffolds with stem cells of allogeneic origin as well as novel chimeric cell therapy for transplant tolerance. These scaffold based therapies are targeted for restoration of limb function by application of new nerve conduits, epineural jackets and epineural patches. Introduction of new, safer, chimeric cell therapies will support transplantation of solid organ and vascularized composite allografts (VCA) such as hand and face transplants. Summary of scaffold and stem cell based approaches is briefly outlined below.

### **Epineural Nerve Conduits for Restoration of Nerve Defects**

We have introduced a new naturally occurring epineural sheath conduit supported with bone marrow stromal cells for enhancement of nerve regeneration over long 6 cm nerve gaps. These conduits are of allogeneic nerve origin and after decellularization constitutively express Laminin B and VEGF which are growth factors supporting nerve regeneration.

These nerve conduits were tested in 2 and 6 cm nerve defects in small - rat and large-sheep animal models respectively and confirmed nerve regeneration comparable to autologous controls.

### **Epineural Sheath Patches for Support of Nerve Regeneration**

To protect nerve regeneration in unfavourable wound conditions, including diabetic wounds, we have developed an epineural patch to cover the neural tissues after nerve trauma such as crush or traction injury, as well as following peripheral nerve decompression and decompression of the spinal cord. We are also introducing a new technology of epineural sheath jackets for prevention and treatment of painful neuromas.

### **Chimeric Cell Therapies for Tolerance Induction**

There is a need for development of new anti-rejection therapies for solid organ and vascularized composite allografts (VCA) such as face and limb transplants to eliminate side effects of currently available immunosuppressive protocols. We have developed a novel tolerance inducing therapy by fusion of bone marrow cells of Donor and Recipient origin and creating Donor-Recipient Chimeric Cells. These cells are recognized by transplant recipient as "Self" and support organ survival. We will introduce Chimeric Cells as supportive therapy for face and limb transplants which will reduce side effects, cost and the need for lifelong immunosuppression.

The other approach we are taking as a continuation of Chimeric Cell therapy application is to create a universal chimera which will serve as universal bone marrow transplantation with direct application to the wounded warrior in case of a nuclear bomb attack. We are currently developing a second and third generation of Chimeric Cells leading to ultimate goal of creating universal Chimeric Cells. We also are testing cryopreservation methods for Chimeric Cell storage and propose to introduce a Universal Chimera Bank for civilians and military applications.

## ***In Vitro* Models and Nanobiointerfaces: a Multidisciplinary Challenge**

Charles James Kirkpatrick<sup>1,2</sup>

[cjkirkpatrick@biomaterials.gu.se](mailto:cjkirkpatrick@biomaterials.gu.se); [james.kirkpatrick@kgu.de](mailto:james.kirkpatrick@kgu.de)

### **INTRODUCTION**

Cellular testing systems begin with relatively simple 2D models for most of biomaterial development, with the lowest level of complexity being permanent cell lines, usually tumour cells, for simple cytotoxicity testing (direct & indirect tests). A greater challenge is to conceive 2D cellular models which give relevant read-outs of biomaterial-associated functionality of a primary cell type of human origin, for example osteoblasts or endothelial cells (EC). The subsequent step to sophisticated heterotypic co-culture systems, in which cells of different phenotypes interact with each other, represents a major element in simulating the *in vivo* situation and is essential for the study of non-bound nanoparticle (NP) systems developed, for example, for drug and gene delivery. Such models are required for the important biological barriers in the body, which would be the natural nanobiointerfaces encountered in clinical translation, depending on the mode of NP application (e.g. inhalation, injection, oral ingestion).

### **EXPERIMENTAL MODELS**

In the past years we have set up mono- and especially co-culture models of important biological barriers both of the lower (air-blood barrier, ABB) and upper respiratory tract (bronchial model)[1-3], as well as of the blood-brain barrier (BBB)[4-6]. Further models are of the intestinal and the skin barrier. All of these, with the exception of the BBB, can be established in a human system, and most readily using suitable permanent cells lines, with the primary cells being the benchmark. The lack of availability of fresh human brain tissue with preservation of capillary EC, pericytes and astrocytes, all of which are required for a genuine BBB, make alternatives necessary. This can be achieved, for example, with porcine cells. In the barrier models for NP interaction special physiological and biological methodologies are necessary to elucidate barrier function as well as the uptake, intracellular transport, distribution and possible storage and secretion of NPs following cellular contact. This usually requires tracer entities, which in the case of fluorescent probes can enable both *in vitro* and *in vivo* follow-up.

For NP uptake across the ABB, various NPs based on silica have been studied in comparison with polyorganosiloxane NPs [7]. The influence of NP characteristics, such as diameter and surface chemistry have been investigated, and cellular uptake mechanisms appear to involve clathrin- and caveolin-independent pathways, for example, via flotillins [8,9]. A further level of complexity in the ABB is the presence of surfactant in the alveoli. This has been found to change NP cytotoxicity [10].

### **FUTURE DEVELOPMENTS**

The described models represent static systems. For more relevance to the *in vivo* situation there is a need to introduce biomechanical factors operating in the niche under consideration. Currently, the role of stretch and contraction forces, which are highly complex and continuously operative in the alveoli, is now being studied [11]. An immunologically relevant triple culture system has also been established for the bronchial model by adding dendritic cells (DCs), and for the air-blood barrier by adding different macrophage phenotypes [12], as these immunocompetent cells are important in barrier defence mechanisms. In addition to these double and triple co-culture systems further developments in the future must include multi-parametric, high throughput micro-systems to permit screening. Moreover, the real life situations in which a nanobiointerface would arise are more complex still, as in most cases there can be different intensities and types of inflammation, hypoxia and the possible stimulating or inhibiting effects of medication [13]. These phenomena will impinge on nano-bio-interactions and must be reflected in the assay systems we establish, especially if the latter are to have predictive function.

## Medical Translational Research: A Different Route to Fundamental Research

R. Geoff Richards

AO Research Institute Davos, Clavadelerstrasse 8, 7270 Davos, Switzerland ([www.aofoundation.org/ari](http://www.aofoundation.org/ari))  
[geoff.richards@aofoundation.org](mailto:geoff.richards@aofoundation.org)

### INTRODUCTION

The AO Research Institute Davos has had over 50 years of experience in translation of ideas to improved surgical techniques for patient care in the field of fracture fixation<sup>1</sup> with the largest world-wide trauma surgeon network for appropriate clinical guidance. These patent protected financially exploitable innovations were either licenced attaining royalty fees or sold to industry.

Despite this long-term successful record in translation, the need for fracture fixation moves now towards faster repair along with treatment of major co-morbidities such as infection at the same time as the economics of the field are driven downwards by many factors including increasing medical approval hurdles and associated costs. The need for cartilage and disc clinical functionality moves more towards regeneration, as a first step to increase the time of use before possible replacement. The policy makers, healthcare providers, insurance companies and patient groups additionally add their demands to the demands and wishes of the surgeons and the industrial producers. From an idea to help a patient's clinical problem to an actual clinical protocol or approved implant at the bedside costs massive resources in knowhow beyond the preclinical research that we are used to as scientists. Clinical guidance is essential at every major step in medical translation research to make sure the idea has any chance in the operation room.

For the preclinical side, accreditation of R&D processes and facilities is important (ISO for an Institute overall and GLP and AAALAC for a preclinical facility) and the team must have a mix of academic and more development oriented members in various fields. In medical translational research it is also extremely important to know very early on (before large investments into the preclinical research) What the current situation on the market is? What is the current clinical solution (or workaround)? What is the financial cost and market for such a clinical problem (regional and world-wide) What are the regulatory hurdles to such a solution? (regionally they may vary); What is the current patent situation for this area and is your idea really novel? (the search cannot be just European, a patent in an individual country can easily kill your patent application many years down the line (and after significant costs). Based upon this, are the estimated R&D costs worthwhile to get a chance of return on investment?

Once you have performed such searches and intend to protect your idea, the project needs to be differentiated from fundamental research projects. PhD's and postdocs

need to publish for their careers while a real medical translational research project needs to be kept confidential at minimum until patent protection is submitted. This can delay academic recognition, yet helps make the idea tradable after filing the patent. Since patent protection is not cheap, initial studies to test your hypothesis are recommended before patent filing, but must not be made public and therefore need to be under the project lead of Research Associates or higher with technician support (whose careers are not based only upon academic publications). Medical translational research projects need special routes and rules and different targets and milestones for the project leaders compared to fundamental research projects. For these project leaders, a balance in fundamental and translational research projects is required, since certainly not all translational projects will be successful.

Despite the professional set up to nurture, approve and expose medical translation projects, key areas of the translation cycle are still missing where the dependence lies with industrial partnerships of the AO Research Institute. As the AO Research Institute has moved more towards biology, tissue engineering and regenerative medicine this century, the steps from bench to bedside are exponentially more difficult than for a simple biomaterial fracture fixation device. There is an increasing clinical demand for the targeted and controlled delivery of active molecules (or cells) to specific parts of the body which requires good extremely well characterised biomaterial delivery platforms e.g. for localised delivery of antibiotics to infection sites or release of stimulants for local tissue regeneration. The biomaterials ideally should be biocompatible, biodegradable and allow controlled temporal release of the active substances. This involves a lot of developmental controls and after proof of concept at the preclinical research level, costs and legal hurdles for the jump from this to get a product to the bedside are enormous. What should one insource and what should one outsource? Many companies no longer will buy a proof of concept. Technology transfer and licencing to industry, certification (e.g. CE), regulatory issues, GLP and GLM for tissue engineering are all areas that have to be considered for this question. This presentation will attempt to show how we at the AO Research Institute Davos are trying to solve these issues of Intellectual Property for technology transfer.

## Vascularization in Tissue Engineering: Alternative Foreign Body Responses

Michael V. Sefton

Institute of Biomaterials and Biomedical Engineering, University of Toronto, Canada  
[michael.sefton@utoronto.ca](mailto:michael.sefton@utoronto.ca)

### INTRODUCTION

The foreign body response is the classic response to an implanted biomaterial or device, resulting in a fibrotic tissue response intending to “wall off” the foreign body and protect the host. We are exploring alternative foreign body responses which result in vascularized rather than fibrotic tissue. A critical issue associated with creating large tissues is the difficulty of supplying nutrients to all the cells in a thick segment of tissue beyond the limits of Fick's law; such vascularized responses are expected to circumvent this issue.

### MODULAR TISSUE ENGINEERING

A three-phase construct containing of endothelial cells (EC), mesenchymal stromal cells (MSC) and collagen using modular components drives a remodelling process that results in a perfusable vasculature. *In vivo*, modules are initially hypoxic and this drives a remodeling process involving the host response (including host macrophages), angiogenesis and pericyte recruitment, among other processes. This remodeling produces, within ~21 days, a mature chimeric and functional vascular supply composed of graft EC (that migrated from the modules) and host EC recruited to the construct as part of the host response<sup>1,2</sup>.

Vascularization depends on the host response to modules in SCID/bg mice (although immune-compromised, they still mount an inflammatory response) or tacrolimus treated rats (allogeneic transplants). Clodronate depletion of macrophages (iv + sc) reduced vessel number suggesting that macrophages are needed for vessel formation. Conversely, GR1<sup>+</sup> neutrophils in the NSG mouse appeared to interfere with vessel formation; antibody depletion restored vessel formation. We have isolated macrophages from the explanted tissue and characterized their phenotype by flow cytometry. Inflammatory cell number (CD45<sup>+</sup>) decreased from day 3 to day 7, while the proportion of CD206<sup>+</sup> M2 cells increased; the presence of adMSC had no substantive effect on these results. We have also begun to assess circulating cells and noted that module injection did increase the levels of various sub-populations which we are still analysing.

Our goal is to engineer a well vascularized subcutaneous niche to support cell transplantation. We need to significantly accelerate mature, functional vessel formation to perfuse transplanted cells as quickly as possible and prevent ischemia. Generating robust, mature vessels at early times is still an unmet challenge, which we believe requires new tools to control the host response.

### ANGIOGENIC BIOMATERIAL

A 45 mole % methacrylic acid copolymer (with MMA) in the form of beads caused a significant increase in the

number of vascular structures in a rat skin graft model that also lead to enhanced ‘take’ of the graft; similar results were obtained in diabetic mice wound healing. This vascularization is a consequence of the host wound healing response.

Gene analysis indicated that upregulation of Sonic Hedgehog (Shh) in the wound is a factor in this angiogenic effect<sup>3</sup>. In order to identify which cells are producing Shh, large (1.5x1.5 cm) full thickness wounds were created on the dorsum of non-diabetic transgenic animals in which Shh and Ptch1 (Shh receptor) were co-expressed with two reporter genes, GFP and lacZ respectively. Hair follicles may be an important source of Shh in this context.

Macrophage-like cells (dTHP1) incubated on smooth 40% MAA films (copolymerized with isodecyl acrylate, IDA) for 96 hours increased the expression of angiogenic genes HIF1 $\alpha$  and SDF1 $\alpha$ , and of inflammatory genes IL1 $\beta$ , IL6 and TNF $\alpha$ , while decreasing the expression of osteopontin. Gene expression changes were more significant above a threshold between 30 to 40% MAA.

Plasma/serum protein adsorption showed that the adsorbed protein on MAA biomaterials and particularly complement levels may be an upstream influence on the wound healing and vascularisation environment while sonic hedgehog is a downstream consequence of that cell-material interaction.

How these separate elements link together to explain why MAA containing materials (and not other materials) cause the profound angiogenic response continues to be a mystery. We are continuing to unravel complexities in how a simple material (a MAA copolymer) has such a profound *in vivo* effect.

### CONCLUSION

MAA is an example of a regenerative biomaterial – a material with regenerative effect without cells or drugs. Like modules, it exploits an alternative foreign body response, that uses *in vivo* remodelling to result in vascularised tissue. We suggest that there are many other biomaterials and devices that can exploit similar host responses to functional benefit.

## Targeted Chemo- and Molecular-Therapy by Self-Assembled Supramolecular Nanosystems

Kazunori Kataoka<sup>1,2</sup>

<sup>1</sup> Departments of Materials Engineering and Bioengineering, Graduate School of Engineering,  
The University of Tokyo, Tokyo, Japan

<sup>2</sup> Center for Disease Biology and Integrative Medicine, Graduate School of Medicine,  
The University of Tokyo, Tokyo, Japan  
[kataoka@bmw.t.u-tokyo.ac.jp](mailto:kataoka@bmw.t.u-tokyo.ac.jp)

Nanosystems with 10 to 100 nm in size can be prepared by programmed self-assembly of block copolymers in aqueous entity. Most typical example is polymeric micelles with distinctive core-shell architecture. Several micellar formulations of antitumor drugs have been intensively studied in preclinical and clinical trials, and their utility has been demonstrated<sup>1,2</sup>. Compared with conventional formulations, such as liposomes, polymeric micelles have several advantages, including controlled drug release, tissue penetrating ability and reduced toxicity. Critical features of the polymeric micelles as drug carriers, including particle size, stability, and loading capacity and release kinetics of drugs, can be modulated by changing the chemical composition of the constituent block copolymers<sup>3</sup>. The development of smart polymeric micelles that dynamically change their properties due to sensitivity to chemical or physical stimuli is the most promising trend toward nanomedicines, directing to the targeting therapy with high efficacy and ensured safety. Notable anti-tumor efficacy against intractable cancer, including pancreatic cancer, of antitumor drug-incorporated polymeric micelles with pH-responding property was demonstrated to emphasize a promising utility of nanosystems for the cancer treatment<sup>4-6</sup>. Furthermore, polymeric micelles loaded with platinum-based anti-cancer reagents successfully treated systemic metastasis even from the early stage of pre-angiogenic micrometastatic niches associated with inflammation<sup>7,8</sup>.

Versatility in drug incorporation is another feasibility of polymeric micelles. Recently, we have succeeded to incorporate proteasome inhibitor, MG132 into polymeric micelles through acid-labile linkage, and verified the micelle efficacy against xenograft tumor model by systemic injection<sup>9</sup>. Notably, selective release of MG132 in acidic endo/lysosomal compartments of tumor cells was observed in time- lapse manner under fluorescent microscopy by the use of fluorescent dye-tagged polymeric micelles loaded with MG132. This result demonstrates the promising features of polymeric micelles as platform nanoformulation for tumor-selective delivery of a variety of molecular-targeted drugs with issues on physicochemical properties, such as solubility, and toxicity against normal tissues and organs.

The success in gene and nucleic acid delivery indeed relies on the development of the safe and effective devices to transport them into target cells. In this regard, polyion complex (PIC) micelles, which are formed between nucleic acid and PEG-polycation block copolymers, have a great promise due to their small size (<100 nm) and excellent biocompatibility.

This presentation will also focus on the development of PIC micelles for systemic delivery of gene, mRNA, and oligonucleotides, including siRNA<sup>10-12</sup>.

## Cell-Made or Man-Made Materials for Bone Reconstruction?

Malgorzata Lewandowska-Szumiel

Tissue Engineering Lab, Department of Histology and Embryology,  
Centre for Preclinical Research and Technology, Medical University of Warsaw, Poland  
[mszumiel@wum.edu.pl](mailto:mszumiel@wum.edu.pl)

The history of use of biomaterials in bone is probably the oldest comparing to other tissues. Coconut shells, wood and ivory were found to be used for bone and teeth repair already in ancient times. Years of research in modern medical sciences resulted in a huge offer of biomaterials used in bone surgery, including metals, polymers, ceramics and composites.

Regardless of the fact we have the plethora of the biomaterials for bone reconstruction, the research oriented towards developing the new materials and improving the existing ones remains still an open platform. It is illustrated by permanently growing number of scientific publications, grants and patents in the field as well as the continuing interest of biomedical enterprises and pharma.

The modern biomaterials are designed especially to integrate with host bone as well as to promote bone organization and remodeling, but they are non-viable and they are recognized by host tissues as “foreigners”. Even the most biomimetic man-made material will be far from the excellence of the natural extracellular matrix (ECM).

ECM provides a perfectly organized structure which is, by nature, an ideal environment able to keep equilibrium with its resident cells and to control cell migration, proliferation, differentiation and specialized function. Currently, after years of intensive work on new man-made materials, this very basic statement is full force spotted. Such an issue attracted significant interest in creating tissue substitutes based on biological scaffolds derived from the decellularized tissues and eventually repopulated with living cells. During the past decade many biomedical products based on this idea have been proposed. The history of using processed ECM in bone is even longer, as the osteogenic properties of demineralized bone matrix was discovered by Urist in 1965. Relating to the title of this lecture, such materials should be classified as the cell-made. However, decellularized ECM is not the only one concept of cell-made biomaterial.

In vitro-generated ECM is an intriguing and promising alternative. The knowledge and experience gained over more than two decades of tissue engineering research performed in cell culture resulted in working out sophisticated culture systems. They are based on different 3D constructions for cells distribution supported by regulated stiffness as well as by multi-cell co-cultures. There is more and more evidence of the successful construction of in vitro cell-made ECM constructs designed directly for transplantation to injured tissues. Even more exiting results indicate high usefulness of such systems as a niche for stem cells as well as a tool in directing cells differentiation into specialized immunophenotypes. Their potential use in regenerative medicine seems apparent.

Therefore, cell-made materials hold a promise perspective in bone reconstruction. The real “taste” of such systems is that they are of biological origin, alive but at the same time perfectly controlled.

Better control of cell-made ECM-based biomaterials needs well-orchestrated engineering job and basic research, which is an issue indicated as critical in the majority of leading opinions in the field.

Several examples of the original research performed in this direction, coming both from the literature and from the experience of our lab, will be given in the lecture. In particular, tissue engineered products obtained via replacement of the degrading scaffold by cell-produced ECM in vitro, similarity of cell-produced mineral to the native one as well as the role of the materials stiffness and architecture in regulating cell fate will be addressed.

Those promising examples are intended to settle the title key issue in favor of cell-made materials.

But even if so, the question still remains - who is an engineer who organizes and controls the production? Hopefully, the answer opens a very nice space for research in a fascinating field of biomaterials.

## Biological-Basis for Designing Biomaterials for the Injured and Degenerated Host - Examples in the Neural Space

Abhay Pandit

Centre for Research in Medical Devices (CÚRAM),  
National University of Ireland Galway, Ireland  
[Abhay.pandit@nuigalway.ie](mailto:Abhay.pandit@nuigalway.ie)

Biomaterials are no longer considered innate structures and using functionalisation strategies to modulate a desired response whether it is a host or implant is currently an important focus in current research paradigms. Fundamentally, a thorough understanding the host response will enable to design proper functionalisation strategies. The input from the host response needs to be weighed in depending on the host disease condition. In addition biomaterials themselves provide immense therapeutic benefits which needs to be accounted for when using functionalisation strategies. Using functionalisation strategies such as enzymatic and hyperbranched linking systems, we have been able to link biomolecules to different structural moieties. The programmed assembly of biomolecules into higher-order self-organized systems is central to innumerable biological processes and development of the next generation of functionalized scaffolds. Recent design efforts have utilized a bottom-up approach toward both understanding and engineering supramolecular protein assemblies. These include functionalisation of micro and nanoparticles with biomolecules that include designed peptide motifs, growth factors and a multitude of gene vector systems. Structural moieties have taken a variety of different forms such as nanofibers and nanoparticulate. In addition, nature itself has abundant structural complexity that can be harnessed for targeted clinical applications. This talk will elucidate some of these ongoing strategies in our laboratory.

### INTRODUCTION

The fight against bacterial infections is a very hot topic in current biomedicine, possibly of even higher importance than a good biocompatibility towards the tissue surrounding the implant. If bacterial colonies are formed on the surface of an implant, e.g. as a biofilm, they are very difficult to combat and may cause the failure of the implant. We will discuss two approaches: First: the application of silver nanoparticles and of silver ions. Second: The application of silver-containing films of calcium phosphate by magnetron sputtering. Third: The genetic transfection of an antimicrobial peptide (defensin) by calcium phosphate nanoparticles

### RESULTS AND DISCUSSION

The biological effect of silver nanoparticles and of silver ions was compared in extensive experiments with eukaryotic cells and bacteria. The toxic nature of silver nanoparticles is due to their slow dissolution with the release of silver ions. These, however, are reacting with components of biological media, e.g. chloride ions and proteins. The active species in silver-containing media are silver chloride nanoparticles as it was demonstrated by extensive physicochemical and cell-biological studies. The therapeutic window of silver, e.g. the difference in toxicity towards bacteria and eukaryotic cells, is smaller than typically assumed.

Silver nanoparticles can be applied to surfaces by different methods. One possibility is the electrophoretic deposition, followed by magnetron-sputtering of a thin layer of calcium phosphate. It is also possible to add silver ions to a layer of calcium phosphate if the sputtering target contains silver.

A completely different approach is the introduction of DNA into cells of the surrounding tissue by transfection with calcium phosphate nanoparticles. If the DNA encodes the formation of the antimicrobial peptide defensin, the cells will start to produce this peptide. The possibilities of this approach will be discussed, based on cell-culture experiments.

### CONCLUSION

Silver offers possibilities to combat infections in the vicinity of an implant, but care must be taken with respect to damage of the surrounding tissue and to the development of bacterial resistance. A silver coating must assure a sufficiently high silver concentration. Transfection of the surrounding tissue offers new possibilities, but the fact that the proteins or peptides are expressed inside a cell restricts this approach.

## INTRODUCTION

The lack of safe and efficient gene delivery systems is a major obstacle to achieve successful human gene therapy. With the growing understanding the mechanisms of non-viral gene delivery, and inspired by the viral structures and functions, much effort has been directed to the development of intelligent macromolecular based bioinspired gene delivery systems. Supramolecular self-assembly of dendrimers is a promising approach to engineer advanced vectors for gene delivery. Such as peptide dendrimers coupled with linear peptides spontaneously assembled into well-defined viral capsid like nanostructure<sup>1</sup>, and the bioinspired supramolecular hybrid strategy<sup>2</sup>. Meanwhile, the dynamic polyplexes based on disulfide linkage modified hyaluronic acid (HA) envelop and diselenide conjugated oligoethylenimine (OEI) caspid were designed for mimicking the delivery functions and structures of viral particles for gene delivery<sup>3,4</sup>.

## EXPERIMENTAL METHODS

Synthesized compounds were structurally characterized by <sup>1</sup>HNMR, GPC and mass spectrophotometer. The biophysical properties, cytotoxicity, cellular association, transfection *in vitro* and *in vivo* of nanovehicles were systematically investigated. Data were expressed as means  $\pm$  SD. Statistical significance ( $p < 0.05$ ) was computed by SPSS version 13.0 software.

## RESULTS AND DISCUSSION

With a rational design, dual-functionalized low generation peptide dendrons self-assemble onto inorganic nanoparticles via coordination interactions to generate supramolecular hybrid dendrimers (SHDs).

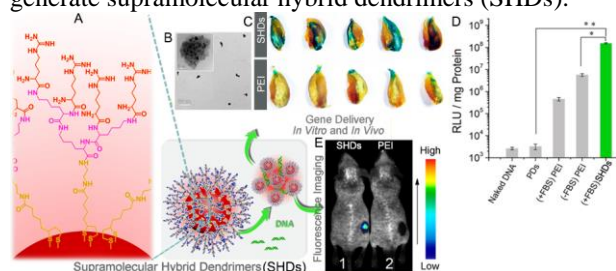

Figure 1. (A) Schematic illustrations for self-assembly of SHDs; (B) TEM of the SHDs/DNA complex; (C) Transfection efficacy of pCMV- $\beta$ -gal in mouse muscles after intramuscular injection; (D) Luciferase activity in HepG2 cells; (E) Fluorescence images of nude mice with HepG2 tumor xenografts after intratumoral injection.

As expected, the bioinspired supramolecular hybrid strategy largely enhances the gene transfection efficiency of SHDs approximately 50000-fold as compared to single dendrons at the same R/P ratio. *In vivo* animal experiments demonstrate that SHDs offer considerable gene transfection efficiency in muscles

and real-time bioimaging capabilities. These SHDs will likely stimulate studies on bio-inspired supramolecular hybrid dendritic systems for biomedical applications.

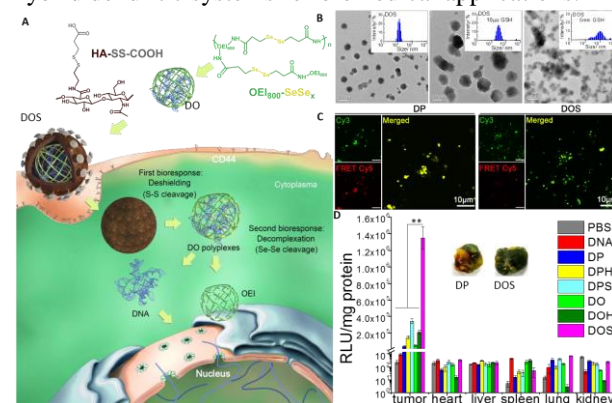

Figure 2. (A) Schematic of DOS for gene delivery; (B) TEM of DOS with GSH; (C) FRET images of DOS on HepG2 cells; (D) Transfection efficacy of pCMV-Luc or pORF-LacZ (insert) after intratumoral treatment.

A new concept of “reduction-controlled hierarchical unpacking” is proposed for developing virus-mimicking gene delivery system. Disulfide linkage modified HA was deposited to the surface of diselenide-conjugated OEI /DNA (DO) to form DNA/OEI-SeSex/HA-SS-COOH (DOS) ternary polyplexes. The cleavage of disulfide linkage in HA envelop and diselenide linkage in OEI-SeSex caspid is triggered by different levels of GSH at tumor site and in the cell, which is confirmed by TEM and FRET. Gene transfection of DOS in nude mice with HepG2 cells xenograft tumor showed significantly enhancement as compared to PEI.

## CONCLUSION

Thus, the intelligent macromolecular based bioinspired design nanovehicles achieved high gene expression *in vitro* and *in vivo*, which provide an encouraging strategy to further develop synthetic gene transfer systems.

## INTRODUCTION

Directional cell migration induced by the stiffness gradient of cell culture substrates is known as a subset of the mechanical-cue-induced taxis, so-called mechanotaxis. To establish the general conditions of biomaterials to manipulate the mechanotaxis, the effect of the shape of the elasticity transition boundary on mechanotaxis should be systematically determined as well as the conditions of elasticity gradient strength. In this report, we focus on the curvature of the elasticity boundary as a simplified factor of expressing variations in the shape of the elasticity boundary in living tissues. Photolithographic microelasticity patterning of gelatinous gels was employed to systematically prepare elasticity boundaries with various curvatures, and the efficiency of mechanotaxis of fibroblast cells around each curved boundary was examined. The curvature of the elasticity boundary was found to markedly affect the efficiency of induction and the direction of mechanotaxis. The mechanism responsible for this phenomenon and the implication for the curvature effect in *in vivo* systems are discussed.

## EXPERIMENTAL METHODS

Photocurable styrenated gelatin (StG) was used for photolithographic microelasticity patterning of the gel, which was synthesized according to the method previously reported by our group<sup>1,2</sup>. StG sol solution was spread between vinylated glass and a normal glass substrate, then irradiated with a custom-built, reduction-projection-type photolithographic system. The elastically-alternating patterns of concentric circles with Rs of 250, 500, 750, and 1000  $\mu\text{m}$ , and semicircles with Rs of 50 and 100  $\mu\text{m}$  were prepared. The surface elasticity of the gels was determined by AFM nanoindentation analysis. The migratory behavior of 3T3 fibroblast cells on the gels was monitored using an automated all-in-one microscope with a temperature- and humidity-controlled cell chamber (BIO REVO BZ-9000; Keyence Corporation, Osaka, Japan). Phase-contrast images of cells were captured every 15 min for 24 h. Moving trajectories of 22–58 isolated cells on 3–6 gel samples were determined using ImageJ software (ImageJ 1.46r, <http://rsbweb.nih.gov/ij/>).

## RESULTS AND DISCUSSION

Cell migrations were observed on the microelastically-patterned gels for 24 h and the trajectories of the cells interacting with the elasticity boundaries were monitored for 12 h (Fig.1).

Firstly for the control linear boundary, usual mechanotaxis behaviors could be seen (Fig.1c). Degree of the biased migrations in the control condition was weak as planned to easily detect curvature effect. Secondary for the convex boundary (Fig.1a), biased

time-dependent migrations toward the hard region were confirmed for boundaries with Rs of 50, 100, and 250  $\mu\text{m}$ , while no biased migrations were detected for the boundaries with larger Rs (500, 750, and 1000  $\mu\text{m}$ ). The convex boundary with an R of 100  $\mu\text{m}$  displayed the largest bias of migration. Thirdly for the concave boundaries

(Fig.1b), biased migrations toward the hard region were confirmed for Rs of 750 and 1000  $\mu\text{m}$ , while biased migrations toward the soft region, i.e., “negative” mechanotaxis, were observed for concave boundaries with Rs of 50 and 100  $\mu\text{m}$ .

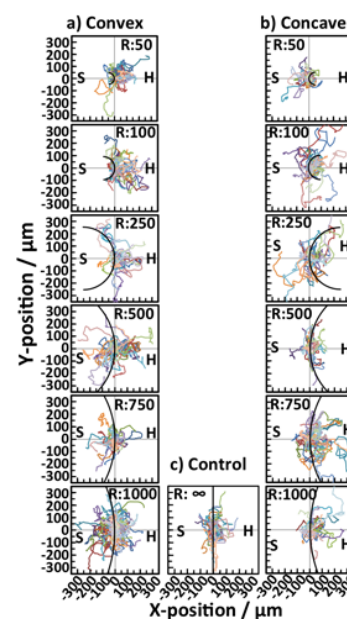

Interestingly, as R in convex boundary got larger to 1000  $\mu\text{m}$ , mechanotaxis was not observed, however, when R approached to infinite, i.e., linear boundary, weak mechanotaxis was observed. Then after, in the reversed curvature condition of R of 1000  $\mu\text{m}$  in the concave boundary, force of mechanotaxis was enhanced. Such enhancement also appeared in the condition of R of 750  $\mu\text{m}$  in the concave boundary. This trend suggests that the concave boundary with optimized R is preferable to induce efficient mechanotaxis<sup>3</sup>.

## CONCLUSION

Highly efficient usual durotaxis was induced on a convex boundary with R 100  $\mu\text{m}$  and on a concave boundary with R 750  $\mu\text{m}$ . Biased migration toward soft regions of the gel, i.e., inverse durotaxis, or “negative mechanotaxis” was first observed for concave boundaries with Rs of 50  $\mu\text{m}$  or 100  $\mu\text{m}$ .

# Dual Release of a Macrophages Recruitment Agent and Growth Factor for Bone Regeneration

Yang-Hee Kim, [Yasuhiko Tabata](mailto:Yasuhiko.Tabata)

Department of Biomaterials, Institute for Frontier Medical Sciences, Kyoto University, Japan

[yasuhiko@frontier.kyoto-u.ac.jp](mailto:yasuhiko@frontier.kyoto-u.ac.jp)

## INTRODUCTION

The process of bone healing can be classified into four histologically distinguishable stages: inflammation, fibrous, callus, and bone formation. Inflammation is the initial and the most vital stage from the viewpoint of bone regeneration. Macrophages are typical inflammatory cells, which infiltrate into injured and defect sites and have a key role in the modulation of the inflammatory response. Recently, it has been demonstrated that the decreased number of macrophages generally implicates their dysfunction of dead cell clearance, the phagocytosis of apoptotic cells, and the up-regulation of pro-inflammatory cytokines<sup>1,2</sup>. This may induce inflammation and delayed tissue repair.

Therefore, as one trial to positively regulate the inflammation and repairing processes, we considered to enhance recruitment macrophages to the defect site by a macrophage recruitment agent release. In addition, we have developed the controlled release technology of platelet rich plasma (PRP) and bone morphogenetic protein (BMP)-2 from gelatin hydrogels to enhance tissue regeneration<sup>3,4</sup>. The purpose of this study is to evaluate the effect of dual release of a macrophage recruitment agent and PRP or BMP-2 from gelatin hydrogels on the modulation of inflammation and bone regeneration.

## EXPERIMENTAL METHODS

A macrophage recruiting agent, SEW2871(SEW) of a sphingosine-1 phosphate agonist, and PRP or BMP-2 were used. The non-water soluble SEW was solubilized in water through micelles formation with L-lactic acid grafted gelatin, and the resulting micelles with PRP or BMP-2 were incorporated into gelatin hydrogels. To investigate their effect on bone regeneration, a bone defect model of rat ulna was prepared, and the bone formation ability was evaluated by histological, radiological, and micro-computed tomographic ( $\mu$ -CT) examinations. In addition, we examined the expression levels of inflammatory cytokines and osteoprotegerin (OPG) of osteoclastogenesis inhibitory factor genes after implantation of the gelatin hydrogels.

## RESULTS AND DISCUSSION

Mixed SEW-micelles and PRP or BMP-2 were released from gelatin hydrogels in a controlled fashion both in vitro and in vivo. The culture of macrophages with a growth factor induced to increase the production of anti-inflammatory cytokines compared with macrophages without a growth factor.

When applied to a bone defect of rats, the hydrogels incorporating mixed SEW-micelles and PRP or BMP-2 recruited a higher number of macrophages than those of hydrogels incorporating either SEW or a growth factor. In addition, the SEW and a growth factor incorporated

Fig. 1 Time profiles of SEW and BMP-2 release from gelatin hydrogels and their degradation in vitro.

into hydrogels enhanced the level of tumor necrosis factor (TNF)- $\alpha$  and interleukin (IL)-6 of pro-inflammatory cytokine, 3 days after application, while pro-inflammatory responses coupled with a significant increase in the expression level of OPG and IL-10 and transforming growth factor (TGF)- $\beta$ 1 of anti-inflammatory cytokine were observed 7 or 10 days postoperatively.

Fig. 2 Histological images of bone regenerated in defects after implantation of hydrogels incorporating SEW and PRP

The hydrogels incorporating mixed SEW-micelles and PRP or BMP-2 promoted bone regeneration to a significant great extent compared with those incorporating PBS and either SEW-micelles or growth factor, such as PRP or BMP-2. This suggests that growth factor stimulated the macrophages recruited and triggered their activation and the production of anti-inflammatory cytokines, which are associated with tissue regeneration. Consequently, the dual release of SEW and growth factor, PRP or BMP-2 would accelerate bone regeneration.

## CONCLUSION

We experimentally demonstrated that the dual release of a macrophage recruitment agent, SEW and PRP or BMP-2 in a controlled fashion from the gelatin hydrogels recruited higher number of macrophages into the bone defects compared with hydrogels incorporating either SEW or a growth factor. In addition, dual release of SEW and PRP or BMP-2 modulated inflammatory responses thereat, resulting in promoted bone regeneration.

### ABSTRACT

Fantastic progress has been made during the last decades in biomaterials science due to improvements in macromolecular chemistry and biology as well as in materials science and surgical techniques. Despite this, the failure rate of biomedical implants remains too high. The underlying causes of failure can largely be attributed to inadequate control of the biological response to the implant leading to a foreign body response and/or infection.

Materials used in the field of implantable medical devices and scaffolds ideally have to present properties of 'perfect compatibility' to the living systems to become accepted in the host (biointegrated). However, such perfection is extremely hard to achieve. The compatibility of an implantable material in the fully operant biological context is directly related to its structural and surface properties and also requires an understanding of the biology of the surrounding tissues. The mechanisms underlying implant failure must be better understood and this must be the constant objective of biomaterials research.

Amongst those mechanisms, the study of protein/surface interactions represents one of the most important since the adsorption of proteins is the very first event to occur when a material is implanted into living tissue [1-3]. The functionalization of polymers and surfaces to make them bioactive is the starting point in controlling the protein/surface interactions which dictates events that follow and may lead to integration or failure of the implant. Failure can involve infection and/or the foreign body response mounted by the immune system of the host [4]. Various strategies have been employed to control protein adsorption including the synthesis of polymers bearing chemical groups capable of modulating the biological response or the functionalization of implant surfaces using those same functional groups to create bioactive surfaces suitable for implant.

These strategies are exemplified by the optimisation of bioactive polymers to control the adsorption of cell adhesive proteins for target tissues such as the adhesion and integration of osteoblast cells and the functionalization of titanium alloy surfaces using bioactive polymers to modulate the protein and cell responses [5-10]. Polymers bearing anionic sulfonate groups have been shown to stimulate osteoblastic differentiation in addition to preventing bacterial adhesion. Poly(sodium styrene sulfonate) that is highly stable in physiological environments and resistant to

enzymatic degradation has been successfully grafted onto Ti6Al4V model surfaces. The distribution of the sulfonate groups from poly(sodium styrene sulfonate) has been found to instigate specific protein adsorption patterns that favor a positive cell response. Examination of the role of fibronectin and vitronectin in the initial attachment and spreading of osteoblast cells to poly(sodium styrene sulfonate) grafted Ti6Al4V surfaces and the role of collagen in the maturation of osteoblast cell on those surfaces has been correlated to results from animal models. Together, outcomes demonstrate that the competitive protein binding behaviour which occurs at the protein-surface interface makes a significant contribution to cellular responses observed both *in vitro* and *in vivo*.

### INTRODUCTION

Numerous biological processes such as tissue formation, remodelling and healing are strongly influenced by the composition and the biochemical properties of the cellular microenvironment. Glycosaminoglycans (GAGs), as major component of the native extracellular matrix (ECM), e.g. in the form of proteoglycans can be chemically functionalized and thereby modified in their binding profiles, both for direct cell interaction<sup>1</sup> and for interaction with mediator proteins (e.g. growth factors)<sup>2</sup>. Thus GAGs and their derivatives are promising candidates for the design of functional biomaterials to control healing processes in healthy and health-compromised patients<sup>3</sup>.

### EXPERIMENTAL METHODS

GAG derivatives based on hyaluronic acid (HA) and chondroitin sulfate (CS) are characterized in their interaction properties with mediator proteins (BMP-2, BMP-4, TGF- $\beta$ 1, and OPG) using surface plasmon resonance (SPR; Biacore<sup>TM</sup>T100), receptor binding studies, immunochemical methods and molecular modelling. The biological property profiles of selected GAG derivatives, either alone or being a component of collagen type I-based artificial ECM (aECM) are studied *in vitro* with cells relevant for healing processes in bone and skin (human mesenchymal stromal cells (hMSC), osteoblasts, osteoclasts, osteocytes, fibroblasts).

### RESULTS AND DISCUSSION

Biophysical studies show that the interaction profiles between growth factors and GAG derivatives are strongly influenced by the (i) sulfation degree, (ii) the sulfation pattern, and (iii) the composition and structure of the GAG backbone. For most mediator proteins HA-based derivatives demonstrate a higher binding strength for the same degree of sulfation compared to CS. These results are in line with biological effects of the respective GAG derivatives, either in solution or incorporated in collagen I-based aECMs, on cells relevant for wound healing processes.

These aECMs are characterized in their GAG association and release behaviour as well as in their GAG-depending biodegradation by matrix metalloproteinases. Prominent effects are (i) an anti-inflammatory, immunomodulatory effects on macrophages and dendritic cells, (ii) enhanced osteogenic differentiation of hMSC, (iii) an altered differentiation of fibroblasts to myofibroblasts, (iv) a reduced osteoclast activity and (v) an

improved osseointegration of aECM coated scaffolds in animal models.

Joint results from biophysical interaction and *in vitro* studies as well as molecular modelling simulations reveal that pre-bound GAGs influence the interaction of growth factors with their respective receptors having major consequences on their bioactivity. For example, results on TGF- $\beta$ 1/GAG complex formation with TGF-receptors indicate that the complex is biologically inactive (Fig. 1).

Fig. 1: SPR response curves for the sequential interaction of immobilized TGF-receptor II with solute TGF- $\beta$ 1 (green circle), followed by solute GAG and TGF-receptor I. GAGs: native HA in comparison to sulfated HA (sHA3) with a sulfation degree of 3.

### CONCLUSION

The presented results contribute to improved understanding on biological interaction profiles of mediator proteins with GAG derivatives. The resulting knowledge on structure-function-relationships of GAGs will enable the design of functional biomaterials to selectively control and promote bone and skin regeneration.

[rgreis@dep.uminho.pt](mailto:rgreis@dep.uminho.pt)

### INTRODUCTION

The selection of a scaffold material is both a critical and a difficult choice that will determine the success of failure of any tissue engineering and regenerative medicine (TERM) strategy. We believe that natural origin polymeric biomaterials are the best choice for many approaches. We have working with this type of systems for the past 20 years. In addition, we have been developing an all range of processing methodologies to produce adequate scaffolds and hydrogels for different TE applications. Furthermore an adequate cell source should be selected. In many cases efficient cell isolation, expansion and differentiation methodologies should be developed and optimized. In our research group we have developed many different strategies to deal with these issues.

### EXPERIMENTAL METHODS

We have been using different human cell sources namely: mesenchymal stem cells from bone marrow, mesenchymal stem cells from human adipose tissue, human cells from amniotic fluids and membranes and cells obtained from human umbilical cords. The potential of each type of cells, to be used to develop novel useful regeneration therapies has been studied. Their uses and their interactions with different natural origin degradable scaffolds and distinct nano and micro-carriers, and smart release systems has been assessed.

### RESULTS AND DISCUSSION

In our research a great focus is given to the different sources of stem cells, the isolation of distinct sub-populations, ways of differentiating them, as well as their interactions with different 3D architectures and materials for culturing them. The use of bioreactors to control cell differentiation, as well as the surface modification of the materials in order to control cell adhesion and proliferation has also been studied in great detail. Several examples of biomimetic and novel hydrogels to combine with adequate stem cells will be described.

### CONCLUSION

Several 3D-architectures, novel hydrogel systems, biomimetic and nanotechnology based strategies to engineer different types of tissues were developed. Some examples to be presented are based on bone, cartilage, osteochondral, skin, neurological tissues, intervertebral disk (IVD) and meniscus.

### ACKNOWLEDGMENTS

The author would like to acknowledge the ERC Advanced Grant 321266, ComplexiTE for partially funding this research.

## INTRODUCTION

Scanning probe microscopy (SPM) techniques have gained immense popularity in the field of biomedical engineering due to their ability to characterise material properties at nano and atomic level. While the imaging capability of these techniques is the most established, more recently several new approaches based on the SPM platform have been developed. Many of these techniques allow probing different material properties, interactions of materials, their degradation and oxidation. Importantly these techniques are typically combined with the imaging capability, thus allow the quantitative imaging. Furthermore, many of these methods is fully applicable for biological samples (cell, tissues, and bacteria) allowing characterisation of material-cell or material-bacteria interactions and probing their properties. Of particular interest for biomaterials are colloidal force probing, force spectroscopy and amplitude modulated force spectroscopy, thermal probe and Lorenz contact resonance spectroscopy.

## EXPERIMENTAL METHODS

Nanomechanical properties of cells.

Cell stiffness is directly related to cell functionality and cell type. Hence, the examination of the cell mechanics is considered as an effective way to interrogate cell interactions with biomaterials, drugs, nanoparticles and it enables studying the impact of these materials on cell fate. Furthermore, cell mechanics is a measure of progression or regression of a disease. Here, effects of cell stiffness on a drug uptake were examined. Cell stiffness was regulated by the incubation with fatty acids (arachidonic acid, AA) and the stiffness was

measured using molecular force probe (MFP-3D-Bio). Figure 1 Effects of incubation of lung tissue model with fatty acids on cell stiffness.

Particle-particle interactions.

A metered-dose inhaler (MDI) is the most commonly used delivery system for treating asthma, chronic obstructive pulmonary disease (COPD) and other respiratory diseases. The ability to disperse given dose of the drug is highly dependent on drug particle interactions. To study single drug particle interactions

(i.e. energy of adhesion, repulsion and attraction forces) colloidal probe nanoscopy was employed. Custom made colloidal probe were fabricated and particle-particle interactions were measured using instantaneous and dwelled forces – Figure 2.

Figure 2 Particle-particle interactions measurement.

High resolution nanomechanical properties mapping.

Amplitude modulated force microscopy (AMFM) and Lorenz contact resonance spectroscopy (LCR) are emerging techniques that enable high resolution mapping of mechanical properties. These techniques were used to study the peptide-induced remineralisation of tooth structure (enamel and dentine). The effect of peptides on remineralisation was evidenced by the measurement of Young's modulus and dissipation energy (AMFM), and viscoelasticity (LCR) – Figure 3.

Figure 2 Map of stiffness and corresponding topography of dentine structure.

## RESULTS AND CONCLUSION

Cell mechanics – it was demonstrated that cell stiffness is directly correlated with the drug uptake and cell incubated with AA were softer and drug uptake was significantly upregulated Figure 1.

Particle-particle interactions – the energy and force of adhesion measured between the particles enable the optimisation of the particles morphology (roughness and porosity) and resulted in the design of more effective drug formulation.

Mapping of nanomechanical properties – AMFM and LCR allowed real time measurement of remineralisation of the tooth structure, and demonstrated the effects of peptides on this process.

### INTRODUCTION

Synthetic polymers endowed with ligands for cell adhesion receptors are promising materials for vascular tissue engineering. These ligands can be attached to the polymers in two forms, i.e. (1) as entire protein molecules or (2) as oligopeptides derived from these proteins, recognized by cell adhesion receptors. These oligopeptides can also ensure binding of extracellular matrix molecules, which are necessary for replacing degradable materials with newly-formed tissue.

### EXPERIMENTAL METHODS

In the first set of experiments, knitted polyethylene terephthalate (PET) vascular prostheses (diameter 6 mm), impregnated with type I collagen (PET/Co), were modified in their lumen by coating them with a network of fibrin (Fb), i.e. a provisional matrix molecule participating in tissue regeneration, and they were seeded with primary human saphenous vein endothelial cells ( $15 \times 10^4/\text{cm}^2$ ). The cells were cultured for 72 h in a static culture system, and then they were exposed to laminar shear stress  $15 \text{ dyn/cm}^2$  for 120 min, generated by a custom-built hemodynamic chamber<sup>1</sup>.

In the second set of experiments, anti-fouling polydopamine-polyethylene oxide (pDOPA-PEO) films, suitable for deposition on PET, were functionalized with an RGD-containing peptide (azidopentanoyl-GGGRGDSGGGY-NH<sub>2</sub>) and a collagen-derived QRQVVGLOGQRGERGFOGLOG-NH<sub>2</sub> peptide binding fibronectin, referred to as Col. These peptides were used either alone or in combination (RGD+Col, ratio 1:1), and in concentrations of  $90 \text{ fmol/cm}^2$  or  $700 \text{ fmol/cm}^2$ . Vascular endothelial CPAE cells ( $17 \times 10^3/\text{cm}^2$ ) were cultured on these surfaces in a static system for 24 hours, and then in a dynamic system Mini Orbital Shaker SSM1 (Stuart) for 7 days.

### RESULTS AND DISCUSSION

After 3-day cultivation in the static system, the numbers of endothelial cells were similar on prostheses with and without an Fb coating. However, after dynamic cultivation, the cell population density on PET/Co dropped to 61%, while the cells on PET/Co+Fb did not show significant detachment (Fig. 1). This result is positive, especially considering the fact that fibrin can be isolated in autologous form from the patient's blood. One day after seeding, the number of cells adhering to surfaces with lower peptide concentrations was very low. On surfaces with RGD+Col, it did not even exceed the number obtained on bioinert pDOPA-PEO surfaces. However, at higher peptide concentrations, the number of cells on all functionalized surfaces approached the value on standard cell culture polystyrene dishes.

Moreover, the cells on surfaces with the RGD+Col combination showed the highest resistance to detachment during dynamic cultivation (Fig. 2).

**Fig. 1.** Human saphenous vein endothelial cells on PET/Co (A, C) and PET/Co + Fb (B, D) 72 h after seeding in static conditions (A, B), and after subsequent application of 120 min of flow (C, D). The flow direction is indicated by the arrows.

**Fig. 2.** The ratio of the cell numbers obtained in dynamic and static cell culture systems on day 7 after seeding on glass, on polystyrene dishes (PS), and on PEO surfaces with RGD, Col, or with a combination of RGD+Col in concentrations of  $90 \text{ fmol/cm}^2$  or  $700 \text{ fmol/cm}^2$  for each peptide. Mean  $\pm$  S.E.M. from 3 experiments. ANOVA, Student-Newman-Keuls method. <sup>##</sup> $P < 0.001$  compared to the other samples.

### CONCLUSION

The surfaces functionalized with a fibrin network or with a combination of an RGD-containing peptide with a collagen-derived peptide binding fibronectin showed the highest retention of the endothelial cells under dynamic stress. These modifications are suitable for endothelialization of vascular prostheses.

## INTRODUCTION

Two Photon polymerization (2PP) is a rapid prototyping technique which benefits from the two photon absorption principle, resulting in the production of scaffolds characterized by a very high resolution with nearly no structural limitations. Gelatin is an ideal scaffolding material due to the presence of RGD peptides which render this protein very cell-interactive.<sup>1</sup> However, currently applied photo-crosslinkable gelatin derivatives lack sufficient mechanical properties for 2PP processing in adequately diluted conditions to enable metabolite and nutrient transfer. To overcome these limitations, the present work aims to develop gelatin-based hydrogels with tunable mechanical properties which reach beyond the capabilities of conventionally applied methacrylamide-modified gelatin (gel-MOD).

## EXPERIMENTAL METHODS

In a first part, the free amines present in gelatin B were functionalized using 2.5 equivalents methacrylic anhydride in a phosphate buffered solution (pH 7.3) (10 w/v%) to obtain gel-MOD with a degree of substitution (DS) of 97%. Additional crosslinkable functionalities were introduced via reaction of the carboxylic acids in gel-MOD with 2 aminoethylmethacrylate (AEMA) (2 equivalents) via conventional EDC/NHS coupling in DMSO under inert atmosphere ( $DS_{COOH} = 30\%$ ). Via film casting, 10 w/v% solutions of gel-MOD (DS 97%) and gel-MOD-AEMA containing 2 mol% of Irgacure 2959 were crosslinked by applying UV-light (365 nm) for 30 minutes. The obtained hydrogels were characterized using DSC, gel fraction/swelling tests, rheology and (HR-MAS) <sup>1</sup>H-NMR spectroscopy. Finally, the biocompatibility was assessed via live/dead staining experiments and a proof-of-concept for 2PP processing was established.

## RESULTS AND DISCUSSION

A first remarkable finding, in contrast to non-modified gelatin and gel-MOD was the solubilization of the gel-MOD-AEMA hydrogel precursors at room temperature. To investigate this phenomenon in depth, DSC experiments were performed which displayed a drop in UCST together with a significant reduction in the associated energy concomitant with this phase transition. Both gel fraction tests as well as HR-MAS <sup>1</sup>H NMR spectroscopy indicated a higher crosslinking efficiency for the AEMA derivatives developed. Real-time rheological monitoring of the crosslinking reaction

further supported the proposed hypothesis. The gel-MOD-AEMA derivative exhibited a storage modulus roughly twice the value of the gel-MOD derivative (see Figure 1). Furthermore, live/dead staining experiments revealed a comparable biocompatibility for both derivatives.

Figure 1: Rheological properties of gel-MOD (blue) and gel-MOD-AEMA (red) during UV crosslinking.

In a final part, preliminary 2PP processing experiments illustrated the potential of the novel hydrogels with respect to reproducibility and structural integrity of the scaffolds developed as gelatin solutions with concentrations of 10 w/v% and below could be processed. The latter is of crucial importance since low concentrations enable superior diffusion of oxygen and metabolites through the scaffolds.<sup>2</sup> The porous scaffolds are currently also being evaluated as cell carriers for tissue engineering purposes.

## CONCLUSIONS

The incorporation of additional crosslinkable functionalities through the reaction of the carboxylic acids present in gel-MOD using AEMA provides an excellent method to increase the structural integrity of gelatin-based hydrogels. Furthermore, the derivatization does not affect the material cytocompatibility. The results further increase the potential of 2PP starting from gelatin-based hydrogel building blocks to yield optimal, mechanically tailored hydrogel scaffolds for soft tissue engineering applications.<sup>1</sup>

## Polypeptide Nanoparticles for Ocular Drug Delivery

Neil R. Cameron

Department of Materials Engineering, Monash University, Clayton 3800, Victoria, Australia

[Neil.cameron@monash.edu](mailto:Neil.cameron@monash.edu)

### INTRODUCTION

Polypeptides are ideal materials for ocular drug delivery vehicles due to their biocompatibility and biodegradability [1]. Polypeptides of desired molecular weight possessing tunable properties, can be synthesized from amino acid building blocks in a controlled manner using ring-opening polymerization (ROP) of *N*-carboxyanhydride (NCA) monomers. In this work, peptide-based nanostructures for ocular drug delivery have been prepared from polypeptides which were synthesized by controlled ROP of NCAs, using modified previously described procedures [2, 3].

### EXPERIMENTAL METHODS

Block copolypeptides were prepared by sequential monomer addition without intermediate purification steps. Different target molecular weights and block ratios were obtained by varying the monomer to (macro)initiator ratio. Example procedure: *N*-Benzyltrimethylsilylamine in DMF (127  $\mu$ L) was added to NCA 1 (0.38 mmol) in 1.5 mL of dry DMF in a Schlenk tube pre-filled with nitrogen, and allowed to stir for 24 h. NCA 2 (0.38 mmol) was then added to the reaction mixture. After 24 h of additional stirring the solution was poured into a 20-fold excess of diethyl ether with stirring. The precipitated solid was collected by centrifugation to afford the block copolypeptide (yield 184 mg, 91%) as a white powder.

Self-assembly into nanoparticles was performed as follows: polymers were first dissolved in THF at a concentration of 1.0 mg mL<sup>-1</sup>. Filtered MilliQ water was added to the solution and it was stirred overnight, allowing the THF to evaporate. If necessary, the solutions were finally filtered through a 0.45  $\mu$ m filter. The final polymer concentration in water was 1.0 mg mL<sup>-1</sup>.

### RESULTS AND DISCUSSION

A range of amphiphilic polypeptide block copolymers was prepared by sequential ring-opening polymerisation of NCAs. Representative data are presented in Table 1. Polymerisations were controlled giving molecular weights that agreed well with predicted values, and narrow dispersities.

Table 1. Characterisation Data for Polypeptide Block Copolymers

Sample	Expected $M_n$ [Da]	Obtained $M_n$ [Da]	$\bar{D}_M$
PBnE <sub>30</sub> - <i>b</i> -ZK <sub>30</sub>	14,700	15,800	1.17
PBnE <sub>30</sub> - <i>b</i> -ZK <sub>15</sub>	10,607	14,500	1.17
PBnE <sub>50</sub> - <i>b</i> -ZK <sub>50</sub>	24,157	30,500	1.27
PBnE <sub>50</sub> - <i>b</i> -ZK <sub>25</sub>	17,607	20,400	1.28

BnE =  $\gamma$ -benzyl-L-glutamic acid NCA; ZK =  $\epsilon$ -carbobenzyloxy-L-lysine NCA; subscript denotes block length.

Block copolypeptides were assembled into nanostructures (micelles or vesicles, depending on copolymer composition) by the solvent evaporation method. Nanostructure characterisation was performed by TEM and dynamic light scattering. The diameter of the nanostructures obtained varied from around 40nm to around 200nm.

Nanoparticles were loaded with dexamethasone (Dx), an anti-inflammatory drug used in treating ocular diseases. Repeated preparation of the Dx-loaded nanoparticles showed excellent reproducibility, giving an average particle diameter of around 180 nm. The release of Dx was then monitored at 37 °C over 16 days (polymer:Dx = 20:1). The Dx loading was 5.5 wt% (HPLC) and loading efficiency was 90%. Around 20% burst release of dexamethasone was observed in the first 24 hours, after which the release was steady over the remaining period of the study. After 16 days, 94% of the loaded dexamethasone had been released (Figure 1).

Figure 1. Release of dexamethasone from PE<sub>50</sub>-*b*-ZK<sub>25</sub> nanoparticles.

### CONCLUSION

Nanoparticles composed of block copolypeptides have been prepared and shown to be capable of releasing the ocular drug dexamethasone over 16 days.

## INTRODUCTION

Soft biomedical electrodes open up new frontiers for neural applications. Fabricated by growth of conducting polymers (CPs) within hydrogels, soft conducting hydrogel (CH) electrodes support integration of living cells. The concept is based on encapsulating living cells within biosynthetic hydrogels designed to overlay the CH as shown in Figure 1. Such tissue-engineered electrodes will deliver the capacity for more direct, physiological stimulation of target neural tissues<sup>1</sup>.

CHs are typically formed on metal electrode substrates to produce robust adhesive coatings (Fig 1). Although this approach is suitable for neural applications using metal electrodes, development of standalone soft conductive materials will support applications where electrode compliance is critical. An example is in soft electroactive cardiovascular patches. The primary aim of this research was to investigate robust approaches for fabricating CH coatings and standalone CHs. Glial cell responses to the CH and to encapsulation within biosynthetic hydrogel constructs were also examined.

Figure 1. Schematic of tissue engineered electrode.

## EXPERIMENTAL METHODS

Nucleation of CP growth within hydrogels was achieved using two key approaches. The first was modification of 16kDa poly(vinyl alcohol) (PVA) hydrogel backbone with taurine, a low molecular weight (MW) sulphonic acid designed to act as an immobilised dopant. The second approach was blending dispersions of chemically synthesised poly(3,4-ethylene dioxithiophene): poly(styrenesulfonate) (PEDOT:PSS; Orgacon<sup>TM</sup>) with PVA hydrogels<sup>4</sup>. Following cross-linking of hydrogels at polymer concentrations up to 20 wt% via UV photo-polymerisation, electrodeposition of PEDOT within EDOT loaded hydrogels was conducted<sup>2</sup>. Characterisation of electrical properties was conducted by cyclic voltammetry and impedance spectroscopy. Cytotoxicity of modified PVA hydrogels was assessed via contact inhibition studies using primary astrocyte enriched glial cell (GC) cultures. Degradable hydrogels were fabricated based on tyramine modified 16kDa PVA (see Lim *et al*<sup>3</sup>) and Schwann cell (SC) response was studied after encapsulation for up to 21 days.

## RESULTS AND DISCUSSION

Robust CH coatings and standalone CH were successfully fabricated. CH coatings had smooth hydrogel-like surfaces (Fig 2a) in contrast with typical rough and friable electrodeposited PEDOT/PSS. Electrical properties of both CH materials were comparable with control conducting polymers based on PEDOT/PSS.

Figure 2. (a) SEM of CH based on 20%PVA modified with ~10 taurine/chain (b) GC cultures following contact with PVA-taurine CH.

Contact inhibition studies showed that GC survived 14 days contact with CH (see Fig 2b). SC encapsulated in the “overlay” degradable PVA hydrogel showed significant growth and matrix production over 21 days *in vitro*. These results confirm that the concept of a layered tissue-engineered construct is feasible.

## CONCLUSION

Elegant strategies confirmed for incorporating dopants into hydrogels included low MW dopant immobilisation on the polymer backbone and blending high MW CP plus dopant into the hydrogel. The capacity to fabricate CH as adhesive coatings or as standalone CH was also demonstrated. *In vitro* studies showed these materials have utility for biomedical device applications. These findings show that this flexible platform is a significant step towards realising standalone tissue engineered electrodes for neural and cardiovascular applications.

## INTRODUCTION

One of the main challenges in tissue engineering is the creation of a suitable *in vitro* environment in which cells derived from native tissue (such as stem cells) can be seeded, grown, and induced to differentiate as they do *in vivo*<sup>1</sup>. There are numerous examples in the literature and in the clinic of artificial environments that provide such a milieu of factors and conditions including smart or intelligent scaffolds that respond to cells with culture progression. Peptide amphiphiles (PAs) constitute a notable example of such self-assembling materials<sup>2</sup>.

This smart coating was formed from a self-assembling peptide amphiphile comprising a protease-cleavable sequence contiguous with a cell-attachment and signaling motif. This multi-functional material was subsequently used not only to instruct human corneal or skin fibroblasts to adhere and deposit discrete multiple layers of native extracellular matrix, but also govern their own self-directed release from the template solely via the action of endogenous metalloproteases (MMP).

## EXPERIMENTAL METHODS

C16-TPGPQG↓IAGQRGDS peptide amphiphile was custom-synthesized by CS Bio (Menlo Park, USA) and spotted and dried on to low-attachment tissue culture plastic at an initial concentration range of  $1 \times 10^5$ - $10^2$  M. After washing, human fibroblasts were cultured on the PA coatings in serum conditions initially in the presence of retinoic acid (RA) to suppress endogenous MMP expression<sup>3</sup> for 90 days followed by 3 days in the absence of RA to illicit MMP derived cleavage of the PA coating and tissue detachment (n=12). Subsequent reattachment of the newly formed tissues onto fresh PA coatings was repeated 3 times (Fig 1). Characterization of the tissue at a gene, protein and ultra structural level was undertaken by qPCR, immuno-blotting, confocal and electron microscopy and compared against normal tissue (skin and cornea) values.

Fig 1. Schematic depicting how cells isolated from human donors were seeded and grown on MMP sensitive PA coatings in RA supplemented media. Lifted tissues were then easily recoverable for repeated reattachment and re-lifting processes.

## RESULTS AND DISCUSSION

The newly-shaped tissues governed their own release from the template via the action of endogenous proteases. Tissues recovered through this physiologically relevant process were carrier-free, and structurally and phenotypically equivalent to their natural counterparts (Fig 2). The tissues were shown to be functional (via contraction assay) (Fig 3).

Fig 2. Transmission electron microscopy, evidencing the multi-layered organization of the tissue, with intercalating layers of fibroblasts and deposited ECM comprised of densely-packed collagen fibrils. Scale bars 500nm (left), 100nm (right).

Fig 3 Myofibroblastic activity of fibroblasts from self released tissues after incubation in serum-containing medium following 3x reattachment (R1-3) at day 0 and day 7. Quantification of tissue contraction expressed as ratio between final and initial area of tissue.

## CONCLUSION

The resulting technology contributes to a new paradigm in regenerative medicine whereby materials are able to actively direct and respond to cell behavior. The novel application of materials as a template coating, directing the formation and detachment of complex tissues solely under physiological conditions, will undoubtedly have broad use in future cell and tissue therapies.

#### INTRODUCTION

The concept of magnetic guidance usually spans from drug delivery and hyperthermia treatment of tumors, to magneto-mechanical stimulation/activation of cell constructs and mechanosensitive ion channels such as magnetic cell seeding procedures and controlled cell proliferation and differentiation. The possibility to extend these concepts to tissue engineering has opened an exciting wide research area of interest.<sup>1-4</sup> The aim of the present work was to assess morphological, mechanical, magnetic and biological performances of nanocomposite magnetic scaffolds obtained through rapid prototyping techniques (RP).

Among all the RP techniques, 3D fiber deposition and stereolithography may provide a morphologically controlled and tailored structure with interconnected pores of specific scale. Furthermore, a superparamagnetic scaffold should provide the fascinating possibility to magnetically "switch-on/switch-off" it in order to deliver biofactors and stem cells, or to stimulate cell adhesion, proliferation and differentiation.

#### EXPERIMENTAL METHODS

Firstly, 3D well-organized cylindrical poly( $\epsilon$ -caprolactone) (PCL) and poly( $\epsilon$ -caprolactone)/magnetic nanoparticles (PCL/MNPs) nanocomposite magnetic scaffolds were manufactured through 3D fiber deposition technique by alternatively plotting fibers along 0°/90° lay-down pattern. Successively, 3D mathematically defined porous polyethylene glycol diacrylate/magnetic nanoparticles (PEGDA/MNPs) scaffolds with a diamond architecture were prepared through stereolithography technique. To this aim, MNPs were mixed in different amount with a solution of PEGDA as photocrosslinkable oligomers, Lucirin TPO-L as biocompatible UV photo initiator, and Orasol Orange G as dye.

The performances of the designed scaffolds were assessed by means of experimental/theoretical *in vitro* investigations. In particular, morphological studies were performed through micro-computed tomography (Micro-CT) and scanning electron microscopy (SEM). Nano-, Micro- and Macro-mechanical analyses were carried out through nanoindentation, tensile and compression tests, respectively.

Human mesenchymal stem cells (hMSCs) were statically seeded on 3D cylindrical scaffolds in order to study the effect of a static and a time-dependent magnetic stimulation on cell adhesion and spreading. Cell viability/proliferation was assessed by using

Alamar Blue assay, whilst cell differentiation was evaluated by ALP activity.

#### RESULTS AND DISCUSSION

Micro-CT and SEM analyses highlighted that 3D fiber deposition and stereolithography are able to manufacture morphologically-controlled scaffolds.

Results from compression and tensile tests showed that beyond a specific limit of MNP amount, by further increasing the nanoparticle concentration, the mechanical performances of the nanocomposite scaffolds decrease because the nanoparticles act as "weak points" instead of reinforcement for the polymeric matrix. In order to locally map mechanical properties, nanoindentation tests were performed showing interesting results in terms of hardness and reduced modulus. Magnetic analysis revealed a superparamagnetic behavior of these materials.

Results obtained from the biological analyses showed that prolonged exposure time to the static or dynamic magnetic field seems to negatively affect cell viability. It is worth noting that in terms of cell viability/proliferation there were some differences between magnetically and not magnetically stimulated scaffolds. Confocal analyses highlighted interesting results in terms of cell adhesion and spreading. An increase in adhered number and a more evident spreading of hMSCs were evidenced. On the other hand, the Alamar Blue assay and ALP/DNA measurements provided a quantitative evaluation of cell viability/proliferation and differentiation, respectively over the culture time.

#### CONCLUSION

3D nanocomposite magnetic scaffolds obtained through RP techniques should be considered as a potential alternative to bone graft substitute with attractive new performances.

### INTRODUCTION

Regenerative medicine holds the promise to create continuous body-part replacements through the combination of cells, biological factors, and scaffolds. First generation products consisted of cells in solution, combined with injectable hydrogels, or seeded on 3D fleeces. Although the initial response to these treatments showed excellent results, long-term follow-ups revealed the formation of fibrotic-like tissue with lower functionality compared to the targeted tissue to regenerate. One of the current viable alternative imply the use of stem cells. Yet, a better control over cell-material interactions need to be achieved to transform this promise into better performing and long-lasting products. In particular, it is still critical to control stem cell differentiation into 3D scaffolds. In our bodies stem cell differentiation is ruled by physical and chemical gradients. Therefore, the design of next scaffold generation should take into account how these phenomena can be actively controlled. In this study, we present a new technique to produce three-dimensional (3D) gradients of protein concentrations within microporous, biodegradable scaffolds.

### EXPERIMENTAL METHODS

The 3D supports were manufactured by fused deposition modeling (SysENG, Germany) of poly-ε-caprolactone (PCL), forming a regularly layered network of microfibers with diameter ( $d_1$ ) = 250 μm, spacing ( $d_2$ ) = 650 μm, layer thickness ( $d_3$ ) = 150 μm. From these values the theoretical porosity (~50%) of the scaffold was calculated.

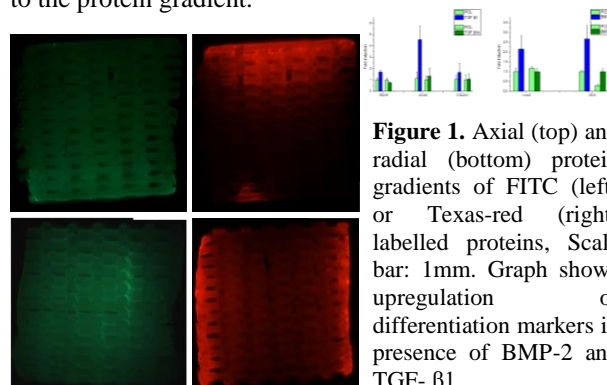

Uniform coating of the scaffold surface with “grafted-from” poly[oligo(ethylene glycol) methacrylate] (POEGMA) brush was adapted from previously published studies on two-dimensional substrates [1]. The coating allowed covalent immobilization of proteins from solution and the formation of 3D protein gradients within the supports. POEGMA brushes on PCL scaffolds were activated by placing them in a dry DMSO solution containing 200 mM of DSC and DMAP. Later on, the samples were incubated in a protein solution containing either 0,4 μM fluorescently labeled BSA or 0,1 μM fibronectin (FN), 10 μM bone morphogenetic protein-2 (BMP2), or 10 μM transforming growth factor β1 (TGF-β1).

Bone marrow derived human mesenchymal stromal cells (hMSCs) were seeded at a density of 500,000 cells in 40 μL per scaffold. After 4 hours, cell culture media was added and cultures were maintained for up to 10 days. Cell adhesion was observed by microscopy, while cell differentiation by polymerase chain reaction and

biochemical assays for the expression and production of specific osteogenic and chondrogenic markers.

### RESULTS AND DISCUSSION

The hydrophilic character of thin brush coatings (10-50 nm thick) strongly affected surface energy and capillary forces within the microporous structure, consequently allowing the controlled diffusion of protein solutions inside the pores. Additionally, the multifunctional character of POEGMA brush enabled the efficient and stable bio-conjugation of proteins via covalent linkages. 3D axial and radial protein gradients were, thus, fabricated enabling a variation of the functional group distribution by varying diffusion time and volume of diffusing solution (Figure 1). Finally, we fabricated different gradients of brush-supported FN, BMP-2, and TGF-β1. The subsequent seeding with hMSCs showed spatially determined cell immobilization and to a certain extent differentiation within the 3D support according to the protein gradient.

**Figure 1.** Axial (top) and radial (bottom) protein gradients of FITC (left) or Texas-red (right) labelled proteins, Scale bar: 1mm. Graph shows upregulation of differentiation markers in presence of BMP-2 and TGF-β1.

### CONCLUSION

We have developed a versatile method to present different configuration of protein gradients, which showed to effectively control spatial cell distribution and hold potential to further control cell differentiation.

## INTRODUCTION

Thermoplastic elastomers (TPE) belongs to high performance polymers with good solvent resistance, elasticity, tear strength and flex fatigue. They already found a wide range of applications in medicine such as medical tubing or equipment parts. Selected TPEs are also used for implant applications [1]. Polyurethane TPU are already used as “gold standard” in blood contacting medical devices, including artificial heart. Their major problem, however, is mechanical instability under cyclic dynamic loading [2] due to environmental cracking. However, there are no literature data reporting how much of the total organic carbon is extracted from PU what could shade the light on their performance. This paper will discuss the static mechanical and dynamic fatigue properties of medical grade polyurethane (PCU) and new segmented polyester TPE containing dimerized fatty acid (PET-DLA), proposed as alternative material to PCU. We will try to find dependence between mechanical performance in simulated body fluid (SBF) and total organic carbon (TOC) extracted from the materials.

## METHODS

Static mechanical testing was performed with Instron 3366 according ISO 527-1:1998. Fatigue testing was carried out using a servo-hydraulic test machine with a digital controller (Instron Electropulse), equipped with a 200-N load cell, a 10 kN cylinder and an environmental chamber. For all tests, the load ratio  $R = \sigma_{\min}/\sigma_{\max}$  was held constant at 0.1. The strain was measured as the real-time clamp displacement. The possible phase shift between the stress and strain signals were minimized below 20  $\mu$ s by the experimental set-up. Testing in simulated body fluid (SBF) was carried out at 24 and 37°C. Testing was carried out using the SILT (Stepwise Increasing Load Test) and SLT (Single Load Test) methods [3]. Water extraction was carried out on material previously purified by solvent extraction. Polymer granules were immersed in water at 37°C for 3, 7, 14, 21 and 28 days in shaking incubator. As reference material, commercially available PCU was used. Water extracts were used for determination of total organic carbon (TOC), turbidity, conductivity and total dissolved solids.

## RESULTS AND DISCUSSION

PET-DLA material containing 60wt% hard segments showed static mechanical properties comparable to medical grade PCU (Table 1). The stepwise increasing load test has been performed for 12K cycles and then, single load test has been performed for 1 mln cycles at ambient temperature (24°C) and in SBF and at 37°C. PCU experienced tremendous dynamic creep ( $\Delta\epsilon$ ), especially at

body temperature (37°C). PET-DLA copolymer showed very good stability of mechanical properties during long term testing. Such different behaviour in PU and PET-DLA can be interpreted based on Takahara's *et al.* [4] suggestions regarding the fatigue of segmented polyurethanes that under the cyclic deformation, the destruction of the hard segment domain and/or intermixing of the hard and soft segments can take place. Interestingly, PCU showed much higher total organic carbon content derived from water extracts as compared to PET-DLA (Fig. 1). This indicates again, much higher chemical stability of PET-DLA as compared to PCU.

**Table 1** Comparison of mechanical properties

Material	$\sigma$ (MPa)	$\epsilon$ (%)	$\Delta\epsilon$ @ 24°C (%)	$\Delta\epsilon$ @ 37°C (%)
PCU	$54.3 \pm 3.2$	$435.9 \pm 26.6$	20.9	217.3
PET-DLA	$24.1 \pm 2.9$	$566.7 \pm 42.1$	3.2	6.5

**Figure 1:** The carbon content in water extracts from materials.

## CONCLUSIONS

The hysteresis method seems to be a useful new method to evaluate the dynamic behavior of elastomeric biomaterials. From this method, and from the extraction results, it can be concluded that PET-DLA showed improved dynamic fatigue properties and higher chemical stability as compared to PCU material.

### INTRODUCTION

Ceramic biomaterials are used for clinical applications as bone grafts to reconstruct bone tissue in defects. Both bone-forming osteoblasts and bone-resorbing osteoclasts play prominent roles in bone formation surrounding the implanted ceramic biomaterials. Osteoclast formation are regulated by osteocytes embedded in bone matrix through the expression of receptor activator of nuclear factor- $\kappa$ B ligand (RANKL)<sup>1</sup>.

We designed the osteocyte-stimulating biomaterials without addition of any growth factors. Osteocytes are most abundant cells in bone, buried in the mineralized bone matrix. Although the osteocytes are used for the evidence for the osteoblast differentiation from the osteoblast progenitors, there are few studies on the interaction between the osteocytes and ceramic biomaterials. In the present study, the interactions of osteocytes with bone marrow cells through the cell-to-cell communications on various types of ceramic biomaterials, were investigated.

### EXPERIMENTAL METHODS

**Cell culture:** Osteocyte-like cells<sup>2</sup> (MLO-Y4, kindly gifted from Prof. Bonewald) were co-cultured with bone marrow cells (BMC) isolated from mouse femurs (C57Bl/6J, male, 10-week-old) on the synthesized ceramic biomaterials such as hydroxyapatite (HA), carbonate apatite (CA) and bone slices as a control.

The fixed cells were also stained for tartrate-resistant acid phosphatase (TRAP) to confirm the differentiation of BMC into osteoclasts. The cells adhered to the samples were stained with rhodamine-phalloidin and Hoechst. After removing the cells, the resorption pits were observed using scanning electron microscope and quantified using laser microscope.

**Implantation into rat femurs:** The ceramic biomaterials were surgically implanted in the femoral diaphysis of Wistar rats (13-week-old, male). At 7 d after the implantation surgery, the femurs were extracted and immersed in 4% paraformaldehyde. After fixation, each sample was decalcified with 10% neutralized ethylenediamine tetraacetic acid (EDTA), dehydrated in an ascending gradient of ethanol concentrations, cleared in xylene, embedded in paraffin, and cut into 5- $\mu$ m sections. Each section was deparaffinized with xylene, rehydrated with ethanol, and stained with hematoxylin and eosin (HE) and for TRAP using standard methods.

### RESULTS AND DISCUSSION

The giant cells with multiple nuclei were formed both on the synthesized CA and bone slices after a co-culture of MLO-Y4 with BMC. These cells were positively stained for TRAP, which indicated that they were differentiated from BMC into osteoclastic cells without any added differentiation factors. Actin rings, which are specific markers for activated osteoclasts to resorb the substrata, were formed in osteoclasts on the CA and bone slices. As a result, the resorption pits were formed on CA and bone slices. The possible explanations of the enhanced differentiation and activation of osteoclastic cells on the CA are the cell-to-cell interactions and secretion of differentiation factors from MLO-Y4 cells.

Fig. Actin rings were formed on the synthesized CA after co-culture of osteocyte-like cells with bone marrow cells without any differentiation factors.

After the implantation of ceramic biomaterials for 7 d into the rat femur, most of the HA surfaces were covered with fibrous tissue layers containing nucleated spherical and flattened fibroblastic cells. Newly formed bones were also found in the regions approximately 100–200  $\mu$ m away from the implanted CA5. Giant and multinuclear osteoclastic cells were found near the implanted CA5 and on the newly formed bone in bone marrow.

### CONCLUSION

TRAP-positive and multinuclear cells with actin ring structures were formed by the interaction with osteocyte-like cells and BMC. The formation of mature and activated osteoclasts was enhanced on the CA compared to HA.

### INTRODUCTION

The multicellularity has required the development of forms of communication and interaction, in order to allow the complex coordination of groups of cells. The intricate control of cell differentiation and synchronization, which occurs during tissue development, is mediated by the intercellular diffusion of signaling molecules through gap junctions. In this context, connexin43 (Cx43), a component of gap junctions, has been found in several types of bone cells and also in mesenchymal stem cells. The importance of Cx43 for osteogenesis and bone formation has been demonstrated *in vitro*<sup>1</sup> and *in vivo*<sup>2</sup>. Interestingly, another family of membrane proteins named pannexins (Panxs) was recently described to present similar characteristics to connexins<sup>3</sup>. Despite the evidence supporting the key role of pannexins in cell communication and function, only a few studies have examined their implication in human cells<sup>4,5</sup> and on human physiology or disease<sup>6,7</sup>. Indeed, no study has yet focused on the implication of pannexins in the osteoblastic differentiation of human bone marrow mesenchymal stem cells (HBMSCs), when in a 3D environment that would favor bone regeneration.

### EXPERIMENTAL METHODS

HBMSCs, isolated from human bone marrow samples, were seeded in 6 mm diameter pullulan/dextran 75:25 (pullulan, MW 200,000, Hayashibara Inc; Dextran, MW 500,000, Sigma) matrix disks at  $4 \times 10^5$  cells/disk and cultured for 1 and 4 days in  $\alpha$ -MEM medium supplemented with 10% (v/v) FCS, with and without the use of Panx1 specific inhibitors probenecid and <sup>10</sup>panx1. At designated time points samples were processed for mRNA and protein extraction, or for immunocytochemistry evaluation. Gene expression of Panx1, Panx3, CaSR, ALP, Cbfa1/runx2, OCN and Cx43 was evaluated by qPCR. Semi quantitative Panx1, Panx3 and Cx43 protein expression was assessed by Western blot analysis. Additionally, scaffolds seeded with HBMSCs were implanted in dorsal subcutaneous sites of 12-week-old NOG mice and explanted at 3 and 8 weeks for histological analysis.

### RESULTS AND DISCUSSION

Here we show that Panx1 is involved in 3D cell-cell organization of human stem cells, demonstrated by the use of the inhibitory drug Probenecid and the mimetic peptide <sup>10</sup>panx1, which specifically block Panx1 channels. Panx1 is involved in the compaction of the cellular aggregates induced by the 3D organization.

Furthermore, our study demonstrates that culturing HBMSCs within 3D scaffolds induces Panx1 and Panx3 expression. Inhibition of Panx1 lead to a reduced expression of osteogenic markers in HBMSCs when in 2D culture, but had a minimal effect on HBMSCs when in 3D, suggesting specific roles of Panx1 in osteogenesis. We also show that the Panx3 gene expression profile correlates with those of osteoblastic markers.

Taken together, our data indicate that Panx1 and Panx3, likely in conjunction with Cx43, may act on HBMSCs cultured in 3D, by improving cellular communication within the dense cellular aggregates and supporting their differentiation towards the osteoblastic phenotype. This study demonstrates that Panx1 and Panx3 are expressed and involved in human bone tissue formation *in vitro* and *in vivo*.

Future studies will focus on the mechanism of how Panx1 impacts on the HBMSCs actomyosin cytoskeleton and how it may regulate cell differentiation towards an osteoblastic phenotype. Additionally, the use of Panx3 specific inhibitors will allow to identify the role of this pannexin in this intricate cell communication process.

### CONCLUSION

This study opens new avenues in the establishment of novel conditions to promote osteogenic differentiation of multipotent MSCs without the addition of external stimuli (i.e. differentiation medium or mechanical stimulus).

### INTRODUCTION

We have previously found that octacalcium phosphate (OCP), if synthesized in a specific condition, shows a higher osteoconductive property than hydroxyapatite (HA), while it is hydrolyzed *in situ* into apatitic phase in critical-sized rat calvaria defects, and that the partial hydrolysis of the OCP material increases its osteoconductivity further in rat tibia defects<sup>1-3</sup>. The osteoconductivity of OCP in rat calvaria defects is more enhanced if OCP is combined with one of natural polymer gelatin (Gel) matrices through co-precipitation, which also exhibits a higher bone regenerative property and biodegradable property<sup>4</sup>. However, the effect of the OCP hydrolysis in the OCP/Gel composite has not been examined yet. The present study was designed to investigate the material characteristics and bioactivity of the OCP/Gel composites *in vitro*.

### EXPERIMENTAL METHODS

OCP was synthesized by introducing calcium and phosphate salts in a gelatin-containing solution under a supersaturated condition with respect to HA and OCP<sup>4</sup>. The resultant composite contained 40wt% of OCP<sup>4</sup>. Hydrolyzed OCP/Gel composites were obtained by a conversion from the synthesized OCP/Gel slurry<sup>3</sup> at 70°C with constant stirring for 6 to 40 h. The hydrolysis rate was compared with that of OCP alone up to 40 h. The hydrolyzed OCP/Gel composites were then lyophilized in a mold to obtain disks with a 9 mm diameter and 1 mm thickness, and then underwent dehydrothermal treatment at 150°C for 24 h in a vacuum drying condition. The resultant composites, having a spongy porous structure<sup>4</sup>, were characterized by chemical analyses, X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FTIR), scanning electron microscopy (SEM), transmission electron microscopy (TEM) and selected area electron diffraction (SAED). Mouse bone marrow stromal ST-2 cells were seeded and incubated on OCP/Gel disks. The cell attachment at 6 h, and the proliferation and the differentiation into osteoblastic cells (the activity of alkaline phosphatase, ALP) were determined up to 21 days. In addition, the effect of co-presence of Gel molecules on the OCP hydrolysis was analysed. Pre-precipitated OCP was hydrolyzed in the presence of Gel with various concentrations (up to 0.45%) at 70°C with constant stirring up to 12 h.

### RESULTS AND DISCUSSION

Transformation of OCP into HA was confirmed by XRD and FTIR. The plate-like morphology of OCP was observed even after the hydrolysis by SEM and TEM. The analysis by SAED suggested that the structure of OCP is still retained even in the most hydrolyzed

product. Ca/P molar ratio of OCP in the composite progressively increased with the advancement of the hydrolysis, but did not reach the stoichiometric HA composition, as seen in the previous hydrolysis study with OCP alone<sup>5</sup>. The presence of Gel in the composite, obtained by the co-precipitation, affected the hydrolysis rate. The OCP/Gel composites tended to hydrolyze faster than OCP alone. Furthermore, an analysis of the hydrolysis of the pre-precipitated OCP in the presence of Gel indicated that OCP hydrolysis tended to advance with increasing the Gel concentration. The results suggest that Gel molecules may interact with OCP crystal surfaces and regulate the rate of the hydrolysis.

The number of attached ST-2 cells on each composite was compatible to that on the Gel disk (without calcium phosphate crystals) at 6 h. ST-2 cells proliferated and reached the same level between all composites and Gel disk until 21 days. The ALP activity of ST-2 cells increased with the incubation time on all composites and was comparable to that on the Gel disk (without calcium phosphate crystals) at 21 days. The results suggest that the OCP/Gel composites with various degree of hydrolysis could have a similar bioactivity with the gelatin material that is widely used as an implantable biomaterial, using a bone marrow derived stromal ST-2 cell line.

### CONCLUSION

The present study provided evidence that the presence of Gel molecules accelerates the OCP hydrolysis. The hydrolyzed OCP/Gel composites show a similar bioactivity with Gel alone in terms of the osteoblastic cellular response. *In vivo* analysis of the hydrolyzed OCP/Gel composites is under way to elucidate the potential effect of the hydrolysis of OCP within the Gel matrix on bone regenerative properties as previously seen in the hydrolysis of OCP without Gel<sup>3</sup>.

### INTRODUCTION

Biomaterials play an important role in bone tissue engineering, since they mimic the structure and composition of human tissue and provide mechanical stability<sup>1,2</sup>. The biodegradable biopolymers like chitosan and collagen serve often as the scaffolds in the development of hybrid materials for bone replacement and regeneration<sup>3</sup>. It was also reported that addition of silica can improve the bioactivity and biocompatibility of the polymeric materials<sup>4</sup>. In this study we have presented the preparation and studies of bioactivity of the novel hybrid organic-inorganic materials based on collagen, collagen-chitosan and chitosan hydrogels containing silica nanoparticles<sup>5</sup>. These materials can be considered as potentially useful injectable scaffolds for bone tissue regeneration. The effect of such parameters as: the type of hydrogel matrix used, the presence of SiNP in the hybrid material, the size of added NPs on promotion of apatite-like mineral structures formation under physiological conditions (incubation in a simulated body fluid, (SBF) was evaluated and discussed.

### EXPERIMENTAL METHODS

The silica nanoparticles were prepared *in situ* by Stöber method. Dynamic light scattering (DLS) and zeta potential measurements were carried out to determine their size and zeta potential values. The silica nanoparticles (SiNP) of two different sizes (S1-210 nm and S2-440 nm) were next dispersed in collagen (Col), collagen-chitosan (ColCh) or chitosan (Ch) sols. These sols were then subsequently crosslinked with genipin. Taking into account the potential application of hybrid organic-inorganic systems as a potential injectable scaffold for bone tissue engineering the *in vitro* experiments with simulated body fluid (SBF) treatment were carried out. For that purpose the samples were incubated in SBF for 21 days. After incubation in SBF the structures of the resulting mineral were examined using scanning electron microscopy (SEM), energy dispersive X-Ray spectroscopy (EDS), and X-ray diffraction (XRD) techniques. In order to demonstrate the usefulness of the presented materials for biomedical applications their cytotoxicity was investigated with Primary Dermal Fibroblasts using colorimetric assay (XTT tests).

### RESULTS AND DISCUSSION

Novel organic-inorganic hybrids composed of biopolymer matrix based on collagen, collagen-chitosan or chitosan with incorporated silica nanoparticles of two different sizes were obtained. By monitoring the gelation process using the anisotropy fluorescence probe technique it was demonstrated that these

materials might be applied as injectable hydrogels. The *in vitro* experiments carried out under SBF conditions have shown that the prepared materials induce the mineralization. The rate of that process can be adjusted by the composition of the material. SEM images revealed mineral phase formation in majority of the obtained hybrid materials while they were exposed to SBF. Applying EDS analysis it was proven that these mineral phases are mainly composed of calcium and phosphorus. The XRD studies confirmed that mineral phases formed during SBF incubation of hybrid materials based on the collagen are bone-like apatite minerals. It was shown that the silica nanoparticles present in hydrogels promote mineralization. Furthermore addition of silica nanoparticles to the sol before the material gelation resulted in occurrence of mineralization not only at the surface but also in the bulk of the material. That is especially important for preparation of scaffolds for bone tissue engineering. It was also demonstrated that silica nanoparticles influenced the viability of the fibroblast cells *in vitro*. In all samples studied they have shown the positive effect, increasing the number of metabolic active cells cultured at these materials.

### CONCLUSION

Novel bioactive organic-inorganic hybrid materials which can serve as injectable hydrogel systems for bone tissue regeneration were successfully obtained. Studies on mineralization process under simulated body fluid (SBF) conditions confirmed the bioactivity of prepared materials. *In vitro* studies on fibroblast cells viability indicated that the hybrid materials are biocompatible. The ability of these materials to undergo *in situ* gelation under physiological temperature, their biocompatibility and bioactivity make them potentially useful candidates for bioactive injectable systems for bone tissue repair.

### INTRODUCTION

Regeneration of deep articular cartilage defects remains a challenging task because of the low self-healing capacity of this tissue. To overcome limitations of autologous grafting such as limited availability as well as donor-site morbidity, many biomaterials have been investigated as synthetic alternative. We have developed an anisotropic bilayered alginate-based scaffold mimicking osteochondral tissue<sup>1</sup>. The material fabrication can be completely conducted under sterile conditions, allowing the easy integration of living cells into the chondral layer. The present study describes differences between embedding of human chondrocytes (hCh) and mesenchymal stem cells (hMSC) as well as the results of a first animal pilot study, performed in sheep.

### EXPERIMENTAL METHODS

Scaffolds were fabricated applying the principle of diffusion-controlled directed ionotropic gelation of alginate. The bony layer consists of a composite made of alginate and hydroxyapatite (HAP), the chondral layer of alginate and hyaluronic acid (HYA). During gelation, channel-like pores are formed which run through the whole length of the scaffold. The two layers are tightly fused together, leading to biphasic but mechanically stable monolithic scaffolds<sup>1</sup>. Either hCh or hMSC were embedded into the chondral layer in the course of the gelation process. Cells were either cultured in presence or absence of chondrogenic supplements over a period of 3 weeks. Viability was analysed by live dead staining as well as measurement of the LDH activity. Chondrogenic differentiation was proven by means of collagen type II ELISA and gene expression analysis of chondrogenic markers. In an *in vivo* pilot study, 8 bilayered hydrogel scaffolds not containing cells were press-fit implanted in osteochondral defects 7 mm in diameter and 5 mm in depth, made in the medial and lateral femoral condyle of 4 Merinos-Sarda sheep. The animals were sacrificed 6 months after implantation and  $\mu$ -CT as well as histological analyses were carried out. Equally sized empty defects served as control.

### RESULTS AND DISCUSSION

Live/dead analysis one day after completed gelation revealed a high viability of both hMSC and hCh embedded into the chondral part of the bilayered scaffolds indicating that the gelation process does not strongly affect the viability. Viability of chondrogenically induced hMSC and hCh was superior compared to that of non-induced hMSC over a period of 21 d, as shown by measurement of LDH activity. The data indicates that the induction of chondrogenesis is crucial for survival of cells embedded in this type of hydrogel matrix. Successful chondrogenic (re)differentiation of induced

hMSC and hCh could be confirmed by gene expression of the chondrogenic markers COL2A1, ACAN and COMP. Additionally, strong deposition of collagen II was verified. The material allowed easy press-fit implantation in osteochondral defects, made in the knee joint of sheep. Micro-CT as well as histological investigations revealed a high biocompatibility and good integration of the hydrogel scaffolds. In most of the explants, regeneration of the chondral tissue layer was observed whereas the bony part of the defects was not yet completely healed 6 months after implantation.

**Fig. 1:** **A** – Photographs showing the bilayered hydrogel scaffolds; bottom: alginate/HAP composite, top: alginate/HYA layer with embedded hCh (dark spots, stained with MTT dye). **B** – Macroscopic view of sectioned femoral condyle of sheep. **C** – Histological images of the implantation site. **B & C:** 6 months after implantation of cell-free biphasic hydrogels.

### CONCLUSION

The developed scaffolds exhibit a structure that partly mimics the complex hierarchical architecture of natural osteochondral tissue. Our data indicate that the bilayered hydrogels are suitable for embedding of hMSC and hCh, respectively, into the chondral part. The superior viability of chondrogenically induced cells within the hydrogel highlights that a successful chondrogenic (re)differentiation is crucial for survival of the embedded cells. The pilot animal study, performed in sheep, yielded the high biocompatibility and stimulating effect of the biomimetic composite scaffold, especially for healing of the chondral part of osteochondral defects.

### INTRODUCTION

Because of a poor self-healing ability, joint cartilage undergoes progressive degradation in the course of aging or following traumatic injuries. One promising therapeutic approach is the use of mesenchymal stem cells (MSC), which have the potential to differentiate into chondrocytes. However, anchorage of MSC to the sites of injury and their differentiation *in situ* require combining cells with a biomaterial releasing a differentiation factor such as TGF $\beta$ 3. Our objective was to design and test a new injectable and active scaffold to support chondrogenic differentiation of human MSC.

### EXPERIMENTAL METHODS

An emulsion-based process was designed to prepare the microspheres using an acidic type I collagen solution and perfluorated oil, stabilized by a surfactant. Spherical microparticles of fibrillar collagen were obtained through a sol-gel transition induced in aqueous droplets in contact with ammonia vapors, in the absence of chemical cross-linkers. Microspheres were impregnated with TGF $\beta$ 3 and release of this factor was measured using a reporter gene assay. Impregnated microspheres were combined with human MSC and cultivated *in vitro* or subcutaneously injected into immunodeficient mice. Expression of chondrocyte markers was monitored by RT-qPCR and immunohistochemistry.

### RESULTS AND DISCUSSION

Microspheres (Fig.1) are constituted by a gel of striated collagen fibrils and are  $300 \pm 67$   $\mu$ m in diameter. Fibrils occupy ca. 5% of the total volume, forming an entangled network with pores of 1-10  $\mu$ m. After MSC adhesion onto the microspheres and *in vitro* culture for 21 days, they differentiate into chondrocytes expressing the specific markers, such as aggrecan and collagen type II (Fig. 2), as assessed by RT-qPCR. The type I collagen matrix is progressively degraded and replaced by the cartilaginous matrix. *In vivo*, MSC form a tissue histologically resembling cartilage which stain positive for aggrecan (Fig.3a) and collagen II (Fig.3b).

Recently, we have successfully adapted the microspheres synthesis to a microfluidic-based process, which widens the possibility for scaffold modifications, as well as control over morphology and mechanical properties. The relatively versatile scaffold processing and association of cells makes it amenable to a wide variety of therapeutic indications.

### CONCLUSION

Here, we demonstrated the feasibility of a novel potential cartilage engineering approach based on MSC and self-cross-linked collagen microspheres carrying TGF- $\beta$ 3. In the present proof of principle study, we were able to successfully induce chondrogenic differentiation *in vitro* and the formation of a tissue resembling cartilage *in vivo*. However, induction of hypertrophy and calcification is an issue that needs to be addressed in future studies. The interest of these collagen microspheres resides in the versatility of the simple impregnation method used for loading the differentiation factor, ease of handling, and potentially rapid transfer to the clinic thanks to the nature and structure of this injectable scaffold which does not require differentiation of MSC prior to implantation.

### INTRODUCTION

Meniscus tears are common knee injuries. They directly result in pain, swelling and locking of the knee joint, and may eventually lead to osteoarthritis. Current repair techniques are associated with both short and long term problems. Therefore, there is an unmet clinical need for new solutions to repair a torn meniscus. Tissue adhesives are considered promising materials for this purpose, since they are easy to apply and cause minimal tissue trauma. However, to date, the development of a strong and biocompatible adhesive material has not been accomplished.

We previously reported that isocyanate-terminated copolymers based on poly (ethylene glycol) (PEG), trimethylolpropane ethoxylate (TMPE) and trimethylene carbonate (TMC) can be successfully used as tissue adhesives. Particularly, the 3-armed structures showed better adhesive properties than analogous linear ones [1]. The aim of this study was to assess novel hyper-branched amphiphilic copolymers as tissue adhesives for meniscus repair. Their interfacial shear stress on meniscus tissue and potential cytotoxicity was compared with the properties of the 3-armed structures.

### EXPERIMENTAL METHODS

Oligomers were synthesized by ring opening polymerization of TMC using linear PEG or three-armed TMPE as initiator. Subsequently, excess of PEG-based oligomer was reacted with citric acid (CA) to introduce branching. Reactive copolymers were synthesized by functionalizing the terminal hydroxyl groups of the oligomers with hexamethylene diisocyanate (HDI). In order to assess the effect of curing time of adhesive materials, a well established push-out test was performed after 1, 4, 8 and 24 hours after application on fresh bovine meniscus tissue [2]. The interfacial shear stress between surfaces of the glued meniscus was tested with BOSE ElectroForce using full thickness cylinder-shaped explants (Figure 1).

Figure 1. Push-out adhesion test using a full-thickness cylindrical bovine meniscus explant model. The area marked in grey is covered with the adhesive material.

The potential cytotoxicity was assessed by adding the adhesives in a trans-well system to bovine meniscus cells. Alamar Blue and live/dead assays were used to determine cells' viability. Moreover, in order to assess

the tissue reaction after contact with adhesives, glued meniscus explants were cultured *in vitro* for 7 days, after which haematoxylin and eosin (H&E) staining was performed.

### RESULTS AND DISCUSSION

The shear adhesive strength of the copolymers significantly increased with the curing time. The adhesive strength measured in the push-out test increased during 24 hours from 10 to 60 kPa for the 3-armed adhesive and from 50 to 140 kPa for the hyper-branched composition (Figure 2). Although the maximum bonding strength was obtained after 24 hours, attachment to the tissue was observed already after 1 hour. The hyper-branched copolymer performed better in the adhesion test than the analogous 3-armed structure, probably due to higher number of reactive isocyanate groups, which can covalently attach to the tissue. Histological inspection of the explants revealed no severe tissue response to none of the two glues. After 1 week of culture vital meniscus fibroblasts were present in the rim area of the tissue directly contacting the glue. This is a confirmation of the *in vitro* culture test, in which we showed that cell viability was not significantly affected by physiological amounts of glue.

Figure 2. Results of the push-out adhesion test of the 3-armed and hyper-branched adhesive materials as a function of their curing time.

### CONCLUSION

The proposed copolymers, particularly the hyper-branched structure, appear to be suitable candidates for resorbable tissue adhesives for meniscus repair. They are biocompatible and able to attach to tissue already after 1 hour and full bonding strength is obtained after 24 hours. Further optimization of the system to decrease curing time still needs to be performed.

### INTRODUCTION

In cartilage tissue engineering, differentiation of mesenchymal stem cells into chondrocytes is crucial to obtain successful cartilage regeneration. Differentiation can be promoted by various biological agents, including polysaccharides. In particular, glycosaminoglycans (GAG) were shown to participate in many biological processes likely through interaction with proteins, such as growth factors, proteases and chemokines<sup>1,2</sup>. Sulfate and carboxylic groups in GAG structure are key factors for interaction setting<sup>1</sup>. Marine bacteria producing exopolysaccharides (EPS) were recently shown to be a promising source of new GAG-like molecules useful for cartilage repair<sup>3,4</sup>. In order to enhance the biological activity of the marine EPS and to provide GAG mimetic compounds, structural modifications are however required.

### EXPERIMENTAL METHODS

GY785 exopolysaccharide (EPS) was produced by *Alteromonas infernus*, a deep-sea hydrothermal bacterium by the fermentation process<sup>5</sup>. In the next step, native high molecular weight (HMW) GY785 EPS was depolymerized to obtain low molecular weight (LMW) derivatives (DR). GY785 DR were therefore sulfated either in dimethylformamide, DMF leading to GY785 DRS-DMF or in ionic liquid (IL), 1-butyl-3-methylimidazolium chloride, BMImCl leading to GY785 DRS-IL. Molecular weight,  $M_w$  before and after sulfation was determined by HPSEC-MALS and sulfur content (wt% S) by HPAEC chromatography. ATR-FTIR and NMR spectroscopy were used to assess the efficiency of sulfation reaction. Cell viability in the medium supplemented with sulfated derivatives was studied by MTS assays. Chondrogenic differentiation of stem cells is currently being assessed.

### RESULTS AND DISCUSSION

In the present study, a new one-step sulfation process was developed in order to design GAG-mimetic compounds able to enhance the chondrogenic differentiation of mesenchymal stem cells, considered as an attractive source of cells for cartilage engineering<sup>3-5</sup>. The effect of EPS molecular weight and sulfur content on chondrogenesis was evaluated.

In the first step, native HMW GY785 EPS of low sulfate content (up to 3 wt%) was depolymerized to obtain LMW GY785 derivatives (GY785 DR). The obtained derivatives were then oversulfated in ionic liquid (IL), considered as a new class of solvent for

carbohydrate chemistry. In comparison, the sulfation was also performed in DMF, a classical organic solvent. The use of IL as solvent allows the sulfation to be carried out in a homogeneous medium in one-step process, whereas, in DMF, an additional step is necessary to obtain the pyridinium salt of EPS in order to improve its solubility prior to sulfation. GY785 DR were efficiently sulfated, as the sulfur content increased from 3 wt% before sulfation to 10-15 wt% after sulfation in either IL (GY785 DRS-IL) or in DMF (GY785 DRS-DMF). The sulfation was devoid of side effects, e.g. depolymerization and degradation.

In the next step, cell viability was evaluated using MTS assay. Stem cells from adipose tissue were cultured in control medium in the absence or in the presence of GY785 DR and GY785 DRS-IL, and GY785 DRS-DMF at different concentrations. It was observed that oversulfated derivatives improved the cell viability *in vitro* and that for some concentrations, GY785 DRS-IL showed better results than GY785 DRS-DMF. To correlate MTS activity with cell proliferation, the number of viable cells was also estimated and revealed that GY785 DRS increased stem cells proliferation in comparison to the control condition. The effect of the presence of GY785 oversulfated derivatives on chondrogenic differentiation is in progress.

### CONCLUSION

The present work describes a new one-step chemical sulfation process based on ionic liquid, BMImCl, as a reaction medium. The sulfation of highly branched anionic heteropolysaccharide from marine origin was shown to be devoid of undesired structure degradation. The potential of new derivatives obtained as GAG-mimetic compounds for cartilage regeneration is being assessed.

## INTRODUCTION

Nitric oxide (NO) is an endogenously found radical species, which plays important roles in many physiological processes, including the control of vascular tone. Microcirculatory disorders associated with the depletion of endogenous NO production are the underlying causes of ischemic diseases and chronic wounds and have demanded biomaterials capable of delivering NO locally to tissues in a controlled manner. Poly(vinyl alcohol), PVA, is a biocompatible hydroxylated polymer already used for medical purposes, which allows chemical modification through condensation reactions with carboxylic acids<sup>1</sup>. In this study we used mercaptosuccinic acid (MSA) to prepare SH-containing, crosslinked PVA membranes (PVA-SH) capable of being further S-nitrosated to release NO locally through thermal and photochemical pathways.

## EXPERIMENTAL METHODS

PVA was esterified with MSA in aqueous HCl-acidified medium under stirring and reflux, followed by removal of half of the water content under heating in an open flask. The membranes were cast by precipitation of the polymeric solutions, through their immersion in acetone, followed by washing with water and acetone, dried by lyophilization and subsequently S-nitrosated with nitrous acid. The dry membranes were characterized regarding their thermal, crystallographic and morphological properties. The S-nitrosated membranes (PVA-SNO) were characterized regarding their NO-releasing properties and ability to promote skin vasodilation in topical application, protected from light and under irradiation with visible light.

## RESULTS AND DISCUSSION

Functionalization of PVA with MSA was confirmed by IR spectroscopy. The PVA-SH membranes displayed a reduced crystallinity degree, as reflected in their X-ray diffraction pattern and DSC thermogram. This result was assigned to the reduction in the number and size of PVA crystallites due to the chemical crosslinking obtained in the esterification reaction. As a consequence, the membranes displayed a swelling degree higher than 600% in water, what makes them suitable for wound dressing. Morphological analysis by SEM showed that the membranes are highly porous. Real time chemiluminescence measurements showed that the S-nitrosated membranes can be charged with up to 90 nmol NO/mg and are capable of releasing NO thermally over more than 3 h after their immersion in water at 37 °C. Irradiation of the hydrated PVA-SNO membranes with visible light led to an increase of ca. 10-fold in the first order rate constant of NO a release. These NO-release properties were shown to lead to

local vasodilation and erythema formation after topical application of the membranes on the forearm of health volunteers, as measured by laser Doppler Flowmetry. In addition, irradiation of the topically applied membranes led to a significant increase in the local vasodilation.

Scheme showing the structure of the sulphydrylated PVA membranes (PVA-SH) and a detail of the MSA ester bridges, which are S-nitrosated yielding PVA-SNO groups. These, undergo thermal and photochemical decomposition releasing free NO, leading to a double crosslinked structure with sulphur bridges.

## CONCLUSION

PVA-SNO membranes can be used for the local delivery of NO on the skin and their rate of NO-release can be modulated through the irradiation with visible light. Therefore, PVA-SNO membranes have potential to be used as NO-releasing biomaterials for the treatment of tissues affected by impaired endogenous NO production.

### INTRODUCTION

The adhesion of bacteria and formation of biofilms is an important issue for implants. The bacterial films can lead to severe infections and might result in revision surgeries. This problem might be overcome with nanoparticles immobilized on the implant surface which can release antibacterial drugs triggered by the infection. Recent studies have shown that nanoparticles based on polysaccharides like chitosan or alginate provide an excellent approach for drug delivery applications.<sup>1,2,3</sup> As the conventional systems lack infection triggered drug release mechanisms the objective of this work is to render the nanoparticles degradable by specific enzymes which are released upon inflammation or infection.

Scheme 1: Schematic overview of nanoparticle preparation and subsequent degradation upon addition of enzyme.

### EXPERIMENTAL METHODS

The nanoparticles were prepared by ionotropic gelation. The characterization with regard to particle diameter and zeta potential was performed by dynamic light scattering (DLS). A simple spray-coating process was applied to coat titanium substrates with the nanoparticle suspension. Surface characterization was carried out by means of ellipsometry, X-ray photoelectron spectroscopy (XPS) and scanning electron microscope (SEM) measurements. During the particle preparation process interferon- $\beta$  was encapsulated. Corresponding encapsulation efficiencies were calculated based on a luciferase assay.

### RESULTS AND DISCUSSION

Two different nanoparticle systems were prepared by ionotropic gelation. Negatively charged alginate was reacted with either positively charged poly-L-lysine or an aggrecanase-labile peptide with lysine sequences as positively charged end groups. According to Dynamic Light Scattering measurements the particles exhibit well-defined particle size and zeta potential. Successful deposition of alginate/peptide layers was proven by ellipsometry, XPS and SEM. Moreover encapsulation and release experiments were undertaken with the antiviral and antitumoral drug interferon- $\beta$ <sup>4</sup>, which could be easily incorporated in the particles.

### CONCLUSION

Ionotropic gelation of alginate with a peptide having lysine-sequences at both ends results in well-defined nanoparticles. Deposited nanoparticle films on titanium can be characterized by surface analytics. In addition the loading with interferon- $\beta$  has been performed to indicate the particles great potential as drug delivery system.

## Polymer Coatings with Liposomal Drug Deposits towards Substrate-Mediated Drug Delivery

Martin E. Lyng<sup>1</sup>, Marie Baekgaard Laursen<sup>1</sup>, Marina Fernandez-Medina<sup>1</sup> and Brigitte Städler<sup>1</sup>

<sup>1</sup>Interdisciplinary Nanoscience Center, iNANO, Aarhus University, Denmark  
[mlynge@inano.au.dk](mailto:mlynge@inano.au.dk)

### INTRODUCTION

Implantable substrates modified with a drug-loaded polymer coating, such as stents or intrauterine devices, are emerging as an efficient tool to administer therapeutic cargo locally. However, challenges with the retention of small hydrophobic molecules or the activity of structurally dependent biomolecules remain. To this end, we report liposomal drug deposits as carriers of both hydrophobic and hydrophilic cargo embedded in a polymer matrix. The liposomes have been immobilized in the polymer film either through the layer-by-layer technique<sup>1</sup> or co-immobilized with poly(dopamine)<sup>2-4</sup> (scheme 1). The interactions between cells and the substrates were assessed with regards to capping layer thickness, types of liposome (e.g. embedding of a lipophilic dopamine conjugate or different charge).

### EXPERIMENTAL METHODS

The assembly of the films containing intact liposomes was monitored with quartz-crystal microbalance with dissipation measurements (QCM-D). Microscopy imaging and flow cytometry were used to assess the cell adhesion and uptake/association of fluorescent lipids embedded in the liposomes as model cargo while cell viability measurements were conducted with the use of cell counting kit-8 and multiwell-plate reader.

Scheme 1. Schematic representation of liposomal drug deposits embedded in a poly(dopamine) matrix for substrate-mediated drug delivery to adhering cells, scale bar 50  $\mu\text{m}$ .

### RESULTS AND DISCUSSION

QCM-D revealed that intact liposomes could be embedded in the polymer film and by using polymer separation layers, a second liposome layer was found capable of adsorbing. Myoblasts, hepatocytes, macrophages and endothelial cells were all found to adhere to the liposome-containing films as confirmed with microscopy. The adhesion was found to be independent of liposome charge with the exception of

endothelial cells which could only adhere to films containing negative liposomes. The cells were observed to be able to take up the fluorescent lipid embedded in the liposomes. The uptake depended on initial dopamine concentration, separation layers, liposome charge and number of liposome deposition steps. The successful delivery of active cargo to adhering cells was demonstrated by incorporating a cytotoxic and hydrophobic molecule, thiocoraline, into the liposomes and measuring the viability of the adhering cells. The uptake pathway was determined to be clathrin-mediated by treating adhering myoblasts with inhibitors against distinct endocytosis pathways. In an attempt to mimic the dynamic environment *in vivo*, microfluidic channels, coated with the mixed films, were connected to a pump which would exert a shear stress on adhering endothelial cells. The cell/substrate interactions were found to be affected by the shear stress as revealed by a decrease in cell mean fluorescence.

### CONCLUSION

Based on the presented results, liposomes have been shown to act as intact drug deposits in a cell adhesive polymer matrix which can be tailored for a controlled cargo delivery. In summary, the various approaches to design liposome-containing polymer films can have great potential in the field of substrate-mediated drug delivery.

### INTRODUCTION

A challenge in modern drug delivery is the transportation of negatively charged and hydrophilic biomolecules like DNA or siRNA, e.g. for transfection or gene silencing in gene therapy.<sup>[1]</sup> For such compounds, the biocompatible and biodegradable polymer poly(D,L-lactide-co-glycolide) (PLGA) was often used as a nanoparticulate carrier system. However, it is difficult to encapsulate hydrophilic molecules into a PLGA matrix by classical emulsion techniques, because they tend to diffuse into the continuous aqueous phase during the synthesis. Thus, the encapsulation efficiency for such compounds is rather low. Therefore, a drug delivery system consisting of calcium phosphate (high affinity to nucleic acids and proteins) and PLGA nanoparticles was developed, to increase the encapsulation efficiencies of hydrophilic biomolecules into PLGA nanoparticles.<sup>[2, 3, 4]</sup> The high affinity of polar biomolecules to calcium phosphate should thereby strongly increase their incorporation into the hydrophobic matrix of PLGA.

### EXPERIMENTAL METHODS

To form calcium phosphate nanoparticles (loaded with anti-eGFP-siRNA or eGFP-DNA, a rapid precipitation method was used. For the incorporation of either eGFP-DNA- or siRNA-functionalized calcium phosphate nanoparticles into PLGA nanoparticles, a water-in-oil-in-water ( $W_1/O/W_2$ ) double emulsion solvent evaporation method was applied in a second synthesis step. To encapsulate FITC-BSA into the nanoparticles, a modified  $W_1/O/W_2$  emulsion solvent evaporation method according to Tang *et al.*<sup>[5]</sup> was used. The nanoparticles were characterized by dynamic light scattering (DLS), scanning electron microscopy (SEM), cell culture experiments (cell uptake studies by confocal laser scanning microscopy (CLSM), transfection and gene silencing experiments as well as cell viability tests). Furthermore, the encapsulation efficiency was determined by UV/Vis spectroscopy.

### RESULTS AND DISCUSSION

The resulting calcium phosphate/PLGA nanoparticles, loaded with either proteins or nucleic acid had a diameter of about 200 nm and a negative zeta potential of -26 mV. The addition of calcium phosphate into the

inner aqueous phase increased the encapsulation efficiency of siRNA, DNA and FITC-BSA by a factor of 3 to 10 compared to PLGA nanoparticles without calcium phosphate. To improve the cellular uptake of these nanoparticles, an outer layer of either chitosan or polyethyleneimine (PEI) was added to reverse the negative zeta potential to  $>+30$  mV. In cell uptake studies, the cationic nanoparticles showed an improved cellular uptake and induced the proton sponge effect as shown by CLSM. Nanoparticles loaded with eGFP-DNA showed good transfection efficiencies in transfection experiments with HeLa cells. In gene silencing experiments, anionic nanoparticles gave knockdown efficiencies of 53%, and cationic nanoparticles (chitosan- or PEI-coated) gave knockdown efficiencies of 68% and 89%, respectively.

### CONCLUSION

The encapsulation efficiency of hydrophilic and anionic biomolecules (siRNA, plasmid DNA and FITC-BSA) into PLGA nanoparticles was strongly increased by the addition of calcium phosphate, probably due to a better adsorption of these hydrophilic biomolecules onto the surface of calcium phosphate nanoparticles. An increased loading, as well as a positive surface charge lead to higher efficiencies in intracellular drug delivery.

# Human Bone Marrow Mesenchymal Stem Cells Responses to Titanium Surface Coated with Type I Collagen Using Natural Cross-linker Genipin

Ying-Sui Sun<sup>1</sup>, Her-Hsiung Huang<sup>1</sup>, Kai-Chun Chang<sup>2</sup>

<sup>1</sup>Department of Dentistry, National Yang-Ming University, Taipei, Taiwan

<sup>2</sup>Institute of Oral Biology, National Yang-Ming University, Taipei, Taiwan  
[hhuang@ym.edu.tw](mailto:hhuang@ym.edu.tw)

## INTRODUCTION

Various surface treatments have been focused on coating bioinert metallic implants with biomolecular in order to regulate the functions of cells on implant surfaces<sup>1</sup>. Type I collagen, the most abundant protein in the bone matrix, has been used to improve the biological activity on implant surfaces<sup>2</sup>. This study sought to immobilize the type I collagen to biologically inert titanium surface through the use of the nontoxic, natural cross-linker genipin. Surface characterizations and cell responses of the treated titanium surfaces for dental implant application were investigated.

## EXPERIMENTAL METHODS

We selected type I collagen for the biomolecular coating. For the sake of simplicity and low cost, we used the nontoxic natural cross-linker genipin as the medium with which to immobilize type I collagen to the machined titanium surface designated TiGC. The untreated machined titanium surface was used as control designated Ti. Surface characterizations, including the morphology, chemistry, hydrophilicity, and roughness, of the test materials were analyzed. Human bone marrow mesenchymal stem cells (hBMSCs) responses, including the adhesion, migration, proliferation, mineralization, and differentiation, to the test materials were performed. At least five samples were used for each test group. Statistical analysis was performed using Student's t-test with alpha of 0.05.

## RESULTS AND DISCUSSION

X-ray photoelectron spectroscopy analysis results demonstrated that the genipin could successfully immobilize the type I collagen to titanium surface. Scanning electron spectroscopy (SEM) analysis results showed that the thickness of the type I collagen coated on titanium surface could be controlled at a nanoscale. The resulting surface of TiGC included a mixture of reticular submicro- and nanostructures (Figure 1(b)) and displayed high hydrophilicity (water contact angle < 22°). Following few months of storage at 4°C, the type I collagen on titanium surface still presented good bonding and functionality, which promoted the mineralization of hBMSCs. Cell responses analysis revealed that the type I collagen coating promoted the adhesion (Figure 2(b)), migration, and osteogenesis of hBMSCs as well as the mineralization of the extracellular matrix (ECM). Compared to the untreated Ti, the type I collagen-coated TiGC had higher expression levels of osteogenic markers, in terms of osteopontin (Figure 3(a)), bone sialoprotein, and osteocalcin (Figure 3(b)).

## CONCLUSION

The use of the natural cross-linker genipin as the medium to immobilize type I collagen to titanium surface promoted the adhesion, migration, and osteogenesis of hBMSCs as well as the mineralization of the ECM. The proposed surface treatment technique is a simple low-cost process that can be potentially employed for titanium dental implant.

## INTRODUCTION

The legless locomotion of snakes has tremendous tribological consequences for the ventral body side [1]. We focused on the influence of microstructures found on ventral scales of the California King Snake (*Lampropeltis getula californiae*) on friction behaviour of the skin. Snake-inspired anisotropic microstructured polymer surfaces (SIMPS) (Figure 1) and other microstructured surfaces with isotropic and anisotropic geometry were compared [2].

In biomedical applications, like in many technical systems, appearance of the stick-slip phenomenon is undesirable due to an increase of abrasion [3], which can reduce the lifetime of e. g. joint implants with negative implications for patients' health and healthcare costs.

Figure 1 From snake to SIMPS, a) Photograph of the California King Snake (*L. g. californiae*). SEM micrograph of b) snake ventral scale and c) SIMPS. Scale bars: 10 µm.

## EXPERIMENTAL METHODS

The frictional coefficient was measured by a microtribometer. The frictional signal was analysed by performing fast Fourier transformations (FFT), allowing to describe the stick-slip motion in a quantitative way. To exclude the influence of physico-chemical variations, all friction measurements were performed on identical epoxy polymer. For details please see [4].

## RESULTS AND DISCUSSION

The ventral microstructures of the snake skin and the SIMPS do not only possess anisotropic frictional properties, but also reduce stick-slip vibrations during sliding. Furthermore, our experimental data did not confirm the previous statement that frictional coefficient correlates with the stick-slip occurrence [5]. It can be assumed, that snakes are able to alter frictional properties of their ventral body surface by the variation of body stiffness and thereby their effective elastic modulus. The observed reduction of stick-slip motion of the skin indicates that the ventral body surface is not only optimised towards frictional properties, but also towards abrasion reduction. Therefore, snake skin is a

very attractive biological model for optimizing technical surfaces under tribological stress.

Figure 2 Frequency analysis of frictional coefficient on (a, b) SIMPS, (c, d) smooth surface. Frictional coefficient signal (a, c) in frequency domain after FFT (b, d). (Only exemplary data, for more data see [4]).

## CONCLUSION

Snake skin is a highly optimized tribological system, which shows anisotropic frictional properties and reduced wear, as well as a reduction in stick-slip vibration, which by itself is known to increase abrasion between sliding partners. We were able to transfer these properties to artificial polymer surfaces (SIMPS).

The investigation of the effects of surface texturing on the frictional coefficient and stick-slip motion in biological surfaces may represent a short cut towards frictional systems with reduced stick-slip vibrations. Additionally, this approach of surface modification by surface texturing opens up the possibility for tribological optimization of state of the art biomaterials, e. g. for implant design.

### INTRODUCTION

In recent years, we elaborated new porous asymmetric scaffolds for tissue engineering. The scaffolds are made of poly(lactic acid) (PLA) and their surface are entirely functionalized by a nanolayer of hyaluronan (HA). Scaffolds show a tridimensional structure with interconnected macro- and micropores. Diameter of pores opened to the surface can be controlled and ranges from 80 to 185  $\mu\text{m}$ . These PLA-HA scaffolds have proved to be well-adapted for adhesion and proliferation of different cell types including mesenchymal stem cells (MSC) and cancer cells like HT-29 colorectal cancer cells. Interestingly, we showed that functionalization of scaffold surface by HA can be performed as much efficiently whatever the HA chain molecular weight. This enables us to use these new scaffolds to investigate the effect of HA molecular weight on cell behavior in a tridimensional environment. Since it is known that both HA is involved in cancer progression<sup>1</sup> and MSC are recruited to tumoral sites<sup>2</sup>, we used our biomaterials for mimicking a tumor microenvironnement: we studied the influence of the molecular weight of HA chains immobilized on the scaffold surface on the interactions between MSC and HT-29.

### EXPERIMENTAL METHODS

Biomaterial discs (16 mm diameter) were placed in 24-well plates. Each disc was seeded with  $10^6$  cells in 2 mL of culture medium ( $\alpha$ -MEM or HDMEM). Cultures were incubated at 37°C under 5 %  $\text{CO}_2$  during 12 days. For each set of experimental conditions, cell culture and analysis were performed in triplicate. Cell proliferation was measured using WST-1 test. To observe cell behavior by video microscope, cells were previously labeled with a blue fluorescent tracer (7-amino-4-chloromethylcoumarin) for MSC and a green fluorescent tracer (5-chloromethylfluorescein diacetate) for HT-29 cells. Membrane antibody arrays were used to detect the expression of proteins in co-culture media. Cytokines in co-culture media and VEGFR-2 in cell lysates were quantified by ELISA.

### RESULTS AND DISCUSSION

Separate cultures of MSC (in  $\alpha$ -MEM) and HT-29 (in HDMEM) showed that proliferation was maximum for both cell types in scaffold with mean pore diameter of 160  $\mu\text{m}$ . When co-cultured, proliferation of cells was significantly dependent on the ratio of seeded cells. The best ratio, 2:1 (MSC:HT-29), was used for all the following experiments. MSC and HT-29 were co-cultured on scaffolds covered with either high

molecular weight HA (HMW-HA,  $3.10^6 \text{ g.mol}^{-1}$ ) or low molecular weight HA (LMW-HA,  $880 \text{ g.mol}^{-1}$ ). In both cases, HT-29 form spheroids (Figure 1) with a necrotic center which reflects the structure of *in vivo* solid tumor. However, co-cultures of the two cell types showed great differences in behavior according to HA molecular weight. In the presence of HMW-HA, there was no evidence of physical interaction between MSC and HT-29 (Figure 1A) whereas MSC came to surround the voluminous HT-29 spheroids in the presence of LMW-HA (Figure 1B). Moreover, with HMW-HA the microenvironnement was found to be proinflammatory, with increased secretion of interleukin 6 and macrophage migration inhibitory factor, while an increased secretion of angiogenic cytokines such as vascular endothelial growth factor and metalloproteases (MMP9) were observed with LMW-HA.

Figure 1: Organisation of MSC (blue) and HT-29 (green) co-cultured in PLA-HA scaffold in the presence of  $\alpha$ -MEM medium as observed by video microscope; A, HMW-HA and B, LMW-HA. Bar corresponds to 100  $\mu\text{m}$ .

### CONCLUSION

The results clearly show that interactions between MSC and HT-29 strongly depend on HA molecular weight and they suggest that these interactions induce different MSC differentiation pathways. This study also indicates that our new biomaterials may constitute useful tools in the field of tumor engineering.

## Topographical and Biochemical Functionalized PEDOT Films as Coating Strategies for Improved Neuroelectrode Functionality

Catalina Vallejo-Giraldo<sup>1</sup>, Marc Fernandez-Yague<sup>1</sup>, Abhay Pandit<sup>1</sup>, Eilís Dowd<sup>2</sup>, Manus Jonathan Paul Biggs<sup>1</sup>

[c.vallejogiraldo@nuigalway.ie](mailto:c.vallejogiraldo@nuigalway.ie)

### INTRODUCTION

Studies with conducting polymers (CPs) as functional electrode coatings have shown to enhance tissue/electrode integration and electrode performance in situ. Current strategies in this field have focused on reducing impedance and the presentation of neurotropic moieties to enhance the integration with brain milieu and to help with cell attachment properties<sup>1</sup>. The use of biochemical functionalization of CPs surfaces is an increasingly utilized mechanism to present biologically active dopants to promote or inhibit specific biological interaction with brain cells. However, a remarkable disruption of the polymer's physio-electrical properties is observed by the incorporation of structural ligands or peptides on the CPs surfaces<sup>2</sup>. This study investigates a range of physical, electrical and biological properties of a conventional conducting polymer PEDOT with dual functionalization by means of micro and nanotopographical modification (nanoimprinting) and entrapped mimetic polysialic acid peptide (PSA) to support the electrode stability and electrical properties via sustained neural integration within the PEDOT electrode coating film.

### EXPERIMENTAL METHODS

**Topographical modification:** PEDOT films were polymerized galvanostatically on platinum coated glass, and characterized by FTIR, EIS, AFM and SEM. PEDOT films were then thermally nanoimprinted using photolithography fabricated Ni masters.

**Bioactive-polymer-composite synthesis:** PEDOT/mimetic molecule films were polymerized galvanostatically on platinum coated glass. The cytocompatibility of the functionalized PEDOT films is evaluated by culturing isolated rat ventral mesencephalon (VM) cells on the polymeric films by alamar blue™, live and dead assay and fluorescent microscopy for adherent cell counting and quantitative immunostaining of relevant neural biomarkers and neural outgrowth.

### RESULTS AND DISCUSSION

The results from an optimization study performed using dissociated hippocampal primary cells as a proof of concept of primary cell viability cultured on pristine PEDOT films indicated the cytocompatibility of this material and no toxicity was detected (Fig.1a). SEM results depicted in Fig.1b show the topographical modification of PEDOT polymeric films after imprinting an ordered array of 1µm wide/deep pits. Also, the mimetic PSA peptide was successfully entrapped during electrodeposition and it preserved biofunctionality as assessed by the preliminary promotion of ventral mesencephalon (VM) cells on PEDOT electrode coating films up to a period of five

days in culture. Furthermore, the polymeric films treated with a combined functionalization of both imprinted films with mimetic PSA peptide incorporation show promotion of VM cells and slightly disruption of the stability and electrical performance of the PEDOT films compared to controls.

Fig.1.a.Fluorescent micrograph of immunostained hippocampal primary cells cultured on pristine PEDOT film formed with 0.4 mA/cm<sup>2</sup> current density. Red β tubulin III, green GFAP and blue Hoeschst, Scale bar = 50µm. b. Scanning electron micrograms (SEM) of a nanoimprinted PEDOT film formed with 0.4 mA/cm<sup>2</sup> current density

### CONCLUSION

Designing an optimized electrode coating material will require a trade-off between desired electrical, morphological, chemical and biological properties. The development of bioactive conductive polymers through biological dopants addresses the cell interaction, selection and attachment when using polymers. However, this only goes part of the way as to solving biological interface interaction as the physio- electrical material properties significantly get disrupted by biological dopants. An alternative approach used to functionalize conducting polymers involves creating polymers with multiple functionalities. The presence of a dual functionalization in the context of both topographical and biochemical modifications presented here, significantly show to be a great enhancement of the PEDOT polymeric films with a promotion of healthy ventral mesencephalon cell population up to a period of five days in culture and with a close preservation of physico-electrical film's properties compared to controls.

### INTRODUCTION

Cellular-based approaches in bone tissue engineering involve culturing human mesenchymal stem cells (hMSC) on three-dimensional scaffolds, which provide support structures<sup>1</sup>. Upon implantation of the intermediate tissue in the bone defect site, transplanted hMSC may establish paracrine relationships with host cells located at their vicinity. Multiple studies have addressed the cross-talk between hMSC and osteoblasts or endothelial cells using conventional co-cultures in which the studied cell types do not establish direct contact. However, it is unknown whether these relationships are affected by the structural features of the substrates that harbor hMSC. To this aim, hMSC from bone marrow were seeded in porous or flat biomaterials and then co-cultured with human osteoblasts (hOB) obtained from bone explants or human umbilical vein endothelial cells (HUVEC), using a transwell insert system that allows humoral contact of both cell types without direct cell contact.

### EXPERIMENTAL METHODS

hMSC were seeded in highly porous scaffolds made of polystyrene or Ti6Al4V, or encapsulated in fibrin hydrogels. As controls, hMSC were seeded in polyester membrane cell culture inserts, which were used as flat permeable supports. In addition, hMSC were seeded on flat Ti6Al4V samples, which surfaces were polished to get a mirror-like finish. hOB or HUVEC were seeded in tissue culture plastic. hMSC seeded in porous or flat substrates were co-cultured with hOB or HUVEC using a transwell system. Co-cultures were incubated in DMEM medium containing fetal bovine serum. In some experiments, media were supplemented with dexamethasone, ascorbic acid and  $\beta$ -glycerolphosphate. Cell viability was assessed using the alamarBlue assay. Secretion of procollagen type I, OPG, soluble RANKL (sRANKL), M-CSF, VEGF and Flt-1 were measured in culture media while levels of TGF- $\beta$  were quantified in cell layers, using ELISA kits. Alkaline phosphatase activity (ALP) was measured in cell layers. Gene expression analyses were carried out by real-time quantitative RT-PCR assays. A scratch assay was used to study changes in HUVEC migration. Tubule formation was assessed in HUVEC seeded on Matrigel-GFR, which were incubated with conditioned media from hMSC cultures.

### RESULTS AND DISCUSSION

Compared to isolated cultures, hOB viability was not affected when co-cultured with hMSC seeded in polystyrene or polyester substrates, but was impaired

when MSC had been seeded in flat Ti6Al4V or encapsulated in fibrin hydrogels. Interestingly, hOB viability increased in co-cultures with hMSC seeded in porous Ti6Al4V. Levels of *COL1A1* and *ALPL* mRNAs were higher in hOB co-cultured with hMSC seeded in porous polystyrene scaffolds than in hOB co-cultured with hMSC seeded on flat polyester substrates. This effect correlated with increased levels of procollagen type I in co-cultures of hOB and hMSC seeded on porous surfaces, as well as with higher osteoblastic ALP activity. The degree of cell layer mineralization and *BGLAP* mRNA levels were lower in hOB co-cultured with hMSC seeded in porous polystyrene than in flat polyester substrates. The OPG/sRANKL ratio in co-culture media was substantially lower when hMSC were seeded in polystyrene scaffolds, while M-CSF levels increased. Compared to hOB co-cultured with MSC seeded in flat polyester substrates, levels of TGF- $\beta$  were diminished in hOB co-cultured with hMSC seeded in polystyrene scaffolds.

Compared to isolated cultures, HUVEC viability and migration ability increased when co-cultured with hMSC seeded in all tested substrates except fibrin hydrogels. The increases were higher in those co-cultures in which hMSC were seeded on porous substrates. Tubule formation was enhanced when HUVEC were incubated with conditioned media from hMSC cultured in polystyrene scaffolds. The paracrine effects of hMSC co-cultured in porous substrates were not mediated through secretion of VEGF or its receptor Flt-1, which mRNA levels were not either sensitive to the substrate features.

### CONCLUSION

The paracrine interactions that hMSC establish with hOB and HUVEC are strongly influenced by the structural features of substrates. Upon implantation of a tissue intermediate, the chemical and topographical characteristics of the scaffold may influence the control of transplanted hMSC on the behaviour of neighbouring osteoblasts and endothelial cells.

## INTRODUCTION

Bone tissue has well-organized hierarchical structure at various scale levels. Original intact bone exhibits specific oriented architecture derived from biological apatite (BAP) crystallite orientation that is closely related to the arrangement of collagen fibrils. Preferential alignment of anisotropic BAP crystallites/collagen fibrils in typical cortical and spongy bones, for example, alters depending on the bone shape, *in vivo* stress distribution, and bone turnover. The preferential alignment of BAP *c*-axis, in particular, tends to arrange along the stress distribution in the original bones, indicating anisotropy of mechanical properties.

In contrast, recovery of anisotropic BAP alignment strongly depends on the portion and period of regeneration process, which is insufficient to reach the original level, while bone mineral density (BMD) is almost improved to its original value [1,2].

The purpose of this study is to develop some strategies which can control the preferential alignment of osteoblasts and the resultant formation of normal anisotropic extracellular matrix (ECM).

## EXPERIMENTAL METHODS

Primary osteoblasts were subjected to various anisotropic environments involving stress field, substrates with step patterning or with aligned collagen fibers. The preferential orientation of osteoblasts and the BAP *c*-axis were analysed. The BAP orientation in secreted ECM, especially, is evaluated by various  $\mu$ XRD systems with collimators that are several dozen or hundreds of micrometers in diameter. The BAP orientation is roughly related to the direction of collagen matrix secreted by cells.

## RESULTS AND DISCUSSION

Control of cellular alignment is one of the methodologies for arranging the oriented ECM of tissue. Figure 1 shows the aligned osteoblasts along the slip traces caused by dislocation gliding. Dislocations are introduced into  $\alpha$ -titanium single crystals by plastic deformation of the prism slip system, which induces a step-like structure with acute angles between the normal surface and the slip plane. The topographical properties of step patterning could be controlled by variation of the compressive plastic strain. The step geometry introduced by plastic deformation strongly influences osteoblast elongation along the slip traces. Cellular alignment is very important because anisotropic control of bone structural formation *in vitro* can be established by organizing cell alignment and the following BAP/collagen preferential orientation [3].

Anisotropic architecture of bone is derived from the collagen fiber scaffold and the related osteoblast

alignment. The oriented collagen scaffolds were fabricated by a hydrodynamic method. Osteoblast orientation is regulated by the degree of the scaffold collagen orientation, with preferential alignment along the collagen molecular orientation. The directional secretion and fibrogenesis of collagen matrix and BAP crystallite formation, which has preferential *c*-axis orientation along the cell direction, is shown in Figure 2. The degree of BAP orientation deposited by osteoblasts depends on the directional distribution of osteoblasts cultured on the oriented collagen scaffolds.

Figure 1 Fluorescent image of osteoblasts aligned along slip traces (10% compressive strain).

Figure 2 Osteoblasts orientation determines the secreted bone matrix alignment.

## CONCLUSION

The appropriate anisotropic ECM structure which enables its proper function can be controlled by surface morphology and the chemical and/or physical environment surrounding the constituent cells.

## Injectable and Self-Healing Supramolecular Hydrogel for Tissue Engineering Applications

Damien Dupin, Pablo Casuso, Natividad Díaz, Adrián Pérez-San Vicente and Iraida Loinaz

Biomaterials Unit, Materials Department, IK4-CIDETEC, Spain

[ddupin@cidetec.es](mailto:ddupin@cidetec.es)

### INTRODUCTION

In-situ forming hydrogel systems have attracted considerable interest as injectable scaffolds for tissue engineering and drug delivery due to their easy applications and minimally invasive injection procedure.<sup>1,2</sup>

Our research group has recently developed a new family of injectable supramolecular hydrogels based on low molecular-weight Au (I) and Ag (I) thiolates.<sup>3,4</sup> Here we present a new family of polymeric hydrogel with self-healing properties and adjustable mechanical properties.<sup>5,6</sup>

### EXPERIMENTAL METHODS

*Hydrogels were prepared* by mixing an aqueous solution of polymer at 10 wt.% with an aqueous solution containing metal salt. *Dynamic rheology* measurements were performed using a TA Instruments AR G2 temperature-controlled rheometer with 20 mm diameter plate geometry.

### RESULTS AND DISCUSSION

Supramolecular polymeric hydrogels were obtained by mixing an aqueous solution of salt metals ( $\text{Ag}^+$  or  $\text{Au}^+$ ) with a solution of thiolated poly(ethylene glycol) [PEG] polymer at physiological pH. The instantaneous gel formation by means of metal-thiolate centres allows its application as injectable hydrogel (Figure 1).

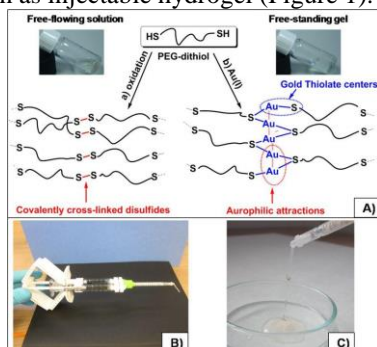

Figure 1. (A) Schematic representation of the metal-thiolate cross-linking and (B,C) its injection using a double barrel syringe.

The supramolecular hydrogel exhibits self-healing (Figure 2a). Varying the amount of metallophilic cross-linker allows tuning the mechanical properties of the hydrogel as judged by reology studies. Moreover, the variation of  $G'$  over  $G''$  indicates the hardening of the material under high frequencies. MTS assay confirmed that the hydrogel is not cytotoxic to cells.

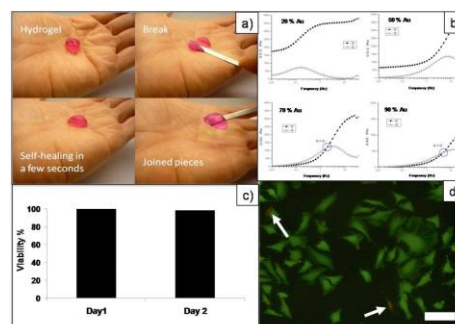

Figure 2. (a) Self-healing behaviour and (b) dynamic mechanical properties of the supramolecular hydrogel. (c, d) MTS assay of the viability of the hydrogel.

Judicious adjustment of the hydrogel concentration and the amount of gold added allowed the use of this material for musculoskeletal applications as a substitute of the synovial fluid or nucleus pulposus for patient suffering arthritis or intervertebral disc degeneration.

### CONCLUSION

The supramolecular hydrogel appears to be an excellent candidate for tissue engineering due to its facile injection and positive cell viability. Thanks to the permanent interchange of metal-thiolate, the supramolecular hydrogel exhibits self-healing properties at physiological conditions. Moreover, the hydrogels could also be designed for different application like viscosupplement material or nucleus pulposus replacement.

## INTRODUCTION

Tyramine modified hyaluronic acid (HA-Tyr) hydrogels have shown great potential in tissue engineering and regenerative medicine<sup>1</sup>. The bio-orthogonal cross-linked mechanism enables independent tuning of mechanical properties and gelation rate of HA-Tyr by varying the hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) and horseradish peroxidase (HRP) concentration, respectively. Recently, we have shown that using 4-(4,6-dimethoxy-1,3,5-triazin-2-yl)-4-methylmorpholinium chloride (DMTMM) as conjugating agent allows to precisely tailor the tyramine functionality and the rheological features of the HA-Tyr hydrogels at constant HRP and H<sub>2</sub>O<sub>2</sub> concentrations<sup>2</sup>.

To answer major questions on how mechanical factors may lead to changes in cell behaviour, it is of paramount importance to provide a precise tailored extracellular environment. However, there is little data on the effect of encapsulated cells, in particular human mesenchymal stromal cells (hMSCs), on bulk mechanical properties of HA-Tyr hydrogels.

In the first part of this study, a modified strategy of DMTMM mediated HA-Tyr synthesis was used to improve rheological properties of the cross-linked matrices. Then, HA-Tyr hydrogels were explored as matrices for encapsulated hMSCs and their impact on bulk visco-elastic hydrogel properties was investigated.

## EXPERIMENTAL METHODS

HA-Tyr was prepared by optimizing a recently described protocol<sup>2</sup>. Briefly, amidation of the carboxylic acid groups of HA with the amine groups of Tyr was conducted in water (dH<sub>2</sub>O) at room temperature (RT) and 37 °C. Degree of tyramine substitution (DS<sub>mol</sub>) was calculated using UV-vis spectrophotometry. hMSCs (Freiburg, EK-326/08) or polystyrene beads (15 µm) were encapsulated in HA-Tyr (2.5% (w/v)) precursor solution containing HRP and H<sub>2</sub>O<sub>2</sub>. Evolution of network formation and visco-elastic properties were monitored in situ by rheology. Live-dead staining and confocal imaging documented viability and spreading of encapsulated hMSCs.

## RESULTS AND DISCUSSION

Coupling of HA-Tyr in dH<sub>2</sub>O reaches significantly higher yields compared to the previously shown synthesis in MES pH 5.5 (Figure 1A). It does not require accurate pH control or shift during reaction. Visco-elastic properties (Figure 1B) of cross-linked HA-Tyr matrices can be controlled by DS<sub>mol</sub>. Thus, DMTMM mediated HA-Tyr synthesis in dH<sub>2</sub>O extends the range of tunable mechanical properties of HA-Tyr hydrogels without affecting H<sub>2</sub>O<sub>2</sub> and HRP concentrations.

**Figure 1** A DS<sub>mol</sub> of HA-Tyr conjugates and B elastic modulus (G') of 2.5% (w/v) HA-Tyr (0.5 U/ml HRP/ 0.34 mM H<sub>2</sub>O<sub>2</sub>; n=3, mean ± SD).

Encapsulation of hMSCs reduces G' of HA-Tyr hydrogels about 300 Pa +/- 50 Pa compared to pure HA-Tyr hydrogels (Figure 2A). Notably, the effect is more pronounced in HA-Tyr hydrogels with low DS<sub>mol</sub>. Replacing the cells with polystyrene beads prolongs evolution of G' without changing final G' (Figure 2A). These results indicate that encapsulated hMSCs may participate in the crosslinking of HA-Tyr hydrogels and therefore reduce bulk mechanical properties of the matrix. Live-dead staining of encapsulated hMSCs demonstrates 90-95% cell viability after 5 days in culture (Figure 2B).

**Figure 2** A Time-sweep of cellular HA-Tyr and beads compared to pure HA-Tyr with PBS only (n=3, mean ± SD). B Live-dead staining (day 5) 5x10<sup>6</sup> hMSCs/ml cultured in DMEM/10% FBS, 1% P/S (scale bar 100 µm)

## CONCLUSION

Here we present an optimized conjugation strategy for DMTMM mediated HA-Tyr conjugation. Higher yields while maintaining precise control of DS<sub>mol</sub> and the physical characteristics provide a precise tailored 3D environment for encapsulated hMSCs without affecting H<sub>2</sub>O<sub>2</sub>/HRP concentrations.

## INTRODUCTION

Biodegradable polymer nanofibrillar structures that mimic native extracellular matrix fibers are extensively studied in tissue engineering. Aside from nanofibrillar architecture, the supportive matrices should as well provide an optimal environment to the cells, modulated along tissue formation through delivery of specific growth factors or bioactive molecules.

The use of biodegradable nanoparticles (NP) to localize and temporally control the delivery of encapsulated or adsorbed biomolecules represents therefore a valuable approach when combined to nanofibrillar (NF) matrices. Although different approaches have been proposed for such combination, a need remains to provide matrices that efficiently incorporate bioactive and homogeneously distributed NP, which can subsequently be released from the NF in a controlled and orchestrated fashion.

While bioactive NP can be safely obtained by nano-precipitation, jet-spraying has been described as a successful way of creating highly porous nanofibrillar scaffolds that allow extensive cell colonisation and tissue formation, unlike electrospinning<sup>1</sup>. Jet-spraying being based on the projection of a polymer solution to create nanofibers, we hypothesised that NP could be directly and permanently deposited onto the NF surface during their formation by co-projection. In addition, we postulated that electrostatic interactions could allow NP post-adsorption and controlled release from the highly porous NF matrices.

To investigate these hypotheses, we synthesized poly(lactic acid) (PLA) fluorescent NP and co-projected them during jet-spraying of poly(lactic-co-glycolic acid) (PLGA) NF. Alternatively, we incubated NP solutions with poly(lactic acid) (PLA) jet-sprayed matrices, either blank or pre-coated with poly-lysine (PLL). The two different approaches were compared in regards of efficiency, safety and distribution of the resulting NF/NP association, while NP release was determined.

## EXPERIMENTAL METHODS

Fluorescent PLA (MW 100000 g/mol) NP were prepared by nano-precipitation, coumarin-6 being dissolved in the acetone phase. Resulting NP size and zeta potential were determined by DLS. NF structures were obtained by jet-spraying PLGA (50/50, MW 80000 g/mol) and PLA (MW 100000 g/mol). Co-projection was achieved by simultaneously spraying NP in water and polymer solutions on the same collection point. Incubation of NP with blank or PLL coated NF matrices (discs of 18 x 1 mm thick) was performed in water solutions for 2 hours at room temperature. Scanning electron microscopy and fluorescence quantitation were used to characterize the hybrid NF/NP structures and determine NP release on matrices discs.

## RESULTS AND DISCUSSION

The produced fluorescent NP were of average 254nm in diameter with a very narrow distribution (Ip 0.05) and a negative zeta potential (-67 mV). Co-projection of NP during jet-spraying of PLGA allowed to efficiently deposit NP on the fibre surface as droplets-like structures. The amount of deposited NP appeared related to the quantity of projected NP and full covering of the nanofibers could be achieved, reaching an amount of 305 µg/mg of nanofibrillar matrix (fig. 1). Interestingly, the resulting nanofibrillar matrix remained visually of high porosity and interconnection.

Fig. 1. Co-projection of NP during jet-spraying of PLGA results in deposition of NP (green arrows) on NF (red arrows), in varying amounts.

Incubation of the negatively charged NP with jet-sprayed PLA nanofibrillar matrices either blank (negative surface charge) or pre-coated with poly-lysine (positive surface charge) resulted in a complete and homogeneous covering of each fibre. Although the amount of NP associated by incubation was lower than for co-projection (respectively 38 and 83 µg/mg for blank and PLL coated NF), it permitted to modulate NP release by electrostatic interaction with PLL, unlike co-projection where NP remained bound to the NF (fig.2).

Fig. 2. Post-incubation of NP with jet-sprayed NF results in homogeneous NP coating (A) which can be released in a controlled fashion (B).

Overall, these results present novel and efficient approaches to associate NP with nanofibrillar matrices and release them in a controlled way. Ongoing experiments with protein-loaded NP will further confirm their safety and resulting bioactivity.

## CONCLUSION

The possibility to associate and release NP from NF matrices in a controlled way is promising to provide defined functionality and bioactivity to inert NF structures.

### INTRODUCTION

Nerve Guidance Conduits (NGC) are increasingly used in surgical peripheral nerve repair. Improving NGC performance is challenging as existing FDA approved materials are bio-inert. Both microtopographical features and surface functionalisation have been proposed to improve neuroregeneration with these materials<sup>1-2</sup>. In this study we focus on both the inclusion of organised micro geometries and plasma polymer surface coating to improve their effectiveness at stimulating nerve regeneration.

### EXPERIMENTAL METHODS

**Microstereolithography ( $\mu$ SL)** - NGC were produced from photocurable polycaprolactone (PCL) or polyethylene glycol (PEG) by microstereolithography ( $\mu$ SL). Photocurable PCL was produced from PCL triol ( $M_n \approx 900$  g/mol) by dissolving in dichloromethane (DCM) and adding triethylamine (TEA) and methacrylic anhydride (MAA) to attach methacrylate end groups. DCM, TEA and excess MAA were removed by precipitating methacrylated PCL in methanol.

The  $\mu$ SL setup consisted of a 405 nm laser and digital micromirror device (DMD). The required image was loaded onto the DMD and the laser light reflected from this, then focused onto the surface of the liquid prepolymer causing it to crosslink. 3D shapes were produced by lowering a stage within the prepolymer (figure 1).

**Plasma Treatment** - Plasma chambers were used to air etch and coat substrates with either acrylic acid (AAc), allylamine (AAm) or maleic anhydride (MA).

**in vitro Experiments** - NG108-15 neuronal cells and RN22 Schwann cells were cultured on surfaces. MTT assay was used to confirm cell viability.

After 72 hours, cells were fixed and labelled with phalloidin-TRITC (actin filaments) and DAPI (nuclei). Cells were imaged by confocal microscopy and neurite growth analysed using ImageJ software.

**in vivo Experiments** - Grooved and smooth NGCs were implanted in *thy-1-YFP-H* mouse common fibular nerve and compared with nerve graft. Regeneration was assessed by confocal-like microscopy.  $n = 5$  for each condition, results are shown as average  $\pm$  SEM.

### RESULTS AND DISCUSSION

Guidance features with dimensions less than 100  $\mu$ m were created on the inner surfaces of the NGC (figure 1). Plasma coating was achieved evenly on the inner

surfaces of NGCs <1 mm internal diameter with a length of 5 mm. Preliminary results show increased cell viability and neurite growth on AAc coated surfaces. Cells adhered well to other coated surfaces but neurite growth was less extensive. Micro geometries showed significantly improved regeneration than smooth NGC and were comparable to autograft.

Fig. 1 Micrographs of NGC produced by  $\mu$ SL

Fig. 2 Sprouting index of *thy-1-YFP-H* mouse common fibular nerve repair

### CONCLUSION

We have produced NGC with user-defined topography and surface chemistry. Plasma treatment may be used to enhance neuronal and Schwann cell responses to otherwise bio-inert materials. Topographical features enhance peripheral nerve regeneration in an animal model.

## INTRODUCTION

Nanofibrous biopolymer scaffolds hold great potential for many biomedical applications, such as tissue engineering, wound dressings and drug delivery, as they closely mimic the natural extracellular matrix (ECM).<sup>1</sup> Three main techniques are currently used to prepare biopolymeric nanofibres: self-assembly, phase separation and electrospinning.<sup>2</sup> These methods often have restrictions in terms of scalability and yield or the use of toxic solvents and electric fields, which can interfere with the biological activity of many biopolymers.<sup>3,4</sup> Here, we present a new approach to prepare protein and polysaccharide nanofibre assemblies, involving extrusion of a biopolymer solution through nanopores, which overcomes such limitations and employs physiological buffers.

## EXPERIMENTAL METHODS

Nanoporous anodic aluminium oxide (AAO) membranes with varying pore diameters were prepared from aluminium by anodisation in polyprotic acids. Different ECM proteins and polysaccharides were dissolved in physiological buffers and extruded through the AAO nanopores and collected on glass substrates for further analysis. Prior to extrusion the substrates were functionalised with 0.1 % (w/v) poly-L-lysine in H<sub>2</sub>O. To detect the presence of nanofibres and their hierarchical assembly into microscopic structures confocal fluorescence microscopy was used. The size and morphology of the extruded nanofibres were analysed by scanning electron microscopy (SEM).

## RESULTS AND DISCUSSION

Using our custom-built extrusion setup we showed for the first time that a large variety of ECM proteins including collagen, fibronectin, fibrinogen, elastin and laminin could be extruded into nanofibres. We also succeeded in the extrusion of various polysaccharides, like hyaluronan, chitosan and chondroitin sulphate, into nanofibres. SEM analysis of the different biopolymer nanofibres revealed that they either assembled into highly aligned micron-sized fibre bundles up to millimetre length or into randomly oriented, porous meshes of single nanofibres (see Fig. 1). Our novel technique also facilitated the first-time preparation of extruded nanofibrous composites consisting of different proteins and/or polysaccharides within single nanofibres, which for instance contained blends of collagen/elastin or collagen/hyaluronan. When we extruded fluorescently labelled proteins in an aqueous environment we observed that the structure of the nanofibrous assemblies did not change over several hours (see Fig. 2). By varying the AAO nanopore diameter and the concentration of the

different biopolymer solutions we could precisely adjust the diameter of the extruded nanofibres between 15 and 200 nm.

Compared to existing methods for the fabrication of nanofibres, we could apply our extrusion technique to a large variety of biopolymers in aqueous environment, which will support their biological functionality. The possibility to reproducibly control the fibre diameter and composition in extruded protein fibres will form the basis for very interesting future cell culture studies on these novel nanofibrous scaffolds.

Fig. 1: SEM images of (A) highly aligned chitosan nanofibres assembled into a micron-sized bundle and (B) a randomly oriented mesh of collagen nanofibres.

Fig. 2: Fluorescence microscopy image of an extruded fibrinogen bundle labelled with Alexa Fluor 647.

## CONCLUSION

Our novel extrusion approach holds great potential for the convenient and well-controlled fabrication of a novel class of biopolymer nanofibres under physiological conditions. In future, this simple and one-step technique can be used to develop smart, nanofibrous protein-based biomaterials for various biomedical applications.

### INTRODUCTION

Fibers based on bioactive glasses can be used for reinforcement in composite [1] or biosensing [2]. Due to their biocompatibility, silica-based glasses such as 45S5 [3] and S53P4 [4] are well-known candidates for different biomedical applications including bone-grafting but they cannot be drawn into fibers [5]. Phosphate glasses have been found to be good alternatives as they are also suitable glasses for biomedical purposes, such as for example bone repair and reconstruction [6]. Recently, boron was found to accelerate the formation of hydroxyapatite layer and bond to bone [7] and SrO was found to enhance gingival fibroblasts adhesion and proliferation.

In this paper, we present our study on the effect of B<sub>2</sub>O<sub>3</sub> addition on the thermal, structural and bioactive properties of phosphate glasses in the P<sub>2</sub>O<sub>5</sub> - CaO - SrO - Na<sub>2</sub>O glass system as well as on the attachment and proliferation of human adipose stem cells. We also show that fibers can be drawn from those glasses.

### EXPERIMENTAL METHODS

The thermal properties of the glasses were assessed using a DTA. Structural properties were determined by FTIR and Raman spectroscopy as well as NMR. In vitro testing was performed in simulated body fluid (SBF). Glass particles were analysed after immersion in SBF using EDX/SEM and FTIR. The solution was also analysed using ICP-OES. Finally human adipose stem cells were plated at the surface of polished glasses and fibers. Viability test was performed.

### RESULTS AND DISCUSSION

The glass transition ( $T_g$ ) and the onset of crystallization ( $T_x$ ) increase with an increase in B<sub>2</sub>O<sub>3</sub> content indicating an increase in the glass connectivity.  $\Delta T = (T_x - T_g)$ , which provides a gauge of the resistance to crystallization is larger than 100°C for all the investigated glasses suggesting that the glasses can be drawn into fiber with good quality. Fibers were successfully processed from the glass with 2.5mol% of boron. In vitro testing was performed in simulated body fluid. All glasses/fibers started to precipitate a calcium phosphate layer at their surface upon immersion in SBF already after 72h. Here, we show that the addition of B<sub>2</sub>O<sub>3</sub> led to a decrease in the phosphate chains length using Raman and FTIR spectroscopy and confirmed by NMR. Such decrease in chains length decreases the rate at which the glass reacts in SBF. With increasing B<sub>2</sub>O<sub>3</sub> content the layer formation was further delayed. The degradation of the fiber was found to be similar to

the degradation of the parent glass. Human adipose stem cells were plated at the surface of the glasses and the fibers. While it was found that the cells did not attach properly at the glass surface, the cells grew at the bottom of the well indicating that the dissolution products from all the glasses are not cytotoxic. The reason for the improper adhesion of the cells at the surface of the glass could be attributed to the too fast glass dissolution and too slow reactive layer formation leading to a surface that does not permit cells to find proper nucleation sites.

### CONCLUSION

The addition of B<sub>2</sub>O<sub>3</sub> in borophosphate bioactive glasses led to a shortening of the phosphate chains reducing the rate at which CaP is formed at the surface of the glasses. Fibers were successfully drawn into fibers. Human adipose stem cells were plated at the surface of the glasses and fibers. While the cells had difficulties to attach to the material due to a too rapid glass resorption, the dissolution products were beneficial and promoted cell growth and proliferation. With this study, we show that those new borophosphate glasses are good candidates as bioresorbable fiber to reinforce composites.

### **INTRODUCTION**

Biodegradable implants can eliminate the need for implant removal procedures and reduce the chances of surgical infections<sup>1</sup>. Magnesium (Mg)-based alloys are popular materials for use in orthopaedic biodegradable implants because of their desirable strength and biocompatibility<sup>2</sup>. Zinc (Zn) and manganese (Mn) are chosen as the alloying elements for pure magnesium to enhance the corrosion and mechanical properties<sup>3</sup>. X-ray microtomography (Micro-CT) can be used to perform continuous non-destructive *in vivo* monitoring and is gaining more attention in Mg implant research<sup>4</sup>.

This paper presents the micro-CT reconstruction findings regarding *in vivo* implantation for pure Mg and two Mg-based alloys. The objective is to investigate the differences in their degradation behaviours by online imaging and to analyse the consequences for bone healing.

### **EXPERIMENTAL METHODS**

**Sample preparation:** Pure Mg, Mg-5Zn-1Mn and Mg-1Zn-1Mn alloys were produced in forms of rods of 4mm long and 1.6mm diameter by extrusion and wire-cutting. Eighteen Sprague Dawley rats (Female, 9 weeks old, 250-300 gram) were divided into three groups of six animals each. Each rat received one implant (99.999% Pure Mg, Mg-1Zn-1Mn, Mg-5Zn-1Mn) on its right femur. The 6-month implantation period was monitored by micro-CT scans at sixteen time points (day 0, week 1, 2, 3, 4, 5, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24). At the experimental endpoint, the femurs were extracted for examination.

### **RESULTS AND DISCUSSION**

3D reconstructions of the implants at day 0, week 6 and week 24 are shown in Figure 1. The unalloyed pure Mg shrank and degraded for a substantial volume. The 5Zn implant fragmented within 6 weeks, which was too fast to provide sufficient mechanical support. The 1Zn implant gradually thinned and was able to remain intact for optimal bone healing.

Figure 2 shows that both the Pure Mg implant and 5Zn implant degraded and were no longer observed on the surfaces of the femurs. On the other hand, a large portion of the 1Zn implant seemed to remain intact and observable on the surface of the extracted femur.

Figure 1. Micro-CT 3D reconstructions of the implants at day 0, week 6, and week 24.

Figure 2. Images of the extracted femurs at the experimental endpoint. The implant or the drill holes can still be seen clearly on the femurs.

### **CONCLUSION**

Micro-CT monitored the degradation process of the degradable Mg-based alloys effectively. The difference between the modes of degradation was illustrated clearly by the 3D reconstructions.

The relatively steady and slow biodegradation of 1Zn alloy made it a better candidate for orthopaedic applications with these samples. A long-term implantation is suggested so that its complete degradation can be observed. Alloys of similar composition can also be produced and compared. Toxicity measurement should also be carried out.

## A Comparative Tribocorrosion Study Between TiN- and DLC- coated Titanium for Loading Bearing Biomedical Applications

<sup>3</sup>Dept. of Materials Science and Engineering, NTNU Norwegian University of Science and Technology, Norway  
[guohua@kth.se](mailto:guohua@kth.se)

### INTRODUCTION

Medical grade titanium and its alloys are today commonly used in different biomedical components as a result of their excellent corrosion resistance and relatively low weight<sup>1,2</sup>. The orthopaedic biomaterials are required to possess high strength, good wear and corrosion resistance as well as biocompatible to bone and tissues. Titanium nitride (TiN) is one of the refractory transition metal nitrides, and it has been used as a coating on the heads of hip prostheses to improve their wear and fatigue resistance<sup>3,4</sup>. Recently, Diamond-like Carbon (DLC) coating has been proven to secure the combining benefits of high hardness, low wear rate, low friction coefficient, and the coating is biocompatible<sup>5,6</sup>. In other words, both TiN and DLC are promising surface modifications/ coatings for load bearing implants.

In this work the electrochemical and tribocorrosion behaviours of a surface modified medical grade titanium substrate, under the combining effects of sliding wear and corrosion, has been studied. The surface modifications used were TiN and a DLC coating. Furthermore, the degradation mechanisms of the different surfaces were evaluated.

### EXPERIMENTAL METHODS

The medical grade pure Ti was cut and polished to mirror-like surfaces before further treatments. The plasma nitriding treatments were performed in a vacuum furnace at a temperature of 550°C, and in an atmosphere containing more than 66 wt% nitrogen. The taC DLC coatings were prepared by using a special arc physical vapour deposition system. The taC DLC coating has the sp<sup>3</sup> fraction of 80-95% with the electric resistivity of 107- 109 μΩcm.

The corrosion resistance of the samples was evaluated by polarization measurements in Phosphate Buffer Solution (PBS) with pH value 7.4 at room temperature. The tribocorrosion properties of the modified materials were evaluated with a linear reciprocating ball-on-plate tribometer, and the tests were performed at open circuit potential conditions. The corrosion potential changes during the wear were recorded by a potentiostat.

### RESULTS AND DISCUSSION

The XRD patterns of the TiN layer exhibited the crystalline peaks that are originated from the TiN (111) and (220) planes, while the DLC coating showed an amorphous background without crystalline peaks. A carbon layer with the thickness of 1.8 μm was observed from the cross-section SEM image. It was established,

from the potentiodynamic polarization measurements, that the TiN and DLC coated titanium substrate lost its passive property and exhibited higher corrosion potential than the pure titanium substrate. In the dry wear tests, however, the DLC coated material showed the lowest friction coefficient (0.12), and the TiN produced the smallest wear track which indicated it has the best wear resistance against the rubbing movement of the alumina ball under dry conditions.

The figure above exhibits the corrosion potential changes during the tribocorrosion measurements. As onset of rubbing, a significant potential drop was observed from the pure Ti sample, followed by a plateau where the potential remains at the lower level. After the rubbing stops, the potential was immediately restored to the initial OCP value. Comparatively, the rubbing did not influence the corrosion potential of TiN and DLC samples. The present results imply that sliding wear may accelerate the corrosion process of passive metal due to the galvanic coupling effect.

### CONCLUSION

The TiN coated titanium substrate exhibited the best wear resistance under dry condition. The DLC coated titanium substrate did, however, prove to have the best wear resistance in the PBS solution. It also proved to have a low friction coefficient, as well as high hardness. Furthermore, passive metals should be avoided in a tribocorrosion environment.

### **INTRODUCTION**

The proper osseointegration of titanium implants is one of the most important factors for their clinical success<sup>1</sup>. Loose sintering and space holder are techniques frequently used that allow to obtain titanium implants, among others. In the present work, these two different methods were evaluated through *in vitro* assays to study how porous titanium surfaces can be modulated to influence the cell adhesion and cell proliferation of different cell lines.

### **EXPERIMENTAL METHODS**

**Samples processing.** Details are described in a previous work of the authors<sup>2</sup>. Commercially pure Titanium (cp Ti, ASTM F67-00, GIV, SE-JONG Materials Co. Ltd., Korea) was used. Space holder used was NaCl (Panreac, purity 99.5%), 30 vol.%. Loose-sintering (LsTi) process was applied to porous cpTi powder that was vibrated for 2 min. Samples were heated to 1250 °C for 2 h ( $5 \times 10^{-5}$  mbar). Space-holder technique (SaTi) used consisted of mixing of titanium and NaCl powders, compaction step with 800 MPa; NaCl was dissolved in distilled water (50–60 °C), and sintering as before. **Cell culture assays.** MC3T3 cell line (CRL 2593, American Type Culture Collection, Manassas, Virginia) was used for a routine passaging of the cell line. Samples were placed into a 24-well plate, and trypsinized cells were seeded at a density of 30.000 cells/cm<sup>2</sup>. Afterwards, 800 µL of pre-warmed culture medium was added, and culture plates were kept at 37°C in a humidified 5 % CO<sub>2</sub> atmosphere. To follow cell adhesion and proliferation it was used C2C12 cell line (CRL 1772 obtained from ATCC). **Cell proliferation.** AlamarBlue® (Invitrogen) was used to assess cell proliferation and cell viability. After incubation, samples were removed and culture medium was exposed to fluorescent read on microplate reader (Biotek FL-600). **Immunocytostaining assay.** Cytoskeletal organization was analyzed using protocols from Texas red phalloidin (Molecular Probes). A two-way ANOVA was performed using Graph Path Prism 6 software, and a value of  $p < 0.05$  was considered significant.

### **RESULTS AND DISCUSSION**

**Fig. 1** shows images in/at real time of C2C12-GFP growing on the samples; these were taken every day to observed differences of cells behavior. C2C12-GFP cells appear well attached to all samples. However, some cells appear widely spread on titanium samples with increased roughness (LsTi and SaTi), with respect to the smooth one (panel A, cpTi).

**Fig 1.** Images of C2C12-GFP cells seeded onto titanium samples at 24 h, 48 h and 72 h, followed by fluorescent microscope. Panel A, 2x, and panel B, 10X.

Alamarblue assessed cell proliferation at 24 h, 48 h and 72 h. It was observed the increase of cell proliferation due to a higher metabolic activity. At 24 h, the metabolic activity was lower comparing to other days. At 48 h and 72 h, the fluorescent levels are similar in all samples and, thus, correspond to cells that are in a proliferative phase. The lowest metabolic activity levels were found in SaTi which contains higher porosity, around 30%. At 72 h, MC-3T3 cells were fixed and immuno-staining was performed.

### **CONCLUSION**

These two methods to obtain different titanium surfaces allow cell adhesion and proliferation, comparing with conventional Ti surfaces, being possible to be used as techniques that can improve the success of titanium implants.

[monika.cieslik3@gmail.com](mailto:monika.cieslik3@gmail.com)

### INTRODUCTION

The development of material bioengineering and deepening medical knowledge cause the need of extending the biomaterials functionality. Currently trends in spinal implants are designed to improve the properties of dynamic stabilization.

Dynamic stabilization (**DS**) is intended to allow the transfer of loads in an elastic-flexible way by mechanical system - implants. However, only the analysis of relationship between DS with elements of bone-muscle-ligament system and formation of the bio-dynamic stabilization (**bDS**) is the basis for evaluation of its safety and suitability for surgical treatment.

The aim of the study was evaluation of dynamism of support beams (made of polyetheretherketone PEEK Optima and Ti6Al4V alloy) for “bridging” posterior spine column by experimental implementation and with the use of model engineering tools. The work also includes the aspect of biocompatibility in *in vivo* animals tests and the safety and clinical conditions.

### EXPERIMENTAL METHODS

In the work several aspects influencing dynamism of spinal rods with diameter 6 mm were analyzed, among others; kind of biomaterial (PEEK and Ti-alloy), the length, shape of rod (straight, with a defined curvature). Strength properties were evaluated in static and fatigue (5 million cycles) tests on MTS MiniBionix (Fig. 1a). The experimental evaluation was supported by FEM simulations - Ansys 14.0 (Fig.1b). Tissue response to biomaterial was evaluated post-mortem approx. 6M after animal tests on the basis of macroscopic observations and histopathological (HP) analysis.

### RESULTS AND DISCUSSION

DS is characterized by a usage of PEEK polymer rods which dynamism is dependent on the angle of curvature and the length of rod (Fig.2). Static and dynamic characteristics of PEEK rods have beneficial dependence hysteresis “load-deformation”. In destructive tests the material flow was observed with maintenance of structural integrity, which is a good indicator of the functional safety.

Polymer rod elements transfer dynamic loads well (5 million cycles). This feature gives the possibility of designing DS, control dynamic properties with the comprehensive clinical factors related to the disease, the extent of stabilization, the number of screws-support “bridging” the spine (Fig.3), which have been taken into account.

HP analysis of tissues adjacent to the PEEK and Ti-alloy indicated that these materials are bioacceptable. Tissue adhesion to the polymer surface shows no osseointegration, which proves its beneficial properties as a “non-fusion” implants. Much better osseointegration was obtained for Ti-alloy, which is a desirable element for “fusion” stabilization.

### CONCLUSION

- 1) Creation of bio-dynamic spinal stabilization is a combination of stabilizer’s mechanical properties with the biomechanical properties of the bone-muscle-ligament system.
- 2) “Dynamics” can be achieved by a suitable choice of biomaterial and/or through construction features.
- 3) Polymer supporting beam has the potential for controlled “dynamism” in the creation of spinal stabilization bDS.
- 4) Introducing bDS stabilization healing processes can be safely promoted by, e.g.:
  - acceleration of bone overgrowth in the area of dysfunction by micro movements presence,
  - offload/regeneration of disc structures and joints,
  - reduction of adverse “stiffness” outside of the stabilization area (e.g. the ASD effect - *Adjacent Segment Degeneration*).
- 5) Obtained results have been confirmed by two years clinical follow up.

### INTRODUCTION

Limitations associated with the treatment of spinal cord injury (SCI), a lesion with an increasing prevalence and high sanitary costs associated, are acting as a fuel to encourage experts in different fields to explore new avenues for neural repair<sup>1</sup>. In this context, graphene and its derivatives (GDM) are attracting significant attention<sup>2</sup>, although their toxicity and biocompatibility *in vivo* is still unclear<sup>3</sup>. Based on our previous findings *in vitro* with 3D flexible and porous scaffolds composed of partially reduced graphene oxide (rGO)<sup>4</sup>, we herein explore the acute tissue response to the implantation of these scaffolds in the injured rat spinal cord to evaluate their feasibility to be part of a guiding platform for neural regeneration in SCI patients. Early responses were thoroughly investigated at the major organs (kidney, liver, lung, and spleen) and the site of implantation (injured spinal cord at C6) by both histological and immunofluorescence studies.

### EXPERIMENTAL METHODS

**Preparation of 3D porous rGO scaffolds:** Samples were fabricated by ISISA as previously described<sup>4</sup>.

**Surgical procedures:** Lesions consisted on a complete hemisection at the right side of C6 on adult male Wistar rats. All experimental protocols adhered to the regulations of the European Commission (directives 2010/63/EU and 86/609/EEC) and the Spanish government (RD53/2013). Treatment groups were: control (C, n = 3), injury (I, n = 6) and injury + scaffold (I+SC, n = 6). Rats were sacrificed at 10 postoperative (PO) days by a perfusion-fixation protocol and the different organs and neural tissue carefully extracted.

**Tissue processing and histology:** Fixed tissues were quick-frozen in OCT compound and cut in sagittal sections (10- $\mu$ m) by using a Microm HM550 cryostat. Samples were examined using hematoxylin-eosin and hematoxylin-van Giesson stainings.

**Immunofluorescence studies:** Spinal cord samples were examined for the presence of map-2, tau, vimentin, glial fibrillary acidic protein (GFAP), ED1, platelet-derived growth factor receptor  $\beta$  (PDGFR $\beta$ ), and Ki67. Cell nuclei were labelled with Hoechst. Fluorescence images were calibrated and processed with ImageJ.

**Statistics:** Values were expressed as mean  $\pm$  standard deviation. Comparisons were done by ANOVA. The significance level was  $p < 0.05$  in all comparisons.

### RESULTS AND DISCUSSION

Organ weight in I and I+SC groups remained unaltered at 10 PO days compared to control. A thorough inspection of major organs revealed no significant

damage or inflammation signals, in agreement with previous work after oral and intraperitoneal injection<sup>5</sup>. No alterations were identified in non-lesion areas close to the injury for the markers studied. At the injury site in both I and I+SC, the amount of cells significantly increased with respect to areas with no lesion, likely indicating the activation of both cell migration and proliferation. Markers for neurons (*e.g.*, map-2 and tau) were totally absent inside the injured area (**Figure**). On the contrary, vimentin was strongly positive in injured areas of both I and I+SC, as well as ED1 and PDGFR $\beta$  (**Figure**). A discrete but evident internalization of GFAP<sup>+</sup> cells into the scaffold was observed in 3 out of 6 animals. Finally, we confirmed the presence of a significant percentage of actively proliferating cells at the injury site in both I and I+SC, contrary to control.

**Figure.** Representative immunofluorescence images of the injured spinal cord in I+SC group. Scale: 100  $\mu$ m.

### CONCLUSION

The absence of systemic and local toxic responses, along with positive signs found at the lesion site (*e.g.*, complete scaffold colonization by cells, discrete sprouting of GFAP<sup>+</sup> cells inside the scaffold) encourage further investigation of GDM as promising components of more efficient material-based platforms for neural regeneration in the CNS.

# Dual Peptide Functionalised Intraluminal Collagen Fibre Conduits Regulates Neurite Outgrowth Of Primary Neurons

Sahana Ganesh, William Daly, Abhay Pandit

Network of Excellence for Functional Biomaterials, National University of Ireland, Galway, Ireland

[sahanag.29@gmail.com](mailto:sahanag.29@gmail.com)

## INTRODUCTION

The process of repair following peripheral nerve injury occurs at the molecular level and the regenerative responses are specific to the biomaterial used to bridge the intraneural gap. Proteomic analysis following implantation of intraluminal collagen fibre conduit in a sciatic nerve injury model identified a number of molecules that are intrinsic to repair, one of them being Myristoylated alanine rich C-kinase substrate (MARCKS) [1]. MARCKS is critical to neurite outgrowth and is dependent on its interaction with Polysialic acid (PSA) on NCAM [2]. Hence we hypothesise that intraluminal fibre conduits functionalised with MARCKS and PSA will enhance nerve repair and functional recovery in sciatic nerve injury model and the specific objective of the present study is to assess the loading efficiency, release profile and to test the bioactivity of MARCKS and PSA functionalised conduit using embryonic rat dorsal root ganglion cells (DRGs).

## EXPERIMENTAL METHODS

Type I bovine atellocollagen (3mg/ml) was mixed with MARCKS (KKKKKRFSFKKSFKLSGFSFKKNKK) (80µg) and intraluminal fibres were fabricated using fibre extrusion method [1]. Loading efficiency of MARCKS was assessed using amino acid analysis. Collagen conduit was fabricated as described in [1] and was functionalised with PSA mimetic peptide (NTHTDPYIYPID) (200µg/ml) by incubating the conduit in loading buffer containing PSA for 24 hours. The loading efficiency was calculated using micro BCA assay. The functionalised fibres were placed in release buffer in the absence and presence of collagenase for a period of 14 days. At specific time points release buffer was collected to assess the release profile of MARCKS using micro BCA assay. The functionalised conduit was placed in release buffer in the absence and presence of collagenase for a period of 14 days and at specific time points release buffer was collected to assess the release profile of PSA using micro BCA assay. Bioactivity of the released MARCKS and PSA in comparison to scramble MARCKS peptide (KKKKKRASAKK-SAKLSGASAKKNKK) and scramble PSA (TNYDITPPHDIYC) was tested by neurite outgrowth analysis using  $\beta$ -III tubulin staining in DRGs.

## RESULTS AND DISCUSSION

Amino acid analysis of the functionalised fibres showed that approximately 70 percent of MARCKS was loaded. In the absence of collagenase less than 20% of MARCKS was released over 14 days however in the presence of collagenase it increased to up to 78%. On the other hand, around 66 percent of PSA was loaded.

into the conduit. In the absence and presence of collagenase the release of PSA over 14 days was 5 and 42% respectively. Preliminary results show that the released peptides are bioactive following neurite outgrowth analysis in DRGs.

**Fig 1. Fluorescent image of fibre functionalised with MARCKS.**

**(A) (B)**  
**Fig 2. A) Concentration of PSA measured in supernatant at 0 and 24 hr, n=3, p<0.001. B) Loading efficiency of PSA.**

**(A) (B)**  
**Fig 3. Light microscopic images of DRGs showing neurite outgrowth in the presence of (A) PSA loaded conduit (B) no neurite outgrowth with scramble PSA loaded conduit after 24 hrs.**

## CONCLUSION

An intraluminal fibre conduit functionalised with MARCKS and PSA has been fabricated in the present study. The release kinetics of both the peptides from the fibre/conduit was found to be mainly governed by collagen degradation. Preliminary results show that both the peptides retained their bioactivity upon release in vitro and resulted in neurite outgrowth in DRGs. The current results will allow for optimisation of future in vitro studies and also will involve implantation of MARCKS-PSA functionalised fibre conduit in a rat sciatic nerve injury model.

### INTRODUCTION

Reconstruction of injured nerves is one of the most demanding processes in regenerative medicine. Even mild injuries can lead to motor or sensory deficits. Natural and synthetic polymers are potential solution for grafting the severed nerve<sup>1</sup>. *In vitro* and *in vivo* studies with the use of neural cells and animals show encouraging results for the application of new synthetic materials. Several polymers have been found as the most promising. Among them polylactide, polycaprolactone and polyesterurethane<sup>2,3</sup>.

In our study a biodegradable polyurethane (PU) based on hexamethylene diisocyanate, poly( $\epsilon$ -caprolactone) and dianhydro-D-sorbitol as a chain extender was investigated. It was blended with polylactide to modify its mechanical properties and degradation rate. Alginate fibers and hydrogels were also applied used to support nerve regeneration. Full characterisation of the materials, *in vitro* cell culture, and *in vivo* studies were performed.

### EXPERIMENTAL METHODS

Blends of polylactide (Purac) and polyurethane (Bayer) were tested. Both polymers were of biomedical grade and used without further purification. PU/PLA blends with various weight ratios (9/1, 8/2, 7/3, 6/4, and 5/5) were prepared. Samples for biological examination were sterilised with the use of the H<sub>2</sub>O<sub>2</sub> cold plasma technique (Sterradyl, ASP, J&J, USA).

The water contact angle, surface roughness, tensile strength, Young's moduli, and elongation at break ( $\epsilon$ ) of the blends were determined. Morphology of the samples was investigated using scanning electron microscopy. *In vitro* assessment of the biomaterials was performed with the use of glial cells. Rat sciatic nerve regeneration was observed *in vivo* after implantation of PU/PLA tubes.

### RESULTS AND DISCUSSION

In our search for a material enabling to fabricate a scaffold for regenerating axons we focused on blending two polymers with very different mechanical properties, i.e. rigid polylactide and elastic polyurethane. Both polymers were biodegradable but differing with the rate of degradation. We found that the morphology and mechanical properties of investigated materials could be easily regulated through mixing different ratios of PU and PLA. Optimal properties for surgical handiness were achieved this way. Porous films and sponges were fabricated by salt leaching. Porosity improves the

communication between cells and facilitates the exchange of metabolites. Moreover, surface roughness and wettability of particular biomaterials has been reported as an important factor responsible for cell adhesion and proliferation. We found that roughness of our investigated biomaterials may be increased through addition of PLA to the pure PU. Roughness of PU/PLA blend was  $5,52 \pm 0,62 \mu\text{m}$ . Water contact angle for pure PU was  $88,6^\circ \pm 2,6$ , whereas for PLA  $80,4^\circ \pm 2,2$ . The PU/PLA blends, however, exhibited the water contact angle of  $95,4^\circ \pm 2,3$ . The pure PLA showed the Young's modulus over 3000 MPa, which resulted in high rigidity and disadvantaged surgical manipulations. Mixing PLA with elastic PU strongly and positively influenced all mechanical properties.

Glial cells were cultured on pure polyurethane and the various blends. After 24 hrs. the cells cultured on pure PU showed decrease in proliferative activity, in relation to the control polystyrene cultures. In contrary, PU/PLA blend slightly increased proliferative activity of glial cells after the first day, what can be an effect of the presence of PLA. After seven days, culture cells on the PU sample still showed decreased PF value in relation to control, while the PU/PLA sample showed the PF value slightly above 1. In pure PLA sample, the proliferative activity of glial cells was considerably decreased. In PU/PLA blend cells showed proper morphology, significant number of p75-positive cells was observed, and the presence of a bipolar shape in fibroblast-like cells.

For *in vivo* evaluation PU/PLDL tubular implants were prepared. They were flexible and compression-resistant with a good shape memory and surgical handiness. Empty tubes and tubes filled with calcium alginate fibers were implanted into a lesion in a rat's sciatic nerve. The latter proved to be especially promising because of the additional stimulus of calcium ions on the regenerating axons.

### INTRODUCTION

Traumatic spinal cord injury (SCI) has a great medical and socioeconomic impact, due to a severe neurological disability<sup>1</sup>. Polymers synthesized by plasma derived of pyrrole and implanted in adult rats with SCI by transection, favor protection of the nervous tissue adjacent to the lesion and the functional recovery of the animals, significantly<sup>2,3</sup>. Animal studies have contributed greatly to a better understanding of the pathophysiology of SCI. However, it has not been possible to translate these findings effectively to improve treatments for SCI human. Therefore, to facilitate the translation of advances made in the laboratory to the clinic it is recommended the use of non-human primates (NHP). Magnetic Resonance Imaging (MRI) enables us to obtain morphometric information of the lesion area and the state of the affected tissue<sup>4,5</sup>. Diffusion tensor MRI (DTI) can be used in order to determinate the white matter microstructure. In this work the evolution of SCI in NHP is evaluated, both, with and without implant, *in vivo* using MRI.

### EXPERIMENTAL METHODS

Polymeric materials used to prepare the implants were synthesized, and analysed according to previous works<sup>2,3</sup>.

#### Spinal Cord Injury and functional evaluations

NHP Rhesus female were used, they underwent to transection SCI, one was implanted with the polymer (NHP-C) and the other one was only injured (NHP-I). The NHPs were treated to our institutions ethics and to "National Institutes of Health Guide for the Care and Use of Laboratory Animals". The 9th spinous process was extirpated. Then a laminectomy was done. Reflex recovery and locomotor behaviour were assessed once a week, for 12 weeks. Reflexes were evaluated with the animal seated in a restrainer.

#### Magnetic Resonance Imaging

MRI studies were taken with a 3T scanner *in vivo* and a 7T scanner *ex vivo*. The studies *in vivo* were carried out: pre-SCI; the SCI day ( $t_0$ ); 4, 8, and 12 ( $t_f$ ) weeks post-SCI; at last *ex vivo* studies were performed.

The animals were euthanized 12 weeks post-injury, for histological studies.

### RESULTS AND DISCUSSION

Functional evaluation after SCI shows recovery comparing both subjects. The withdrawal reflex present in NHP-I is highlighted. MRI in the NHP-I shows the spinal cord decreased to 81% at  $t_0$  and recovered to 91% at  $t_f$  from its baseline. The PPy/I decreased, this is consistent with the experience obtained in rats where the material tends to disintegrate it and allow tissue to grow through it<sup>4</sup>. DTI shows different behaviour between the subjects in the epicentre of the lesion as  $t_f$ : in the PNH-C a rostral and caudal separation exists, while the PNH-I shows transversal spinal cord reconnection of the diffusion (Fig1). The MRI data are concordant with the histological studies.

Fig1. Tractography for non-human primate implanted at the day of SCI (A) and 12 weeks after SCI (B). Shows transversal spinal cord reconnection of the diffusion.

### CONCLUSION

The monkey implanted with the plasma polypyrroles after spinal cord transection are capable of slight voluntary movements, also the implant contribute to the conservation of the histoarchitecture near the lesion epicentre, and promotes tissue growth through it. The results were consistent according to the experiences in rats, indicating that it is possible to reduce the paralysis when are implanted immediately after the SCI. With MRI is possible to monitor the *in vivo* state of the surrounding tissue to the area of SCI in a model of NHP.

# Cell Membrane Capsules for Encapsulation of Chemotherapeutic and Cancer Cell Targeting *in vivo*

Zhengwei Mao<sup>1\*</sup>, Yuanhong Zhang<sup>1</sup>, Lihua Peng<sup>2</sup>, Jianqing Gao<sup>2</sup>

<sup>1</sup> MOE Key Laboratory of Macromolecular Synthesis and Functionalization, Department of Polymer Science and Engineering, Zhejiang University, P.R. China

<sup>2</sup> Institute of Pharmaceutics, College of Pharmaceutical Sciences, Zhejiang University, P.R.China

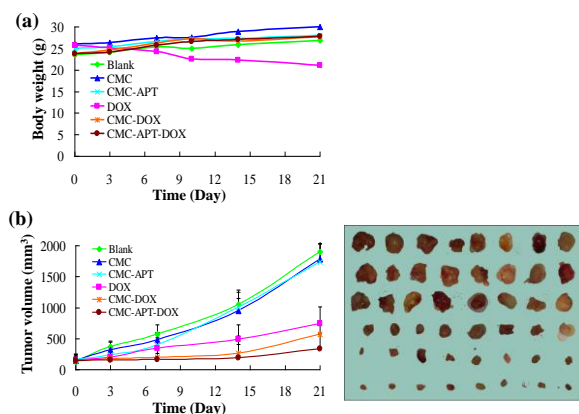

[zwmao@zju.edu.cn](mailto:zwmao@zju.edu.cn)

## INTRODUCTION

Systemic administration of chemotherapeutic agents results in indiscriminate drug distribution and severe toxicity. Until now, encapsulation and targeting of drugs have typically relied on synthetic vehicles, which cannot minimize clearance by the renal system and may also increase the risk of chemical side effects. Cell membrane capsules (CMCs) provide a generic and far more natural approach to the challenges of drug encapsulation and delivery *in vivo*.

## RESULTS AND DISCUSSION

Here aptamer AS1411, which can recognize and bind over-expressed nucleolin on cancer cell membrane, was chemically conjugated onto CMCs. As a result, AS1411 modified CMCs showed enhanced ingestion in certain cancer cells *in vitro* and accumulation in mouse cancer xenografts *in vivo*. Chemotherapeutics and contrast agents with therapeutically significant concentrations can be packaged into CMCs by reversible permeating their plasma membranes. The systematic administration of cancer targeting CMCs loaded with doxorubicin can significantly inhibit tumor growth in mouse xenografts, with significantly reduced toxicity compare to free drug. These findings suggest that cancer targeting CMCs may have considerable benefits in drug delivery and cancer treatment.

**Figure 1.** (a) Body weight and (b) tumor volume of BALB/c nude mice with xenograft tumors as a function of culture time after first treatment. Digital images show tumors harvested from mice treated with different groups for three weeks (from top to bottom: blank/saline, CMCs, Apt-CMCs, free DOX, CMCs/DOX, and Apt-CMCs/DOX groups).

## CONCLUSION

In this study, biocompatible cell membrane capsules were prepared from human endothelial cells with preserved membrane structure and functions. Cancer cell targeting aptamer AS1411 was conjugated onto the CMCs, resulted in enhanced ingestion of CMCs in certain cancer cells and accumulation of CMCs in mouse tumor xenografts. Chemotherapeutics and contrast agents can be packaged into the CMCs by reversible permeating their plasma membranes. The systematic administration of cancer targeting CMCs loaded with doxorubicin can inhibit tumor growth in mouse xenografts, with significantly reduced toxicity compare to free drug. These findings suggest that targeting CMCs may have considerable benefits in drug delivery and cancer treatment.

### INTRODUCTION

Electrospinning is a widely used technique for the preparation of nanofibrous materials. Due to its high surface to volume ratio and microporous structure, its potential for biomedical applications is increasing, especially for tissue engineering and drug delivery system. In fact, thanks to its flexibility, this technique provides different strategies for drug loading, such as the one step strategy that consists on electrospinning the polymer-drug mixture, or the two steps strategy where the electrospun membrane is afterwards dipped into a drug solution [1]. In this study, the first strategy was adopted. A first system was obtained from the electrospinning of a chitosan-triclosan solution (CHT-TCL system). The release of TCL and the antibacterial activity of the loaded mats were studied. As an improvement of this system, a second one including cyclodextrin (CD) is proposed.

### EXPERIMENTAL METHODS

**Preparation of CHT based solutions:** 3.5wt% of CHT/polyethylene oxide (PEO) mixtures (ratio 9:1) were dissolved in 90% acetic acid aqueous solution. In order to stabilise nanofibrous mats in aqueous medium, 0.05wt% and 0.1wt% of genipin (a biosourced crosslinker) was added into the electrospun solution and obtained membranes were then exposed to water saturated atmosphere at 37°C in order to activate genipin-CHT reaction [2]. 5%, 10% and 20% (with respect to total polymer concentration 3.5wt %) of TCL were also added into the polymer solution.

**Electrospinning conditions:** the following parameters were optimized for the preparation of nanofibres: 0.8mm for the inner diameter of the needle, 0.3ml/h for the flow rate, 13kV for the applied voltage and 200mm for the tip to-collector distance. Temperature and relative humidity were kept at 23°C and 30% respectively.

**Drug release study:** CHT based nanofibres loaded with TCL were immersed in PBS and incubated at 37°C for 10 days. The amount of released triclosan was measured by UV-vis spectroscopy at 280nm (n=3).

**Microbiological evaluation:** The Kirby-Bauer disk diffusion method was carried out to determine the antibacterial properties of the CHT based nanofibres, containing or not TCL, against Gram-positive bacteria (*S.aureus*) and Gram-negative bacteria (*E.coli*) after 24h of incubation (n=3).

### RESULTS AND DISCUSSION

CHT nanofibres blended with PEO were successfully developed by electrospinning. The fibres diameters are in the range of 100 - 250 nm (figure 1.a).

The stability of membranes in aqueous medium was improved by a genipin crosslinking. The membranes collapse completely without genipin (figure 1.b)

whereas they are not affected with genipin (figure 1.c).

Figure 1: SEM observations of chitosan based nanofibres (a) in aqueous medium without (b) and with genipin treatment (c). The release profile (figure 2.A) shows a *burst* effect for all the TCL loaded nanofibres, and then a sustained release. The time of release increases with the drug loading of the mats.

According to the antibacterial assays, all tested membranes displayed an inhibition on both bacteria whose diameter varied with the initial TCL loading (figure 2.B).

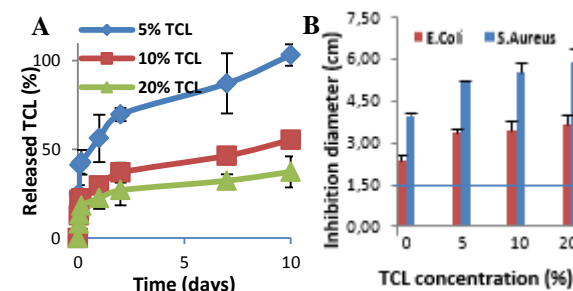

Figure 2: A) The release profile and B) Antibacterial activity of TCL loaded nanofibrous membranes.

The next part of this work is to limit the *burst* effect and to improve the sustained release. Therefore, we are developing new systems consisting on mixing CDs/TCL inclusion complexes, in order to control more efficiently the TCL release. Nanofibres of 150 to 280 nm diameter were obtained. Release study and antimicrobial assays will be attempted in order to demonstrate the expected effect of those CDs based nanofibrous systems.

### CONCLUSION

Nanofibres were successfully prepared by electrospinning a CHT/PEO/TCL solution. The release study has shown that this strategy did not allow to obtain a sufficient sustained release. Though, considering our former works in this field, the perspective of using cyclodextrin-TCL complex is a promising path for improving the sustained release performances.

### INTRODUCTION

The traditional strategy for the treatment of implant-related infection involves systemic administration of high doses of antibiotics. This strategy is, however, associated with systemic toxicity and may result into antibiotic resistance [1]. Therefore, local and sustained delivery of multiple bacteria susceptible antiseptics, e.g. silver and chlorhexidine (CHX), is advocated as a new treatment modality. Besides, synergistic antibacterial effects could be achieved by combining release of Ag<sup>+</sup> and CHX. To achieve a controlled delivery, chitosan-based nanofibres have been widely used as carriers due to their high drug encapsulation efficiency, superior biocompatibility, and ease of processing [2]. Consequently, the objective of this study was to develop a chitosan-based nanofibrous drug carrier system containing silver nanoparticles (AgNPs) for the dual release of Ag<sup>+</sup> and CHX.

### EXPERIMENTAL METHODS

Nanofibrous matrices containing AgNPs were prepared by one-step electrospinning of a chitosan/poly(ethylene oxide) (PEO) (75:25) solution containing different amounts of AgNO<sub>3</sub> without any other reductive reagents. In situ formation of AgNPs was investigated by cryo-transmission electronic microscopy (TEM) and energy dispersive X-ray microscopy (EDX). CHX was loaded onto the matrix through a post-diffusional loading method and the release of CHX was detected by high performance liquid chromatography. Long-term release of Ag<sup>+</sup> was monitored by inductively coupled plasma mass spectrometry. Antibacterial effects of the membrane were confirmed by a zone of inhibition test against *S. aureus*.

### RESULTS AND DISCUSSION

Uniform, defect free nanofibres were obtained (Figure 1A). AgNPs were formed and distributed homogeneously throughout the fibres (Figure 1 B, C, D and E), which is attributed to the self-reductive ability of the chitosan solution. Compared to other methods for the preparation of electrospun nanofibres containing AgNPs, no reductive agent or other reductive treatment (e.g. UV) was used in this study. Besides, no AgNPs were observed using TEM when 0.1 wt% AgNO<sub>3</sub> (ratio to polymer) was added into chitosan/PEO solution, and the AgNPs became visible when the amount of AgNO<sub>3</sub> was equal or higher than 1 wt%, which corresponds to the lowest amount of AgNO<sub>3</sub> required in this system to form TEM-detectable AgNPs.

Burst release was observed for CHX, irrespective of the amount of CHX loaded (Figure 2A), which

indicated that there was no interaction between CHX and the nanofibres. In contrast, Ag<sup>+</sup> was released in a sustained manner for more than 28 days (Figure 2B). Moreover, identical patterns of release of Ag<sup>+</sup> from matrix with or without CHX were obtained (Figure 2B), which indicated that the loading of CHX on the nanofibres had no influence on the release of Ag<sup>+</sup>.

Figure 1 Characterization of chitosan/PEO nanofibers containing 5 wt% AgNO<sub>3</sub>. Scanning electron micrograph (A), transmission electron micrograph of the fibres (B) and fibre cross-section (D), TEM-EDX pictures of the nanofibers in bright field (C) and elemental distribution of silver and carbon (E).

Figure 2 Release kinetics of chlorhexidine (A) and Ag<sup>+</sup> (B) from chitosan/PEO electrospun nanofibrous matrix.

### CONCLUSION

A simple one-step electrospinning procedure was developed for the formation of nanofibrous chitosan/PEO matrices containing AgNPs without addition of any other reductive reagent. The AgNPs were distributed homogeneously throughout the fibres. Burst-type release of CHX at the early stage and sustained release of Ag<sup>+</sup> at the later stage were obtained. This drug delivery system has strong potential great for the treatment of implant-associated infections.

### INTRODUCTION

Hydrogels made from a number of natural and synthetic polymers have been studied for their ability to deliver therapeutics directly into the central nervous system<sup>1</sup>. In particular, hyaluronic acid (HA)-based gels have been used to deliver trophic factors<sup>2</sup> or cells into the injured spinal cord<sup>3</sup>. Type I collagen (COLL) is also an appealing candidate for neural tissue regeneration. In fact it self-assembles to form a fibrillar structure at physiological conditions and interacts with cells to guide their adhesion, migration, survival, proliferation, and differentiation<sup>4</sup>.

The aim of the present work has been designing and characterizing injectable COLL/HA acid-based semi-interpenetrating polymer networks (semi-IPNs) for the delivery of neuroprotective proteins (e.g. 70 kDa-heat shock proteins, Hsp70) or cells in the treatment of Alzheimer's and Parkinson's diseases, focusing on the role of HA molecular weight.

### EXPERIMENTAL METHODS

COLL and COLL/HA-based gels differing from the molecular weight of HA (100 or 1600 g·mol<sup>-1</sup>, COLL-LMW HA or COLL-HMW HA, respectively) were designed and characterized.

Their dynamic moduli were evaluated as a function of frequency (0.1-10 Hz) by small amplitude oscillatory shear tests and their viscosity was assessed as a function of shear rate (0.01-100 s<sup>-1</sup>) by steady shear measurements, while their injectability was confirmed by an INSTRON 5566 testing machine mounting a syringe with a 30 G needle. Hydrogel morphology was observed by scanning electron microscopy (SEM) and transmission electron microscopy (TEM). Hydrogel biological behavior was assessed both *in vitro* and *in vivo*. SH-SY5Y human neuroblastoma cell line were embedded within gels and their metabolic activity was quantified by MTS assay on days 1, 4 and 7. LMW HA, HMW HA and the semi-IPNs were injected in mouse striatum. After 7 days, the inflammatory response was evaluated by glial fibrillary acidic protein (GFAP) and CD11b staining on 30 µm-thick coronal sections. In particular, the quantitative evaluation of both GFAP and CD11b reactivity was performed by recording the number and the area covered by positive cells at 20X magnification.

### RESULTS AND DISCUSSION

Small amplitude oscillatory shear tests have shown that COLL and COLL-HA share a gel-like behavior, with

the storage modulus  $G'$  that is always greater than the loss modulus  $G''$ . In particular, for COLL-LMW HA  $G'$  is lower than for COLL-HMW HA gels. Steady shear tests have shown a shear thinning behavior and the viscosity of COLL-LMW HA is always lower than for COLL-HMW HA gels. Regarding the injectability tests, the values of maximum and plateau loads for COLL-HMW HA are almost double than for COLL-LMW HA matrices. TEM images have shown that COLL fibrils are coated by HA in COLL-LMW HA, while HA does not seem to follow the fibrillar network of COLL in COLL-HMW HA gels. MTS assays has indicated that cell metabolic activity increases with time, suggesting that SH-SY5Y cells may proliferate within gels. Results from *in vivo* injections have shown that the inflammatory response elicited by LMW HA is negligible (Fig.1).

Fig.1: GFAP staining after LMW HA injection

### CONCLUSION

The available results have suggested that the rheological and preliminary biological properties shown by both the proposed collagen/hyaluronic acid-based gels are suitable for brain applications.

Future studies will focus on the suitability of COLL-HA gels for the delivery of Hsp70.

### INTRODUCTION

Currently, the use of extra corporeal membrane oxygenation (ECMO) devices, which is indicated for patients awaiting lung transplantation, is limited to a few weeks only, due to thrombus formation and deposition of blood components within the device. Therefore, the basic idea is to improve the haemocompatibility by endothelialisation of the poly-4-methyl-1-pentene gas exchange membranes (PMP), which necessitates the development of coating techniques for the mediation of endothelial cell adhesion to the hydrophobic polymers. The pulsed vacuum cathodic arc plasma deposition (PVCAPD) technique has been shown to enable the coating of thermosensitive polymers. Hence the eligibility of titaniumdioxide (TiO<sub>2</sub>) deposited on PMP using PVCAPD as an effective coating technique for enabling the endothelialisation was assessed.

### EXPERIMENTAL METHODS

PMP film samples were coated with TiO<sub>2</sub> via PVCAPD and characterised by SEM, contact angle measurement and oxygen transfer rate assessment. Umbilical cord blood derived endothelial cells (hCBECs) were seeded on such samples and incubated for 24 h. Established monolayers were investigated for the expression of activation-relevant marker genes and subjected to a leucocyte adhesion assay. The integrity of the monolayer was investigated by immunofluorescence staining for the adherence junction protein VE-Cadherin as well as the focal adhesion protein vinculin. Flow resistance and self-healing capacity of the established EC-monolayer were assessed in a parallel plate laminar flow chamber applying 30 dyne/cm<sup>2</sup> for 24 h.

### RESULTS

SEM analysis confirmed the homogeneous deposition of a thin layer consisting of nanoscale TiO<sub>2</sub> particles, which resulted in a decrease in the oxygen transfer rate by 22%. The coating increased the wettability of the PMP surface, which was detected by contact angle measurements (uncoated PMP: 82,79°, TiO<sub>2</sub> coated PMP: 57,48°).

hCBECs exclusively adhered to areas of the PMP film coated with TiO<sub>2</sub>. Gene expression analysis revealed that hCBECs seeded on TiO<sub>2</sub> coated surface retained the non-activated state, additionally confirmed by a leucocyte adhesion assay. The integrity of the cell layer was confirmed by the detection of the adherence junction protein VE-Cadherin, homogeneously expressed at sites of cell-cell contacts. The cell-substrate contacts could be detected by immunofluorescence staining of the focal adhesion protein vinculin. Furthermore, the established monolayer was resistant to a high physiologic shear rate of 30 dyne/cm<sup>2</sup>, for 24h. Besides planar PMP, the coating technique was successfully applied to 3D hollow fibres.

### CONCLUSION

This study demonstrated that TiO<sub>2</sub> coating via PVCAPD is a promising technique for coating thermosensitive PMP gas exchange membranes, enabling the generation of a non-activated, flow-resistant and integer EC monolayer.

[edgarw@physics.usyd.edu.au](mailto:edgarw@physics.usyd.edu.au)

## INTRODUCTION

Orthopaedic implantable devices encounter two major obstacles to long-term stability: the dual demands for biological and mechanical compatibility. Current implantable devices made of titanium are biologically benign, but are too rigid and lead to bone degradation via stress shielding<sup>[1]</sup>. Attempts to alter the elastic moduli of implantable devices to values similar to bone have met with limited success<sup>[2]</sup>. Polyether ether ketone (PEEK) is a promising candidate for the next generation of orthopaedic implants because of its tensile similarity to bone. However, PEEK produces a bone-implant interface strength that is inferior to titanium<sup>[3]</sup> – a critical determinant for orthopaedic implantation. In this study we use Plasma Immersion Ion Implantation (PIII) to activate a surface layer of PEEK by introducing radicals that covalently bind proteins to improve bone-implant interface strength and integration.

## EXPERIMENTAL METHODS

**PIII treatment:** PEEK (Victrex, UK) was treated using a 100 W nitrogen plasma at a pressure of  $2 \times 10^{-3}$  Torr. Ions were accelerated towards the surface with a pulsed bias of -20 kV, a current of 1.4 mA, and pulse length of 20  $\mu$ s at 50 Hz. **EPR:** Spectra were obtained using a Bruker EMX Xband spectrometer with a centre field of 3485 G, sweep width of 100 G, a microwave frequency of 9.76 GHz and power of 8 mW at 21°C. The receiver gain was set to  $1 \times 10^5$ , with modulation amplitude of 5 G, a time constant of 82 ms and sweep time of 83 s. **FTIR:** Spectra were obtained using a Digilab FTS 7000 spectrometer fitted with an attenuated total-reflection trapezium germanium crystal at an angle of incidence of 45°. Spectra were averaged over 50 scans with a resolution of 4 cm<sup>-1</sup>. Covalent protein attachment was determined by washing in a 5% SDS solution in PBS at 80°C for 60 minutes. **Cell attachment:** PEEK samples were incubated in tropoelastin solutions varying from 2–50  $\mu$ g/ml in PBS for 12 hours at 4°C, and then blocked with denatured BSA for 60 minutes. SAOS-2 osteosarcoma cells were seeded ( $13.2 \times 10^4$  cells/cm<sup>2</sup>) onto the surface for 60 minutes. Bound cells were then fixed, stained and quantified.

## RESULTS AND DISCUSSION

EPR measurements (Figure 1) show that radicals are created within the PIII treated surface. The concentration of radicals increases with treatment time, and decreases with aging time. The radicals produced are long-lived, enabling an activated surface with a long shelf life.

Figure 2A shows the fraction of tropoelastin remaining on PEEK samples after SDS washing as a function of the coated protein concentration. The removal of nearly all tropoelastin from the untreated PEEK indicates that

Figure 1 Density of radicals created by PIII treatment of PEEK as a function of aging time.

the protein is simply physically adsorbed to the surface. In contrast, the high protein retention on the PIII treated PEEK indicates that the majority of tropoelastin molecules are covalently bound to the surface. Figure 2B shows attachment of SAOS-2 cells to PEEK as a function of protein coating concentration. Untreated and PIII treated PEEK coated with tropoelastin concentrations  $\geq 5$   $\mu$ g/mL show similarly high cell attachment activity, in contrast to BSA-blocked PEEK. Tropoelastin retains osteoconductivity when covalently bound to the treated surface (data not shown).

Figure 2A: Tropoelastin was covalently bound to PIII treated (red) but not untreated (blue) PEEK, as shown by protein retention after SDS washing. 2B: Tropoelastin bound to PIII treated PEEK (red) supports high levels of bone cell attachment.

## CONCLUSION

Plasma Immersion Ion Implantation modifies the surface of PEEK by introducing radicals. The radicals are capable of covalently binding proteins in a robust and reliable way. The immobilised protein retains its biological activity and cannot be displaced through vigorous washing. The treatment produces a surface that can cloak the underlying PEEK structures so that bound proteins can interact favourably with cells to improve the bone-implant interface.

## INTRODUCTION

Electrophoretic deposition (EPD) can be used to coat different surfaces with (nano)particles to enhance their bioactivity. The coating of implants by EPD is a versatile technique in modern biomaterials science.<sup>[2]</sup> Nanoparticles can be used for the transport of drugs and nucleic acids because they are easily taken up by cells and no other transport vectors are necessary.<sup>[1]</sup> Alginate, a hydrogel derived from marine brown algae, is a highly suitable matrix to immobilize nanoparticles. Alginate is often used for cell encapsulation and easy to modify according to specific cell characteristics and applications.<sup>[3]</sup> Here we report on the coating of alginate hydrogels with calcium phosphate nanoparticles which had been previously deposited on a silicon surface.

## EXPERIMENTAL METHODS

Three kinds of calcium phosphate nanoparticles were used for EPD. All nanoparticles were stabilized with polyethylenimine (PEI). Spherical nanoparticles were synthesized by precipitation, followed by functionalization. The particles can be functionalized with fluorescent molecules like tetramethylrhodamine (TRITC) and also with biomolecules like DNA or proteins and synthetic drugs. In addition, calcium phosphate nanorods (Ostim<sup>®</sup>)<sup>[4]</sup> were dispersed in water with PEI. After redispersion of the nanoparticles in ethanol, a high voltage can be applied for EPD. In aqueous dispersion, however, a low voltage is necessary (Table 1).

Table 1. Parameters for EPD of calcium phosphate nanoparticles on silicon from different dispersion media.

Dispersion medium	Ethanol	Water
Voltage	50 V, DC	2 V, DC
Deposition Time	30 s to 2 min	30 min to 5 h

Alginate beads were produced with an air-jet droplet generator as described in Refs.<sup>[3, 5]</sup> Alginate beads were coated with the calcium phosphate nanoparticles by rolling them over a nanoparticle-coated silicon surface.

## RESULTS AND DISCUSSION

Fig. 1 shows typical results of electrophoretically-deposited calcium phosphate nanorods on silicon. Fig. 2 shows an alginate bead, coated with red-fluorescing nanoparticles. The transfer of the nanoparticles to the alginate bead was highly efficient as it is evident from the strong fluorescence intensity. As indicator of the changed surface properties of alginate, introduced by coating with calcium phosphate nanoparticles, the attachment of fibroblasts was quantified after 24 h. 76±21% of the cells attached to nanoparticle-coated alginate hydrogels, while only 1.8±2.2% of the cells

were attached to native alginate hydrogel surfaces. This demonstrates the increased affinity of the very hydrophilic alginate surface to cells after coating with calcium phosphate nanoparticles.

Fig. 1. SEM image of a calcium phosphate nanorod-coated silicon surface.

Fig. 2. An alginate bead, coated with TRITC-labelled (red) calcium phosphate nanoparticles.

## CONCLUSION

Calcium phosphate nanoparticles were deposited by electrophoretic deposition onto silicon and transferred to alginate beads by rolling. The adhesion of fibroblasts to the coated alginate beads was much higher than to the native alginate surface.

### INTRODUCTION

Tantalum-based implants were known to be successful since the research conducted by Burke<sup>1</sup> in 1940's. Although its relatively high cost effectively impedes the widespread application of this biocompatible metal there are some attempts to bring this material into affordable price-range with the use of porous structures. Additional advantage of such approach is reduction of implant's weight and enlarging its surface area<sup>2,3</sup>.

Bioactive coatings on valve metals such as titanium or tantalum (mainly enriched with Ca and P) can be obtained by a myriad of ways<sup>4</sup>. Plasma electrolytic oxidation (PEO) presents relatively inexpensive yet effective method of formation of thick oxide coatings with an ability to introduce electrolyte components into the oxide layers<sup>5</sup>. Manipulation of process parameters such as voltage, current density or electrolyte composition gives control over coatings' parameters<sup>6</sup>. Herein, a study of bioactive behaviour of PEO coatings obtained on tantalum in Ca and P containing solutions is described. The coatings were characterised in terms of their surface morphology, thickness, chemical and phase compositions, corrosion resistance and *in vitro* bioactivity.

### EXPERIMENTAL METHODS

Anodic oxide coatings were obtained by anodising (Kikusui 800H DC power supply) tantalum workpiece (discs -  $\phi$ : 9 mm; height: 5 mm; BIMO metals) in  $\text{Ca}(\text{H}_2\text{PO}_2)_2$ ,  $\text{Ca}(\text{HCOOH})_2$ ,  $\text{Mg}(\text{CH}_3\text{COOH})_3$ ,  $\text{Na}_2\text{SiO}_3$  and  $(\text{NH}_4)_3\text{PO}_4$  solutions with different compositions and voltages (200-500 V). Surface morphology of the tantalum specimens was investigated using SEM/EDX (Hitachi S-3400N / Thermo Noran), their phase composition by XRD (X-Pert Philips PW 3040/60) and chemical composition by XPS (PHI XPS Versaprobe 5000). Corrosion resistance of the samples was assessed in Ringer's solution at 37°C with the use of potentiostat (Parstat 4000) and bioactivity of the coatings was studied by SBF soaking. Adhesion of the coatings was assessed using Micro-Combi-Tester (CSM).

### RESULTS AND DISCUSSION

Surfaces of anodic oxide coatings were determined to be composed mainly from Ca and P (calcium hypophosphite and calcium formate bath) or Ca, P and Mg (calcium hypophosphite and magnesium acetate bath) as was determined with EDX analysis. Tantalum was present in small amount. Furthermore, only little Si

and Na was incorporated into tantalum oxide layers at low voltages in the case of sodium silicate/ammonium phosphate baths, however, at higher voltages the oxide layer was covered with relatively thick amorphous silica layer. It was shown that anodising voltage increases the amount of electrolyte species introduced into the oxide layer. Higher concentration of electrolyte components in the anodisation bath increases this percentage as well. Upon anodising at 500 V additional surface features were observed in the case of all anodised samples. These were identified as highly crystalline with (depending on the choice of bath) calcium tantalate, hydroxyapatite and tricalcium phosphate species within their structure. Increase of anodisation voltage increased the adhesion of the obtained coatings. Corrosion resistance of tantalum in Ringer's solution was significantly improved by anodisation, regardless of the process conditions. SBF soaking tests revealed that the proposed method of surface modification induces precipitation of calcium phosphates (apatites) on the immersed surfaces. The effect is more pronounced in the case of calcium- and phosphorus-rich oxide layers.

### CONCLUSION

Plasma electrolytic oxidation of tantalum in solutions containing Ca, P, Mg and Si was investigated as a potential method of improvement of bioactivity of the bare Ta. Results suggest that the properties of the coatings can be easily tuned by means of process conditions and yield different amounts of electrolyte species incorporated into oxide layers. These layers protect the metal from corrosion and induce apatite formation after immersion in SBF for 4 weeks. *In vitro* biological tests are the next step in the assessment of bioactivity of anodised tantalum.

## Human E-cadherin Fusion Protein Matrix Improving the Proliferation and Hepatic Differentiation of Human Mesenchymal Stem Cells

Jun Yang<sup>1</sup>, Jinbin Xu<sup>1</sup>, Yan Zhang<sup>1</sup>, Toshihiro Akaike<sup>2</sup>

<sup>1</sup>College of Life Sciences, Nankai University, Tianjin 300071, China

<sup>2</sup>Department of Biomolecular Engineering, Tokyo Institute of Technology, Yokohama 226-8501, Japan  
[yangjun106@nankai.edu.cn](mailto:yangjun106@nankai.edu.cn)

### INTRODUCTION

The development of novel biomaterials constitutes a major challenge for materials science and regenerative medicine. The functional bioactive materials present various microenvironmental cues and ultimately determine cell behaviour by eliciting specific intracellular signalling response. Proteins were known as mainly inter-related signaling molecules in the interface between biomaterials and cells for regulating cell adhesion, proliferation and in some cases differentiation. New biological materials of recombinant protein are now being developed using common genetic engineering to create well-defined, multifunctional materials. In recent years, the recombinant protein materials with tissue engineering applications have been studied including structural protein, growth factor and cell-bind protein. In this study, a fusion protein consisting of human E-cadherin extracellular domain and the immunoglobulin G Fc region (hE-cadherin-Fc) was biosynthesized and used as a cell-cell adhesion biomimicking matrix for the expansion and differentiation of human mesenchymal stem cells (hMSCs) *in vitro*.

### EXPERIMENTAL METHODS

The hE-cadherin-Fc fusion protein was expressed and purified by the Free-Style MAX 293 Expression System was analyzed by western blotting. The purified hE-cadherin-Fc solution was added to a 96-well PS plate at various concentrations. After incubating at 4°C overnight, the plates were washed with PBS three times and used for cell culture. The immobilization of hE-cadherin-Fc was determined with ELISA assay, AFM and water contact angle (WCA) measurements.

Human bone marrow mesenchymal stem cells (hMSCs) (HUXMA-01001, Cyagen Biosciences, China) were cultured with OriCell™ Human Mesenchymal Stem Cell Growth Medium (HUXMA-90011, Cyagen Biosciences, China) containing 10% (v/v) fetal bovine serum, glutamine and the antibiotics penicillin and streptomycin under 5% (v/v) CO<sub>2</sub> at 37°C and 95% air humidity. The hMSCs between passages 3 and 6 were used in all experiments. The adhesion and proliferation of hMSCs were MTT assay and cell cytoskeleton staining. The mRNA and protein expression of stem cell feature were characterized by RT-PCR and western blotting.

Statistical significance was assessed with two-way ANOVA ( $P \leq 0.05$ ,  $P \leq 0.01$ ,  $P \leq 0.001$ ) using GraphPad Prism Version 5.0 software (GraphPad, San Diego, CA). All results were reported as the mean  $\pm$  SD.

### RESULTS AND DISCUSSION

Water contact angles (WCA) and Atomic Force Microscope (AFM) showed that the hE-cadherin-Fc was stably immobilized onto hydrophobic surface and enhanced the surface wettability and topography. The hE-cadherin-Fc matrix markedly promoted the cell adhesion and proliferation of hMSCs comparing with the tissue culture-treated plate (TC-PS) and gelatin. The expanded hMSCs on the hE-cadherin-Fc were positive for CD105, showing the hE-cadherin-Fc matrix could maintain the undifferentiation of hMSCs. The expressions of E-cadherin and  $\beta$ -catenin in the hMSCs were improved on the hE-cadherin-Fc matrix, suggesting that the cell-cell adhesion junctions were substituted by the interactions between the hE-cadherin-Fc matrix and the hMSCs at the initial culture stage in the absence of cell-cell interactions.

Compared with TC-PS and gelatin, the hE-cadherin-Fc matrix effectively stimulated the hMSCs to progress toward the polygonal morphology of hepatocyte, upregulated hepatocyte-specific genes (ALB, CK18 and HNF4) and live-specific functions (the glycogen storage, ICG uptake, albumin secretion and urea production) after 4 weeks of hepatic differentiation culture. These results show hE-cadherin-Fc may be a promising artificial extracellular matrix for the hMSCs differentiation via the homophilic interaction of hE-cadherin and the synergy between cell adhesion molecular and growth factors.

### CONCLUSION

hE-cadherin-Fc was successfully prepared as a cell-cell adhesion biomimicking matrix which can be used for the surface modification of hydrophobic materials effectively. The hE-cadherin-Fc fusion protein matrix could enhance the adhesion and proliferation of the hMSCs, and improve the hepatic differentiation of hMSCs by the synergy of adhesion junction and cell growth factors. The hE-cadherin-Fc was shown to be a promising artificial ECM for hMSCs.

### INTRODUCTION

Recombinant DNA technology enables the synthesis of artificial proteins with highly controlled structure and properties [1-2]. In our group we designed, produced and characterized a silk- and collagen- inspired block copolymer (CSC) [3], which forms self-assembled, pH-responsive hydrogel networks. Additionally, we produced a protein variant that is rich in integrin-binding (RGD) domains (CSC-RGD). The main aim of this study was to obtain scaffolds from artificial proteins and study their 3D cell culture performance.

### EXPERIMENTAL METHODS

Silk-collagen- inspired proteins (CSC) and RGD-modified CSC proteins were obtained in the process of *P. pastoris* fermentation and purified by selective precipitation.

Cell culture scaffolds were prepared by dissolving protein at low pH and subsequently increasing the pH to physiological values to induce gelation. Scaffolds, made of pure CSC protein, CSC mixed with 50% CSC-RGD and pure CSC-RGD protein at total protein concentration 1%, 2% and 4%, were prepared in cell culture inserts (ThinCerts™). For 7 days, MG63 cells were cultured inside the gels and cell behaviour was analysed with AlamarBlue assay, DAPI/actin staining and LIVE/DEAD assay (data not shown).

### RESULTS AND DISCUSSION

Figure 1. AlamarBlue assay after 7 days of cell culture; sign.diff. ( $p < 0.05$ ) in comparison to: \* - 100% RGD, 1% gel, \*\* - 100% RGD, 2% gel, \*\*\* - 100% RGD, 4% gel, \*\*\* - 0% RGD, 1% gel

An alamarBlue assay was used to estimate cell activity (fig.1.). Based on the results we conclude that cells were most active in the RGD functionalized gels containing low protein concentrations.

This observation was confirmed by image analysis using confocal microscopy (fig.2.). After 7 days of culture, cells spread much better in the gels with high RGD content and low protein concentration. At higher protein concentrations cells could not spread, regardless of the high RGD content.

Figure 2. Cells after 7 days of culture in 100% RGD, 1% gel (left) and 100% RGD, 4% gel (right); scale bars = 100µm

The results indicated that for improved cell behaviour RGD functionality is not the sole requirement. The gel matrix needs to exhibit the right mechanical properties and architecture for cells to grow. For example, studies show that by introducing porosity cell performance can be enhanced [4]. We improved the architecture of our scaffolds by decreasing the protein concentration, thereby creating more space for cells in the gel matrix and making the network more deformable.

### CONCLUSION

We synthesized hydrogel scaffolds from artificial protein polymers and performed a 3D cell culture. Optimum cell behaviour was obtained by incorporation of RGD-domains in the proteins and decreasing protein concentration.

## Fluorescent Hydrogel for Improved Traceability of Biomedical Devices *in Vivo*

Ibáñez-Fonseca A., Arias F.J., Rodríguez-Cabello J.C.

BIOFORGE, CIBER-BBN, Universidad de Valladolid, Spain  
[aibanez@bioforge.uva.es](mailto:aibanez@bioforge.uva.es)

### INTRODUCTION

The increasing applications of genetically engineered materials, such as elastin-like recombinamers, in the field of biomedicine have led to the developing of different devices for tissue engineering, e.g. biocompatible and bioactive hydrogels used as scaffolds that simulate extracellular matrix, with a transition temperature below 37°C allowing its usage as an injectable solution<sup>1</sup>.

One of the issues regarding these devices is the correct and certain traceability of the material when implanted or introduced in an organism. For the purpose of addressing this problem, a silk-elastin-like recombinamer (SELR)<sup>2</sup> fused to enhanced green fluorescent protein (EGFP)<sup>3</sup> by recombinant DNA technology has been developed. This recombinamer is able to form nanoparticles at low concentrations and physically cross-linked hydrogels at higher ones, increasing the potential applications of this material.

### EXPERIMENTAL METHODS

SELR synthesis was done by molecular biology recombinant DNA techniques, assessed by agarose gel electrophoresis, and expression in *E. coli* analyzed by SDS-PAGE and fluorescence measurement. Characterization of the obtained material included MALDI-TOF mass spectrometry, amino acid composition by HPLC, differential scanning calorimetry (DSC) to determine transition temperature (T<sub>t</sub>), dynamic light scattering (DLS) to evaluate particle size, zeta potential measurement and rheology. *In vitro* cell cultures were performed in human fibroblasts (HFF-1 cell line). Fluorescence was studied qualitatively by fluorescence microscopy and quantitatively in a fluorometer.

### RESULTS AND DISCUSSION

Results regarding physicochemical characterization of the recombinamer showed a right molecular weight according to theoretical data. Transition temperature was observed at 16.8°C in physiological solution, allowing a gel phase when implanted *in vivo*. Furthermore, fluorescence was assured at different pH conditions and concentrations of the material, determining the non-influence of the SELR backbone on the correct folding of the EGFP, even observing fluorescent bacteria while expressing the recombinamer. Zeta-potential was -25mV because of the glutamic acid residues included in the elastin derived amino acid sequences.

Dual particles were also achieved through the covering of the fluorescent nanoparticles with another ELR with cell-adhesive properties positively charged by the presence of lysine residues, taking advantage of the electrostatic interaction with the negatively charged EGFP recombinamer, resulting in a positive zeta-potential and larger nanoparticles. These particles showed cell interaction and even internalization, being observed by fluorescent microscopy, suggesting bioactivity and biocompatibility.

Hydrogels made of the fluorescent recombinamer were formed at 150mg/mL showing stability through time and mechanical properties desirable for different applications in the field of biomedicine. Their fluorescence was assessed qualitatively and results showed high intensity, suggesting that a minimum amount of this material could lead to a successful traceability when implanted *in vivo* combined with other bioactive materials.

### CONCLUSION

A fluorescent and hydrogel-forming material has been successfully developed. *In vitro* cell cultures showed other applications working as nanoparticles and good biocompatibility. Its properties make it a potential candidate to be included in biomedical devices allowing hydrogel traceability and determination of the biodegradation and migration *in vivo*. Non-expensive instruments can be used for these purposes, taking advantage of the 2-photon fluorescence.

### INTRODUCTION

The development of topical ophthalmic formulations for the treatment of eye diseases such as glaucoma, present a challenge<sup>1</sup>, since most drugs are hardly absorbed, having bioavailabilities from 1-10%. Among other factors, such low bioavailability is consequence of a rapid and extensive loss of the formulation from the pre-corneal area due to the turnover of the lacrimal drainage. An alternative to increase the residence time of formulations in the area of application is the use of bioadhesive systems. Taking this into account, here we developed an elastin-like and a silk-elastin like recombinamers<sup>2,3</sup>, named respectively as ELR and SELR, for their incorporation in an ophthalmic formulation against glaucoma. Our hypothesis is that due to the thermo-sensitive behavior of these materials, the formulation could be administered topically as drops, and once sensing the temperature of the eye, suffer a shift to a gel system, which could help to prolong the permanence of the formulation in the eye, and therefore, could enhance the therapeutic effect.

### EXPERIMENTAL METHODS

The recombinamers were obtained by molecular biology standard techniques. Rheological tests were performed to assess the thermogelling properties of both systems. Circular dichroism (CD) and FTIR analysis were carried out evaluate conformational changes on the differences in the rheological behavior. *In vivo* studies were performed on New Zealand rabbits. Each formulation was placed into the conjunctival fornix and the intraocular pressure (IOP) was measure by a Tonovet tonometer.

### RESULTS AND DISCUSSION

Both recombinamers display clearly differences on the rheological properties. Concretely, the SELR show a dual physical gelation process, as consequence of the presence of the silk domains intercalated with amphiphilic engineering elastin-blocks, whereas the ELR displays a single gelation step. Such differences in the reological behavior were consequence of different conformational features of both materials, as verified by CD and FTIR.

Relative to their pharmacological application, it should be pointed that the self-assembly nature of both recombinamers allowed facile encapsulation of the therapeutics within the gel. *In vivo* tests evidenced that formulations containing the recombinamers further decreased the IOP when compared with the control formulation (without any of the recombinamers). Furthermore, SELR-formulation was found to be more effective that its counterparts ELR-formulation, which agrees with the enhanced mechanical properties provided by the presence of the silk moieties.

### CONCLUSIONS

These results evidenced that the self-gelling ELR and SELR have great potential for its use as components of ophthalmic pharmaceutical formulations.

The initial liquid-like state of the recombinamers allows easy topical administration with ulterior gelification as consequence of the thermosensitive properties. *In vivo* studies show an enhanced reduction in IOP provided by the presence of the recombinamer, which was more accentuated in the case of SELR. Finally, the crosslinking mechanism based on self-assembly makes its preparation biologically friendly and very simple.

## INTRODUCTION

One of the critical challenge facing tissue engineering strategies relate to simultaneous generation of multiple tissues and its functional assembly that lead to complex organ systems[1]. The gradient of structural and mechanical properties present in tissues have led to engineering strategies that focus on this interface. The tissue-to-tissue interface is the most crucial parameter in the approach to multitissue repair. Tissue interfaces present a chemical hierarchical structure leading to different mechanical properties. The interface is the transition between two adjacent tissues as it presents a highly heterogenous structure of chemical and biological organization[2,3]. The hypothesis in this study is that differential functional properties can be engineered by modulation of macromolecules gradient in a cell seeded three-dimensional hydrogel system. Specifically, differential paracrine secretory profiles can be engineered using hBMS. Hence, the specific objectives of this study are to: assemble the macromolecular gradient from natural materials (gellan gum, hyaluronic acid and collagen); to evaluate whether the gradient is suitable for hMSC encapsulation by cellular viability assesment; and screen the paracrine secretion of hBMS over time within this gradient hydrogel system.

## EXPERIMENTAL METHODS

Three different solutions of methacrylated gellan-gum (GG-MA) and hyaluronic acid (HA) were assembled keeping GG-MA constant at 15mg/ml while HA was incorporated at different ratios (5, 2.5 and 0.5 mg/ml). A similar approach was used for GG-MA – Collagen I (Col I) but with different ratios of Col I (2, 1 and 0.1mg/ml). The gradient hydrogels were fabricated into cylindrical silicon moulds with higher ratio solutions assembled at the bottom of the mould and adding the two solutions consecutively on top of each other. Crosslinking was performed by phosphate buffer solution (PBS). PBS cations interact only with GG-MA chains allowing the chains to get closer and create the crosslinked network. Controls of GG-MA (15mg/ml) were also fabricated. FITC-labelling HA and Col I was used to confirm the fabrication of the gradient. AFM was used to assess the differential mechanical properties. Human Bone Marrow Stem Cells (hBMS) at passage three (P3) were loaded into each batch solution at  $10^6$  cells/ml solution and gradient hydrogels were produced as previously described. The hBMS were observed under confocal microscopy after staining with Calcein AM and Propidium Iodide (PI). Secretory cytokine measurement for pro-inflammatory factors was carried out using ELISA.

## RESULTS AND DISCUSSION

The gradient hydrogel was successfully constructed and validated by fluorescent emission of FITC labelled HA and Col I (Figure 1 (B) Additionally,

AFM analysis demonstrated a different stiffness for two distinct regions of the gradient.

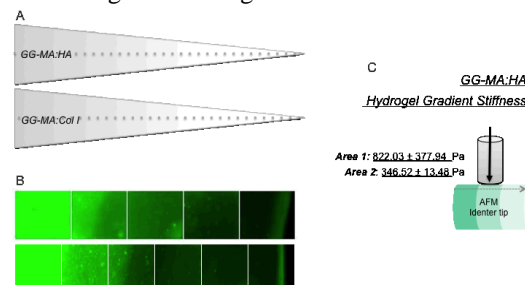

Figure 1: **A:** Schematic representation of hydrogel gradients; **B:** FITC-Fluorescent labeling macromolecules (HA/COL) incorporating the hydrogel gradient; **C:** Stiffness by AFM analysis of GG-MA: HA gradient hydrogel across layers.

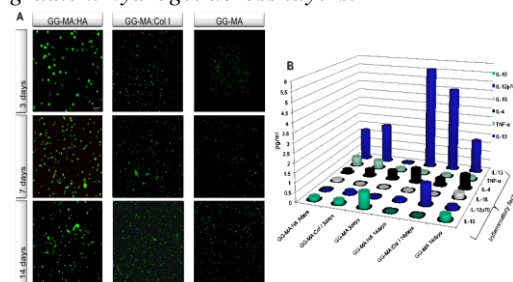

Figure 2: Gradient hydrogel microenvironment alters hMSC viability and protein expression. **A:** Confocal images from Live/Dead staining (Calcein Am/PI) showing hBMS cells viability of encapsulated cells within gradient hydrogels up to 14 days. **B:** Multiplex ELISA protein expression of hMSCs on the gradient hydrogel controlled for 3 and 14 days timepoint.

Viability of hBMS was studied by the green emission of Calcein AM conversion on the membrane of live cells. There is a positive effect on cell viability of both macromolecules (HA and Col I) on the overall gradient. Preliminary results from protein analysis show significant differences in the levels of cytokine production in the HA and Col I gradient hydrogels when compared to those of the control and over time.

## CONCLUSION

The macromolecular gradient hydrogel systems were successfully achieved combining either HA or Col I with GG-MA demonstrating differentially secretion of pro-inflammatory factors by encapsulated hBMS within the gradient hydrogel systems.

## INTRODUCTION

*Ex vivo* generation of functional tissues and organs still faces challenging limitations particularly concerning construct size and matrix composition. Mass transfer and oxygen diffusion into the inner space represent two of the major constraints. Additionally, designing and engineering suitable scaffolds is an arduous task due to the complexity and dynamic composition of the native cellular niches. To this aim, bottom-up strategies wherein microtissue blocks are assembled to form a macroscopic tissue are gaining ground<sup>1</sup>.

In our study, microtissues are directly obtained from rat mesenchymal stromal cells seeded on biodegradable poly-(lactic) acid (PLA) microparticles (MP). This strategy overcomes low seeding efficiencies and poor cell distributions. Besides, MP facilitate cell expansion, and induces osteogenic phenotype<sup>2</sup>. In the end, to avoid nutrient and oxygen diffusion issues during *ex vivo* matrix deposition, cell-laden MP are transferred to a chamber in a perfusion system allowing the formation of a clinical-relevant construct.

## EXPERIMENTAL METHODS

PLA MP are obtained following a solution jet break-up polymer precipitation technique, using Ethyl Lactate as environmental-friendly solvent<sup>3</sup>. Adhesion and proliferation studies are performed on collagen-I covalently coated MP. Experiments are performed both in static and dynamic culture, using a spinner flask bioreactor. Cell morphology is evaluated using Confocal and Scanning Electron Microscopy (SEM). Cell-laden MP are then transferred into a transparent chamber connected to a perfusion system for the formation of a 3D scaffold. In this, cell proliferation and survival are evaluated by constitutive expression of luciferase and bioluminescence emission. Scaffold size, cell survival, matrix composition are evaluated at different time points for 14 days.

## RESULTS AND DISCUSSION

The obtained MP dimensions, ranging between 60 and 120  $\mu\text{m}$ , allow cell-cell interactions for the formation of the extracellular matrix (ECM). Several approaches have used diverse MP sizes such as 20-60  $\mu\text{m}$ <sup>4</sup> and 400-700  $\mu\text{m}$ <sup>5</sup>. They reported the deposition of a dense matrix on the outer region of the construct, matching our results. Static conditions for cell culture showed a positive and constant proliferation rate over a week, and then became steady. On the contrary, others<sup>6</sup> reported constant increases within 30 days, proving the importance for macroporous surfaces on the MP.

Immunofluorescence after 21 days revealed the presence of collagen, laminin and fibronectin within the matrix (Figures B, C, and D). ECM distribution was evaluated by SEM micrographs (Figure A) and a dense matrix entrapping the MP was observed. Cells penetrated 0.75mm from the scaffold surface, which stays within the limits previously reviewed<sup>7</sup>. However, deeper invasion faces mass transfer constraints.

In order to facilitate cell distribution throughout the construct, spinner flask bioreactor was used for a homogenous microsphere initial colonization. After 8h of dynamic stirring, 80% of MP were uniformly colonized. Afterwards, cell-laden MP were transferred into a chamber, and culture medium was perfused through the circuit. Non-invasive bioluminescence is used to assess cell growth, survival, and distribution in the perfused system. Moreover, further decellularization techniques will be evaluated by this means.

## CONCLUSION

These results state the bases for the production of cell-derived ECM using PLA MP. Cells are able to proliferate and secrete their own and specific ECM. Macrotissue formation following this bottom-up strategy entails diverse applications which include the formation of functional tissues to repair or substitute damaged ones. Furthermore, this methodology can aid in the expansion of cells which are unable to maintain their phenotype *ex vivo*, creating a suitable niche. As well as to create biological models for *in vitro* testing to limit the use of animal models.

### INTRODUCTION

Type I diabetes mellitus (T1DM) is a condition in which the body cannot adequately control glucose levels in the blood due to a reduction in the ability of  $\beta$ -cells to produce the insulin. T1DM is a chronic condition requiring drugs and insulin therapy to manage the disease. However, current methods of disease management cannot fully prevent the development of long term health complications associated with the disease. Transplantation of insulin producing  $\beta$ -islet cells offers promise as a minimally invasive, long-term solution to regain normoglycaemia. However, a shortage of suitable donors together with sub-optimal islet engraftment and loss of cell mass due to the host's immune response limit the procedures success. Chitosan has been exploited as a successful drug delivery vehicle and is now being explored as a microencapsulation material to prevent the immune attack on the transplanted  $\beta$ -cells. As an extension of this approach, this work reports the use of chitosan nanobeads with carboxybetaine (CB) functionalities to facilitate the tethering of nanobeads with  $\beta$ -cell glycocalyx. The aim was to increase the number of viable cells available for transplantation, by forming bioengineered pancreatic pseudo-islets from single  $\beta$ -cells using functionalised nanobeads as biocompatible scaffolds.

### EXPERIMENTAL METHODS

#### Nanobead synthesis

Chitosan was dissolved in acetic acid and diluted 1:1 with methanol before *N*-succinylating with 14% (w/v) succinic anhydride in acetone solution. Ionic gelation at a 1:1 mass ratio with 1mg/mL sodium tripolyphosphate in dH<sub>2</sub>O was used to form nanobeads, the surface of which was cross-linked with CB, activated through reaction with 10x Molar excess N-(3-dimethylaminopropyl)-N'-ethylcarbodiimide hydrochloride (EDC) and 25x Molar excess N-hydroxysuccinimide (NHS) in 0.1M MES buffer pH 6.0. Beads were desalted into dH<sub>2</sub>O using dialysis with 3.5kDa MWCO cellulose tubing and syringe filtered at 0.45 $\mu$ m before lyophilising. Characterisation was carried out using Fourier transform infrared spectroscopy (FTIR), scanning electron microscopy (SEM) and dynamic light scattering (DLS).

#### In vitro experimentation

MIN-6 mouse pancreatic  $\beta$ -cells were cultured in Dulbecco's Modified Eagle Medium (DMEM) at low glucose, with 10% fetal calf serum. Cells were seeded in 24 well cell culture plates at a density of 4.0 x 10<sup>4</sup> cells/cm<sup>2</sup> and incubated with or without nanobeads at 24 and 48 hours. Cells were stained with 70 $\mu$ L of

90%:5%:5% (v/v) growth media: propidium iodide: Hoechst stain and incubated at 37°C for 5 minutes and analysed for live/apoptotic cells within the populations using UV microscopy.

### RESULTS AND DISCUSSION

Bioengineered pancreatic pseudo-islets were only formed from single MIN-6  $\beta$ -cells grown as monolayers when incubated with *N*-succinylated chitosan nanobeads functionalised with CB. These pseudo-islets, formed after 48 hours incubation at nanobead concentrations exceeding 0.3mg/mL and were larger in diameter than those formed using Matrigel™ (Fig 1). Aggregates of nanobeads were visible at the periphery of pseudo-islet structures, with no indication of significant cell death.

**Figure 1:** MIN-6  $\beta$ -cells incubated with *N*-succinylated chitosan nanobeads after 48h incubation (n=3). Scale bar = 100 $\mu$ m.

### CONCLUSION

The data suggests that 3D clustering of MIN-6  $\beta$ -cells is enhanced due to the aggregation of chitosan nanobeads which allows anchoring of the cells. Functionalisation with CB is thought to improve this process by exploiting superior anti-fouling properties of the zwitterionic surface coating, resulting in larger, rougher nanobead aggregates that promote enhanced cell adhesion and improved cell viability. These bioengineered pancreatic pseudo-islets show superior morphology more representative of *in situ* islet of Langerhans structures. Further studies are underway to confirm the cells ability to produce and release insulin.

### INTRODUCTION

Marine organisms are rich in a variety of materials with potential use in Tissue Engineering and Regenerative Medicine. One important example is fucoidan (Fu), a sulphated polysaccharide extracted from the cell wall of the brown seaweeds, with higher solubility in water<sup>1</sup>. Fucoidan is composed by L-fucose and glucuronic acid including sulphate groups and have important bioactive properties such as antioxidative, anticoagulant, anticancer and in the reduction of blood glucose<sup>1,2</sup>. In this work, the biomedical potential of fucoidan was assessed by processing modified fucoidan (MFu) into microparticles by photocrosslinking using superamphiphobic surfaces and visible light<sup>3,4</sup>. Biological performance on the developed constructs was further explored.

### EXPERIMENTAL METHODS

To design the materials structures, fucoidan was modified by methacrylation reaction<sup>3</sup>. Briefly, 4% (wt/v) of Fu aqueous solution was mixed with methacrylated anhydride (MA) in volumes of 8% (MFu1) and 12% (MFu2) (v/v) at 50°C to react for 6h. The modified fucoidan was dialyzed against water and purified by washing it with acetone to remove the unreacted material. Further, both MFu1, 2 were processed as micro-particles using superamphiphobic surfaces and then photocrosslinked with visible light<sup>4</sup>. Microparticles were characterized by FTIR, <sup>1</sup>HNMR, quantification of sulphate degree and zeta potential. The ability of the developed materials to support adhesion and proliferation of cells was assessed by suspension culture of L929 cells (3.5x10<sup>5</sup> cells/ml) in contact with MFu microparticles up to 14 days.

### RESULTS AND DISCUSSION

The chemical modification performed on Fu was confirmed by the presence of vinyl and methyl peaks in the <sup>1</sup>HNMR of modified fucoidan. The mentioned peaks do not appear in Fu spectrum. Methacrylated fucoidan was obtained with different methacrylation degree, (Table1) which depended on the reaction conditions. This fact could indicate that methacrylation reaction is not selective and sulphate groups may be involved in the reaction. Differences on sulphate degree were evidenced (Table1). In addition, the zeta potential measurement confirmed the anionic charge of fucoidan. These findings also revealed that the zeta potential decrease after modification. This result could be related to the introduction of methacrylated groups. The results (Fig.1A, B) show that produced fucoidan porous particles have round shape and average diameter between 1.42 mm and 1.53mm, in dry state (Fig.1C). The direct contact assay demonstrated (Fig.1D) that the

MFu particles are not cytotoxic for L929 cells. The results (MTS and DNA) also revealed a good adhesion, viability and proliferation. The cells show a spindle-like shape and are able to migrate into the particles core during the culture period studied (Fig. 1D).

Samples	Methacrylation degree (%)	Sulphation degree (%)	Zeta potential (mV)
Fu	-----	38.60 ± 6.97	-30.40
MFu1	2.78	14.62 ± 3.66	-32.98
MFu2	6.50	24.24 ± 5.38	-62.10

Table 1: Properties of modified fucoidan obtained by different techniques.

Figure 1: A, B) Modified fucoidan-particles, C1,C2,C3) SEM images of porous MFu particles and D1,D2,D3) confocal microscopy images of L929 cells seeded onto MFu1 after 7 days in culture; staining of actin (red) and nuclei (blue).

### CONCLUSION

This work demonstrates the successful production of fucoidan-based-microparticles with a versatile mechanical, physical and biological performance. The proposed technology based on the methacrylation of fucoidan, using visible light and superamphiphobic surfaces, may result in a method to obtain particles and partial insoluble fucoidan in water, which can be applied alone in tissue engineering applications.

### INTRODUCTION

Bioactive glass nanospheres (BGNs) are of interest for bone regeneration application due to their high bioactivity, osteoconductivity and osteoinductivity<sup>[1]</sup>. The ionic dissolution products of bioactive glasses play a critical role in the properties related to osteogenesis and angiogenesis<sup>[2]</sup>. Among the ionic dissolution products,  $\text{Ca}^{2+}$  favours osteoblast proliferation, differentiation, mineralization of the extracellular matrix, and stimulates the expression of growth factors<sup>[3]</sup>.

The Stöber method is the most convenient way to synthesize BGNs. However, the introduction of  $\text{Ca}^{2+}$  into BGNs by using calcium salts as precursors could lead to severe agglomeration and irregular shapes. Moreover, the addition manner of calcium precursors could also affect the  $\text{Ca}^{2+}$  distribution on the BGNs.

The aim of this study is to understand the influence of calcium nitrate addition timing on the morphology, dispersity and  $\text{Ca}^{2+}$  distribution of BGNs.

### EXPERIMENTAL METHODS

BGNs were synthesized by a modified Stöber method<sup>[4]</sup>. To investigate the addition timing on BGNs, calcium nitrate was added 0, 10, 30 or 60 min after the induction of Stöber reaction. The corresponding synthesized samples were labelled as BGN-0, BGN-10, BGN-30, and BGN-60, respectively. The as-synthesized BGNs were calcinated at 700 °C to remove catalyst, solvent and nitrate groups.

The morphology and dispersity were studied using transmission electron microscopy (TEM), field emission scanning electron microscopy (FE-SEM) and zeta potential measurement.

$\text{Ca}^{2+}$  distribution in BGNs was studied using inductively coupled plasma (ICP), solid-state nuclear magnetic resonance (MAS-NMR), Energy-dispersive X-ray spectroscopy (EDS) and auger electron spectroscopy (AES).

### RESULTS AND DISCUSSION

Figure 1 shows the BGNs synthesized under different calcium nitrate addition timing. It can be seen that monodispersed BGNs can be synthesized by adding calcium precursor >30 min after the induction of Stöber reaction. However, the incorporated amount of calcium decreased with the increasing of time gap between induction and calcium precursor addition. According to the ICP results, the composition of BGN-0 was similar to the pre-determined nominal composition, while BGN-60 contained the least amount of calcium.

The MAS-NMR results showed that more Q2 and Q3 structures were in BGN-0 compared with other

samples. In BGN-30 and BNG-60, only limited Q2 or Q3 structures could be found compared with the samples synthesized under the same conditions except for addition of calcium nitrate. All the above results indicated that only limited  $\text{Ca}^{2+}$  could enter the silicate network of monodispersed BGNs. In addition, the ICP results showed that  $\text{Ca}^{2+}$  was not released continuously together with  $\text{Si}^{2+}$ . This phenomenon combined with the MAS-NMR results could suggest that most of  $\text{Ca}^{2+}$  was only distributed on the surface but not incorporated in the silicate network.

Figure 1 SEM images of (a) BGN-0; (b) BGN-10; (c) BGN-30; (d) BGN-60.

### CONCLUSION

In summary, monodispersed BGNs were synthesized by optimizing the addition timing of calcium nitrate in a modified Stöber process. A critical point that more  $\text{Ca}^{2+}$  was incorporated while the monodispersed spherical morphology was maintained could be determined. Moreover, incorporated  $\text{Ca}^{2+}$  was mainly distributed on the surface of BGNs, while only limited  $\text{Ca}^{2+}$  could enter the silicate network.

<sup>1\*</sup> Department of Biomedical Sciences, Chubu University, Japan, [sy-esi@isc.chubu.ac.jp](mailto:sy-esi@isc.chubu.ac.jp)

### INTRODUCTION

Titanium (Ti) metal is widely used in orthopedic and dental fields because of its good biocompatibility and high mechanical strength. However, it does not bond to living bone. The present authors earlier showed that Ti metal bonded to living bone through an apatite layer formed on their surfaces in a living body, when a Ca-deficient calcium titanate layer had been produced on the metals by NaOH, CaCl<sub>2</sub>, heat and water (Ca-heat) treatments [1]. Recently, it has been found that along with Ca ions, various other kinds of metallic ions such as Sr, Mg can be incorporated on the surface of Ti metal by modifying the Ca-heat treatment [2].

Gallium (Ga) is known for its inhibitory effect on calcium release from bone tissue, thus effective for preventing bone resorption. Gallium has also shown clinical efficacy in suppressing osteolysis and bone pain and has been suggested as a treatment for osteoporosis [3].

In the present study, Ga ion incorporation was attempted on the surface of Ti metal by the modified Ca-heat treatment. Apatite formation on the surface of the resultant product in a simulated body fluid (SBF) and release of Ga ions in a phosphate-buffered solution (PBS) are discussed in terms of the surface structure.

### EXPERIMENTAL METHODS

Ti metal with the size of 10 × 10 × 1 mm<sup>3</sup> were soaked in 5 M NaOH aqueous solution at 60 °C for 24 h, then subsequently in 100 mM GaCl<sub>3</sub> or a mixed solution of 99.95 mM CaCl<sub>2</sub> and 0.05 mM GaCl<sub>3</sub> at 40 °C for 24 h. They were heated at 600 °C for 1 h, and then soaked in hot water at 80 °C for 24 h. Then the samples were washed by flowing ultra-pure water for 30 sec after each solution treatment.

Surfaces of the samples were examined by a field emission scanning electron microscope (FE-SEM) equipped with energy dispersive X-ray analyzer (EDX), thin-film X-ray diffractometer (TF-XRD), and laser Fourier Transform Raman spectrometer (FT-Raman). Apatite formation on the samples were examined by soaking in SBF with ion concentrations (Na<sup>+</sup> 142.0, K<sup>+</sup> 5.0, Ca<sup>2+</sup> 2.5, Mg<sup>2+</sup> 1.5, Cl<sup>-</sup> 147.8, HCO<sub>3</sub><sup>-</sup> 4.2, HPO<sub>4</sub><sup>2-</sup> 1.0, and SO<sub>4</sub><sup>2-</sup> 0.5 mM) nearly equal to those of human blood plasma at 36.5 °C [4] for 3 days. The samples subjected to the chemical and heat treatments were soaked in 2 ml of PBS at 36.5 °C. After soaked in PBS for various periods up to 3 days, Ca and Ga ion concentrations in PBS were measured by inductively coupled plasma emission spectroscopy (ICP).

### RESULTS AND DISCUSSION

FE-SEM observation showed that nano-scaled network structures had been produced on the surface of Ti metal by the initial NaOH treatment, and it was maintained even after the subsequent solution and heat treatments. EDX analysis revealed that the Ca enriched surface layer containing 1.9 % Ca and 1.1 % Ga was produced on the metal when the metal was soaked in the mixed solution of 99.95 mM CaCl<sub>2</sub> and 0.05 mM GaCl<sub>3</sub> following the NaOH treatment. In contrast, 7.7 % Ga was incorporated into the surface of the metal when the metal was soaked in 100 mM GaCl<sub>3</sub> instead of the mixed solution. TF-XRD and FT-Raman analysis revealed that former produced Ga-containing calcium titanate, rutile and anatase on its surface by the subsequent heat treatment, whereas latter formed gallium titanate in addition to the rutile and anatase. These crystalline phases were not changed even after the final water treatment.

When the treated metals were soaked in SBF, both of them formed apatite fully on their surfaces within 3 days. When they were soaked in PBS, the metal with the Ga-containing calcium titanate slowly released Ga ions up to 0.3 ppm within 3 days, whereas the metal with the gallium titanate released 1.3 ppm. The difference of released amount of Ga ions might be due to Ga contents in the surface layer.

It was reported that significant inhibition was observed on osteoclastic resorption activity of rabbit bone cells by adding 0.7 – 7 ppm of Ga ions to a culture medium [5].

Based on these results, it is expected that the treated metal with the gallium titanate layer in the present study could prevent osteoclastic resorption so as to prevent bone resorption by releasing Ga ions, and tightly bond to bone through an apatite formed on its surface.

### CONCLUSION

Ti metal with gallium titanate layer able to release Ga ions was prepared by the chemical and heat treatments.

It is expected that the treated metal might bond even to osteoporotic bone, since it releases Ga ions in a living body to prevent bone resorption and induces apatite formation on its surface.

## INTRODUCTION

Calcium phosphates (CaP) are attractive osteoconductive materials for healing bone defects however brittleness and low flexural strength limit their application to non-load-bearing sites<sup>1</sup>. The mechanical behavior of CaP scaffolds is further compromised by high porosity required for bone ingrowth. The load-bearing properties of CaP can be improved by forming a composite material, through addition of a ductile second phase. An attractive combination of strength and ductility was reported for  $\beta$ -tricalcium phosphate ( $\beta$ -TCP) reinforced with 30-40 vol.% polylactic acid (PLA)<sup>2</sup>. Even better mechanical properties can be achieved if the weak polymer component is replaced with a stronger and tougher metal, e.g. iron. Fe is slowly resorbed in the body and its corrosion can be accelerated by dispersing silver nanoparticles that are cathodic towards Fe matrix. An additional benefit of Ag is its recognized antimicrobial activity<sup>3</sup>. In this work, we report the preparation of strong  $\beta$ -TCP-30 vol.% (Fe-Ag) composites and macroporous scaffolds by attrition milling, high pressure consolidation and a modified particulate leaching method<sup>3</sup>.

## MATERIALS AND METHODS

$\beta$ -TCP nanopowder was prepared by chemical precipitation and calcination. Fe powder ( $\sim 2 \mu\text{m}$ ) was mixed with 10, 20 and 30 vol.% silver oxide ( $\text{Ag}_2\text{O}$ ) powder ( $< 2 \mu\text{m}$ ) by high energy attrition milling for 4 h in hexane under Ar, at 20:1 balls-to-powder ratio. 30 vol.% of the obtained Fe-Ag blend was admixed to  $\beta$ -TCP and milled for additional 4 h.  $\beta$ -TCP-Fe-Ag blends were compacted at 400 MPa and annealed at  $450^\circ\text{C}$ , 1 h in  $\text{H}_2$ -flow to reduce  $\text{Ag}_2\text{O}$ . The compacts were then high pressure consolidated at 2.5 GPa, at  $T_{\text{room}}$  and annealed at  $400^\circ\text{C}$  for 4 h. To produce 3-D scaffolds,  $\beta$ -TCP-Fe-Ag compacts were crushed and sieved to produce small (100-200)  $\mu\text{m}$  and large (200-300)  $\mu\text{m}$  non-dense granules that were then mixed with 50-80 vol.%  $\text{Na}_2\text{SO}_4$  porogen of comparable size. The blends were consolidated at 2.5 GPa and porogen removed in water. The final scaffolds were 11 mm in diameter and 3 mm thick. Dense composites and scaffolds were examined in a scanning electron microscope (SEM) and tested in bending and/or compression. Scaffolds permeability was measured by the Darcy test.

## RESULTS AND DISCUSSION

The density of all high pressure consolidated  $\beta$ -TCP-30(Fe-Ag) specimens, before and after annealing, was  $\geq 95\%$  TD. SEM examination revealed a homogeneous distribution of submicron metal phase in  $\beta$ -TCP matrix. Strength characteristics of dense specimens are shown in Fig. 1. Both the compressive ( $\sigma_c$ ) and bending ( $\sigma_b$ ) strengths increase with increasing Ag content. The strength is significantly improved by annealing,

presumably due to enhanced bonding integrity of  $\beta$ -TCP-metal interfaces. For all the  $\beta$ -TCP-30(Fe-Ag) compositions,  $\sigma_c$  and  $\sigma_b$  are several-fold higher than the 320 and 62 MPa reported for  $\beta$ -TCP-30PLA<sup>2</sup>.

Fig.1: Bending and compressive strengths of  $\beta$ -TCP-30 vol.% (Fe-Ag) composites before and after annealing at  $400^\circ\text{C}$ .

All the produced  $\beta$ -TCP-30(Fe-Ag) scaffolds had an interconnected pore structure, Fig. 2. Increasing the porosity decreased compressive strength ( $\sigma_c$ ) and increased permeability ( $k$ ), Table 1. The scaffolds exhibited good combination of compressive strength and permeability comparable to trabecular bone.

Fig.2: SEM images of  $\beta$ -TCP-30(Fe-20Ag) scaffolds: a - 80% porosity, large porogen; b - 70% porosity, small porogen.

Table 1. Properties of  $\beta$ -TCP-30(Fe-20Ag) scaffolds prepared using small (100-200)  $\mu\text{m}$  granules and porogen

Porosity, %	50	60	70	80
$\sigma_c$ , MPa	17.1	7.6	4.8	3.3
$k$ ( $\times 10^{10}$ ), $\text{m}^2$	1.5	2.4	4.7	6.2

## CONCLUSION

The developed  $\beta$ -TCP-(Fe-Ag) composites and porous scaffolds prepared by the modified salt leaching method offer an attractive combination of properties and should be further tested as potential bone repair materials.

### INTRODUCTION

Mesoporous bioactive glasses (MBGs) are a new generation of bioceramics intended for regenerative therapies of bone<sup>1</sup>. They comprise the bone bonding capabilities of melt-derived and sol-gel bioactive glasses<sup>2</sup>, as well as the porous structure of SiO<sub>2</sub> based mesoporous materials<sup>3</sup>.

The synthesis of MBGs requires the addition of a structure directing agent (SDA). In most of the cases, the SDA is an amphiphilic molecule with self-organizing properties at the supramolecular level. The SDA determine the textural properties of MBGs, such as porous structure, pore volume, pore size and also the surface area. However, very little is known about the local atomic environment within the pore walls of MBG, and how it affects their bioactive behaviour. In this work we demonstrate that by adding the appropriated SDA we can tailor the bioactivity of MBG by controlling both, textural properties and local atomic environment.

### EXPERIMENTAL METHODS

MBGs of composition SiO<sub>2</sub> 85-CaO 10-P<sub>2</sub>O<sub>5</sub> 5 (% mol) were synthesized by the evaporation induced self-assembly (EISA) method. For this aim, Pluronic P123, F68 and F127 were used as structure directing agents. Tetraethyl orthosilicate (TEOS), triethyl phosphate (TEP) and calcium nitrate were used as SiO<sub>2</sub>, P<sub>2</sub>O<sub>5</sub> and CaO sources, respectively. The MBGs characterization has been carried out by XRD, FTIR spectroscopy, N<sub>2</sub> adsorption porosimetry, solid-state NMR and HR-TEM. Assessments of in vitro bioactivity were carried out soaking the MBGs into simulated body fluid (SBF). The evolution of the glass surface was analysed by FTIR spectroscopy and TEM.

### RESULTS AND DISCUSSION

Figure 1 shows the HR-TEM of the SiO<sub>2</sub> 85-CaO 10-P<sub>2</sub>O<sub>5</sub> 5 mesoporous glass prepared with F68. The images evidence an excellent porous arrangement that corresponds to a 2D hexagonal symmetry with a *p6mm* planar group. Mesoporous orderings were also obtained in MBGs prepared with P123 and F127.

Figure 1. HR-TEM images of MBG prepared with F68

The pore size of the mesoporous glasses can be easily tailored as a function of the surfactant size. In addition, the local atomic environment can be controlled as evidenced by the evolution of the SiO<sub>2</sub> network

connectivity (*NC*) as a function of the SDA used. These data are collected in the table below.

MBG (SDA used)	Structure	Pore size	<i>NC</i> (SiO <sub>2</sub> )
MBG-F68	<i>p6mm</i>	3.36	3.79
MBG-P123	<i>p6mm</i>	5.92	3.80
MBG-F127	<i>p6mm</i>	7.18	3.96

The in vitro bioactivity tests demonstrate that after 6 hours in SBF, only the MBG prepared with F68 developed hydroxyapatite onto the surface, as evidenced by the doublet at 585 and 604 cm<sup>-1</sup> in the FTIR spectra and TEM-ED studies (figure 2).

Figure 2. FTIR spectra after 6 hours in SBF (left); TEM image of MBG-F68 after 6 hours in SBF. HA indicates newly formed hydroxyapatite (right).

MBG-F68 exhibits the lowest *NC* among MBGs studied. High silica *NC*, like that observed for MBG-P123 and MBG-F127, indicates that Ca<sup>2+</sup> cations are not acting as SiO<sub>2</sub> network modifiers required to initiate the bioactive process. <sup>31</sup>P NMR studies evidenced that in these cases Ca<sup>2+</sup> cations are sequestered as calcium phosphate (CaP) heterogeneities. MBGs with small pore size, like MBG-F68, contain a low amount of CaP heterogeneities, indicating that the formation of these clusters is also conditioned by steric factors. Consequently there is more Ca<sup>2+</sup> available to react with the SBF and thus the bioactive response is enhanced.

### CONCLUSION

The porosity and atomic environment of MBGs can be controlled by adding the appropriated SDA. The bioactivity of these biomaterials can be adjusted to be faster or slower. These results open new possibilities for tailoring mesoporous bioactive glasses as bone grafts for each specific clinical case.

### INTRODUCTION

From the age of 30 years onwards all human tissue progressively deteriorates<sup>1</sup>. Due to extending life expectancies, redevelopment of human tissues *via* tissue engineering is no longer an option but a requirement. In the 1960s Hench developed Bioglass<sup>®</sup>, which was shortly followed by Wilson who developed the glass ionomer cement<sup>2</sup>. These developments marked early moves from the use of bioinert to bioactive biomaterials for medical implants. Since these early developments of bioactive glasses, progress to new applications has been slower. Today the field has transitioned from bioactive material implants to tissue engineering materials and regenerative medicine.

Bioactive glass compositions can rapidly regenerate trabecular bone. However, to-date bioactive glasses have been largely limited to hard tissue engineering applications. This study focuses on the application of bioactive glasses in soft tissue engineering applications. The authors have developed a novel glass formulation that can control the setting of a flexible hydrogel composite, producing a material ideal for minimally invasive soft tissue applications or tissue engineering constructs. The glass examined is based on a glass ionomer cement formulation wherein neurotoxic aluminium is replaced by gallium. Alginate forms the surrounding hydrogel matrix.

### EXPERIMENTAL METHODS

Four CaO-Ga<sub>2</sub>O<sub>3</sub>/Al<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub>-P<sub>2</sub>O<sub>5</sub>-CaCl<sub>2</sub> glasses were produced with varying Al<sub>2</sub>O<sub>3</sub>/Ga<sub>2</sub>O<sub>3</sub> ratios from 0 to 1. Differential thermal analysis (Stanton Redcroft STA 1640, Rheometric Scientific, UK) was carried out at a heating rate of 10 °C min<sup>-1</sup>, to 900 °C. The structure of the glasses was analysed using Si<sup>29</sup> and Al<sup>27</sup> Magic Angle Spinning Nuclear Magnetic Resonance (MAS-NMR). These glasses were then mixed with glucono-delta-lactone and a polymeric alginate solution to form composite hydrogels. Working and setting times of each glass were analysed using methods modified from ISO9917. The aluminium free gel was freeze dried at time points of 10 seconds, 60 seconds, 5 minutes, 60 minutes and 24 hours after mixing. The chemistry of the setting reaction was analysed using Fourier Transform Infrared (FTIR) spectroscopy between 4000 and 400 cm<sup>-1</sup>. Compression samples were produced (9.00 mm, height 15.00 mm) and stored in 20 ml of Dulbecco's modified eagle medium containing 1 vol.% penicillin streptomycin before being loaded, at a rate of 2 mm/min until failure, using a Zwick BT1-FR005TN test machine fitted with a 500N load cell.

### RESULTS AND DISCUSSION

Glass transition temperatures were in the range of 732-764 °C, with no significant difference across the glass series. The high T<sub>g</sub> values indicate high network connectivity (NC) and their limited variability suggests similar NC across the series. Al<sup>27</sup> MAS-NMR analysis indicated a predominantly tetrahedral coordination of the aluminium containing glasses, with minimal octahedral and pentavalent coordination. Si<sup>29</sup> MAS-NMR exhibited a typical broad peak, which centred around -80 ppm, indicating a Q<sub>2</sub>/Q<sub>3</sub> structure. No shift in Si<sup>29</sup> MAS-NMR was observed across the glass series, regardless of Al<sub>2</sub>O<sub>3</sub>/Ga<sub>2</sub>O<sub>3</sub> ratio, which indicates no substantial alteration in the network. The NMR analysis strongly suggests that gallium is also predominantly tetrahedrally coordinated.

FTIR results indicate that, with time, the characteristic band of the carbonyl stretching of the free carboxylic acid groups at 1780 - 1710 cm<sup>-1</sup> disappears and is replaced by weaker C=O stretching bands at 1640-1690 cm<sup>-1</sup>, indicating that alginate is becoming increasingly complexed with cations released from the glass phase. Substitution of aluminium for gallium lengthened working times and shortened setting times (242%, 24% respectively), which is beneficial for many minimally invasive procedures where a 'snap' set is required. Compressive strength was shown to increase with Ga/Al ratio and strength continued to increase over 7 days.

### CONCLUSION

A novel glass hydrogel was produced, based on ionomer cement glasses, where neurotoxic aluminium was replaced with gallium. It was shown that like aluminium, gallium adopts a charge balanced tetrahedral coordination resulting in a high network connectivity glass with long working time, snap set properties, and exhibiting increased compressive strength (244%). Strength continues to increase over up to 7 days of incubation (130%).

## INTRODUCTION

Porous scaffolds based on bioactive glass are intensively studied for various tissue engineering applications<sup>1,2</sup>. When fabricated from melt-derived bioactive glasses the hot-working conditions must be optimized to avoid crystallization of the glass<sup>3,4</sup>. In addition, the release rate of inorganic ions from the glass must be controlled to provide the desired tissue healing or regeneration capacity in the body. Today, the biological response of several inorganic ions in the interfacial solution of the biomaterial is known<sup>5</sup>. In this work we report the effect of partial substitution of ZnO and SrO for MgO and CaO on the thermal and in vitro properties of bioactive glass 1-98. Implants of 1-98 have shown positive effects on osteogenesis<sup>6</sup>. ZnO and SrO enhance bone formation, and ZnO also shows anti-inflammatory effects<sup>5</sup>. The effect of these oxides on the properties of bioactive glasses is not well established.

## EXPERIMENTAL METHODS

Bioactive glass 1-98 (in mol-%: 53.8SiO<sub>2</sub>, 5.9Na<sub>2</sub>O, 7.1K<sub>2</sub>O, 7.6MgO, 23.9 CaO, 0.9 P<sub>2</sub>O<sub>3</sub>, and 0.9 B<sub>2</sub>O<sub>3</sub>) and two experimental glasses, Zn2Sr4 and Zn4Sr2, were melted in-house as described previously<sup>7</sup>. The glass codes give their ZnO and SrO contents in mol-%. ZnO and SrO were substituted for MgO and CaO, respectively in glass 1-98. The annealed glasses were cut into plates or crushed and sieved to give particles of various size ranges. The thermal properties were measured using differential thermal analysis (TGA-DTA/DSC, Netzsch STA 449F1 Jupiter) and hot stage microscopy (HSM/ODHT, Misura, Expert System Solutions). The ion dissolution was measured for glass plates in static simulated body fluid, SBF up to 168h. The ion release in dynamic conditions was measured for a fresh SBF fed through glass particles<sup>7,8</sup>. The pH and ion concentrations (ICP-OES, Optima 5300 DV, Perkin Elmer) in SBF were measured at selected time points. Formation of silica rich and hydroxyapatite layers at the glass surfaces were studied using SEM-EDX (LEO 1530 Gemini, EDXA from Thermo Electron Corp.). All measurements were done for 3-5 parallel samples.

## RESULTS AND DISCUSSION

In static conditions, the pH of SBF for all glasses increased. However, for 1-98 a constant value was reached at 78 h, while for Zn2Sr4 and Zn4Sr2 the increase was less and did not reach a stable value during 168 h. Similarly, in dynamic conditions 1-98 gave clear pH changes, while only minor effects were recorded for Zn2Sr4 and Zn4Sr2. This suggests that ZnO and SrO decrease the in vitro bioactivity.

ZnO and SrO had only minor effects on the crystallization temperature ( $T_p$ ), while they clearly decreased the sintering range,  $T_{si}-T_{xi}$  (Table 1). The

glass transition temperature,  $T_g$  was lowest for Zn2Sr4. Melting of crystals,  $T_{xf}$  started at the lowest temperature for glass Zn2Sr4. The results suggest that ZnO and/or SrO slightly increase the hot-working range of 1-98.

Table 1. Characteristic hot-working temperatures

Glass Code	$T_g$ ( $\pm 3^\circ\text{C}$ )	$T_p$ ( $\pm 3^\circ\text{C}$ )	$T_{si}$ ( $\pm 3^\circ\text{C}$ )	$T_{xi}$ ( $\pm 5^\circ\text{C}$ )	$T_{xf}$ ( $\pm 5^\circ\text{C}$ )
1-98	609	1001	681	827	1028
Zn2Sr4	593	998	663	850	1013
Zn4Sr2	605	996	669	831	1030

The release of silicon was highest for 1-98. For this glass, the phosphorous concentration decreased most with increasing immersion time. Zinc was released only in modest amounts. For Zn4Sr2 the zinc concentration was 0.34 mg/l at 168 h. In contrast, strontium concentration reached around 10 mg/l at 168 for Zn2Sr4. These results suggest that Zn is strongly bonded in the glass network, while Sr acts as a network modifier and dissolves more easily than Zn.

SEM images show reaction layers at each time point only at 1-98, while layers with a measurable thickness were detected only after 168 h at the two other glasses.

## CONCLUSION

Partial substitution of MgO and CaO for ZnO and SrO, respectively in bioactive glass 1-98 resulted in minor increase in the hot-working range. ZnO and SrO decreased the in vitro reactivity expressed as rate of HAP layer formation. Only minor concentrations of Zn were measured in the solution, while Sr concentrations showed levels that may be of interest for tissue engineering scaffolds based on bioactive glass.

## Bioresorbable Chitosan- Bioglass Nanocomposite Scaffolds for Drug Delivery Applications

Emad El-Meliegy<sup>1</sup> and Sara Ali<sup>2</sup>

<sup>1,2</sup>Department of biomaterials, National Research Centre, Cairo, Egypt  
[emadmeliagy@hotmail.com](mailto:emadmeliagy@hotmail.com)

### INTRODUCTION

Tissue engineering is a promising technology that has the potential to create tissues and organs. It involves in vitro seeding of human cells onto porous bioresorbable scaffolds by attachment. Once the scaffolds are implanted, the human cells proliferate, migrate and differentiate into specific tissues. 1

Synthetic biodegradable nanocomposite scaffolds based on biopolymers and bioglasses have excellent tissue compatibility and safety profiles critical for their successful utility in the human body. A wide variety of drugs and supplementary therapies can be encapsulated into nanocomposite scaffolds for easy delivery to specific human cells. In order for the produced scaffolds to guarantee effective delivery of drugs, the structure of the scaffolds should show control over pore size distribution and have networked interconnected pores. 2

Thus, the objective is to generate scaffolds with effective 3D interconnected pore structure that would allow cells to migrate deep into the scaffold for drug delivery applications. The pore size distribution and the in vitro cytotoxicity will be evaluated.3

### EXPERIMENTAL METHODS

This work involved the synthesis of bioglass nanoparticles, and chitosan-bioglass nanocomposite scaffolds therefrom by freeze drying of bioglass/chitosan nanodispersions at a temperature at -75°C. The nanoparticles and nanocomposites were characterized by XRD and DTA, SEM and TEM.

The pore size distribution of the prepared scaffolds was tested using HG- Porosimeter. The biodegradability of the scaffolds was evaluated in vitro in SBF and distilled water. Furthermore, the cytotoxicity of the scaffolds was tested to evaluate the cell viability.

### RESULTS AND DISCUSSION

The results showed that the particle size of bioglass nanoparticles is found to be 6-12nms. The XRD and

DTA of bioglass heat treated up to 700°C showed no signs of crystallization.

The prepared scaffolds have shown porous structure with >70% porosity and interconnected pore morphology. Pores ranges in size between 200-400µm, which is preferred in hosting various living cells and supplementary drugs. The results of degradation in SBF and distilled water indicated controlled degradation profiles over weeks of time.

The results of cytotoxicity indicated no toxicity and in role, showed effective cell viability, growth and proliferation, the fact that enhance the potential of nanocomposite scaffolds for drug delivery applications.

### CONCLUSION

Nanocomposite 3D scaffolds based on chitosan- nano-bioglass with higher pore volume and interconnected pore structure were developed. The results proved that the scaffolds have excellent bioresorbability, no toxicity and effective cell viability indicating their potential for biomedical applications.

## Generation of Limbal Epithelial Cell Progenitors by Two Methods: by Differentiation from iPS Cells and by Direct Trans-differentiation from Human Dermal Fibroblasts

The corneal epithelium is maintained by a small pool of tissue stem cells located at the limbus. Through certain injuries or diseases this pool of stem cells may get depleted. This leads to visual impairment. Standard treatment options include autologous or allogeneic limbal stem cell transplantation, but graft rejection and chronic inflammation lowers the success rate over long time. Induced pluripotent stem (iPS) cells have opened new possibilities for treating various diseases with patient specific cells, eliminating the risk of immune rejection. In recent years, several protocols have been developed, aimed at the differentiation of iPS cells into the corneal epithelial lineage by mimicking the environmental niche of limbal stem cells. However, the risk of teratoma formation associated with the use of iPS cells hinders most applications from lab into clinics.

Here we show that the differentiation of iPS cells into corneal epithelial cells results in the expression of corneal epithelial markers showing a successful differentiation, but the level of gene expression for the pluripotency markers does not vanish completely and Klf4 is expressed at very high levels, probably due to transgene activation. Therefore, we have tested a direct transdifferentiation approach to circumvent the intermediate state of pluripotency (iPS-stage). The resulting cells exhibited corneal epithelial cell morphology and expressed corneal epithelial markers (please see the attached figure). We show for the first time a direct transdifferentiation of human dermal fibroblasts into the corneal epithelial lineage. Thus, easily-obtainable autologous human dermal fibroblasts may serve as progenitors for the production of corneal epithelial cells for transplantation approaches.

### INTRODUCTION

Cell-based tissue engineering strategies have limited clinical applicability due to delayed extracellular matrix (ECM) deposition and consequent prolonged production time. Scaffold-free tissue production *in vitro* can be enhanced by macromolecular crowding (MMC)<sup>1</sup>, a biophysical phenomenon that governs the intra- and extra-cellular milieu of multicellular organisms<sup>2</sup>. Although MMC has been proven to be an effective tool in enhancing ECM deposition in permanently differentiated cells<sup>1</sup>, its effectiveness in mesenchymal stem cell (MSC) culture has still to be fully assessed. It is hypothesised that MSCs cultured under MMC and low oxygen tension (2%)<sup>3</sup> conditions will maintain their phenotype and function, resulting in multipotent and ECM-rich cell sheets for a variety of clinical targets.

### EXPERIMENTAL METHODS

Human bone marrow MSCs were cultured for 7 and 14 days with 100 µg/ml of carrageenan (MMC) at 20% and 2% oxygen tension at 37°C and 5% CO<sub>2</sub> in a humidified atmosphere. Collagen I deposition was assessed using sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE). Phenotypic assessment was performed by flow cytometry for the expression of cell surface markers CD90, CD105, CD73, CD44 and lack of expression of CD34, CD11b, CD19, CD45 and HLA-DR. Staining for Oil Red O, Alizarin Red S and Safranin O / Fast green was used to assess adipogenic, osteogenic and chondrogenic differentiation.

### RESULTS AND DISCUSSION

**Figure 1:** Under MMC conditions, collagen I deposition was significantly increased at both 20% and 2% oxygen tension, as compared to the non-crowded control (CTR) counterparts at both time points.

**Figure 2:** Expression of positive cell surface markers evaluated by flow cytometry represented in the form of median fluorescence intensity (MFI). Graphs show fold increase over the appropriate isotype control for 7 and 14 days and except for CD105, MMC and low oxygen tension (2%) did not affect the expression of positive surface markers, indicating maintenance of the multipotent phenotype.

**Figure 3:** Oil Red O staining of hMSCs (A) and Alizarin Red S staining (B) and respective quantification shows that the cells still maintained their multidifferentiation potential, after exposure to MMC and 20% or 2% O<sub>2</sub> tension; adipogenic potential seems to be diminished at 2% O<sub>2</sub>.

### CONCLUSION

MMC and low oxygen tension can be used effectively to enhance extracellular matrix deposition in human MSC culture, without detrimental effect on cell phenotype and function. This multifactorial approach paves the ways for the development of scaffold-free cell therapies for various clinical targets.

## Cryptic Cell Cycle Stasis of Human Pluripotent Stem Cells Revealed by Culture in a Biocompatible Thermo-responsive Copolymer Gel

Irene Canton,<sup>1,3</sup> Nicholas J. Warren,<sup>3</sup> Richard Weightman<sup>1</sup>, Andrew Wood,<sup>1</sup> Harry Moore,<sup>1\*</sup> and Steven P. Armes<sup>3\*</sup>

<sup>1</sup>The Centre for Stem Cell Biology, and <sup>2</sup>The Centre for Membrane Interactions and Dynamics (CMIAD), Department of Biomedical Science, The University of Sheffield, Western Bank, Sheffield, S10 2TN, United Kingdom. <sup>3</sup>Department of Chemistry, University of Sheffield, Brook Hill, Sheffield, S3 7HF, United Kingdom, [i.canton@sheffield.ac.uk](mailto:i.canton@sheffield.ac.uk)

### INTRODUCTION

The physicochemical interaction between stem cells and the extracellular milieu is crucial for determining their fate. The routine maintenance of human pluripotent stem cells *in vitro* (PSCs; embryonic and induced pluripotent) usually involves rapid proliferation after adherence to extracellular matrix, resulting in cells displaying a short cell cycle (16-18 h) characterized by a rapid G<sub>1</sub> phase (~ 2.5 h) and complete absence of any arrest at the G<sub>0</sub> stage<sup>1</sup>. However, pre-implantation embryos in certain mammals (e.g. marsupials) exhibit cellular arrest or diapause *in utero* for days or months while preserving pluripotent capacity<sup>2</sup>. Although there is no evidence of diapause-like processes in many mammals including humans, recent evidence shows that diapause can be induced in certain species that do not naturally undergo this process<sup>3</sup>.

Here we describe induction of cell cycle stasis on human PSCs colonies and blastocysts in a wholly synthetic thermo-responsive gel comprising poly(glycerol monomethacrylate)-poly(2-hydroxypropyl methacrylate) [PGMA-PHPMA] diblock copolymer worms<sup>4</sup>.

### EXPERIMENTAL METHODS

PGMA-PHPMA diblock copolymer worm gels were synthesized by RAFT polymerization in physiological buffers. The polymers were extensively dialyzed and freeze dried prior to assessment of cell biocompatibility by MTT assay. Human PSCs were suspended in 6% PGMA-PHPMA-polymer cell medium solution at 5 °C and gelation was triggered by incubation at 37 °C. Cell colonies were kept for extended periods of time in the thermo-responsive gels (7, 14 and 21 days) and recovered by simply cooling at 5 °C. Live (Syto9)/Dead(PI) imaging staining was used to investigate PSCs viability while in the gels. Total DNA quantification over time was used to assess proliferation. Immunolabelling of the cell proliferation marker (ki-67) and the stasis marker, (nuclear envelope statin) were used to investigate quiescence. Stem cell markers (oct-4, Tra-1-60, SSEA-4 and SSEA-1) were monitored by flow cytometry and immunolabeling.

### RESULTS AND DISCUSSION

The non-adherent gel culture system preserved the viability and pluripotency of PSCs in non-proliferative G<sub>0</sub> quiescence and without passage for up to three weeks. Cooling to 5 °C causes degelation via a worm-to-sphere transition, which in principle enables facile cell harvesting. The isolated cell colonies spontaneously re-enter the cell cycle within hours and resume

proliferation while maintaining the expression of stem cell markers. Human blastocysts in Matrigel fragmented after just two days, whereas those within the worm gels were stable for up to 8 days (embryo development day 14) (Figure 1E and 1B). Furthermore, blastocysts within worm gels were positive for the expression of nuclear envelope statin, indicating stasis (Figure 1C).

**Figure 1. Human blastocysts gelled in PGMA-PHPMA gels or in Matrigel.** Hatched human blastocysts at 6-day embryo development (A and D) were gelled in PGMA-PHPMA gels or Matrigel<sup>TM</sup>. On day 4 after gelation (10-day embryo development), matrigel embryos fragmented (E), whereas PGMA-PHPMA embryos appeared non-fragmented (B). PGMA-PHPMA embryos were kept up to 8 days in the gels (14-day embryo development) and they were stained for nuclear envelope statin (C, red: nuclear envelope statin; C, blue: nuclei).

### CONCLUSION

The discovery of a cryptic cell arrest mechanism for PSCs serves to illustrate the importance and prevalence of quiescence in homeostasis. Far from remaining merely passive, the 3D niche actively influences adult stem and PS cells. The design of novel synthetic stem cell niches may provide solutions for new therapeutic avenues, from facilitating short-term storage to arresting disease processes or promoting regeneration.

### INTRODUCTION

Because of the strong angiogenic property of ADSCs<sup>1</sup>, the addition ADSCs to BMSCs can enhance the revascularization of implanted BMSCs for bone regeneration. However, considering the lower osteogenic potential of ADSCs compared to BMSCs<sup>2</sup>, we thought about ways to decrease the proportion of ADSCs while further enhancing angiogenic and osteogenic effect as a further step. More potent angiogenic ADSCs that is effective even when treated in a small number can further advance the combined cell therapy.

Vascular endothelial growth factor (VEGF) has been identified as one of the most potent inducer of angiogenesis and lymphangiogenesis, being a highly specific mitogen for endothelial cells<sup>3</sup>. Treatment with exogenous VEGF has been shown to promote fracture healing<sup>4,5</sup>.

In this study, we devised a potent angiogenic ADSC by the transfection of VEGF gene using electroporation system and tested the in vitro angiogenesis and osteogenesis and in vivo repair of critical size defect when combined in various proportion to BMSCs. The aim of this study was to evaluate the potential of VEGF-transfected ADSCs (ADSCs<sup>VEGF</sup>) to direct formation of a vascular network, and thereby promoting bone regeneration when added in small proportion to BMSCs.

### EXPERIMENTAL METHODS

ADSCs were transfected with pEGFP-C1 vector containing human VEGF gene using electroporation. ADSCs/VEGF was added to BMSCs and cocultured in variable proportion (BMSCs : ADSCs/VEGF ratio of 0.025~0.5). In vitro osteogenesis was evaluated by ALP and Alizarin Red S staining, calcium quantification, real-time qPCR and ELISA for osteogenic makers. In vitro angiogenesis was evaluated by tube formation assay of human umbilical cord vascular endothelial cell. In vivo angiogenesis was assessed by subcutaneous transplantation of BMSCs and ADSCs<sup>VEGF</sup> with fibrin in nude mice. In vivo bone regeneration and neovascularization were carried out with critical sized defect in rat calvarias by co-transplantation of BMSCs and ADSCs/VEGF.

### RESULTS AND DISCUSSION

ADSCs<sup>VEGF</sup> produced 27-fold greater level of VEGF as compared to untransfected ADSC. ADSCs<sup>VEGF</sup> or ADSCs<sup>VEGF</sup> with BMSCs (BMSCs : ADSCs<sup>VEGF</sup> ratio of 0.025~0.5) induced significantly greater number of tube formation in human umbilical vein endothelial cells than untransfected ADSCs. Higher VEGF release

seems to have caused greater number of tube formation of HUVEC with ADSCs<sup>VEGF</sup> when compared with untransfected ADSCs.

The coculture of BMSCs and ADSCs<sup>VEGF</sup> at the ratio of 1: 0.025~ 0.1 showed significantly greater in vitro osteogenic differentiations and mineralization than BMSCs alone. These findings suggest that ADSCs<sup>VEGF</sup> can exert synergistic osteogenic effect even when treated in small number.

The vascular structure counting from CD31 IHC of cutaneous tissues showed that ADSCs<sup>VEGF</sup>, either by themselves or implanted with BMSCs, induced significantly more vascular structures than BMSCs alone.

When critical size calvarial defects in rats were implanted with mixture of BMSCs and ADSCs<sup>VEGF</sup> along with hydroxyapatite/beta-tricalcium phosphate granules, BMSCs and ADSCs<sup>VEGF</sup> at the ratio of 1:0.05 showed significantly greater bone area, volume and mineral density on the regenerated defect than BMSCs alone. The results of current study are in line with the previous reports that VEGF-A gene transfer enhances mineral density in bone fracture healing<sup>4,5</sup>.

VEGF has an activity in promoting vascularization during endochondral bone formation, as well as multifarious activities including regulation of the survival and activity of endothelial, chondrogenic and osteogenic cells in bone development<sup>6</sup>. Both microvessel density and staining intensity counts of CD31 demonstrated that ADSCs<sup>VEGF</sup> alone or co-transplantation of BMSCs/ADSCs<sup>VEGF</sup> at 1:0.5 induced significantly higher CD31 expression than those of BMSCs alone ( $p < 0.05$ ) while BMSCs/ADSCs<sup>VEGF</sup> at 1:0.05 induced increase only in signalling densities.

### CONCLUSION

Our results demonstrated that ADSCs/VEGF enhanced neovascularization and angiogenesis as well as mineral density in bone regeneration.

## Effect of Mechanical Stimulation on Osteogenesis of Self-Assembled Collagen-Cell Seeded Microspheres

Maryam Shariatzadeh, Cécile M. Perrault, Damien Lacroix

INSIGNEO Institute for in silico medicine, Mechanical Engineering Department, University of Sheffield, UK  
[m.shariatzadeh@sheffield.ac.uk](mailto:m.shariatzadeh@sheffield.ac.uk)

### INTRODUCTION

Mechanical forces and 3D topological environment can be used to control differentiation of Mesenchymal Stem Cells (MSCs)<sup>1, 2</sup>. However, the effects of physical and mechanical cues of the microenvironment on MSC fate determination have not yet been fully understood. This study investigates and compares the effect of mechanical stimulations on soft cellular microspheres when subjected to dynamic fluid compression in 3 different in-vitro systems: microfluidic chamber, compression bioreactor and orbital shaker. It is hypothesised that dynamic compressive strains influence cell morphology and expression of osteogenic cell marker heMSCs.

### EXPERIMENTAL METHODS

Microspheres were produced by gelation of bovine collagen type I with concentrations of 2 mg/ml and 2500-3200 heMSC cells per 5µl droplet. Three loading conditions were studied: (1) the microspheres were forced to flow through the chamber (D=0.7mm) at a flow rate of 200 µl/min for 3 cycles/day for 5 days; (2) 10% dynamic compression strain was applied by a Bose biodynamic bioreactor for 15 and 40 min/day for 5 and 10 days; (3) fluid shear stress was applied by an orbital shaker at 50 rpm for 40 min/day for 10 days. All experiments started at day 6 post-encapsulation. Cell viability and proliferation, alkaline phosphatase activity and mineralization were monitored and compared with free floating control samples.

### RESULTS AND DISCUSSION

Low concentration of bovine collagen was shown to be an efficient microenvironment for cellular growth which supported cell proliferation and viability up to 28 days post-encapsulation, as shown by DNA pico green assay (Fig. 1). ALP activity level increased steadily from day 6 post-encapsulation up to day 28 with a slight drop at day 21 for most conditions (Fig. 2). All samples showed a peak for ALP activity at day 28 post-encapsulation with the highest level for free floating (0.0014) and 5 days controls (0.0013). Microfluidics condition manifested the lowest ALP level at day 21 among other experiment groups (> 0.0003). Also deposition of calcium and mineralisation were confirmed in all samples from day 14 post-encapsulation onward by alizarin red staining (ARS). The highest ARS colour intensity was reported in cyclic compression group but calcium deposition could not be detected due to the very low cell number and mineral expression level. Rotation of collagen microspheres through microfluidic chamber and shaker experiment may cause nonhomogeneous transfer of fluid flow shear stress and compression forces to the cells. Therefore,

cells in different areas of a microsphere may experience more random mechanical forces.

Fig. 1: Fluorescent staining of live / dead heMSCs day 7 and day 28 post encapsulation (left), heMSCs cell proliferation (right).

Fig. 2: ALP activity of cyclic compression samples compare to the free floating controls (top), Microfluidic experiment (lower left) and fluid shear stress experiment (lower right).

### CONCLUSION

Mechanical forces can stimulate the differentiation of mesenchymal progenitors in micro-environment. Our results showed that despite similar cell viability, on average the level of ALP activity in 5 days dynamic compression regime was nearly two times higher than 10 days compression. Also, free floating samples presented the highest cell number and ALP activity compare to other conditions. Application of compression cycles on heMSC cells could be used as a model to study the effect of mechanostimulation on osteogenesis. Future work will assess qPCR and gene expression to identify the role of osteogenesis marker genes and new gene / protein pathways in heMSCs mineralization.

## 5-Azacytidine Mediated hMSC Behaviour on Electrospun Scaffolds to Induce Myogenesis

Ines Fasolino, Vincenzo Guarino, Valentina Cirillo, Marica Marrese, Luigi Ambrosio

Institute for Polymers, Composites and Biomaterials, Department of Chemical Sciences & Materials Technology, National Research Council of Italy, V.le Kennedy 54, Naples, Italy

[vincenzo.guarino@cnr.it](mailto:vincenzo.guarino@cnr.it)

### INTRODUCTION

Incomplete regeneration after traumatic muscle injury or muscular dysfunction is a common problem in regenerative medicine. The main goal in skeletal muscle engineering is to replicate the structure and function of skeletal muscle tissue *in vitro* and *in vivo* to obtain a therapeutic implantable device.

For this purpose, it is required to design bio-inspired platforms which convey all the main features of native extracellular matrix - i.e., morphological and biochemical signals - and to properly address muscle cells towards myotube differentiation and maturation. According to current pharmacological therapies, they have to assure the efficient interaction of cells with selected drugs, such as 5-Azacytidine (5-AZA) - a DNA-methylation inhibitor just known for promoting up-regulation of muscle genes and hMSC differentiation - thus promoting the formation of *in vitro* tissues with functional contraction<sup>1</sup>.

Here, we investigate the *in vitro* response of human mesenchymal stem cells (hMSC) on electrospun fibres made of Polycaprolactone (PCL) or PCL and Gelatin (PCL/Gel). Firstly, we demonstrate the ability of hMSCs to differentiate in mature myofibres under specific conditions. Then, we evaluate the effects of 5-azacytidine on myotubes generation thus underlining the contribution of 3D fibre network on the pharmacological activity of protein in the myogenic regeneration process.

### EXPERIMENTAL METHODS

PCL and PCL/Gel fibres were produced by using an electrospinning equipment (Nanon01, MECC, Japan) as reported elsewhere<sup>2,3</sup>. SEM, TEM, AFM in Tapping Mode (TM) were employed to obtain more information on morphological features of electrospun fibres and defects (i.e., beads, branched fibres). Bone marrow hMSCs (passages 4-6) were grown in myogenic culture medium [high-glucose DMEM supplemented with 10% fetal bovine serum (FBS; GIBCO), 5% horse serum (HS; GIBCO), non essential amino acids (LONZA) and 100 mM 2-mercaptoethanol (GIBCO)] in a humidified incubator (37°C, 5% CO<sub>2</sub>).

Cells plated onto electrospun PCL and PCL/Gel were treated with 5-AZA (1 and 5 µM) from 7 to 28 days. 5-AZA was added to myogenic medium and culture medium was replaced twice a week. Skeletal muscle differentiation was assessed by YIP-1B - a muscle specific protein - expression whereas cellular morphology by SEM. Skeletal muscle cells formation was analyzed by Azan Mallory stain.

### RESULTS AND DISCUSSION

In order to produce PCL/Gelfibres, lower polymer concentration and a high polar solvent have been used respect to PCL ones. This determines a reduction of average fibres diameter to  $(0.71 \pm 0.15) \mu\text{m}$ , also minimizing the formation of beads due to the stronger interaction of polar solvent with the electric field forces. Moreover, TEM images showed a preferential exposure of protein along the fibre surface also confirmed by roughness ( $R_q$ ) measurement calculated by AFM. The addition of Gelatin in PCL fibres determines an increase of  $R_q$  value to  $(22.3 \pm 5.15) \text{ nm}$ , in comparison with PCL fibres  $(16 \pm 2.72) \text{ nm}$ . According with peculiar morphological and biochemical features of fibres, we have recognized some differences in hMSC behaviour mediated by 5-AZA. In particular, 5-AZA significantly increases YIP-1B expression (index of myogenic differentiation) both in the presence of PCL and PCL/Gel fibres compared to plate control (5-AZA 1 µM alone). Most interestingly, an effect of drug concentration on hMSC activity may be recognized. Indeed, for higher amounts of 5-AZA (5 µM), YIP-1B expression does not change in the presence of PCL fibres, even showing a decay in the case of PCL/Gel ones. Accordingly, SEM images indicate a higher stretching of hMSC after 5-AZA treatment, so resembling to myotubes, whereas Azan Mallory staining confirms the hMSCs differentiation in skeletal muscle cells.

### CONCLUSION

Summarizing, we verified that hMSCs *in vitro* differentiate after treatment with 5-azacytidine, so forming mature myofibres. In particular, 3D fibre network concurs to corroborate the biological effect of 5-azacytidine protein, mainly amplifying the pharmacological activity of protein during the *in vitro* process of myogenic regeneration.

### INTRODUCTION

Microvesicles (MVs) are membrane-enclosed particles shed into the extracellular environment by direct budding from the cell plasma membrane or may be derived from the endosomal compartment. MVs may carry bioactive components of cell cytoplasm and membrane including mRNAs, miRNAs, proteins and lipids and may act as mediators of cell-to-cell communication by transferring such content from parent to target cells.

In this study, for the first time, we examined phenotype and bioactive content of MVs derived from human induced pluripotent stem cells (iPS) produced in our laboratory. We also investigated the transfer of selected miRNAs and mRNAs by such iPS-MVs to mature cardiac cells. We examined functional impact of the transferred components on selected functions of primary heart cells including metabolic activity, viability and survival in hypoxia as well as angiogenic and cardiac differentiation potential *in vitro*.

### EXPERIMENTAL METHODS

MVs were isolated by ultracentrifugation from conditioned media harvested from iPS cells cultured in novel optimized feeder layer-, serum-, and xeno- free conditions. The level of selected several transcripts including genes related to cardiac and angiogenic differentiation was examined in donor iPS cells and iPS-MVs by real-time RT-PCR. Multiantigenic profile of iPS cells and iPS-MVs including the expression of selected markers related to stemness as well as angiogenic and cardiomyogenesis was examined by classical and high-sensitivity cytometry (ApoGee). Moreover, extended regulatory microRNA profile was evaluated by employing microarray assays by real time RT-PCR,

while global proteome was examined by mass spectroscopy.

### RESULTS AND DISCUSSION

We established that several bioactive transcripts including mRNAs and microRNAs as well as proteins expressed in iPS cells are transferred to iPS-MVs. Moreover, we found that MVs may carry and transfer the bioactive content to primary mature cardiac cells. Importantly, we found significant impact of such transfer on selected functions of target cells including metabolic activity, survival as well as angiogenic differentiation potential *in vitro*.

### CONCLUSION

The data indicate that iPS- derived MVs may represent natural nanocarriers of several proangiogenic, cardiomyogenic and antiapoptotic agents to mature heart cells. Such iPS-MVs may potentially represent important carriers enforcing both function and survival of mature heart cell when delivered into ischemic myocardium. Thus, this report suggests the potential future role of microvesicles including iPS-MVs in heart repair that represents an example of a novel rising approach in applications of stem cells and their derivatives in tissue regeneration.

### INTRODUCTION

Antimicrobial peptides have recently been investigated for their broad antimicrobial activity against gram-positive and gram-negative bacteria [1] as well as for their immunomodulatory properties [2]. In this study the immobilization of antimicrobial peptides on titanium alloy surfaces have been studied to improve the antibacterial properties of the surface. The peptide studied is the Tet-124 sequence KLWWMIRRW, which was previously synthesized by Hilpert *et al.* [3]. The immobilization strategy is based on the electrostatic interactions of the peptide with a titanium alloy surface and the modification of both N- and C-terminus with glycine-3,4-dihydroxyphenylalanine-glycine (G-DOPA-G). The DOPA amino acid was added to the sequences to promote adhesion to titanium alloy surfaces by the catechol moiety due the possible formation complexes with the metal and metal oxide surface [4].

### EXPERIMENTAL METHODS

Quartz crystal micro balance with dissipation (QCM-D, Q-Sense E4, Sweden) was used to evaluate the adsorption on titanium coated quartz crystals with peptides solutions at pH=4.75 (acetate buffer 0.1 M, 0.3mg/ml) and 6.9 (deionized water, 0.18mg/ml).

The attachment of *Escherichia coli* (*E.coli*, DSM 10290, 4 h in contact) and fibroblast (cells L929) on 1cm<sup>2</sup> Ti-6Al-4V substrates modified with Tet-124-G-DOPA-G and unmodified (control) was evaluated.

### RESULTS AND DISCUSSION

The adsorption due to the crystal contact with the peptide solution was monitored in real time for all the overtones (n=1, 3, 5, 7...) at a temperature of 25°C. Figure 1 A and B shows the frequency changes due to the mass adsorption crystal in contact with the Tet-124 and Tet 124-G-DOPA-G respectively. The peptides show similar adsorption rate behavior. No desorption upon rinsing with buffer is detected. Also rigid layers were formed on the surface accordingly with the changes on the dissipation coefficient (data not shown).

Figure 2. Frequency changes A) Tet-124 B) Tet-124-G-DOPA-G, 0.33 mg/ml in acetate buffer 0.1 M.

Figure 2. A shows lower adsorption rate and mass of the Tet-124 in comparison with Tet124-G-DOPA-G at pH=6.9

Figure 2 Frequency changes A) Tet-124 B) Tet-124-G-DOPA-G, 0.18 mg/ml deionized water.

### CONCLUSIONS

The layer formation at pH 4.75 of the Tet-124 and both Tet-124-DOPA specimen is related to the electrostatic interaction with the negatively charged titanium oxide layer. At pH 6.9 the influence of the DOPA moieties enhance the adlayer formation due to the Ti(IV) catechol complexes formation. This study shows that it is possible to change the mass adsorption coverage of the antimicrobial peptide layer on the surface depending the pH and salt concentration. The modification of the Ti-6Al-4V with the Tet-124-G-DOPA-G does not change the attachment of *E.coli* bacteria to its surface; however. The results indicate also indicate that the surface modification does not influence the biocompatibility and cell attachment of fibroblast to the surface. The G-DOPA-G N and C terminal sequence modification peptide can be used as immobilization strategies of antimicrobial peptides on titanium alloy surfaces.

### INTRODUCTION

Titanium and its alloys are commonly used in regenerative surgery protocols in oral and maxillofacial surgery. Despite high success rate ranging up to 98%, biological complications such as *periimplant mucositis* and *periimplantitis* are still possible threat for implant treatment and may be diagnosed in 28- 56% patients in their implant sites 12-43%. Despite a variety of therapeutic options infected implants are difficult to treat and often require removal. Therefore, one of proposed strategies to prevent implant infection rate is to decrease bacterial adhesion, while maintaining material biocompatibility. Nanosilver is a material which gained much attention in biomedical science in last decade. It is assumed that silver nanoparticles (AgNPs) in controlled amounts exhibit sufficient antimicrobial properties and present little or non-toxic effect on hosts tissue. The aim of this study was to evaluate a potential applicability of silver nanoparticles modified titanium for oral implantology.

### EXPERIMENTAL METHODS

Commercially pure titanium Grade 2 in shape of discs, 10 mm in diameter were used. Surface of all samples was pre-treated by the authors formula- triple surface etching (TSE). In order to provide incorporation of AgNPs onto titanium surface, Tollens reagents formula was adapted. Incubation in Tollens reagents solution were performed for 10, 5, 2 minutes and 30 seconds respectively. Surface roughness, wettability, silver ion release and *in vitro* bioactivity were evaluated. The antibacterial behaviour was estimated by observing the sample ability to stop bacterial proliferation around it (zone of inhibition- ZOI). Seven clinical strains of each: *Streptococcus mutans*, *Streptococcus salivarius*, *Streptococcus oralis* and *Streptococcus mitis* as well as *P. Gingivalis* (ATCC 33227). For evaluation of osseointegration, 6 titanium sinter implants [2] pre-treated for 30s with aforementioned formula with AgNPs, were tested *in vivo* in healthy 6 New Zealand white rabbits. Each Rabbit received a total of 2 implants: implant coated with AgNPs in one leg and reference implants (pure sintered titanium) in the other. The implant retrieval was performed after 12 weeks. All statistical analyses were performed by Anova with the student t- test. A *p*-value of 0,05 was considered statistically significant.

### RESULTS AND DISCUSSION

AgNPs deposition by Tollens method influenced mean surface Ra only marginally. SEM observations revealed that AgNPs did not affect surface nanofeatures. However, they significantly influenced the surface wettability. In the PBS buffers surfaces continuously released silver ions with characteristic burst release during first 24 hours of incubation. Also a moderate surface enrichment in calcium and phosphate after 6 weeks of incubation was noticed.

Antimicrobial assay confirmed high antimicrobial properties of all titanium specimens with AgNPs against oral *streptococci* species as well as *P. Gingivalis* inhibition halos were > 1mm (*p*<0,05). Time of surface treatment with AgNPs did not have a statistically significant influence on antimicrobial activity (*p*>0,05). However, there were a statistically significant differences between mean ZOIs for tested bacteria. The most susceptible species to AgNPs were *P. Gingivalis* followed by *S. mitis*. *S. mutans* was the least susceptible. All animals reached the endpoint of the study. Histopathological and radiographic findings confirmed full osseointegration of the titanium sinters with AgNPs comparably to the control group (*p*>0,05).

### CONCLUSION

Tollens method for silver incorporation may exert a diversified effect on physicochemical properties of titanium surface. Incorporation of AgNPs provides an efficient antimicrobial properties against both: early (oral *streptococci*) and late (*P. Gingivalis*) colonizers of the dental implant. *In vivo* biocompatibility tests confirmed a good biotolerance of titanium implants modified with nanosilver thus such materials may find clinical application in oral implantology.

### INTRODUCTION

Infection at the implant surface is one of the biggest challenges in biomaterial research. Reducing the risk of infection during and after surgery, without using antibiotics, would be of great benefit to both patients and the healthcare system. It has recently been suggested that nanotopographies found in nature, act as bactericidal surfaces by physically damaging bacteria<sup>1</sup>. By mimicking such topographies on relevant materials, it may be possible to create antimicrobial implant surfaces. In this work we have produced nanowire surfaces on Ti alloy substrates which are capable of killing bacteria while maintaining mammalian cell functionality<sup>2</sup>.

### EXPERIMENTAL METHODS

Two fabrication methods, hydrothermal synthesis and controlled thermal oxidation, were used to produce nanowires on pure Ti and Ti-6Al-4V (Ti64) surfaces. Hydrothermal synthesis was carried out in NaOH solution at 240°C for 2-3 h on Ti substrates, followed by ion exchange and crystallisation. Ti64 samples were heated to 850°C in a tube furnace under Ar atmosphere. At the final temperature, acetone vapour was introduced at 500sccm for 45 minutes, and finally the furnace was allowed to cool under Ar. The substrates were then annealed in air at 600°C for 1h to remove carbon residue. *Pseudomonas aeruginosa* and *Staphylococcus aureus* were cultured on smooth (control) and nanowire surfaces at 37°C for 1h. The cells were then either stained for LIVE/DEAD and examined using fluorescence and confocal laser microscopy, or cultured with assays to examine cell viability.

### RESULTS AND DISCUSSION

Figure 1. Side view SEM of nanowires grown on Ti (left) and Ti64 (right) substrates.

Figure 2. Fluorescence microscopy images of LIVE/DEAD stained *P. aeruginosa* on smooth Ti64 (left) and nanowire Ti64 (right). Green = live cells. Red = dead cells.

Figure 3. Cell viability measured with AlamarBlue, of *S. aureus* and *P. aeruginosa* on smooth Ti64 and nanowire Ti64. \*  $P < 0.05$ .

Figure 4. 14 day viability plot of MG-63 cells seeded on Control, hydrothermal TiO<sub>2</sub> nanowire (3 hHT) surfaces by absorbance reading of the PrestoBlue stain and converted into cell population.

Figure 5. Confocal images showing the cell coverage on two different surfaces from day 1, 4 to 7 (from left to right). The cells on the Control surface (first row) have already established a monolayer coverage by day 4 (top, middle) and multilayers were formed by day 7 (top, right). The cells on hydrothermal TiO<sub>2</sub> nanowires (second row) were quite sparse at day 1 but the cells appeared to have formed clusters by day 4, instead of an even monolayer spread. The clusters were still evidence by day 7 but in larger numbers. The cell morphology were elongated but possessed a much flatter, spread morphology, which were rounder in shape (not as spread out).

### CONCLUSION

Sharp nanowire features were produced on Ti and Ti64 alloys by hydrothermal and controlled thermal oxidation methods. The nanowires were able to kill Gram-negative bacteria by physical means but can maintain the cell viability. These surfaces have potential for antimicrobial surfaces for orthopaedic implants.

## INTRODUCTION

Postsurgical infections are one of the causes of implant rejection and prolonged healing of the implantation sites. Functionalization of surfaces with Antimicrobial Peptides (AMPs) can be a tool which is more effective against bacterial infection than the currently used methods such as antibiotics administration.

AMPs are short molecules, which have a broad spectrum of antibacterial, antifungal and antiviral properties.<sup>1</sup> They can act by interaction with bacterial membranes leading to their destruction, while they do not affect eukaryotic cell membranes.<sup>1</sup>

Attachment of AMP molecules on the surface of materials with the use of an adhesive polymer, such as polydopamine<sup>2</sup> could provide a successful method to introduce antimicrobial properties to medical surfaces.

## EXPERIMENTAL METHODS

Fluorescently labelled and unlabelled AMPs were synthesised using Solid Phase Peptide Synthesis (SPPS), followed by purification with High Pressure Liquid Chromatography (HPLC) and mass characterisation with Mass Spectroscopy (MS).

The effect of AMPs on the bacterial and eukaryotic cell membrane was tested with Circular Dichroism Spectroscopy (CD) in dodecylphosphocholine (DPC) and sodium dodecylsulphate (SDS) micelle environment that mimics eukaryotic and bacterial cell membranes.

Polished titanium alloy (Ti6Al4V) plates were coated with the adhesive polymer via a dip coating method.

Peptides were then conjugated to the polymer coated on the Ti6Al4V by using Schiff base chemistry.

The thickness of the polymer-AMP layer was measured by Atomic Force Microscopy (AFM) and Ellipsometry.

Hydrophobicity changes of coated and uncoated surface of Ti6Al4V were measured by Water Contact Angle.

Scanning Electron Microscopy (SEM) images were used to analyse the coating of the polymer on the surface of Ti6Al4V plates.

Plates prepared with fluorescent label were analysed under fluorescence microscopy to visualise the coating of AMPs on the surface of titanium.

## RESULTS AND DISCUSSION

Synthesised AMPs were purified to give  $\geq 95\%$  purity and the MS showed agreement of peptides molecular weights with the theoretical molecular weights.

The Ellipsometry and AFM studies showed the polymer-AMP coating thickness to increase with increasing coating time (Table 1).

The water droplet angles showed decrease of hydrophobicity of Ti6Al4V surface when the polymer

and polymer-AMP were coated on the surface (coating time 72 h) (Table 2).

**Table 1:** Adhesive polymer-AMPs thickness changes with increasing time of coating.

Time	24 h	48 h	72 h
Thickness of Coating	5.2±1.1 nm	32.8±5.1 nm	50.4±7.0 nm

**Table 2:** Changes of the water contact angle with the applied coating.

Surface	Ti6Al4V	Ti6Al4V polymer	Ti6Al4V polymer - AMPs
Water contact angle	82 ± 10°	60 ± 6°	54 ± 11°

SEM images and fluorescence microscopy images showed uniform coatings of polymer and polymer-AMPs on the surface of Ti6Al4V plates (Figure 1a and b).

**Figure 1:** a) SEM image of a boundary between polymer coated surface and uncoated surface of Ti6Al4V, b) Fluorescence microscopy image of AMPs linked on the surface of Ti6Al4V via an adhesive polymer.

## CONCLUSION

The functionalization of Ti6Al4V surfaces with polymer and polymer-AMPs resulted in a coating of nanosize thickness which depends on the time of polymerization. The coverage of coating was shown to be uniform. Functionalization of the surface with the coating caused a decrease in hydrophobicity which can have an effect on the attachment of bacterial and mammalian cells.

### INTRODUCTION

Peri-implantitis, an inflammation caused by biofilm formation, constitutes a major cause of implant failure in dentistry[1]. Thus, the detection of bacterial pathogens at the early steps of biofilm growth represents a very powerful strategy to prevent from implant-related infections. Among different methods to detect pathogenic bacteria, electrochemical biosensors, especially impedance-based systems (EIS), present key advantages in terms of miniaturization, improvement in sensitivity and low cost.

In this regard, antimicrobial peptides (AMPs), which are highly sensitive and active towards are well-known components of the immune system and display a broad range of bacteria [2], can be used to develop highly effective biological recognition elements. Thus, the aim of the present study is to combine the use of miniaturized and integrated EIS and the ability of AMPs as robust biorecognition moieties to obtain biosensors with high sensitivity, specificity and low detection limits for pathogenic bacteria.

### EXPERIMENTAL METHODS

**1. Synthesis of hLf1-11:** The hLf1-11 peptide (Lys-(Ahx)<sub>3</sub>-GRRRRSVQWCA-NH<sub>2</sub>), a potent AMP derived from the human lactoferrin, was synthesized by solid-phase chemistry (Figure 1)

Figure 1: Chemical structure of the hLf1-11 peptide

**2. Sensor biofunctionalization.** a) *Production of the electrodes:* The planar interdigitated electrode and the three dimensional interdigitated electrode arrays (3D-IDEA) were produced by microfabrication technique [3]. b) *Silanization:* The electrodes were silanized with epoxysilane either via gas or liquid-phase and the AMP hLf1-11 in a PBS solution immobilized on the surface.

**3. Characterization of the surfaces.** a) *Chemical characterization:* The immobilization method was characterized and optimized by X-ray photoelectron spectroscopy to obtain the highest density of peptide attachment. b) *Impedance characterization:* Characterization of functionalization of the surface was also performed by impedance measurements in a 100 Hz to 1 MHz frequency range.

**4. Bacterial Adhesion Assays:** Bacterial detection assays were performed using *S.sanguinis* as model of oral bacteria. Functionalized sensors were incubated with bacterial suspensions at different concentrations in bacterial culture broth or synthetic/human saliva, and the presence of bacteria analyzed by impedance measurements, microscopy and live/dead methods.

### RESULTS AND DISCUSSION

**Chemical characterization of the surface:** The atomic composition of all surfaces was analyzed by means of XPS. The coating of planar sensors with peptide by physical adsorption and covalent immobilization resulted in significant increases in the percentages of carbon and nitrogen, and reductions in the detectable amounts of TaSi<sub>2</sub>. Gas-phase silanization with GPTES and peptide immobilization at pH=8 resulted in the highest extent of peptide attachment on the biosensors.

**Bacterial Adhesion Assays:** The presence of the hLf1-11 peptide on the electrodes surface resulted in an increase in the adhesion of *S.sanguinis* within the first 2 hours of incubation, followed by a reduction of bacterial adherence after 4 h, most likely due to the bactericidal effect of the hLf1-11 peptide. This effect was more pronounced when the peptide was covalently attached to the sensors (Figure 2). Thus, these results illustrate that impedance-based sensors coated with AMPs can effectively detect bacterial colonization on the surfaces.

Figure 2: Bacterial Adhesion and Detection Assay

Moreover, the detection limits, stability and selectivity of the biosensors, as well as experimental data on bacteria determination in synthetic and human saliva, will be presented.

### CONCLUSION

The interaction of bacteria with the AMP on the sensor surface provoked changes in the impedance spectra, which were univocally associated with the presence of bacteria. Results of this work suggest that our approach can be effective in preventing the formation of biofilms due to an early detection of primary colonizers and their reduction by therapeutic means.

[virtuousie@naver.com](mailto:virtuousie@naver.com)

## INTRODUCTION

Small interfering RNA (siRNA) has become a potent next-generation medical breakthrough, since it has excellent gene silencing effects and has no side effects<sup>1</sup>. So far, diverse carrier systems have been developed for siRNA delivery. Meanwhile, current delivery systems have been challenged in using siRNA for clinical applications<sup>2</sup>. The main issues, related with nanocarriers for siRNAs, are their poor stability and lack of tumor targetability *in vivo*. To address these needs, we developed biostable gold-installed nanocomplexes (GICs) as siRNA carriers for enhanced tumor targeting.

## EXPERIMENTAL METHODS

The GICs were prepared using the layer-by-layer method. For growth of gold nanoparticles (AuNPs) on the complexes, gold chloride solution as slowly added to the complex solution. The stability of GICs was evaluated in a 50% serum solution. The gold-deficient complexes (GDCs) and free siRNA were used as controls. The complexes were incubated with rat serum solution at 37°C. An aliquot was removed from the samples at predetermined time points. The released siRNAs were visualized by electrophoresis. Melanoma cell line (B16F10) and embryo fibroblast cell line (NIH3T3) were dispersed into a 6-well plate at  $5 \times 10^4$  cells/well and incubated for 24 h at 37 °C. siRNA was labelled with YOYO-1 dye ( $\lambda_{ex} = 491$ ,  $\lambda_{em} = 509$ ). The cells were treated with serum-free medium containing free siRNA, GICs or GDCs for 3h. After washing and fixation, the cells were visualized using a confocal LSM 700 microscope. Tumor-bearing mice were prepared by subcutaneously injecting a suspension of  $1 \times 10^6$  SCC7 cells into the left flank of mice. The Cy5.5-labeled complexes (10  $\mu$ g of siRNA/mouse) were injected into the tail vein of the mice ( $n = 3$  for each group). The time-dependent *in vivo* biodistribution of the complexes was observed with a whole-body animal imaging system. The statistical significance among the groups was analysed using one-way ANOVA. The figure, marked with an asterisk, was considered significant if  $p$ -value was less than 0.05.

## RESULTS AND DISCUSSION

In order to obtain GICs, gold was installed on the PEI/siRNA complexes by growing AuNPs through reduction of HAuCl<sub>4</sub>, followed by surface coating with PEGylated hyaluronic acid (HA). As shown in Table 1, the hydrodynamic size of PEI/siRNA, GDCs and GICs increased gradually and finally present negatively charged. This implies that the complexes were efficiently coated with PEGylated HA.

Sample	Size (nm)	$\zeta$ (mV)
PEI/siRNA complexes	$213.0 \pm 5.56$	$44.4 \pm 2.46$
GDCs	$247.6 \pm 1.63$	$-5.58 \pm 0.18$
GICs	$327.6 \pm 10.2$	$-7.58 \pm 0.81$

Table 1. Characteristics of the PEI/siRNA complexes, GDCs and GICs.

Figure 1. Stability of free siRNA, GDCs and GICs (a) Gel images (b) Relative intensity graph of bands.

The GICs showed remarkable stability compared to the GDCs or free siRNA in the presence of serum as shown in Fig 1.

Figure 2. *In vitro* cellular uptake of complexes (a) B16F10 (b) NIH3T3 cells. The scale bar represents 20  $\mu$ m. *In vivo* (c) Whole body images of the mice. (d) Relative fluorescence intensity of tumor ROI.

For the CD44-overexpressed B16F10 cells, strong fluorescent signals were observed, whereas no detectable signals were found for the CD44-deficient NIH3T3 cells (Fig 2a and b). Finally the GICs selectively accumulated at the tumor site after systemic administration into tumor-bearing mice ( Fig 2c and d).

## CONCLUSION

GICs were prepared and investigated as siRNA carriers for efficient delivery. The results suggested that GICs had outstanding stability and high tumor targetability through receptor-mediated endocytosis. Consequently, the GICs exhibited excellent *in vivo* gene silencing efficiency.

## INTRODUCTION

Elastin-like recombinamers are natural elastin derived polypeptides with growing applications in the biomedicine fields<sup>1-3</sup>. The use of genetic engineering techniques allow the total control over their chemical and physical features such as surface charge, polydispersity, self-assembly and biocompatibility. The design of positively charged ELR to complex plasmatic DNA is essential to trigger the formation of structures called polyplexes. MUC1 glycoprotein is aberrantly overexpressed in breast cancer<sup>4</sup>. In this study, the functionalization of polyplexes with MUC1 aptamers is carried out and their ability to target MUC1 expressing tumor cells is tested.

## EXPERIMENTAL METHODS

Genetic engineering techniques were utilized to design the ELR whereas production and purification methods were used as described elsewhere<sup>5</sup>. The incorporation of aptamers to polyplex was assessed at different ratios N/P/Pap by size, zeta potential and TEM analysis. Biocompatibility assays were accomplished with MCF-7 (MUC1 +) and HepG2 (MUC1 -) tumor cell line and transfection assays were accomplished also with normal cells such as MSC, HUVEC and HFF-1.

## RESULTS AND DISCUSSION

The ELR was designed, produced in *E. coli* and characterized by chemical and physical methods. MUC1 aptamers were bound to the polyplexes at different ratios where the size and zeta potential was measured. The selected ratio for the polyplex-aptamer complexes had a highly positive zeta potential and an appropriate size for cell uptake.

These complexes were tested *in vitro* in terms of biocompatibility in tumoral cells (MCF-7 and HepG2) and transfection in tumoral and normal cells. The results showed a polymeric based device able to transfect in a specific manner breast cancer cells (Fig.1) and maintain a protective effect over the human normal cells.

Fig.1. Cellular uptake of polyplexes-aptamer with fluorescein-labeled pDNA. (A) Fluorescence microscopy image of MCF-7 treated with polyplexes-aptamer nanoparticles labelled with FITC. Scale Bar corresponds to 50  $\mu$ m. (B) Flow cytometry analysis of treated MCF-7 cells. Black line corresponds to cells incubated with pDNA and blue with polyplexes-aptamer.

## CONCLUSION

We have developed a non-viral gene delivery device formed by ELR and MUC1 aptamers. The resulting polyplexes showed specific uptake in breast cancer cells besides of cytotoxic effect when a plasmid containing the p53 transgene was used. The ELR-aptamer device constitutes a promising strategy in the delivery of therapeutic genes of interest targeted to breast tumor cells.

## INTRODUCTION

Hydroxyapatite (HA) nanoparticles (NPs) have gained intense interest as carriers for gene delivery due to their excellent biocompatibility and good affinity to DNA molecules<sup>1</sup>. Since gene delivery is dependent on cellular uptake, assessment of the interaction of HA NPs with cells is of key concern. Although ionic substitution into HA bulk materials has shown such a vast range of improvements over pure HA in orthopaedic applications<sup>2</sup>, there is very limited data on the effect of HA NPs on cell behaviour for cellular internalization applications. Thus, the main goal of our work is to evaluate the effect of ionic substitution on cell behaviour and ensure optimal design of HA NPs for gene delivery.

## EXPERIMENTAL METHODS

**NPs preparation and characterization:** HA NPs were synthesized at 40°C mixing 100ml of 2.475g Ca(OH)<sub>2</sub> suspension with H<sub>3</sub>PO<sub>4</sub> (0.2mol/L) that was added dropwise (1mL/min) to the above suspension until the pH value was 8. The solution was left overnight for maturation. The precipitate was then washed with milliQ water and freeze dried. To prepare ion-doped HA NPs, the salt of interest (SrCl<sub>2</sub>·6H<sub>2</sub>O, ZnCl<sub>2</sub> or FeCl<sub>3</sub>·6H<sub>2</sub>O) was first mixed with Ca(OH)<sub>2</sub> or H<sub>3</sub>PO<sub>4</sub> (e.g. tetraethyl orthosilicate (TEOS)) before titration. Various salt concentrations ranging from 1-20wt% were explored. Characterization of the NPs comprised X-ray diffraction (XRD), transmission electron microscopy (TEM), Fourier infrared spectroscopy, He pycnometry, N<sub>2</sub> adsorption.

**In vitro cytotoxicity test:** Osteoblast-like MG63 cells and rat mesenchymal stem cells (rMSCs) were seeded onto 96 well plates at a cell density of  $1 \times 10^4$  cells/well and incubated at 37 °C in 5% CO<sub>2</sub> atmosphere for 24h. Afterwards, cells were exposed to NPs (100µg/mL) for 24h in cell culture medium containing or excluding 10% of foetal bovine serum (FBS). Lactate dehydrogenase (LDH) assay was performed to assess cell viability.

## RESULTS AND DISCUSSION

The XRD patterns indicated that all NPs were phase pure as only peaks corresponding to HA were detected (Fig.1). The diffraction peaks showed a gradual shift to higher or lower 2θ angles depending on the degree of substitution and the doping ion, proving their incorporation. TEM images (Fig.1) showed that doping had little influence on the morphology of NPs as in all cases they kept their needle like structure.

Fig.1 XRD patterns and TEM images of the different NPs.

LDH results showed that the various ion-doped HA NPs did not produce any cytotoxic effect in MG63 cells if FBS was present in the culture medium (Fig. 2). However, when FBS was excluded, Zn- and Fe-doped HA NPs induced a significant increase in MG63 cells proliferation, while Sr-doped HA caused a slight decrease in the cells viability. Interestingly, unlike for MG63 cells, there were no significant differences in rMSCs cells viability that could be attributed to the presence of the different ions (Fig. 3).

Fig. 2 Cytotoxic effects of NPs on MG63.

Fig. 3 Cytotoxic effects of NPs on rMSCs.

## CONCLUSIONS

Ionic substitutions in HA NPs have been shown to play a major role in cell behaviour depending on cell type. The noticeable increase in cell proliferation for Zn- and Fe-doped NPs can be foreseen to have great potential for gene delivery.

### INTRODUCTION

Trimethyl chitosan (TMC) has been described as a promising gene delivery vector for biomedical applications<sup>1</sup>. In the design of non-viral vectors for gene therapy, biomaterial degradation and the fate of the resulting by-products are important features that must be taken into consideration. TMC enzymatic biodegradation occurs between acetylated monomers and is mostly affected by the degree of acetylation (DA)<sup>2</sup>. In this work, we investigated the impact of the DA on the enzymatic degradation and biological performance of TMC-based nanoparticles, exploring top-notch bioimaging techniques as imaging flow cytometry.

### EXPERIMENTAL METHODS

TMC with 43.3 kDa, 11% DA and 30% degree of quaternization (TMC<sub>11</sub>) was used as starting material. TMC<sub>11</sub> was deacetylated and subsequently re-acetylated to achieve polymers with different DAs<sup>3</sup>. TMC:pDNA nanoparticles with different N/P ratios (moles of quaternized amines:moles of phosphate groups) were prepared in 20 mM HEPES buffer with 5% (w/v) glucose at pH 7.4. To evaluate TMC nanoparticle enzymatic degradation, an enzymatic competition assay was performed, where chitosan with the same molecular weight was used as control<sup>3</sup>. Nanoparticles internalization profile, as well as nanoparticle-loaded vesicles (NLVs) and pDNA nuclear localization were evaluated by imaging flow cytometry between 0.5 to 24 h of incubation with ND7/23 cells (neuronal cell line). Data has been confirmed by TEM (transmission electron microscopy) analysis (TMC being labeled with quantum dots and DNA with gold nanoparticles). Finally, the impact of nanoparticles biodegradation rate on transfection efficiency was assessed 72 h post-transfection, using eGFP as reporter gene.

### RESULTS AND DISCUSSION

TMC<sub>11</sub> was successfully deacetylated (DA 2%, TMC<sub>2</sub>) and subsequently re-acetylated (DA 17%, TMC<sub>17</sub>), with no significant alteration to the polymer molecular weight (confirmed by GPC). TMC:pDNA complexes were efficiently prepared (>95% of complexation efficiency), with an average diameter of 200 nm at physiological conditions, irrespectively of the N/P ratio and polymer DA. No major differences were observed between the different TMC nanoparticles in terms of internalization profile, neither in the number of particles bounded to the cell membrane or cytoplasm localized

nanoparticles. However, when considering the number of NLVs per cell or the percentage of pDNA nuclear localization one observed significant differences between TMC's. TMC<sub>11</sub> nanoparticles are present in a higher amount of vesicles in the initial time-points and then the number NLVs decreases significantly, suggesting that these nanoparticles are being released to the cytoplasm (confirmed by TEM). Regarding nuclear pDNA localization, a significant difference was seen between TMC's, with TMC<sub>11</sub> and TMC<sub>17</sub> mediating the delivery of a higher quantity of pDNA to the cell nucleus. In terms of transfection efficiency, TMC<sub>11</sub>-based nanoparticles promoted the higher transfection efficiency (>20% of transfected cells). These results suggest that the biodegradation rate of these nanoparticles affects their intracellular trafficking and pDNA protection capacity and, consequently, their efficiency to transfect cells. Taking this into account, we are currently characterizing the nanoparticle intracellular track conducting confocal microscopy studies in which we labeled both nanoparticles (polymer and pDNA) and vesicles from the endocytic pathway (endosomes/lysosomes) to further dissect the mechanisms ruling nanoparticle mediated pDNA delivery.

Figure 1. Representative images from imaging flow cytometry - ImageStream<sup>X</sup>. (A) pDNA from nanoparticles was labeled with YoYo-1. In blue are represented masks defined by the user that identify the cell membrane and cell cytoplasm; (B) Quantification of Nanoparticle-loaded vesicles per cell.

### CONCLUSION

TMC nanoparticle biodegradation is influenced by the polymers DA. The 24 h bioimaging study of the nanoparticles intracellular route disclosed important data about the process of intracellular trafficking indicating that biodegradation, hence associated DNA availability, is a key feature for the overall transfection process.

## INTRODUCTION

Cervical cancer has the second highest mortality rate amongst women worldwide, despite the production of recombinant protein HPV vaccines. Limited access in poorer regions, the prophylactic nature of current vaccines and poor patient compliance contribute to a rising incidence. Furthermore, the current vaccine is not effective for those patients with pre-existing HPV lesions. There is a critical need for a more potent vaccine that can be self-administered. DNA vaccination evokes both therapeutic and prophylactic responses.<sup>1</sup> The bottleneck in the DNA vaccination market lies in an effective delivery technology. The 'solution' to this problem is in the two-pronged approach of our technology; i) a peptide delivery system, termed RALA, that is able to wrap the DNA into nanoparticles, protect the DNA from degradation, enter cells, disrupt endosomes and deliver the DNA to the nucleus ii) a microneedle patch (MN) that will house the nanoparticles within the polymer matrix, painlessly breach the skin's stratum corneum barrier and dissolve upon contact with skin interstitial fluid thus releasing the nanoparticles into the skin to the antigen presenting cells. Using our novel technology platform we have created a DNA vaccine for cervical cancer in a dissolvable microneedle patch. More specifically the MN patch is loaded with RALA/E6-E7 nanoparticles and this study demonstrates stability, functionality and a prophylactic and therapeutic response to cervical cancer tumours *in vivo*.

## EXPERIMENTAL METHODS

The RALA/E6/E7 nanoparticles were characterized in terms of gel retardation, size and zeta-potential analysis and transmission electron microscopic imaging. The functionality of the RALA/E6-E7 nanoparticles within the polymeric microneedle matrix was assessed by analysis of transfection efficacy in fibroblast NCTC cells via western blot analysis. Cellular toxicity was also assessed via WST-1 assay. Balb-C mice were immunized with the RALA-E6/E7 in a prime-boost-boost regimen and blood serum was isolated to measure specific IgG responses and IFN- $\gamma$  levels via ELISAs. Balb-C mice were also immunised with the MN-RALA/E6-E7 patches and challenged with cervical cancer. A therapeutic response study was performed *in vivo*. Finally the RALA/E6-E7 nanoparticles were lyophilised to increase the dose that can be loaded into the MN patch. This was also evaluated *in vivo*.

## RESULTS AND DISCUSSION

The RALA/E6-E7 nanoparticles had a positive zeta-potential, particle diameter <50 nm and TEM

confirmed their spherical shape. These are all optimal characteristics for successful cellular transfection. These DNA-containing nanoparticles were combined with a rapidly dissolving poly(vinylpyrrolidone) polymeric microneedle delivery platform. Results proved that RALA was essential for stability of the E6-E7 DNA in PVP (Fig.1) and that MN-RALA/E6-E7 evokes a more consistent humoral mediated immune response (Fig. 2). Tumour challenge studies indicate the MN-RALA/E6-E7 vaccine patch is preventing the uptake of tumours and treating established tumours. Lyophilisation studies are ongoing and the dose that can be delivered from one patch is currently at 50  $\mu$ g.

**Fig. 1.** Functionality of the RALA/E6-E7 following release from 20% PVP MNs. MNs were dissolved and added to NCTC cells. 24 h later protein was analysed.

**Fig. 2.** Detection of E6/E7 specific IgG levels following booster immunisations in Balb-C mice. (Naked E6/E7, NPs delivered IM or via MN patches)

## CONCLUSION

We have created a fully functional prototype MN/RALA/E6-E7 DNA vaccine for cervical cancer.

## INTRODUCTION

Biomaterials capable of both enhancing cell adhesion and delivering controlled quantities of bioactive agents, while maintaining mechanical integrity, represent a significant challenge, but also an excellent opportunity toward a variety of cell contacting applications. We propose two new thin film biomaterials, one that contains a reservoir for biomolecules, such as growth factors, for an efficient local and controlled release of biomolecules, and one that is formed from biomolecules from the extracellular matrix, such as fibronectin, in order to mimic the extracellular environment and promote cell behavior.

## EXPERIMENTAL METHODS

Thin films are formed by the layer-by-layer assembly of poly(L-lysine) and poly(L-glutamic acid) or Fibronectin. Carboxy-functionalized latex nanoparticles (25 nm) are incorporated as template. Films are cross-linked (EDC/NHS) to increase mechanical rigidity. Tetrahydrofuran (THF) is used to dissolve nanoparticles and create porous films to enable loading of bioactive species, as BMP2.

## RESULTS AND DISCUSSION

We describe here two strategies to control cell behavior. First, a nanotemplating strategy toward porous, polyelectrolyte-based thin films capable of controlled biomolecular loading and release is presented. Films are formed via the layer-by-layer assembly of charged polymers and nanoparticles, chemically cross-linked to increase mechanical rigidity and stability, and finally exposed to tetrahydrofuran to dissolve the NP and create an intra-film porous network<sup>1</sup>. We report here on the loading and release of the growth factor bone morphogenetic protein 2 (BMP-2), and the influence of BMP-2 loaded films on contacting murine C2C12 myoblasts.

We observe nanotemplating to enable stable BMP-2 loading throughout the thickness of the film, and find the nanotemplated film to exhibit comparable cell adhesion, and enhanced cell differentiation, compared to a non-porous cross-linked film (where BMP-2 loading is mainly confined to the film surface)<sup>2</sup>.

The second strategy involves the direct incorporation of the extracellular matrix protein Fibronectin (Fn) during film construction, in order to mimic the extracellular environment and influence the cell behavior. Fn serves as the anionic polymer during layer-by-layer assembly. We investigate the influence of Fn on film construction and physicochemical and mechanical properties, and the influence of Fn containing films on pre-osteoblastic cells. We observe Fn-based thin films to enhance cell adhesion, spreading and proliferation compared to a Fn monolayer, and Fn present in the films to be structurally reorganized by contacting cells.

## CONCLUSION

We engineer, design and construct bioactive thin films biomaterials able to direct the behavior of contacting cells. Nanotemplated polyelectrolyte films can be employed to spatially and temporally release bioactive molecules, such as as BMP2. Fn incorporation within layer-by-layer films leads to Fn-rich films, which enhance cell adhesion, spreading and proliferation compared to a standard 2D Fn layer.

## INTRODUCTION

Matrix Metalloproteinases (MMPs) are a family of zinc-dependent endoproteinases found within the extracellular matrix of vertebrates<sup>1-3</sup>. Besides their physiological role in degrading major structural tissues, they have been linked to pathological processes such as arthritis<sup>4</sup> and skin ulceration<sup>5</sup>. Although the specific catalytic bond scissile mechanism is understood, crystallographic data suggest that the active site is too narrow to encompass a collagen protein. Either MMP adjusts to encompass the width of the collagen protein<sup>6</sup> or the collagen protein uncoils locally near the active site to facilitate insertion and cleavage<sup>7</sup>. We present a Molecular Dynamics (MD) study on the structural properties of a full MMP1-collagen crystallographic structure (4AUO)<sup>8</sup>, whilst exploring the thermodynamic properties of *opening* the active site entrance with and in the absence of collagen. Finally, we map the Free Energy Surface (FES) of the collagen along a set of collective variables (CV) used to facilitate uncoiling and insertion of collagen into the active site.

## EXPERIMENTAL METHODS

The crystallographic geometry was parameterised using the Amberff99SB force field and implemented into Gromacs. The collagen-MMP1 complex was fully solvated and maintained a neutral charge. Partial charges on the two zinc atoms and coordinating side chains were derived from electron structural calculations using PyRED. The collagen-MMP1 complex was equilibrated following a steepest descent energy minimisation by progressively reducing protein backbone restraints over 10 ns. Restraints were removed and the system was allowed to evolve for 50 ns. Meta-dynamics were performed using PLUMED. Gaussian potentials were added over a set of collective variables every 500 MD steps.

## RESULTS AND DISCUSSION

Our MD trajectory demonstrates a stable MMP1 secondary structure with little in the way of deviation from the initial crystal structure. We observed two distinct polar ridges on the MMP1 active site, which are seen to interact with the collagen backbone and thought to keep the substrate bound. Distance based CVs were used to encourage sampling of an *open* active site conformation. After 30 ns, a converged lone deep energy-well in the FES (Figure 1.) of unbound MMP1 suggests a preferable *neutral* active site conformation. Furthermore, when collagen was introduced, an

independent calculation yielded a similar singular FES energy-well also suggesting a preferable *neutral* conformation. Upon observation, as the cavity widens in sync with the increase in free energy, potential hydrogen-bonds separate resulting in a clear disruption to collagen binding. Finally, coercion of collagen local to the active site to uncoil and insert into the cavity along CVs is considered to be energetically favourable.

Figure 1. FES of unbound MMP1 along two distance CVs defined at the entrance of the active site.

## CONCLUSION

Our work is the first to map potential hydrogen-bond interactions between collagen and MMP1 from an MD trajectory of the crystal structure. We observed persistent interactions between enzyme and substrate and a single conformation for the active site. The insertion of a lone collagen peptide into a *neutral* active site may further the argument for a localised uncoiling mechanism.

## INTRODUCTION

The success of a surgical implant is dependent on an appropriate biological response to the implant surface<sup>1</sup>. Wound healing around implants is a complex process in which water molecules from the surrounding blood first come in contact with the surface. In the next step, ions and blood proteins adsorb and a fibrin network is formed, before osteoblastic cells respond to the protein-covered surface<sup>2</sup>.

Blood protein adsorption and blood coagulation are greatly influenced by the topography of titanium surfaces<sup>3,4</sup>, which may further impact the eventual adhesion, migration and differentiation of primary human osteogenic cells on a titanium implant. It is therefore of major importance for implantology to understand the early interaction between blood and the implant and how this further steers osseointegration.

Roughness gradients are a very promising tool to investigate the effect of surface topography on a biological system, as a wide range of parameters can be explored in a single experiment. Additionally, homogenous conditions are ensured during all measurements<sup>5,6</sup>.

## EXPERIMENTAL METHODS

To study the effect of nano-roughness on protein adsorption and blood coagulation, nanoparticle density gradients were fabricated. The gradients were exposed to protein mixtures or single protein solutions. The adsorption of specific proteins in the solution was studied by fluorescent labelling of individual proteins (albumin, fibrinogen or fibronectin). To achieve an easy and rapid data read-out, a fluorescence micro-array scanner was used to map all adsorbed proteins.

In the second step, the same gradients were used to study blood coagulation by incubation of the gradients for 2 to 10 min with partially heparinized (0.5 IU/ml) whole human blood from healthy volunteers. The formation of the blood clot was investigated by scanning electron microscopy and fluorescence microscopy.

## RESULTS AND DISCUSSION

Gradients with particles of different sized diameters (12, 39 and 72 nm) were tested. The protein-adsorption experiments showed no significant influence of nano-features on protein adsorption for gradients with 39 and 72 nm nanoparticles. On the contrary for 12 nm gradients, fibrinogen in competition with albumin and fibronectin or serum, showed a higher adsorption in the high-particle-density region of the gradient (see Figure 1).

Fig. 1: Albumin and fibrinogen adsorption on 12 nm gradient.

In Figure 2 SEM images taken every 2 mm along a 12 (a) and 39 (b) nm nanoparticle density gradient following a 5 min blood-incubation experiment are presented. It is clearly visible that the appearance of the blood-surface interaction changes along the particle-density gradient. For the 39 nm gradient, coagulation/fibrin formation was observed everywhere on the sample, a denser fibrin network could be detected towards the high-density end of the gradient. For the 12 nm gradient, a similar trend but in an earlier stage of fibrin network formation is visible. High-density nanostructures seem to have an accelerating effect on the fibrin-network forming process.

Fig. 2: SEM images taken every mm along nanoparticle density gradient. a) 12 nm gradient and b) 39 nm gradient after incubation for 5 min in whole human blood.

## CONCLUSION

Nanostructures were shown to enhance blood coagulation, but appear to have only little influence on protein adsorption from solutions. This study suggests that implant surfaces with a high-density nanostructure show improved blood clot formation and should therefore enhance osseointegration.

## INTRODUCTION

The extracellular matrix (ECM), which provides physical and (bio)chemical cues for the regulation of cell behavior, presents a complex structure on the micro- and nanoscales. The creation of environments mimicking the ECM is a challenge of importance in biomaterials science and tissue engineering. Type I collagen, a self-assembling protein, is one of the main components of ECM, and provides adhesion signals to cells. The supramolecular organization of collagen at interfaces is known to depend of the physico-chemical properties of the substrate, including its wettability<sup>1</sup>. The aim of the present work is to create a variety of biointerfaces with different supramolecular organizations of type I collagen, obtained by collagen adsorption on chemically heterogeneous substrates. Then, the behavior of preosteoblasts cultured on the designed biointerfaces is investigated.

## EXPERIMENTAL METHODS

**Preparation of organized collagen layers:** Polymer demixing upon spin-coating was used to create surfaces containing hydrophobic inclusions in a more hydrophilic matrix or conversely, to further create heterogeneity in the supramolecular organization of adsorbed collagen. The immiscible polymers used for demixing were polystyrene (PS) and poly(methyl methacrylate) (PMMA). Several polymer concentration ratios and solvents were tested to obtain a range of substrates showing different nanoheterogeneities. Collagen adsorption was then performed on homogeneous and heterogeneous substrates by immersion for 2 h in 30 µg/ml collagen solution in phosphate buffer. The topography of the surfaces obtained before and after collagen adsorption was assessed by atomic force microscopy (AFM), while their surface chemical composition was determined using X-ray photoelectron spectroscopy.

**Cell culture:** A murine osteoprogenitor cell line, MC3T3-E1, was cultured on the created protein layers. Cell morphology and density were investigated after 4h and 6 days in serum-containing medium, using fluorescence microscopy (actin, nucleus and vinculin labeling).

## RESULTS AND DISCUSSION

After spin-coating of several PS/PMMA blends, four interesting substrates were identified: substrates with PMMA inclusions in a PS matrix, and conversely, substrates with PS inclusions in a PMMA matrix, the inclusions being either under the form of pits or islands. The obtained surface morphologies could be linked to the respective solubility of the polymers in the solvents used.

The organisation of collagen layers was different

depending on the nature of the polymer substrate (Figure 1): the layer was quite smooth on pure PMMA, while large assemblies were found on pure PS. Collagen adsorption on heterogeneous substrates led to surfaces presenting a heterogeneous distribution of collagen. The more the substrate contained PS, the more the collagen layer contained fibrils. Moreover, when PS domains size was lower than ~600 nm, assemblies larger than the ones observed on pure PS were formed<sup>2</sup>.

Figure 1. AFM images showing collagen organization on PS/PMMA blends, in function of PS surface fraction (from left to right: 0, 15, 21, 64 and 100 % PS)

MC3T3-E1 cells adhered on all collagen-coated surfaces. Cell density remarkably increased on heterogeneous surfaces compared to homogeneous ones, especially when very large collagen fibrils were present. Besides, the observed cell morphologies were also different depending on the biointerface architecture. Quite small and round cells were found on the smooth collagen layer formed on PMMA, while cells were bigger and more elongated on the collagen fibrils found on PS. Intermediate cell morphologies were observed on the heterogeneous PS/PMMA surfaces after collagen adsorption.

After 6 days, remodeling of the collagen layer probably occurs, and while a strong effect of substrate heterogeneity is still observed, the same effect is also found on the naked substrates, in absence of collagen.

## CONCLUSION

The present work demonstrates that chemical and topographical nanoheterogeneities, obtained by polymer demixing, interfere with collagen adsorption. The protein layer organization (smooth layers vs supramolecular assemblies; size of assemblies) is indeed altered by the presence of domains of different chemical nature (PMMA vs PS) at the surface of the substrate used for adsorption. Culture of preosteoblasts highlights major differences between cell behaviors observed on the different biointerfaces obtained by collagen adsorption on pure PMMA, PS/PMMA heterogeneous surfaces, and pure PS. A better control of cell-material interaction may thus be obtained through tailoring of ECM protein layers.

**The oxygen plasma functionalization of parylene C implant coating leads to nanoroughness generation and insertion of oxygen groups. It is a tool for tuning the physicochemical properties, biocompatibility and provides the possibility of further biofunctionalization. The oxygen plasma treatment significantly influenced the chemistry and physical properties of the polymer becoming an effective tool in surface preparation for the better osteoblast-like cells adhesion. At the same time it did not stimulate bacterial growth.**

### INTRODUCTION

Parylene C is an excellent protective coating material for metal implants due to its *in vivo* compatibility, mechanical properties and stability in body fluids<sup>1</sup>. However, for better adhesion of the osteoblast-like cells, parylene C surface must be modified via insertion of functional groups<sup>2</sup>. Low pressure oxidative/reductive plasmas are considered as a universal tool for such surface treatment<sup>3</sup>. Moreover, by precise adjustment of the plasma parameters (power, exposition time, oxygen partial pressure), the surface can be modified in a controlled way<sup>2</sup>. The aim of this study was to investigate the influence of oxygen plasma treatment on the surface functional properties of parylene C coating. The general strategy of preparation of the multilayer therapeutic coating based on functionalized parylene C is presented in Fig.1. The polymer coating was thoroughly characterized in terms of structure and nanoscale morphology (XRD, AFM, E-SEM), surface composition (XPS, LDI-MS, contact angle, TG/DTA) and biofunction such as biocompatibility (MG-63 cells) and microbiological tests (*S. aureus*, *S. epidermidis*, *P. aeruginosa*).

### EXPERIMENTAL METHODS

Parylene C films were prepared by CVD technique (ParaTech Coating Scandinavia AB). In order to modify the parylene C surface, the oxygen plasma treatment was carried out using a Diener electronic Femto plasma system. The morphology of the samples was investigated using E-SEM (Quanta 3D FEG) and AFM (Park Scientific Instrument Autoprobe CP II). The changes in chemical composition were observed using XPS (XPS-UHVS with SES R4000, Al K $\alpha$ ) and LDI-MS (Bruker UltraFlex TOF with SCOUT-MTP).

### RESULTS AND DISCUSSION

The strong effect of oxygen plasma treatment on parylene C topography and chemical composition was observed. The unmodified parylene C is smooth, but after the plasma exposure it becomes

corrugated with large irregularities of the order 40-60 nm in depth and 200-300 nm in width as revealed by AFM and E-SEM. The XPS and LDI-MS results clearly indicate the insertion of oxygen into the parylene C surface after the plasma treatment. The identified oxygen-containing groups were -COOH, -COH, -OH. The observed changes have significant impact on the wettability and surface free energy of parylene C. The water contact angle ( $\theta_w$ ) of the unmodified parylene C is  $\sim 90 \pm 2^\circ$ , immediately after plasma modification the  $\theta_w = 0^\circ$  and after 24h it slowly grows up to  $\theta_w = 50^\circ \pm 5^\circ$ , never reaching the value of the untreated, hydrophobic samples. In order to evaluate the biological response of the obtained surface, MG-63 cells and microbiological tests were carried out. There was a significant increase in the number of adhered cells and their surface area on the oxygen plasma modified parylene C. It was found, that the most suitable for cells adhesion is the surface exposed to oxygen plasma with the optimized parameters ( $p = 0.2$  mbar,  $P = 50$  W and  $t = 10$  min). The microbiological results did not indicate any significant changes in the bacteria attachment between the unmodified and the oxygen plasma treated parylene C.

Fig. 1 The general strategy pathways of the preparation with dedicated experimental methods of the multilayer therapeutic coating based on functionalized parylene C

### CONCLUSION

Oxygen plasma treatment is an efficient technique for the surface functionalization of parylene C protective films. The oxygen insertion into the polymer surface provides a suitable platform for the osteoblast-like cells and further functionalization such as bonding of drug-loaded nanoparticles or biodegradable polymer

## INTRODUCTION

The main challenge for tissue engineering is to produce 3D tissue equivalent of macroscopic dimension. The greater problem related to it, is due to oxygen supply within three-dimensional cell culture system in order to obtain no necrotic zone inside the final tissue equivalent. In an effort to enhance oxygen delivery, we report the feasibility of using a new oxygen depot capable to release oxygen under hypoxic conditions by conjugating of human haemoglobin (Hb) to gelatine microspheres.

## EXPERIMENTAL METHODS

Biodegradable gelatine micro-beads (GM) were obtained by an emulsion process [REF]. To realize the Hb-based oxygen micro carriers (HbOC), the Hb were conjugated to GM by means of two-step reaction: (i) firstly a polyurethane spacer was added to GM surface and then (ii) Hb was linked to the spacer. GM functionalization has been studied by means of FTIR and HPLC and UV-vis analysis. In order to study the oxygen storage/release capability of the HbOC in *in vitro* 3D tissue culture, HbOC were loaded in rat tail collagen / NIH system and cultured statically for up to 72 h. Three experimental configurations has been explored: (a) collagen / NIH; (b) collagen / NIH / GMs; (b) collagen / NIH / HbOC. Cells viability profile and cell proliferation rate were evaluated by immunofluorescence and used as index of HbOC functionality in the 3D cell culture.

## RESULTS AND DISCUSSION

Prior to be used in 3D cell culture we demonstrated the capability of HbOC to work as a system able to catch oxygen from the surrounding saturated environment. HbOC was then able to release the captured oxygen when kept under hypoxic environment until equilibrium condition. Static 3D cell culture was used as model to assess the capability of the HbOC to work in hypoxic biological environments. The cell viability profile within the systems Collagene/NIH, Collagene/NIH/GMs and Collagene/NIH/HBOCs, was evaluated. In Fig. 1 are reported the reconstructed sections (0.4mm x 2mm) of the Collagen/NIH system at 0h and 72 h (A-B), and Collagen/NIH/HBOC (C-D). At 0h it was observed a uniform cell distribution and low amount of died cells, compared with the number of living cells. The fraction of living cell ( $\phi$ ), as a function of the thickness (Fig. 2), was used to compare the cell viability profiles at each culture time (0, 24, 48, 72h). At time 0, no variation of  $\phi$  was observed along the sample thickness (100% viability) and no differences were found between the three experimental configurations. For the other time points, in both

systems Collagen/NIH and Collagen/NIH/GM, no difference are detected, while for the Collagen/NIH/HBOC system, the cell viability fraction was found to be statistically higher than in the control systems (Collagen/NIH and Collagen/NIH/GM). The decrease in the cell viability in the system Collagen/NIH/HBOC was due to the total cell proliferation. Indeed, in the Collagen/NIH and Collagen/NIH/GM system, cell density reached a plateau value. In contrast, in the Collagen/NIH/HBOC system the cell density continued to increase up to 72h. Such increase in the total cell number led to an increase in the metabolic request and the cell viability decreased due to insufficient oxygen supply.

FIG.1 3D cell culture in collagen gel: Coll + NIH3T3 (left); Coll + NIH3T3 + HBOC (right)

FIG.2 Cell viability profile within 3D cell culture at different culture time

## CONCLUSION

In this work we demonstrated the capability to develop an hemoglobin-based oxygen carrier able to overcome the oxygen transport limitations in 3D static culture up to 72h. Such oxygen releasing microcarriers can be either loaded inside hydrogel scaffolds or can be sintered to build up a oxygen releasing porous scaffold.

## INTRODUCTION

Biocompatible Polyurethane (PU) is used routinely in biomedicine and tissue engineering as heart valves, blood contacting catheters and bio membranes due its excellent tissue and blood compatibility<sup>1</sup>. To ensure patency in any given application biodegradation, elasticity and responsiveness to physiological cues such temperature, pH needs to be optimized and continues to remain a significant challenge.

In this work we introduce a family of segmented polyurethanes (SPUs) that incorporate many of the aforementioned properties in a single system. A high degree of customization in properties was achieved by judicious choice and chemical tailoring of hard segments derived from biodegradable poly(hydroxy acid) (PHA), in combination with an inorganic polymer that imparts flexibility and elasticity<sup>2</sup>. Using this novel polymer architecture, properties such as shape change in physiological temperature range, and mechanical properties that match natural cardiovascular tissue components could be realized.

## EXPERIMENTAL METHODS

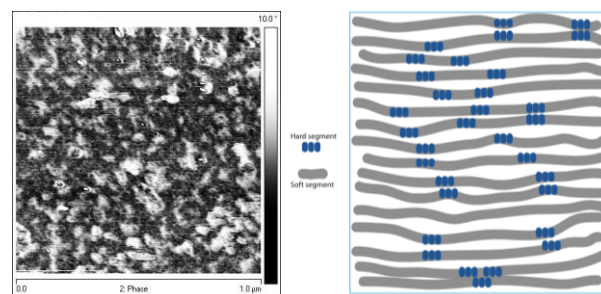

**Polymer Synthesis:** The SPUs were synthesized by polycondensation of PHAs of well-defined MW and narrow polydispersity with hexamethylene diisocyanate. PHAs were synthesized by ring opening polymerization (ROP) of either lactide or glycolide using inorganic polymer initiator blocks.

**Analytical Techniques:** *Nuclear Magnetic Resonance* (NMR) (<sup>1</sup>H and <sup>13</sup>C) and *Fourier Transform Infra-red Spectroscopy* (FTIR) were used to confirm the chemical structure and incorporation of different segments in the polymer backbone. *Thermogravimetric Analysis* (TGA) and *Differential Scanning Calorimetry* (DSC) were used to determine thermal stability, processing temperature, and glass transition temperature (*T<sub>g</sub>*) respectively. Elastic modulus and elongation at breakage were determined using tensile test. *Atomic Force Microscopy* (AFM): Cryo-fractured interface of SPU block were analyzed using tapping mode AFM.

## RESULTS AND DISCUSSION

The chemical architecture of the SPU was confirmed using <sup>1</sup>H- and <sup>13</sup>C-NMR. Additionally, the vibrational and stretching bands associated with the PHA and inorganic domains were confirmed by FTIR. By using PHA segments of different molecular weights (initiator:lactide ratio 1:1, 1:1.5 and 1:2) SPUs that exhibit phase-separated microstructure were realized. The Atomic force micrograph of 1:1 SPU (**Figure 1**) revealed a bulk phase-separated microstructure. These

SPUs show high thermal stability up to 300 °C making them suitable for melt processing. By optimizing the

**Figure 1:** AFM image of a typical SPU surface showing phase

PHA and inorganic polymer component in the polymer backbone, SPUs with glass transition temperatures at, below and above 37 °C could be synthesized, thus making them suitable for manipulation in physiological conditions. By controlling the lactide composition the mechanical properties of the SPUs could also be tuned

**Figure 2:** Tunability of mechanical properties in SPUs

(**Figure 2**). SPUs investigated having Young's modulus in the range of 80 – 800 MPa, with elongation at break as high 37%. Ongoing degradation studies have shown that these SPUs undergo

degradation in physiological conditions while retaining their mechanical properties.

## CONCLUSION

Degradable, thermoplastic polymers with high-content (≥ 50 weight %) PHA, showing excellent mechanical and elastic properties has been synthesized. Currently, they are being optimized for implementation in temperature triggered cardiovascular implants.

### INTRODUCTION

Protein-bound toxins are difficult to remove by conventional dialysis, while their accumulation plays an important role in uremic complications, in particular in cardiovascular disease.

Previously we showed that protein-bound toxin removal can be improved by use of a mixed matrix membrane (MMM)<sup>1</sup>. This membrane consists of 2 layers: an outer layer with adsorptive particles incorporated in a porous polymer and a particle-free hemocompatible inner layer (see figure 1). The double layer concept of MMM combines benefits of adsorption and diffusion and thus boosts removal of uremic toxins. The first generation MMM showed a potential for improved protein bound toxin removal, but had relatively large dimensions with a diameter of 984  $\mu\text{m}$ .

In this study we develop new generation MMM with diameter comparable to conventional dialysis membranes, with improved mass transfer characteristics.

smaller modules with excellent clearance of uremic toxins can be produced.

Figure 1 – A and B show first generation MMM. C and D show new fibers with reduced diameter.

### EXPERIMENTAL METHODS

The inner and outer layer of hollow fiber MMM were produced from a polyethersulfone / polyvinylpyrrolidone polymer blend. Activated carbon was loaded in the outer polymer matrix layer for adsorption of protein-bound toxins. The membranes were characterized by scanning electron microscopy (SEM) and clean water flux and dialysis/adsorption experiments were with plasma spiked with uremic concentrations of the protein-bound toxins indoxyl sulfate (IS) and p-cresyl sulfate (pCS), and ultrapure water dialysate.

### RESULTS AND DISCUSSION

By optimizing spinning conditions we produced fibers with an inner diameter of 450  $\mu\text{m}$  and inner membrane layer thickness of 21  $\mu\text{m}$  (Figure 1C and 1D), which is markedly smaller than previously reported MMM fibers (Figure 1A and 1B). Clean water permeability of the newly fabricated is close to the permeability of conventional low flux dialysis membranes, and 20 times lower than first generation MMM. The adsorption of IS and pCS per gram of membrane is ~3-4 times than that of previously reported MMM. These results suggest that

### CONCLUSION

Due to lower mass transport resistance, smaller diffusion length and increased surface to volume ratio new MMM with smaller diameter and thinner inner membrane layers show improved removal of protein-bound toxins.

### INTRODUCTION

Constructs developed for tissue engineering present very limited potential due to massive death of transplanted cells after engraftment into the tissue-construct. This issue can be overcome by *in situ* supplying glucose that acts as the main metabolic fuel for Mesenchymal Stem Cells (MSCs) in severe hypoxia and significantly enhances their survival<sup>1</sup>. In this study, a composite construct is engineered to provide sufficient level of glucose to MSCs and to enhance their survival and function when transplanted in the ischemic milieu *in vivo*. Two combined strategies are developed. The glucose leakage outside the tissue construct is limited/delayed by increasing the intrinsic viscosity of the aqueous phase of the fibrin hydrogels by supplementation with starch. The starch polysaccharide alternatively serves as the main reservoir and source of glucose. The long-term (weeks) supply of glucose is achieved by designing, preparing and using gels with  $\alpha$ -amyloglucosidase (AMG)-containing poly(lactic-co-glycolic acid) (PLGA) nanoparticles. Sustained delivery of  $\alpha$ -amyloglucosidase into the starch-loaded fibrin gel provides continuous production of glucose *in situ* via the enzymatic hydrolysis of starch.

Schematic representation of the composite construct.

### EXPERIMENTAL METHODS

hMSCs were isolated from the bone marrow samples obtained as discarded tissue during routine bone surgery at the Lariboisiere Hospital (Paris, France) as previously described. AMG-containing PLGA nanoparticles (NPe) are prepared using a double emulsion technique previously described<sup>2</sup>. Gels are prepared as follow. Starch, human fibrinogen, AMG-containing PLGA nanoparticles, and hMSCs are mixed together. Human thrombin is subsequently added. The polymerization is carried out during 1h at 37°C. Hydrogels are fully characterized, followed and used for *in vitro* and *in vivo* experiments.

### RESULTS AND DISCUSSION

Hydrogels containing fibrin, starch and AMG (free or encapsulated) are self-supported and present a storage moduli superior to 1 kPa. Glucose production and glucose release diffusion kinetics are in accordance with the amount required by the cells for their survey and growth over a month.

Models demonstrated that AMG diffusion outside the gel is non-negligible after 5 days. Entrapping the enzyme into nanoparticles is a suitable way to maintain the enzyme inside the composite.

PLGA particles prepared by double emulsion technique where nearly monodisperse, with nanometric size (average of 280 nm), and a highly efficient encapsulation rate of AMG (~65%). Enzymes containing-nanoparticles are able to progressively produce glucose over a month and allow sustained glucose delivery inside hydrogels.

After 7 days of *in vitro* culture, in the presence of glucose-containing medium, the viability of hMSC was increased 6-fold compared to cells cultured w/o glucose. In presence of both starch and AMG (either within or w/o NP) cell viability was similar than in presence of glucose. In absence of AMG, the hMSC viability dramatically decreased after 14 days of implantation *in vivo* (0.3 to 0.5-fold compare to the signal at day 1). In comparison, in presence of AMG, the hMSC did not only survive but also proliferated within the hydrogels over the 14 day-period of implantation. Incorporation of the enzyme within the NPs further (2-fold) improved the hMSC proliferation.

### CONCLUSION

This work is a proof of concept that an innovative-engineered construct, based on a starch hydrogel containing  $\alpha$ -amyloglucosidase is able to deliver glucose *versus* time. It also represents a highly pertinent system to enhance Human Mesenchymal Stem Cells survival in cell constructs for up to 14 days *in vivo*.

## In Situ Skin Regeneration by the Gene-Activated Materials

Lie Ma, Luyan Li, Xing Liu, Rui Guo, Changyou Gao

MOE Key Laboratory of Macromolecular Synthesis and Functionalization, Department of Polymer Science and Engineering, Zhejiang University, Hangzhou 310027, China

[liema@zju.edu.cn](mailto:liema@zju.edu.cn)

### INTRODUCTION

Skin loss caused by trauma, burn and chronic diseases has become one of the most serious problems in clinic. Recent advances in regenerative medicine have developed diverse methods for skin repair and regeneration<sup>1</sup>. However, there are still many obstacles, such as angiogenesis, hypertrophic scar, and loss of appendix organs, should be overcome to realize the full regeneration as the living skin<sup>2</sup>.

As an important aspect of regenerative medicine, tissue engineering has been brought ever closer to achieve its potential as life-saving and life-improving option for patients. As a general principle of tissue engineering, the scaffold, acting as the artificial extracellular matrix (ECM), should present well-designed multiple chemical, physical and biological cues to build a suitable cellular microenvironment to achieve proper tissue function and regeneration. The spatial and temporal delivery of bioactive molecules (including low molecular weight drugs, peptides, growth factors, cytokines, and mediators for gene therapy) mediated by the scaffold has been the subject of intensive researches<sup>3</sup>. Compared to the instability and high cost of cell growth factors, the gene-activated materials (GAM) which is prepared by loading of functional plasmid DNAs into the scaffolds, can locally transfect cells and produce the required cell growth factors at the wound site<sup>4</sup>. In this study, the gene-activated strategy was applied in the design of the materials for skin regeneration.

### EXPERIMENTAL METHODS

TMC was applied to form nano-sized complexes with pDNA or siRNA. The influence of N/P ratio on particle size, binding affinity and serum stability was assessed by DLS and polyacrylamide gel electrophoresis (PAGE). The TMC/pDNA complexes were then loaded into collagen/chitosan scaffold through physical adsorption. By using Ribogreen staining and PAGE, the release profile of pDNA from scaffold was examined. The successful uptake of the complexes by HDFs in scaffold was confirmed by fluorescent staining. For in vivo study, the gene-loaded scaffold was combined with a silicone membrane to build a bilayer dermal equivalent (BDE) and then transplanted into full-

thickness incisional wounds in a porcine model. Gross observation was performed and tissue samples were harvested on pre-determined time points post-surgery. The levels of the key growth factors were tested by immunohistochemistry, RT-PCR and Western-Blotting.

### RESULTS AND DISCUSSION

Two kinds of gene-activated scaffolds were reported, which were fabricated by incorporating pDNA-VEGF and siRNA-TGF- $\beta$ 1 with the collagen-chitosan scaffold to enhance the angiogenesis and inhibit the scar formation, respectively. Firstly, a gene vector derived from chitosan-trimethyl chitosan was synthesized and used to accelerate the transfection of pDNA and gene-silence of siRNA, respectively. By in vitro and in vivo tests, the properties of enhanced angiogenesis and inhibited scar of the gene-activated scaffold were evaluated. By the combination of gene technologies and stem cells therapy, the possibility of the regeneration of skin appendages by the gene-activated material was investigated.

### CONCLUSION

A gene functionalized bilayer dermal equivalent is fabricated for skin regeneration, with capabilities to up/down-regulate targeted tissue regeneration-related factors and yield a repaired full-thickness skin in pig model with enhanced angiogenesis, successful scarring inhibition and the regeneration of skin appendages.

## Modulation of Inflammatory Macrophage Activation by StarPEG–Heparin Based Hydrogels to Improve Impaired Wound Healing

Nadine Lohmann<sup>1,3</sup>, Elke Wandel<sup>1,3</sup>, Inka Forstreuter<sup>1,3</sup>, Lucas Schirmer<sup>2,3</sup>, Uwe Freudenberg<sup>2,3</sup>, Carsten Werner<sup>2,3</sup>, J.C. Simon<sup>1,3</sup>, Sandra Franz<sup>1,3</sup>

[sandra.franz@medizin.uni-leipzig.de](mailto:sandra.franz@medizin.uni-leipzig.de)

### INTRODUCTION

Impaired wound healing is a problem of immense clinical and economic relevance. Persistent inflammation in impaired wound healing is primarily driven by unresisted inflammatory M1 macrophage (infM1) activation. Therefore, hydrogel-biomaterials capable to bring unopposed inflammation under control by repressing infM1 activity and thus enabling inflammatory resolution represent a promising approach as wound dressings for the treatment of non-healing wounds<sup>1</sup>. Since cellular functions are known to be influenced by physicochemical and biomolecular cues of the extracellular matrix (ECM) hydrogels that are capable to modulate such extracellular signals are of great interest within this context<sup>2</sup>.

Here, we use biohybrid hydrogels composed of four-armed (star-shaped) poly(ethylene glycol) (starPEG) and heparin derivatives varying in their sulfation pattern. Heparin acts as multifunctional cross-linker allowing functionalization of the hydrogels through biomimetic presentation of growth factors. Delivery of pro-angiogenic factors FGF-2 and VEGF by starPEG-heparin hydrogels was shown to encourage angiogenesis<sup>4</sup>. Since both reduction of uncontrolled inflammation and induction of vascularization are suggested to improve an impaired healing response, we tested different starPEG-heparin-based hydrogels with respect to their immunomodulating capacity on infM1.

### EXPERIMENTAL METHODS

Biohybrid hydrogels were prepared by reacting the carbodiimide/N-hydroxysulfosuccinimide (EDC/s-NHS)-activated carboxylic acid group of heparin with amine-functionalized starPEG. Different heparin derivatives were utilized including standard heparin (SH) and two selectively desulfated heparins: N-desulfated heparin (N-DSH) and 6-O/N-desulfated heparin (6ON-DSH). RGD peptides were covalently attached to the hydrogels to provide cell adhesion sites. Inflammatory M1 macrophages were derived from human CD14<sup>+</sup> monocytes by differentiation with GM-CSF for 6 days and subsequently seeded on the different starPEG-heparin-based hydrogels. After 3 days culture on the hydrogels survival (XTT cell viability assay) and adhesion of infM1 were assessed and inflammatory functions (cytokine response) upon stimulation with LPS were determined (ELISA, qPCR). Additionally, interaction of the hydrogels with infM1-derived mediators was analysed in a cytokine adsorption assay.

### RESULTS AND DISCUSSION

StarPEG-heparin-based hydrogels functionalized with RGD adhesion sites promote survival and adhesion of infM1. Inflammatory activation of infM1 was modulated by starPEG-heparin-based hydrogels via two mechanisms: i) downregulation of cytokine expression and release in infM1, and ii) binding of cytokines released from infM1. Interestingly, modulation of the cytokine response is determined by the sulfation level of heparin. Hydrogels based on standard heparin predominantly bind and sequester inflammatory mediators including TNF, IL-12p40, IL-23, IL-8 and MCP-1 released from infM1. In contrast hydrogels based on desulfated heparin derivatives predominantly downregulate production of pro-inflammatory cytokines in infM1 as seen by reduced expression and release of TNF, IL-12p40, IL-23 and MCP-1. However they did not induce expression and release of IL-10, which represents a crucial cytokine for inflammatory resolution.

### CONCLUSION

From these results we conclude that starPEG-heparin-based hydrogels exert anti-inflammatory effects on infM1 and are capable to modulate the cytokine environment of infM1. The immunomodulating capacities of the hydrogels may be fine-tuned by usage of heparin derivatives with adjusted levels of sulfation. We suggest that starPEG-heparin-based hydrogels are capable to modulate unopposed infM1 activity in conditions of chronic inflammation. Inflammatory resolution may be additionally enhanced by delivery of mediators (IL-10/IL-4) promoting regulatory macrophage phenotypes through these hydrogels. We are currently testing immunomodulating effects of starPEG-heparin-based hydrogels in different settings in vivo mice models of impaired wound healing.

### INTRODUCTION

Patients with 50 per cent Total Body Surface Area (TBSA) full-thickness burn wounds have only 50 per cent of undamaged skin left which could be used for split-thickness skin harvesting. Donor sites would add to the total wound size resulting in a wound area covering 100 per cent of the body. Donor sites also heal with some scarring and may be very painful; hence an additional analgesic pharmacological load is required. Moreover, depending on the thickness of the dermis, only three to four split-thickness skin harvests are possible from the same site and re-cropping is delayed by the time necessary for re-epithelialization. Alternative life-saving approaches in the treatment of extensive burn wounds, where donor sites for SSG harvesting are not available, include the use of bioengineered skin substitutes.

The basement membrane of a human skin is a specialized extracellular matrix providing compartmentalization along with cell attachment and signaling factors. The dermal layer comprises mostly of nano/microfibrous collagens while the epidermal layer is a compact sheet of cell layer. For successful development of skin graft, it is important to reciprocate the nano/microscalar architecture of tissue matrix as well as its biological cell recognition character. Nanofiber morphology facilitates good cellular response owing to their high surface area, interconnected pore, simplicity, environmentally friendly nature, cost-effectiveness, scalability and tailorable mechanical properties

### EXPERIMENTAL METHODS

In this study, chitosan/PCL/collagen nano-microfibers were fabricated followed by crosslinking resulting in a highly porous dermal equivalent. The microstructures of samples were evaluated by scanning electron microscopy (SEM). FTIR spectroscopy, mechanical properties, swelling behavior, biodegradation kinetics of matrices was studied for their suitability as skin regenerating scaffold. Normal human fibroblast and keratinocyte were culture and cell adhesion properties were observed through SEM and Rhodamine-DAPI.

Healing of burn wound was tested on rat by wound area closure rate and histochemical analysis

### RESULTS AND DISCUSSION

SEM results showed formation of nanofibrous layer of PCL/chitosan with collagen. The matrices showed swelling of upto 200%, slower degradation rate, high mechanical strength and contact angle of nanofiber is 90°. SEM results showed good cell attachment on nanofiber layer. MTT assay Rhodamine-DAPI staining, assay indicated cytocompatibility of the scaffold. Animal experiment revealed faster healing of burn wound with proper formation of skin tissue with its appendages.

### CONCLUSION

Incorporation of chitosan and collagen increased hydrophilic as well as well degradation rate of the scaffold. Results using primary keratinocyte and fibroblast showed, non-toxic and cytocompatible nature of the matrix. Material characterization yielded definite results proving the scaffolds potential for tissue engineering application specially for healing extensive burn wound.

## INTRODUCTION

Tissue transglutaminase (TGase 2) is known as enzyme with versatile functions depending on its location and conformation, mediating, e.g., crosslinking of proteins through its  $\text{Ca}^{2+}$ -dependent transamidase activity or enhancement of interactions between fibronectin, integrins, and syndecan-4 via its role as scaffold protein. Both functions are proposed to be important for biomaterial-cell or -tissue interactions. Additionally, TGase 2 is a key player during the development of fibrosis. Consequently, TGase 2 is a potential target for the improvement and visualization of tissue regeneration following biomaterial implantation. Here, we studied the expression pattern of TGase 2 in the response to novel gelatin-based hydrogels with tailorable elastic properties and degradation behavior due to different degrees of crosslinking with lysine diisocyanate ethyl ester.

## EXPERIMENTAL METHODS

Solutions of 10 wt.-% gelatin were crosslinked with 3- (G10\_LNCO3) or 8-fold (G10\_LNCO8) excess of isocyanate groups of lysine diisocyanate ethyl ester compared to amino groups of gelatin. Primary human aortic endothelial cells (HAEC) and human leukemia THP-1 and HL-60 cells, differentiated to macrophages ( $\text{M}\phi$ ) or granulocytes ( $\text{G}\phi$ ), were seeded either directly on the hydrogel films or cultivated with material eluates in order to simulate hydrolytic or enzymatic hydrogel degradation *in vivo*. Expression levels of intracellular and secreted TGase 2 were quantified via Western blotting. Additionally, hydrogels were implanted subcutaneously in immunocompetent, hairless SKH-1 mice. TGase 2 expression at the implantation site was detected *ex vivo* by immunohistochemistry at several time points up to 112 days after implantation.

## RESULTS AND DISCUSSION

HAEC showed high expression and secretion of TGase 2, independent from hydrogel contact. THP-1  $\text{M}\phi$  highly expressed TGase 2, and increased its secretion only after direct hydrogel contact. In contrast, HL-60  $\text{M}\phi$  and  $\text{G}\phi$  exhibited enhanced expression of TGase 2 after direct contact to the hydrogels, without secreting TGase 2. These results demonstrate that TGase 2 expression and secretion by  $\text{M}\phi$  and  $\text{G}\phi$  are influenced by contact to the hydrogel surface structure and not by hydrogel degradation products. Additionally, the hydrogels with higher content of diurea lysine

junction units (G10\_LNCO8) induced higher effects than G10\_LNCO3. It should be noted that the two hydrogels differ in elasticity, with G10\_LNCO8 having a Young's modulus of  $55 \pm 11$  kPa and G10\_LNCO3 of  $13 \pm 3$  kPa. *Ex vivo* analysis of tissue sections by immunohistochemistry revealed enhanced expression levels of TGase 2 around the hydrogels 14 and 21 days after implantation (Figure 1), indicating a role of TGase 2 in hydrogel integration and tissue remodelling.

Figure 1: TGase 2 expression 14 days after implantation of G10\_LNCO8 in SKH-1 mice visualized by immunohistochemical staining. (A) TGase 2 expression in a cross section of the mouse skin with the implant. (B) Detailed location of TGase 2 around the implant and in immigrating cells. (B') Detail with control staining (IgG). Scale bars represent 200  $\mu\text{m}$ .

## CONCLUSION

Our results revealed that contact to the gelatin-based hydrogels influenced TGase 2 expression and secretion by  $\text{M}\phi$  and  $\text{G}\phi$  *in vitro*, as well as TGase 2 expression *in vivo*. This underlines TGase 2 to be a promising theranostic target during biomaterial integration processes. Nevertheless, the subcellular location of TGase 2 and its functionality remain to be elucidated to gain further insights into the exact role of this enzyme.

## Functionalization of Scaffold Surfaces: Role of Ce Valence States of Cerium Oxide Nanoparticles in Control of Cell Proliferation

Tamaki Naganuma<sup>1\*</sup>

### INTRODUCTION

A fundamental understanding of the interaction between cells and biomaterial surfaces is essential for the design of scaffold and artificial niche surfaces in tissue engineering. Functionalized biomaterial surfaces play a significant role in control of cell adhesion, proliferation and differentiation. Our research has focused on use of cerium oxide nanoparticles (CNPs) in functionalization of scaffold material, because CNPs have a capability to enhance cell proliferation.<sup>1</sup> The mechanism of cellular interaction with extracellular CNPs is, however, unclear. As for the therapeutic ability of CNPs, e.g. scavenging of reactive oxygen species in cells, it is known that  $\text{Ce}^{3+}$  and  $\text{Ce}^{4+}$  ions in CNPs mimic the enzyme activities of superoxide dismutase and catalase, respectively.<sup>2-3</sup>  $\text{Ce}^{3+}$  ions in CNPs also show the potential to inhibit redox-dependent apoptosis.<sup>4</sup> For these reasons, we hypothesised that Ce valence states in CNPs also correlate with proliferation behaviour of adherent cells. This study investigated the influence of Ce valence states of CNP surfaces on cell proliferation.<sup>5</sup> To evaluate the interaction between adherent cells and CNPs with  $\text{Ce}^{3+}$  and  $\text{Ce}^{4+}$ , we created CNP layers (CNPLs) with dominant  $\text{Ce}^{3+}$  and  $\text{Ce}^{4+}$  ions on poly-L-lactide acid substrates.<sup>5-7</sup> We utilized these CNPLs to investigate cell adhesion, migration and proliferation behaviour on the  $\text{Ce}^{4+}$  and  $\text{Ce}^{3+}$  regions of CNPLs.

### EXPERIMENTAL METHODS

In brief, typical CNPs with dominant  $\text{Ce}^{4+}$  ions were deposited on PL surfaces as a nano-ordered layer ( $\text{Ce}^{4+}$ -CNPLs). Ar ion irradiation was used to partially form a region of high  $\text{Ce}^{3+}$  concentration on the CNPLs ( $\text{Ce}^{3+}$ -CNPLs).<sup>5-7</sup> Cell proliferation behaviour of osteoblast-like cells (MG63) and human mesenchymal stem cells (hMSCs) was observed onto the surfaces of  $\text{Ce}^{3+}$ - and  $\text{Ce}^{4+}$ -CNPLs. Morphology of cells migrating between the  $\text{Ce}^{3+}$  and  $\text{Ce}^{4+}$  regions of CNPLs was also observed. To compare cell adhesion levels, single cell force spectroscopy was used to measure cell detachment force from CNPL surfaces.

### RESULTS AND DISCUSSION

Fig. 1a shows proliferation behaviour of MG63 cells on  $\text{Ce}^{4+}$  and  $\text{Ce}^{3+}$  regions at 3 days after seeding. Interestingly, cells rapidly proliferated on  $\text{Ce}^{4+}$  regions, whereas proliferation on  $\text{Ce}^{3+}$  regions was slow (Fig. 1a).<sup>5</sup> Most cells attached to both  $\text{Ce}^{3+}$ - and  $\text{Ce}^{4+}$ -CNPLs survived. It is noteworthy that even spherical shaped cells on  $\text{Ce}^{3+}$  CNPLs also survived. In addition, a comparison of cell attachment force on each  $\text{Ce}^{4+}$  and  $\text{Ce}^{3+}$  region was carried out by single cell force spectroscopy (Fig. 1b). Detachment force of a cell from the  $\text{Ce}^{4+}$ -CNPLs was clearly higher than that involving  $\text{Ce}^{3+}$ -CNPLs.<sup>5</sup> This result suggests that the strong

interaction of cells with  $\text{Ce}^{4+}$  regions promotes proliferation, while the weak  $\text{Ce}^{3+}$  region interaction inhibits proliferation.

After immersion in culture medium, surface characteristics of all CNPLs: (i) converted to negatively-charged and (ii) became moderately-hydrophilic.<sup>5</sup> Although CNPLs immersed in culture medium display phosphorus adsorption only on  $\text{Ce}^{3+}$  regions, the total amount of protein and BSA adsorption on both  $\text{Ce}^{4+}$ - and  $\text{Ce}^{3+}$ -CNPLs was similar.<sup>5</sup> It appears that these surface characteristics slightly affect cell proliferation behaviour on  $\text{Ce}^{4+}$ - and  $\text{Ce}^{3+}$ -CNPLs. These findings suggest that the Ce valence states of CNPLs influence, at least indirectly, cell proliferation.

Figure 1 (a) Cell proliferation behaviour on the  $\text{Ce}^{4+}$  and  $\text{Ce}^{3+}$  regions and (b) schematic drawing of single cell force spectroscopy to evaluate detachment force of a single cell from substrate surfaces.

### CONCLUSION

The influence of Ce valence states of CNPLs on cell proliferation was investigated. It was determined that the valence states of  $\text{Ce}^{4+}$ - and  $\text{Ce}^{3+}$  ions on CNPLs, at least indirectly, promote or inhibit cell proliferation. Findings in this study may be utilized in the design and development of biomaterials (e.g. scaffolds and artificial niches) to control cell proliferation in tissue engineering.

## INTRODUCTION

Biocompatible materials with antibacterial yet bioactive surfaces are continuing to attract attention of the medical and materials science communities, nevertheless no “dream material” has been developed so far. The present study aims to establish the optimal range of Ag concentration and its state of agglomeration in bioactive nanocomposite TiCaPCON films which would provide a strong bactericidal effect without compromising the material biocompatibility and bioactivity.

## EXPERIMENTAL METHODS

Different Ag contents and distributions were achieved by two different methods: sputtering of composite  $\text{TiC}_{0.5}\text{-Ca}_3(\text{PO}_4)_2$  target followed by  $\text{Ag}^+$  ion implantation (sample denoted as F1) and magnetron co-sputtering of composite  $\text{TiC}_{0.5}\text{-Ca}_3(\text{PO}_4)_2$  and Ag targets (F3). Both types of films were additionally treated by ion etching to remove an Ag rich surface layer (F2 and F4, correspondingly).

The films were characterized using different analytical techniques including X-ray diffraction, scanning and transmission electron microscopy, glow discharge optical emission spectroscopy, atomic force microscopy, Fourier transform infrared spectroscopy, inductively coupled plasma mass-spectrometry.

The antibacterial effect of the Ag-doped TiCaPCON films was evaluated against clinically isolated *Escherichia coli* O78 (*E. coli*). The influence of the surface chemistry on spreading, proliferation, and early stages of MC3T3-E1 osteoblastic cell differentiation was also studied.

## RESULTS AND DISCUSSION

The as-deposited TiCaPCON-Ag films were characterized by the presence of numerous Ag nanoparticles with a diameter of 5-10 nm.  $\text{Ar}^+$  ion etching resulted in partial (ion implantation) or complete (co-deposition) removal of Ag nanoparticles. Depending on the preparation method, the films demonstrated different  $\text{Ag}^+$  ion release behavior. Film F3 demonstrated rapid initial and stable continuous

$\text{Ag}^+$  ion release during 5 days. Ion etching didn't change the kinetics of  $\text{Ag}^+$  ion release. Films F1 was characterized by relatively slow ion release rate, which further slows down after ion etching. The strongest antibacterial effect (100%) against *E. coli* bacteria was observed for F3 films. After additional ion etching, the antibacterial effect was less pronounced. Films F1 and F4 exhibited a strong antibacterial activity toward *E. coli* bacteria already after 24 h. After the preliminary incubation of all the tested samples in PBS for 7 days, the antibacterial activity was markedly increased. Cytocompatibility tests showed that films F1 and F2 provided good adhesion, spreading, and proliferation of osteoblastic cells. In contrast, MC3T3-E1 cells were poorly attached and spread on the surface of films F3 and F4. Proliferation of osteoblastic cells on the surface of sample F3 was slightly retarded, whereas film F4 showed a toxic effect. We did not find any statistically significant differences in the level of alkaline phosphatase activity between MC3T3-E1 cells cultivated on the surface of Ag-doped and Ag-free films F1-F3. In the case of film F4, a drastic decrease of the ALP activity of MC3T3-E1 cells was observed.

## CONCLUSION

Bactericidal yet bioactive TiCaPCON-Ag films were successfully produced on titanium alloys by sputtering of composite  $\text{TiC}_{0.5}\text{-Ca}_3(\text{PO}_4)_2$  target followed by  $\text{Ag}^+$  ion implantation using a magnetron sputtering process. Under optimal conditions in terms of Ag content and agglomeration, the Ag-doped TiCaPCON films are highly efficient against *E. coli* bacteria and, at the same time, provide good adhesion, spreading, proliferation and differentiation of osteoblastic cells which reflect high level of biocompatibility and bioactivity of the films.

# Differential Response of Human Bone Marrow Cells on Aligned vs Randomly Oriented Carbon Nanotubes

Anthoula Kroustalli and Despina Deligianni

Department of Mechanical Engineering & Aeronautics, University of Patras, Greece  
[deligian@mech.upatras.gr](mailto:deligian@mech.upatras.gr)

## INTRODUCTION

Studies on the interaction of cells with carbon nanotubes have been receiving increasing attention owing to their potential for various applications. Through mediation of integrin clustering, their nano-scale surface structure directly affects cell binding and subsequent behaviour<sup>1,2</sup>. In this work, interactions between human bone marrow mesenchymal cells (hBMSCs) and multi-walled carbon nanotube (MWCNT) films were investigated and focused on how morphological structures of MWCNT films affected cellular behavior.

## EXPERIMENTAL METHODS

The pristine MWCNTs were obtained from Nanothinx, Nanomaterials, and Nanotechnology R&D (purity 98.3%), who also prepared the aligned, vertically oriented MWCNT films. Randomly oriented MWCNT films were prepared by filtration in the lab. Substrates were observed with SEM

hMSCs, obtained by aspiration from the marrow of femoral diaphysis of healthy patients, undergoing hip surgery after trauma, were cultured in specific conditions to form osteoblasts.

Cell spreading, proliferation, differentiation, cytotoxicity and integrin mediated adhesion were quantified after 1, 3, and 7 days of incubation, either cultured on MWCNTs films or on TCP (control). LDH expression (using the standard protocol for a commercially available colorimetric proliferation assay), intracellularly or in the culture medium, was used to quantify cell proliferation or cytotoxicity, respectively. ALP enzyme activity of hMSCs was quantified by the specific conversion of p-nitrophenyl phosphate into p-nitrophenol. For cytoskeletal organization, cells were observed under an inverted confocal microscope at 60x magnification, after being stained for nucleus, F-actin and FAK.

Data were collected from three separate experiments and analyzed statistically using SPSS software. Overall differences between groups were assessed by ANOVA and individual paired comparisons were analyzed post hoc with Scheffé's test.

## RESULTS AND DISCUSSION

Cells settled and extended earlier on both MWCNT surfaces than on TCP, toward a polygonal shape. On TCP cells have a more fibroblastic appearance. The results of cell adhesion and proliferation for 1, 3, and 7 days are shown in Fig. 1. The cells attached and proliferated on all surfaces and a statistically significantly ( $p < 0.01$ ) increased number of attached cells in all days was observed on aligned MWCNTs surfaces in relation to the other substrates.

ALP/cell number of the cells cultured on both

MWCNTs films was lower than that on control (aligned < randomly oriented < TCP) at each culture time point, suggesting that when hBMSCs increase their proliferation, their differentiation is delayed<sup>2</sup>.

On aligned MWCNTs, the numbers of FAK-positive focal adhesions increased continuously from the 1<sup>st</sup> day, whereas on randomly oriented, the respective numbers were lower.

Aggregated CNTs were observed on the randomly oriented MWCNT films in the SEM images, increasing film roughness. Further work is necessary to elucidate whether surface roughness or the more structured topography is the main contributor to the cells response.

Fig.1. hMSCs proliferation after 1, 3, and 7 days of culture on the three substrates.

Fig. 2. Fluorescent staining of the f-actin (red), DNA (blue) and FAK (green), after 7days in culture on aligned, randomly oriented MWCNTs and TCP.

## CONCLUSION

Despite literature evidence supporting the nano-structures' ability to be both osteoconductive and osteoinductive, there is still disparity regarding how nanostructures regulate the progression towards an osteoblastic phenotype. It is necessary to explore various architectures, to understand how they initiate osteoinductive or proliferating signals. Further work is require to define the specific mechanisms operative in proliferating cells that allow for increased phenotypic alterations and the signals that promote progressive differentiation of the hBMSCs.

## INTRODUCTION

Progress in the field of biomedical engineering solutions can effectively combine materials science with alive cells <sup>1</sup>. The essence of the work is novel coated surfaces with self-assembling topography mimicking the cellular niches, formed by the controlled share of the residual stress and focused on the stem cell capturing from the whole flowing blood <sup>2</sup>. At this stage of the work the coating structure was developed and optimized towards the haemocompatible properties.

## EXPERIMENTAL METHODS

The medical grade PU has been covered by different types of coatings by using PVD technique. The layer structure and the mechanisms of the coating anchoring to the substrate were analysed using electron microscopy techniques. The cross section study was performed by the transmission electron microscopy equipped with field emission gun <sup>3</sup>. The physical surface structuring was done using plasma based techniques. The blood- material interaction analysis was done in arterial flow condition simulator with whole human blood. Blood used in test was collected from healthy male volunteer. The blood collected from above the sample was mixed with the antibodies CD61-PerCP, CD62P, PAC-1 in order to estimate platelet activation upon contact with the material. The platelet activation was analysed using flow cytometry technique and scanning confocal microscopy.

## RESULTS AND DISCUSSION

Microstructure analysis confirmed by electron diffraction revealed amorphous structure of the thin coatings deposited on PU substrate (Fig. 1). When exposed on physiological like conditions, blood components were activated which may result in platelets and leukocytes adhesion to the surface of biomaterials. The quality of the blood after the dynamic interaction with the tested material is presented in Fig.2. The active blood cells attached to the surface (Fig. 3) were considered as CD 62 (blood clotting cascade activation- active platelets) and CD 45 (immune response activation- active leucocytes) positive.

Fig. 1 TEM microstructure of the deposited coatings

Fig. 2. Flow cytometric analysis of the blood: PLT-AGR- platelets aggregates, considered as two platelets- SMALL and over two platelets BIG

Fig. 3. Confocal laser scanning microscopy analysis of active platelets and leukocytes on the surface

## CONCLUSION

Coatings based on amorphous carbon and diamond-like coating resulted in improved haemocompatible performance. It was found the strong dependence of the microstructure on the blood-material interaction. Different topography of coatings have direct influence on blood-material interactions.

### INTRODUCTION

The trachea (windpipe) consists of rigid cartilage rings in a soft tissue network. In infant airways, deficiency of these supportive structures (Tracheomalacia) may occur at 1.3 affected per million children below the age of 16, predisposing airway constriction (tracheal stenosis)<sup>1</sup> and leading to significant problems with breathing. Current treatment options involve reconstructive surgery. However when this fails a cardiovascular balloon expandable stent is used in the trachea<sup>2</sup>.

The stent is required to provide mechanical support for a minimum of 18 months to allow maturation of the dysfunctional tracheal cartilage<sup>3</sup>. Issues arise however with commercially available permanent metallic airway stent materials (Nitinol or stainless steel) which require multiple surgical procedures for surveillance, removal, resectioning and possible reconstruction of the airways. Mg alloys have received attention for use as medical implants, but until now have not been clinically approved for use in airway stents. In this study the degradation behaviour and associated changes in mechanical properties with *in vitro* degradation of AZ31 Mg alloys was used to test the hypothesis that a biodegradable metallic tracheal expansion stent with appropriate mechanical and degradation characteristics can be developed for use in neonates.

### EXPERIMENTAL METHODS

**Degradation test:** AZ31 Magnesium alloy specimens were immersed in 4000ml of Phosphate Buffered Saline (PBS) and incubated at 37°C for 1, 3, 6 months and the degradation media was renewed every 2-5 days (1 cycle). After each immersion cycle the specimens were cleaned with acetone, rinsed in water, dried and weighed to calculate average mass change and degradation rate. The pH of the degradation media was adjusted to 7.5 at the start of each immersion cycle and recorded at the end.

**Mechanical Tests:** An Instron 5984 was used to perform uniaxial tension tests to failure (at 0.033s<sup>-1</sup>) on dumbbell shaped AZ31 Mg specimens (150x60x2mm) at 0, 1, 3 and 6 months (n=5 per time point) *in vitro* degradation. Force-displacement data was used to calculate stress-strain graphs and to compare ultimate strength, strain at failure and modulus at each time point. Fatigue and four point bend tests (MTS810) were used to evaluate the ability of the stent material to accommodate tracheal dilatation and on going cyclic loading.

**Statistical techniques:** Significance tests (Student's t-test) were performed using Prism v.5 (GraphPad Software, La Jolla, CA). \*Indicates statistically significant differences between groups, p < 0.05.

### RESULTS AND DISCUSSION

**Fig1:** Average percentage mass change & degradation rate of AZ31 samples over 1 month in PBS

**Fig2:** Mean tangent modulus and tensile strength of AZ31 Mg specimens at 0 and after 1 month degradation

A slow, but continuous, mass loss was observed from day 3 (total <3% in a month). Degradation rate (DR) of AZ31 varied with time showing an initial drop after 3 days and a steady rise to a maximum of 0.1445 mg cm<sup>2</sup> hr<sup>-1</sup>, reflecting a well established pattern<sup>4</sup>. This material when subject to *in vitro* degradation for 4 weeks showed a trend towards a slow reduction in mechanical properties.

### CONCLUSIONS

The results demonstrate that AZ31 Mg alloy offers sufficient mechanical properties for at least one month in an aggressive degradation environment similar to that presented by bodily fluids. AZ31 Mg therefore represents a promising biomaterial candidate for use in airway stents counteracting tracheal stenosis in infants and eradicating the requirement for multiple life threatening surgical procedures.

### INTRODUCTION

Total joint prostheses composed of ultra-high molecular weight polyethylene (UHMWPE) and metal or ceramics have been widely applied. The crosslinking, addition of vitamin E and phospholipid coating to UHMWPE have reduced wear and extended the life of joint prostheses. However, wear problems have not yet been completely solved under severe conditions, where direct contacts can occur in mixed or boundary lubrication. Therefore, another method to establish no wear and low friction is required. The application of poly(vinyl alcohol) (PVA) hydrogel with high water content as biomimetic compliant artificial cartilage is expected to reproduce similar multimode lubrication mechanism to natural synovial joints<sup>1</sup>. In this study, the friction and wear behaviors in PVA hydrogels prepared by three kinds of methods were evaluated.

### EXPERIMENTAL METHODS

As artificial hydrogels, three kinds of PVA hydrogels were prepared using the repeated freeze-thawing (FT) method<sup>1</sup>, the cast-drying (CD) method<sup>2</sup> and hybrid method<sup>3</sup> with a layered structure as CD on FT, which are physically crosslinked with hydrogen bonding but differ in terms of structure and mechanical properties. CD gel has lower permeability than FT gel. The reciprocating tests were conducted for sliding pair of an ellipsoidal PVA hydrogel with 2 mm thickness and flat glass plate. Lubricants were saline solution and simulated synovial fluid (0.5 wt% hyaluronate (HA) solution containing 1.4 wt% albumin, 0.7 wt% gamma-globulin and 0.01 wt% L alpha-dipalmitoyl phosphatidylcholine). Molecular weight of HA is  $9.2 \times 10^5$  Da. The sliding speed, stroke length and load were 20 mm/s, 35 mm, and 2.94 N respectively. The extent of wear was observed by optical microscopy.

### RESULTS AND DISCUSSION

In saline solution, three kinds of hydrogels exhibited very different frictional behaviors as hybrid < CD < FT as shown in Fig.1. It is noteworthy that the hybrid gel maintained very low friction until the end of test. The CD gel showed slightly higher friction with gradual increase. Meanwhile, the FT gel showed initial medium friction and a gradual increase over 0.25 at final stage. Slight wear features were observed in all gels. In contrast, in simulated synovial fluid containing main lubricating constituents, friction levels were remarkably decreased for all PVA hydrogels, but the order of

Fig.1 Frictional properties of three kinds of PVA hydrogels (Error bars: standard deviation, n = 3)

coefficients of friction were same as hybrid < CD < FT (Fig.1). On CD gel surface which was smooth surface, some scratchings were observed, but little wear was noticed on hybrid and FT gels. As described above, hybrid gel showed very low friction and minimum wear in similar environment to human joint. This is attractive hydrogel for clinical application as artificial cartilage. It is considered that at initial stage the biphasic lubrication is more effective for hybrid gel than for CD gel as evaluated by biphasic finite element analysis, but with repetition of rubbing, the superior surface lubricity of hybrid gel plays an important role.

### CONCLUSION

Hybrid PVA hydrogel as layered structure of CD gel on FT gel for artificial cartilage had a superior lubricity with very low friction and minimum wear in simulated synovial fluid in reciprocating test.

## Sr- and Zn-Substituted Calcium Phosphates-Based Composites for Osteochondral Tissue Engineering Scaffolding

Sandra Pina<sup>1,2</sup>, Joaquim M. Oliveira<sup>1,2</sup>, Rui L. Reis<sup>1,2</sup>

<sup>1</sup> 3B's Research Group – Biomaterials, Biodegradables and Biomimetics, University of Minho, Headquarters of the European Institute of Excellence on Tissue Engineering and Regenerative Medicine, Guimarães, Portugal

<sup>2</sup> ICVS/3B's - PT Government Associate Laboratory, Braga/Guimarães, Portugal

[sandra.pina@dep.uminho.pt](mailto:sandra.pina@dep.uminho.pt)

### INTRODUCTION

The repair and regeneration of osteochondral (OC) defects has been increasing owing the high number of trauma related injuries or osteoarthritis. Although current clinical options are effective for the treatment of the OC defects, new therapeutic options are necessary for the complete regeneration of the damaged articular cartilage which has a limited healing capacity. The main purpose for OC tissue engineering is to recreate a biomimetic scaffold consisting of a cartilaginous layer and an underlying osseous layer, for regeneration of cartilage and bone, respectively, involving different combinations of materials, morphologies and properties in both parts of the scaffolds<sup>1</sup>. Composite scaffolds composed of biopolymers (silk fibroin) and calcium phosphates incorporating different ions (Sr, Zn), for the simultaneous repair/ regeneration of cartilage and bone are herein developed. These scaffolds present great bioresorbability and osteointegration, and high mechanical strength<sup>2</sup>. In particular, Sr and Zn plays vital roles in the formation, growth, and repair of bone, thus it can promote osteogenesis and angiogenesis<sup>3</sup>. Besides, these elements can lend controlled degradation and increase the mechanical strength of the biomimetic materials.

### EXPERIMENTAL METHODS

Sr- and/or Zn-substituted calcium phosphate powders were prepared by aqueous precipitation from  $\text{Ca}(\text{NO}_3)_4 \cdot 4\text{H}_2\text{O}$ ,  $(\text{NH}_4)_2\text{HPO}_4$ ,  $\text{Sr}(\text{NO}_3)_2$ , and  $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ , with  $(\text{Ca}+\text{Sr})/\text{P}=1.48$ , followed by heat treatments at 800-1000 °C and milling. Silk fibroin (SF) was extracted from *Bombyx mori* cocoons.

Porous composite scaffolds with distinct cartilage and bone sides were produced through solvent casting and particulate-leaching technique, followed by freeze-drying. Cartilage layer was engineered using 100 wt.% SF, and bone layer was obtained by combining 85 wt.% SF with 15 wt.% Sr-, Zn-doped powders.

XRD, FTIR, SEM/EDS and  $\mu$ -CT techniques were employed to characterize the starting powders and scaffolds. Current studies are on-going to evaluate the scaffolds *in vitro* degradation and ions release profiles, and mechanical properties.

### RESULTS AND DISCUSSION

Rietveld analysis of XRD patterns of the powders heat-treated at 1000 °C, confirmed the incorporation of the ionic-dopants into calcium phosphate structure by the changes in lattice parameters, resulting in a phase

composition of 92 wt.% doped  $\beta$ -tricalcium phosphate (TCP) and of 8 wt.% calcium pyrophosphate.

SF/Sr-, Zn-doped  $\beta$ -TCP composite scaffolds presented macroporosity highly interconnected and microporosity with sizes around 500  $\mu\text{m}$ , and 1-10  $\mu\text{m}$ , respectively, with TCP powder well distributed throughout the scaffolds as shown in Figure 1.

The microstructure of the scaffolds was quantitatively studied by  $\mu$ -CT, as presented in Table 1.

Structure	Porosity (%)	Mean pore size ( $\mu\text{m}$ )	Mean trabecular thickness ( $\mu\text{m}$ )	Interconnectivity (%)	SrTCP (%)
SF/SrTCP	69.8	491.7	260.3	85.2	12

### CONCLUSION

The present work demonstrates the feasibility of formulating porous composite scaffolds incorporating Sr and Zn, with promising applications in OC tissue engineering.

### INTRODUCTION

It was believed that biomaterial selection was performed based on its macroporosity, biocompatibility and degradability properties but recently its ability to withstand biomechanical stress has also been considered. Discher et al. [1] have indeed shown that material stiffness induces critical effects on cell behaviour and differentiation. Therefore, we have recently embarked on the development of mechanically-competent hydrogels for bone and cartilage tissue engineering. We prepared a cellulose based polymer capable of self cross-linkage (Si-HPMC) to avoid any toxicity issues resulting from using cross-linking chemicals or photo cross-linking. Therefore, LIOAD has been working on the development of hydrogels as ECM for bone and cartilage regeneration. The objectives of the present work are to modulate the physico-chemical and biological properties of our hydrogels by mixing two silated polysaccharides Si-HPMC and Si-Chitosan.

### EXPERIMENTAL METHODS

The self cross-linkable polymer (Si-HPMC) was prepared according to an already published method developed in LIOAD [2]. Silanol groups were linked to amine moieties of the chitosan via thio-urea bond.

**Hydrogel characterizations:** Hydrogels and reinforced hydrogels were characterized physico-chemically to determine their elastic moduli using MARS rheometer ( $G'$ ), Dynamic Mechanical Analysis ( $E'$ ) and microscopy.

Biological investigations have been done with human nasal chondrocytes by determining the cell viability in 2D using MTS, 3D by confocal microscopy after Live&Dead staining.

In vivo investigations have been performed in subcutaneous sockets in nude mice, in rat calvaria defects and in knee focal defects in rabbit.

### RESULTS AND DISCUSSION

The characterizations showed that adding Si-Chitosan within Si-HPMC hydrogels increases the elastic moduli without interfering with the biocompatibility. Indeed, all the constructs that we used in this study showed no toxicity both in 2D and 3D (as shown in figure 1). Culturing cells in 3D within our hydrogel containing Si-Chitosan

also induces cell adhesion onto the matrix as I can be observed on confocal micrograph in figure 2.

It is worth noted that after 5 weeks of implantation, the chondrocytes showed a good viability and still express a chondrocyte phenotype. Moreover, during the surgery, due to the presence of chitosan, our constructs showed good adhesion behaviour onto the cartilage focal defect.

Fig 1: left: 2D hASCs viability in contact with Si-HPMC/Si-Chitosan hydrogels (Positive control : cells alone, control for cell death : actinomycin D). Right: Confocal micrograph showing living cells (green) and dead cells (red) after 7 days of culture inside hydrogels.

Fig 2: Confocal micrographs showing cell adhesions after 7 days culture in Si-HPMC/Si-Chitosan hydrogel.

### CONCLUSION

The study demonstrates the feasibility of our approach to modulate our self-setting hydrogel while keeping them biocompatible.

### INTRODUCTION

Macrophages (Mφs) were initially recognized by Elie Metchnikoff as phagocytic cells responsible for pathogen elimination and housekeeping functions in a wide range of organisms<sup>1</sup>. Mature macrophages are virtually present in every tissue of the body. Macrophages are key innate immune cells with multiple immunoregulatory functions that include clearance of pathogens and apoptotic cells, regulation of ECM turn over, initiation and control of inflammatory reaction by activation of various cell types of innate and adaptive immunity<sup>2,3</sup>. Macrophages are activated in a specific way during anti-bacterial, anti-parasitic and allergic responses, as well as during wound healing and implantation<sup>4,5</sup>.

Macrophages develop tissue specific phenotypes (osteoclasts in bone tissue, microglia in CNS<sup>6</sup>.) Frequently the devices aiming to provide a newer solution for a specific problem face the host's foreign-body response<sup>4</sup>. In this work we have studied the survival and response to cytokine induction of macrophages in order to control macrophage phenotype in 3D conditions. Reported work is being performed with the immobilization of macrophages. For that, naïve human monocytes have been immobilized within gelatin and modified with hyaluronic acid molecules gelatin gels, mimicking ECM components to investigate the behaviour of these cells within an ECM-like environment.

### EXPERIMENTAL METHODS

CD14<sup>+</sup> monocyte cells were isolated from human peripheral blood. Cells were immobilized within 6 wt-% gelatin gels and 4% tyraminated hyaluronic acid (TyrHA)/gelatin gels both enzymatically crosslinked with 10 wt-% transglutaminase (TG) and HRP at a density of 6 million cells/mL of material. Cells were cultured up to six days in a 5% CO<sub>2</sub>:7% O<sub>2</sub> atmosphere at 37° C with macrophage-SFM and physiological levels of dexamethasone (10<sup>-8</sup> M) with the addition of M2-like phenotype inducing cytokines. At a given timepoint samples were analysed for cell viability and cell proliferation using CASY® Cell Counter and Particle Analyzer (Scharfe Systems, Germany) and reactive oxygen species (ROS) production using CellROX® Orange Reagent (Life Technologies).

### RESULTS AND DISCUSSION

We have observed an increase in total cell number over the six days of the culture, in both gel conditions. As the proliferation of naïve macrophages was not

observed by us and other groups in 2D experiments, additional experiments are necessary to elaborate on the underlying mechanism in this increase<sup>7</sup>.

“Figure 1. A) The total number of cells after gel dissolution of naïve monocytes immobilized within gelatin and Tyraminated HA Gelatin 3D gels; B) phase contrast image in Gelatin hydrogel”

Moreover it was detected that ROS production is not significantly different between Gelatin. TyrHA/gelatin gels both at day 1 and day 6. In addition, two different conditions were compared (no LPS, lipopolysaccharide, and stimulated with LPS) with no major differences detected. These results show that human macrophages can be immobilized and that they can be differentiated in M2-like cells *in vitro*. Further analysis were carried out such as ELISA analysis of cytokines (TNF-α (M1, non-detectable) and CCL-18 (M2, present in small amounts produced by human macrophages).

### CONCLUSION

Gelatin and Tyraminated gelatin promote higher cell survival as well as prevent production of reactive oxygen species. This system can be used for controlling macrophage phenotype in 3D conditions.

## 2D Cell Monolayer and 3D Cell Construct Cryopreservation by Slow Vittrification

Kazuaki Matsumura<sup>1</sup>, Keiko Kawamoto<sup>1</sup>, Suong-Hyu Hyon<sup>2</sup>

<sup>1</sup>School of Materials Science, Japan Advanced Institute of Science and Technology, Japan

<sup>2</sup>Center for Fiber and Textile Science, Kyoto Institute of Technology, Japan

[mkazuaki@jaist.ac.jp](mailto:mkazuaki@jaist.ac.jp)

### INTRODUCTION

Cryopreservation is used for long-term preservation of biological materials containing cells. Two primary techniques of cryopreservation are slow freezing and vitrification, in which water transition directly to the glassy state without crystallization. Slow freezing methods, which utilize 10% dimethyl sulfoxide (DMSO) as a cryoprotectant, are effective for numerous cell lines. However, the method is not acceptable for the effective cryopreservation of large volume cell such as oocyte or 2D or 3D cell constructs.

Vitrification methods have been developed with the advent of preservation techniques for oocytes and embryos, primarily in the field of reproductive medicine. We previously utilized carboxylated poly-L-lysine (COOH-PLL) [1], a novel polymer cryoprotectant as a component of vitrification solution of human iPS cells by using its recrystallization inhibition property [2].

In this study, we reported the development of slow vitrification technique for the effective cryopreservation of 2D and 3D cell constructs by using novel cryoprotectants.

### EXPERIMENTAL METHODS

We previously reported the synthesis of the polymeric cryoprotectant, COOH-PLL[1]. We prepared a vitrification solution (VS) based on 6.5 M ethylene glycol (EG, Wako) and 0.75 M sucrose (Wako) in PBS. COOH-PLL was added to the solution at 10% w/v to evaluate the effect of the polymer. A DAP213 solution [2 M DMSO, 1 M acetamide and 3 M propylene glycol (all from Wako), in PBS] was used as control.

One mL of VS was added on the human mesenchymal stem cells (MSCs) sheet cultured in the dish. And after 5 min, the VS was removed by aspiration and held various distance above the surface of liquid nitrogen. The temperature of the MSC monolayer was monitored with the thermocouple attached on the monolayer. After 20 min, the vitrified MSC monolayer sheet was soaked into liquid nitrogen. The MSC monolayers were warmed on the same day by gently addition of the pre-warmed medium (2mL) and after 3min, monolayer was washed with DMEM twice for 5min each. The cell viability was evaluated by Live/Dead assay kit.

To compare stabilities of the glassy states among these vitrification solutions, thermal analysis was performed using a differential scanning calorimeter (DSC).

### RESULTS AND DISCUSSION

The freezing speed could be varied from 0.58-0.08 degree/sec by changing the distance between the bottom of MSC culturing dish and surface of liquid nitrogen. Cell viability of MSC sheets after thawing with

vitrification through various freezing speed was shown in Fig.1. The live/dead assay results of thawed MSC sheets after vitrification through 0.58 and 0.08 degree/sec were shown Fig.2. From these results, COOH-PLL addition was very effective on the vitrification with low freezing speed. The mechanisms might be related with the ice crystallization inhibition and inhibition of de-vitrification properties of COOH-PLL, which were evaluated by DSC measurements. And also our vitrification system could be applied for 3D cell constructs and tissue-engineered skin vitrification successfully.

Fig.1 Cell viability after vitrification of MSC sheets with various vitrification solution through various freezing speed.

Fig.2 Microphotographs of MSC sheets by Live/Dead assay after vitrification with various vitrification solutions at a freezing speed of 0.08 degree/sec.

### CONCLUSION

It was shown that COOH-PLL improved effectively the vitrification properties of current vitrification system due to its inhibition of recrystallization property. From our results, tissue constructs can be cryopreserved in glassy state at relatively slow freezing speed such as 0.08 degree/sec.

## Interaction of Sub-Compartmentalized Microreactors with Hepatocytes

Yan Zhang<sup>1</sup>, Brigitte Städler<sup>1</sup>

<sup>1</sup>iNANO Interdisciplinary Nanoscience Centre, Aarhus University, Denmark  
[yanzhang@inano.au.dk](mailto:yanzhang@inano.au.dk)

### INTRODUCTION

Microreactors have the potential to become a desirable method to maximize the efficacy of therapeutic treatments in numerous ways, because they can synthesis and release their contents by responding to external triggers or biomarkers [1]. Microreactor could be used for encapsulation of enzymes, substrate, catalyst, gene and peptide cargo [2, 3]. Sub-compartmentalized microreactors are of particular interest, since they mimic the hierarchical structure of cells, allowing for the co-encapsulation of multiple cargo and for triggered activity. [6] Although therapeutic cell mimicry is an interesting approach which the potential to substitute for missing or lost cellular function, most of the research has so far been done in cell-free environment. The objective of this work is to understand, if microreactors co-cultured with hepatocytes can induce a (positive) effect in the growing cell sheet. Therefore, it was investigated whether soft alginate (Alg) particles and hard polystyrene (PS) particles could be co-culture with hepatocytes for assembling interacting cell-particle constructs. Further, the Alg particles were equipped with trypsin loaded liposomes as a model microreactor and its activity was assessed in cell culture.

### EXPERIMENTAL METHODS

Alg particles (~41 µm diameter) without and with different enzyme-loaded liposomes were prepared by droplet microfluidics. Alg particles and PS particles (~41 µm diameter) were coated with poly (L-lysine), cholesterol-modified poly (methacrylic acid, (PMA<sub>c</sub>) or (PMA), co-cultured with hepatocytes (HepG2) and their interaction was analyzed at different time points. The enzyme trypsin was trapped in the liposomal subunits and the enzymatic activity was assessed using bisamide substrate of rhodamine 110 as substrate which can be converted into a fluorescent product by trypsin.

### RESULTS AND DISCUSSION

When bare PS particles were co-cultured with hepatocytes, the particles were only badly incorporated into the cell sheet. After surface modification of the particles, the PLL and PMA<sub>c</sub> coated particles were found to be suitable for the assembly of particle-cell constructs when co-culture with hepatocytes for up to 10 days. A similar trend has been observed for the Alg particles. The coated particles were better incorporated into the hepatic tissue. Further, tested particles did not negatively affect the cell viability.

In order to assemble a microreactor, different amounts of liposomes were loaded into Alg particles yielding increasing fluorescence intensity with increasing amount the fluorescence liposomes. Trypsin was loaded

in liposomes and the conversion of the substrate occurred in a temperature controlled manner. The enzyme loaded liposome-containing Alg particles were co-cultured with hepatocytes, and after incubating with the substrate, the cells became fluorescence, which showed that the product was released from Alg particles.

Figure 1. (i) Scheme of a PS particle- hepatocytes cell construct. (ii) Representative CLSM image of PS particles co-cultured with hepatocytes for 7 days. The scale bar is 10 µm.

### CONCLUSION

We demonstrated that subcompartmentalized enzyme loaded Alg particles can be incorporated into the growing hepatocyte cell sheet and that the product produced by the microreactor could be internalized by the cells. These findings are a major step towards the assembly of bionic tissue – a combination of biological and synthetic entities.

## Macrophage-Laden 3D Fibrin Gels: Effect of Fibrinogen Concentration on Inflammation

Vera Malheiro<sup>1</sup>, Arie Bruinink<sup>1</sup>, Katharina Maniura<sup>1</sup>

<sup>1</sup>Biointerfaces, EMPA Swiss Federal Laboratories for Materials Science and Technology, Switzerland  
[vera.malheiro@empa.ch](mailto:vera.malheiro@empa.ch)

### INTRODUCTION

Fibrin is the first temporary matrix at the tissue-implant interface. Its primary role is to stabilize the wound site and provide the matrix through which cells can migrate to the implant surface. As such, fibrin is inherently related to healing. Changes in its structure can interfere with cell function and resultant tissue repair [1]. Fibrin is formed from the conversion of fibrinogen to an insoluble matrix through a complex natural polymerization mechanism. The properties of fibrin are affected by fibrinogen concentration [2], which varies in human plasma due to disease, demographic and environmental factors [3]. Macrophages are the predominant cell type at the wound site by 48-72 hours post-injury and thus potentially responsive to variations in the fibrin-rich extracellular matrix.

In the current work we have encapsulated macrophages onto 3D fibrin gels and examined whether gels produced from non-physiological concentrations of fibrinogen interfere with the cell viability and inflammatory response.

### EXPERIMENTAL METHODS

Macrophages encapsulation onto fibrin gels was achieved by mixing a fibrinogen solution with a macrophage cell suspension and a Tris- buffered saline solution containing 2 IU/mL of thrombin and 5 mM CaCl<sub>2</sub>. Complete gelification was achieved following 1 h incubation at 37 °C.

THP-1 monocytic leukemia cell line was used as cell model. Macrophage viability was examined by live & dead staining and LDH release. Macrophage distribution in the gel was analysed by confocal laser scanning microscopy, whereas its morphology and adhesion to the fibrin gel was examined by scanning electron microscopy. As a measure of inflammatory response, the secretion of the inflammatory cytokine TNF- $\alpha$  was determined by an enzyme-linked immunosorbent assay.

### RESULTS AND DISCUSSION

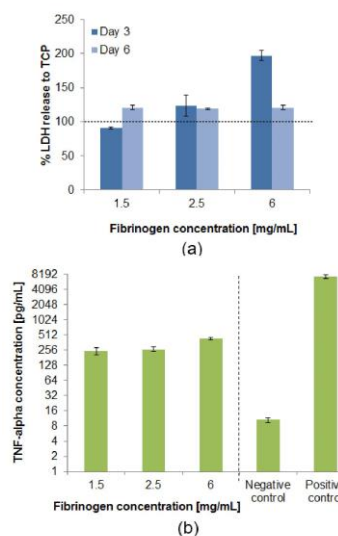

Typical gels architecture are illustrated by the scanning electron micrographs (SEM) shown in Fig. 1. Whilst all gels show similar random fibre orientation, the frequency of fibres with a smaller diameter and the fibre and branch-point density seems to increase as the fibrinogen concentration increases.

Macrophages were homogeneously distributed within the fibrin matrix, and showed direct contact with fibrin fibres. Macrophage viability within fibrin gels was comparable to that on tissue culture treated polystyrene (TCP) control, except for fibrin gels produced with supra-physiological concentrations

where a decrease of viability was noted on day 3 in culture (Fig.2 (a)). TNF-alpha release was increased in fibrin gels in comparison to TCP negative control (Fig.2 (b)), with a maximum value detected for fibrin gels produced with supra-physiological concentrations of fibrinogen. LPS treated cultures served as positive control.

**Fig. 1:** SEM images of fibrin gels formed with a concentration of fibrinogen increasing from (a) sub-physiological, to (b) physiological and (c) supra-physiological levels.

**Fig. 2:** Effect of fibrinogen concentration on (a) Lactate dehydrogenase (LDH) and (b) TNF-alpha release from macrophages encapsulated onto fibrin gels. TNF-alpha release was determined after 6 days in culture and is presented in the logarithmic scale.

### CONCLUSION

Macrophages can be successfully encapsulated in fibrin gels. Higher concentration of fibrinogen affects macrophage viability. TNF-alpha release is increased by macrophages encapsulated in fibrin gels.

<sup>3</sup>Center of Excellence in Biomaterials and Tissue Engineering, Middle East Technical University, Turkey

### INTRODUCTION

Biodegradable synthetic polymers such as poly ( $\epsilon$ -caprolactone) (PCL) and poly (ethylene glycol) (PEG) have been frequently used for scaffolding in tissue engineering studies because of their biocompatibility, non-cytotoxic degradation products, easily tailored degradation rates and porosity<sup>1,2</sup>. PEG has been utilized to form various block copolymers with PCL<sup>3</sup>. Extensively, ring opening polymerization is applied to form PCL and PEG block copolymers having various thermoplasticity, degradability and hydrophilicity<sup>4</sup>. Clinoptilolite is an aluminosilicate mineral which has  $(Ca, Fe, K, Mg, Na)_3-6Si_3OAl_6O_{72} \cdot 24H_2O$  as general formula<sup>5</sup>. While showing good mechanical properties, clinoptilolite can also be used as a protein adsorbent<sup>6</sup>. In this study, highly porous and interconnective Clinoptilolite/ PCL-PEG-PCL composite scaffolds were fabricated by particulate leaching method and also it was hypothesized that they can enhance bone tissue growth and induce osseointegration by providing a controlled and sustained release of protein or growth factors.

### EXPERIMENTAL METHODS

PCL-PEG-PCL triblock copolymer was synthesized from  $\epsilon$ -caprolactone (pure >99%) and PEG ( $M_n=4000$ , pure 99%) by ring opening polymerization under 140 °C for 24 hours. Obtained triblock copolymer was characterized spectroscopically by <sup>1</sup>H NMR and FTIR analyses. Furthermore, DSC and TGA analyses were conducted for thermal characterization of triblock copolymer. Clinoptilolite mineral having overall size between 1  $\mu m$  and 50  $\mu m$  was sintered at 250 °C for 24 hours. In addition, clinoptilolite was analysed for protein adsorption capacity using Bovine Serum Albumin (BSA) 0.1 M PBS at pH 7.4 for various time intervals (10, 30, 60, 360 and 1440 min). Finally, clinoptilolite, PCL-PEG-PCL triblock copolymer and sodium bicarbonate (< 50  $\mu m$ , pure >95%) were mixed at various ratios. Mixtures were obtained by disperser (15000 rpm, 5 min) utilizing ethanol (pure, 99%) in order to powder and form homogenous mixture while averting use of any organic solvent. Homogenous mixture was vacuumed overnight under 40 °C overnight to remove ethanol and powder was compressed under 250 MPa for 3 min at 25 °C and scaffolds having 13 mm diameter and 6 mm thickness were obtained. Scaffolds were observed under SEM to investigate surface and cross-sectional porosity as well as analysing the overall pore sizes. Porosities of scaffolds were calculated through Archimedes' Principle and compressive mechanical properties were obtained by uniaxial compression under 2.5 kN load cell at a rate of 3 mm/min up to 25% strain.

### RESULTS AND DISCUSSION

From the spectroscopic analysis by <sup>1</sup>H NMR, it was shown that the PCL-PEG-PCL triblock copolymer was synthesized successfully (Fig 1). FTIR, DSC and TGA analyses were also complementary to NMR results.

Figure 1. (a) <sup>1</sup>H NMR results for PCL-PEG-PCL triblock copolymer. (b) Protein adsorption onto 25 mg clinoptilolite powder samples

SEM images indicated that upper, lower and side surfaces and cross-sections were highly porous while overall pore size ranged between 10 to 50  $\mu m$ . Scaffolds with highest sodium bicarbonate concentration showed 55% porosity (3:1 salt to copolymer) and with lowest salt concentration show 35% porosity (1:1 salt to copolymer). Corresponding to porosities, scaffold compressive strengths ranged between 1.8 MPa for most porous scaffold to 4.8 MPa for least porous scaffold. Moreover, it was shown that clinoptilolite presence increased the compressive moduli when compared with non-clinoptilolite groups which were used as control groups.

### CONCLUSION

Porous, interconnective and mechanically stable composite PCL-PEG-PCL scaffolds were developed successfully. Clinoptilolite was shown to absorb large amounts of protein ( $q_e=4$  mg/g clinoptilolite) so that clinoptilolite will enable composite scaffolds to be used for the delivery of bioactive molecules both in vivo and in vitro. Furthermore, bioactivity, direct and indirect cytotoxicity and differentiation studies for developed scaffolds are under study..

## INTRODUCTION

Bone augmentation is one of the most important problems in dental implantology. Only recently proposed, so called bone ring technique allows bone augmentation and the implant placement to be performed in a single operation [1, 2]. For this purpose, either autologous bone grafts or pre-fabricated bone rings of processed allogenic donor bone are currently in use. In order to avoid well-known limitations connected with tissue transplantation, in this study we have evaluated and verified at the pre-clinical level, the alternative original system based on use of the ceramic rings - either enriched with osteogenic cells or not.

## EXPERIMENTAL METHODS

Commercially available blocks of HA/ $\beta$ TCP (Maxresorb®), with open porosity of 80% were used. The ring-shape samples with an internal diameter of 3.3mm, outer diameter of 10mm, high to 5mm were cut and prepared for the implantation. In order to mimic the ring technique, the animal model was developed. The rings were implanted into the mandible of Göttingen minipigs and were fixed by commercially available dental implants. There were two experimental groups. In one group the rings were pre-soaked in cell culture medium, seeded with autologous pig adipose derived stem cells (ADSC) at the density of 700000cells/ring and put to the *in vitro* culture for 14 days. Before implantation cell viability was examined in the XTT assay. In the second group, rings pre-soaked in a medium but without ADSC were prepared.

Two rings were implanted into each animal: one seeded and the other one non-seeded with ADSCs. Individual rings were implanted on the right and left side of a mandible in parallel. Six weeks after implantation the animals were euthanized and the rings together with a surrounding tissues were excised. The excised rings were fixed in 10% buffered formalin solution and prepared to histological analysis: the Hematoxylin and Eosin (HE) and Sirius Red staining were used. Moreover, stability of the implants fixation was measured immediately after implantation and at the end of the experiment.

## RESULTS AND DISCUSSION

As confirmed by XTT test, ADSC seeded on the ceramic rings were alive at the time of implantation. Six weeks after implantation there were no macroscopic differences between cell-seeded and non-seeded rings. All rings were overgrown by tissue and stably embedded in a mandible bone with no intervening soft tissue layer or signs of inflammation. The mean implant

stability was about 70 ISQ, with no significant differences between the groups. The histological analysis revealed the presence of well vascularized and well organized connective tissue in the pores of the rings. Numerous bone trabeculae were observed. They were organized mainly at the internal surface of pores. Interestingly, the amount of the new bone tissue present inside the ceramic rings was significantly higher in the scaffolds non-seeded with ADSC before implantation. Similar results were previously presented, by F.G. Lyons et al. [3] who found that the cell-seeded groups of scaffolds showed poor bone infiltration as compared to the unseeded groups (studies on critical-sized rat cranial defect). The differences may be related to the higher activity of M1 (pro-inflammatory) macrophages in the cell-seeded implants as well as the more beneficial localization of M2 (pro-repair) macrophages in the unseeded ones.

The legitimacy of the use of cell-containing implants is an important issue for the further development of tissue engineering. We believe that our research brings an interesting contribution to this discussion and gives a good basis for further investigations.

Regardless of the issues related to the role of the cells in bone tissue engineered products, our results encourage the use of ceramic implants instead of bone grafts in a ring technique of simultaneous bone augmentation and dental implant placement. If rings without prior-to-implantation-cell-seeding are good enough or even better than those enriched with cells, then off-the-shelf man-made rings can be offered for reconstruction of vertical bone losses.

## CONCLUSION

Synthetic rings prepared from a porous ceramic material and as such, free from the limitations associated with using bone grafts, can replace bone rings currently used in dental surgery. HA/ $\beta$ TCP rings are capable of simultaneous reconstruction of a vertical bone loss and introduction of implants in dental surgery. Addition of cells to the ceramic rings may worsen their overgrowth with bone tissue.

[terzoe@gmail.com](mailto:terzoe@gmail.com)

### INTRODUCTION

N-(2-Carboxybenzyl)chitosan (CBCS) is a chitosan derivative which presents a wide range of properties that make it appropriate for tissue engineering applications, such as non-toxicity, biodegradability, biocompatibility, antibacterial and antifungal activity, water solubility (which can be controlled by the degree of substitution), high viscosity, large hydrodynamic volume and ability to form pH sensitive hydrogel. Moreover, various studies demonstrate that by combining bioactive materials with bioresorbable polymers, composites of tailored physical, biological, and time-dependant mechanical properties can be produced, allowing new tissue, as it grows naturally, to take over its load-bearing capability<sup>1</sup>. Hence in this work, CBCS foams containing either microsilicized bioglass or nanosized titania (CBCS/TiO<sub>2</sub>) were prepared by freeze-drying technique and studied as potential tissue engineering scaffolds. In Regenerative Medicine cytocompatible scaffolds for cell therapies are commonly used. Cytotoxicity, stability, cell adhesion, proliferation and spreading are factors that influence effectively the regenerative medicine applications<sup>2</sup>.

### EXPERIMENTAL METHODS

In this work 0.5, 2.5 and 5% TiO<sub>2</sub> nanoparticles and 2.5% Bioglass 45S5 (BG45S5) were added during the carboxyalkylation reaction, in order to obtain different CBCS composites. The scaffolds were prepared by freezing and lyophilizing CBCS solutions. The sample tubes employed had an inner diameter of 1.5 cm and a 1.2 mm wall thickness. For comparison purposes, chitosan xerogel was also prepared with the same method. The porous structure of scaffolds was obtained by freeze-drying technique and characterized using SEM. Compression test (n=5 per condition) were performed using an Instron 3344 with a crosshead speed of 5 mm min<sup>-1</sup>. The swelling, degradation and in-vitro biomineralization of the composite scaffolds were also studied. Mesenchymal stem cells are collected by enzymatic digestion of Wharton's Jelly. Prior to cell seeding, the scaffolds were incubated with culture medium and the mesenchymal stem cells were placed dropwise on to the top of the scaffold. Cell attachment studies, proliferation assays of cells on the scaffolds were evaluated using fluoresce microscopy. Furthermore viability of cells on the scaffolds was evaluated using MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay. Finally the morphology of cells on the scaffolds was evaluated by using SEM, TEM and photonic microscopy.

### RESULTS AND DISCUSSION

SEM micrograph of composite scaffolds showed that scaffolds were macroporous in nature with interconnected pore system, important for cell loading in tissue engineering and cell in-growth in tissue induction. Pore size varied from 150–300 µm. Very few agglomerates appear on the walls of the pores, which may constitute fragments that were formed during the cross-section process.

Figure 1: Swelling ratio of the scaffolds

In addition, the swelling test results (Figure 1) suggest that the composite scaffolds indicated increased swelling ratio, with increase of the concentration of the inorganic fillers. Compressive strength values verified that the modification of chitosan backbone in combination with the presence of inorganic fillers can attribute significant mechanical stiffness to the chitosan scaffold, too. The in vitro biomineralization test confirmed that all the samples are bioactive as mineral deposits were detected after incubation in SBF, using X-ray diffractometry. The cells appeared to attach around the pores and most of the pores are filled with cells. Cells keep their morphology, proliferate and migrate across the scaffold and show consistent and proved cytocompatibility.

### CONCLUSION

All studied composites have high cytocompatibility and maintain the biological properties of the seeded cells. So these could be appropriate for tissue regeneration.

[erik.brauer@charite.de](mailto:erik.brauer@charite.de)

### INTRODUCTION

The mechanical microenvironment is known to have a fundamental influence on cell behaviour and might be decisive for tissue regeneration. BMP growth factors are potent inducers of bone formation with known effects on cellular processes such as differentiation and migration<sup>(1)</sup>. Aside of their impact on cell fate, less is known about how BMP affects structural and mechanical properties of the extracellular matrix (ECM) in the process of tissue regeneration<sup>(2)</sup>. We hypothesize that BMP stimulation alters ECM formation in a 3D *in vitro* environment, which serves as a model for the early phase of wound healing in bone.

### EXPERIMENTAL METHODS

Microtissues were created by culturing primary human dermal fibroblasts inside macroporous porcine collagen I scaffolds in expansion medium containing 2% FBS and 1.36 mM ascorbic acid. Biochemical stimulation was performed with 500 ng/ml rhBMP-2 for 6, 24 and 72h (gene expression) and 14 days (histology and mechanical testing). Gene expression was quantified via q-RT-PCR from mRNA isolated from the microtissues. Newly formed collagen I inside the scaffold pores was visualized via immunohistochemistry (IHC). To quantify structural properties, microtissue mechanical properties were analysed via a monoaxial compression test after 2 weeks of stimulation.

### RESULTS AND DISCUSSION

Figure 1: IHC for newly synthesized collagen I (green) and scaffold by SHG (white).

We started to investigate the gene expression of the main fibrillar component of bone extracellular matrix, collagen I with and without BMP-2 stimulation over a time course of 3 days (data not shown). No significant differences were found in the expression patterns but significant differences in collagen network structure of the ECM were found after 2 weeks with highly condensed collagen fibres in stimulated vs. more loose networks in controls (Figure 1).

Structural properties showed an increase in stiffness after 2 weeks of stimulation (Figure 2). Microtissues exhibit viscoelastic material properties, thus we

furthermore analysed stress relaxation succeeding mechanical compression. Experimental data was fitted with an exponential decay function ( $\sigma(t) = \sigma_0 + \sigma_A \cdot e^{(-t/\tau)}$ ). While we didn't observe changes in the amplitude  $\sigma_A$  of stress relaxation, analysis of relaxation time constant,  $\tau$ , revealed a clearly altered relaxation dynamics upon BMP-2 stimulation (Figure 2).

Figure 2: Analysis of mechanical properties after 2

weeks of culture, comparison of BMP-2 stimulated and unstimulated to empty scaffold. Left: Young's Modulus; middle: stress relaxation time constant  $\tau$ ; right: Amplitude  $\sigma_A$  [%] of relaxation.  $p < 0.05$ ,  $n = 4$

### CONCLUSION

We analysed the changes in mechanical properties of microtissues upon BMP-2 stimulation to better understand the influence of the ligand on ECM formation in the early phase of wound healing. Our data indicates, that BMP-2 not only drives fracture healing by induction of osteogenic differentiation of mesenchymal stem cells, but also guides early steps of wound healing and tissue formation. The observed differences in structure and mechanical properties of the collagen network may play an additional role in the invasion of stem cells and their differentiation in order to restore tissue function. Thus our data may hold clues for the future design of bioartificial environments supporting bone regeneration.

### INTRODUCTION

Titanium (Ti) is the gold standard biomaterial used to produce dental implants thanks to its physical properties and superior ability to osseointegrate<sup>1</sup>. In addition to the implant characteristics, the clinical success of this treatment is also related to patient health conditions and local bone quality and quantity, both affected by aging. As elderly is the main population that needs dental implants, it is of relevance to understand how aging affects bone/implant interactions. Thus, the aim of this study was to evaluate the effect of aging on osteoblastic differentiation of mesenchymal stem cells (MSCs) grown on Ti.

### EXPERIMENTAL METHODS

Discs of commercially pure Ti (12 mm in diameter and 1.5 mm thick) were polished using 320 and 600 grit silicon carbide, cleaned by sonication, sterilized and air-dried. Bone marrow MSCs were obtained from the femurs of 1-month (young) and 21-month (old) male Wistar rats and were cultured in growth medium until reaching subconfluence. Then, MSCs were cultured in osteogenic medium on Ti discs for periods of up to 21 days. During the culture period, cells were incubated at 37°C in a humidified atmosphere of 5% CO<sub>2</sub>, and the medium was changed every 3 days. Cell proliferation was evaluated at days 4, 7 and 10 with 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT). At the same time-points, alkaline phosphatase (ALP) activity was determined by measuring the release of thymolphthalein from thymolphthalein monophosphate using a commercial kit. Extracellular matrix mineralization was detected at day 21 by alizarin red staining and calcium content was measured by a colorimetric method. Quantitative real-time polymerase chain reaction (PCR) was performed at day 10 to evaluate the gene expression of the osteoblast markers, runt-related transcription factor 2 (RUNX2), osterix (OSX), ALP, bone sialoprotein (BSP), osteocalcin (OC) and osteopontin (OPN), and adipocyte markers, peroxisome proliferator-activated receptor gamma (PPARγ), adipocyte protein 2 (aP2) and resistin (RTN). The data obtained in three time-points were analyzed using two-way ANOVA followed by Student Newman Keuls post-test and in one time-point using Student's t-test. For all experiments the level of significance was set at  $p \leq 0.05$ .

### RESULTS AND DISCUSSION

Cell proliferation was higher in cultures from 1-month compared with 21-month rats at all evaluated time-points ( $p < 0.001$  for all time-points). Besides, the cell

number increased ( $p < 0.001$ ) over time in cultures from 1-month rats, while no significant difference ( $p = 0.127$ ) was observed between 7 and 10 days in cultures from 21-month rats. Cells from 1-month rats showed higher ALP activity compared with cells from 21-month rats at 7 and 10 days ( $p < 0.001$  for both time-points), while no significant difference ( $p = 0.561$ ) was observed at 4 days. In addition, the ALP activity increased ( $p < 0.001$ ) over time in cultures from 1-month rats, while no significant difference ( $p > 0.050$ ) was observed between 4, 7 and 10 days in cultures from 21-month rats. Mineralized extracellular matrix was detected on Ti discs irrespective of cell source, with cells from 1-month rats producing the most dense and regularly distributed matrix. Additionally, the calcium content was higher ( $p < 0.001$ ) in cultures from 1-month compared with 21-month rats. The gene expression of all evaluated osteoblast markers, RUNX2, OSX, ALP, BSP, OPN and OC was higher ( $p < 0.001$  for all genes) in cultures from 1-month compared with 21-month rats. On the other hand, the gene expression of all evaluated adipocyte markers, PPARγ ( $p < 0.007$ ), aP2 ( $p < 0.050$ ) and RTN ( $p < 0.001$ ) was higher in cultures from 21-month compared with 1-month rats.

These findings indicate that aging reduces osteoblast differentiation of cells cultured on Ti as described elsewhere<sup>2</sup>. Additionally, it was observed that this reduction is associated with an increased adipogenic differentiation.

### CONCLUSION

Our results showed that the reduced osteogenic potential of MSCs derived from aging rats goes along with the increased adipogenic potential in cultures grown on Ti. As a consequence, the development of therapies to recover the balance between osteoblast and adipocyte differentiation, which could be associated with dental implant treatment in the elderly population, is of great interest.

# Controlled Release of Amorphous Calcium Phosphate from Titania Nanostructures Induces Osteoblastic Differentiation in Human Mesenchymal Stem Cells

Robert McLister, Mura McCafferty, George Burke, Brian J. Meenan

Biomaterials and Tissue Engineering Research Group, University of Ulster, Northern Ireland

[mc\\_lister-r@email.ulster.ac.uk](mailto:mc_lister-r@email.ulster.ac.uk)

## INTRODUCTION

It is well established that sputter deposited amorphous CaP coatings have osteoconductive properties that can be advantageous for directing cell response (1). This non-crystalline form of CaP is highly soluble in aqueous cell culture media and its controlled release in combination with key topographical features could be beneficial for encouraging osteoblastic differentiation of human mesenchymal stem cells (hMSCs) without the use of osteogenic media. In this work, the response of hMSCs to sputtered CaP coatings deposited onto titanium substrates with various nanoscale topographies has been determined. The focus of the work is on the role that specific forms of titania nanotopography can have in controlling CaP dissolution and how this subsequently influences hMSCs *in vitro*. The response of hMSC that have been cultured in osteogenic media prior to exposure to the surfaces is also reported.

## EXPERIMENTAL METHODS

Titania Nanotube (TiNT) surfaces were created by electrochemical anodisation of titanium coupons at 20V for 120 minutes in a solution of ethylene glycol with 0.3% wt NH<sub>4</sub>F and 3% wt DI H<sub>2</sub>O. Polycrystalline titania surfaces with nanostructured features were prepared by RF magnetron sputtering from titanium (98.9%) targets onto the same titanium coupons. Both types of surface were then coated with an amorphous CaP coating via RF magnetron sputtering from hydroxyapatite surfaces was carried out at a source power of 50 watts for 9 hours. A number of samples were annealed at 500°C to increase their relative crystallinity. Dissolution studies were undertaken by immersion in 2ml of DI H<sub>2</sub>O at 37°C for 7 days. XPS (Kratos Axis Ultra DLD spectrometer) was used to detect changes in the CaP coating after dissolution. *In vitro* cell studies were carried out using passage 5 hMSCs cultured in high glucose DMEM media with 10% foetal bovine serum (FBS). Osteogenic media was created by supplementing normal media with 10nm dexamethasone, 50µm ascorbic acid-2-phosphate and 10nM β glycerophosphate. Pico green and alkaline phosphatase (ALP) assays were carried out at days 1, 3, 7, 14, 21 to determine cell viability and osteoblastic differentiation, respectively. RNA extraction and qPCR analysis was undertaken at days 7, 14, 21 and 28 to assess Runx2, BMP and osteocalcin gene expression.

## RESULTS AND DISCUSSION

Figure 1 shows the high resolution Ca<sub>2p</sub> and P<sub>2p</sub> XPS spectra for sputtered deposited amorphous CaP coatings on titania nanotubes after 7 days dissolution. The percentage change in each element is indicated in the histogram for before (blue) and after (red) dissolution.

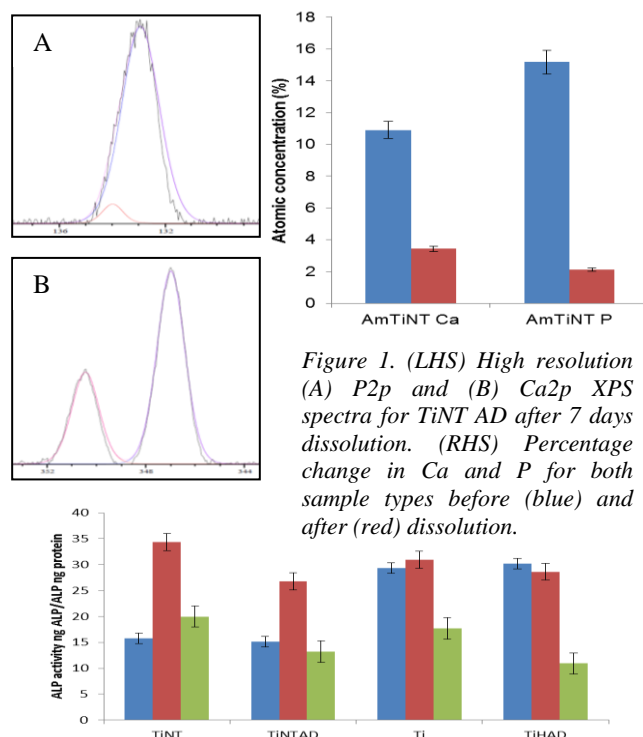

Figure 1. (LHS) High resolution (A) P<sub>2p</sub> and (B) Ca<sub>2p</sub> XPS spectra for TiNT AD after 7 days dissolution. (RHS) Percentage change in Ca and P for both sample types before (blue) and after (red) dissolution.

Figure 2. ALP expression at days 7, 14 and 21 from hMSCs cultured on titania nanotube surfaces (TiNT), titania nanotube with Am CaP after 7 days dissolution (TiNT AD), polycrystalline titanium coating (Ti) and polycrystalline coating with Am CaP after 7 days dissolution (TiHAD).

PicoGreen assay indicates the presence of viable cells on all surfaces at each time point. ALP expression from hMSCs cultured in normal media indicates their differentiation to an osteoblastic lineage with the highest expression observed at days 7 and 14. A significant decrease then occurs at day 21. qPCR data for hMSCs cultured in normal media shows osteocalcin at day 28 for CaP on both types of nanotopography after dissolution for 7 days.

## CONCLUSIONS

XPS shows that the dissolution of sputtered CaP is influenced by titania nanotopography. ALP assay data indicates that all the surfaces studied can promote differentiation of hMSC to osteoblastic lineage. qPCR confirms osteocalcin expression at day 28 from hMSCs cultured on a combination of nanoscale topography and amorphous CaP without the use of osteogenic media.

## INTRODUCTION

Articular cartilage is an avascular tissue whose ability to self-repair is extremely low. Even minor injuries may thus lead to painful osteoarthritic damages. Cartilage tissue engineering is one of the most promising approach for treatment of these damages. It is henceforth clear that this approach requires constructs associating at least a matrice scaffold and cells<sup>1</sup>. Among the several cell sources, mesenchymal stem cells (MSC) provide the greatest advantages<sup>1,2</sup>. Scaffold for cartilage tissue engineering should satisfied many requirements including biocompatibility, bioresorbability, porosity, and bioactivity<sup>2</sup>. Although there have been significant advances in cartilage tissue engineering, it remains challenges to overcome such as deposition of a hyaline rather than a fibrocartilaginous matrix<sup>1,2</sup>. Using an inversion phase process we prepared porous asymmetric scaffolds made of poly(lactic acid) which show a tridimensional architecture with interconnected macro- and micro-pores. Macropore mean diameter can be controlled and ranges between 80 and 185  $\mu\text{m}$ . Scaffold surface was entirely functionalized by a nanolayer of hyaluronan which is known to play an important role in hyaline cartilaginous matrix<sup>1,2</sup>. In this context, our work aims to study adhesion, proliferation and differentiation of umbilical cord MSC in our new biomaterials.

## EXPERIMENTAL METHODS

Biomaterial discs (16 mm diameter) were placed in 24-well plates. Each disc was seeded with  $10^6$  MSC in 2 mL of supplemented HDMEM culture medium containing  $0.15 \text{ ng.mL}^{-1}$  TGF- $\beta$ 3. Cultures were incubated at  $37^\circ\text{C}$  under 5 %  $\text{CO}_2$  during 42 days. For each set of experimental conditions, cell culture and analysis were performed in triplicate. Cell proliferation was measured using WST-1 test. Cell viability was quantified with the Vybrant<sup>TM</sup> Apoptosis assay using Alexia Fluor 488 annexin V as probe for apoptotic cells and propidium iodide as probe for necrotic cells. Cell profile was characterized by flow cytometry using fluorescent monoclonal antibodies. Gene expression of SOX-9, collagens I and II was analysed by RT-PCR.

## RESULTS AND DISCUSSION

MSC proliferated in the scaffold when its surface was covered with HA. However proliferation was significantly higher in scaffold with mean pore diameter of 160  $\mu\text{m}$  than in those with mean pore diameters of 130 and 185  $\mu\text{m}$ . This clearly shows that pore diameter strongly influences cell behavior. On the basis of this result, scaffold with mean pore diameter of 160  $\mu\text{m}$  was selected for following experiments. All along the 42-

days of culture, more than 90 % cells stayed alive, less than 10 % were apoptotic cells and no necrotic cell were detected indicating that our biomaterial does not cause cellular stress. We used the simple enzymatic method we developed to retrieve large numbers of viable cells for phenotypic analysis. Flow cytometry analysis showed that expressions of CD 90, CD 105 and CD 166 receptors<sup>3</sup> on cell surface strongly decreased after day 7 whereas expression of CD 49c and CD 151 receptors<sup>4</sup> strongly increased from day 14 to day 42. For each receptor, the level reached at day 42 was very closed to that measured for P2 chondrocytes. This change in phenotypic profil revealed MSC differentiation into chondrocytes<sup>3,4</sup>. Figure 1 shows RT-PCR analysis results. While the expression of SOX-9 and collagen I indicated the chondrogenesis condensation phase, that of collagen II revealed the maturation phase with deposition of a hyaline cartilaginous matrix<sup>5</sup>.

Figure 1: RT-PCR analysis of the expression of SOX-9, collagens I and II by cells during the 42 days of culture. GAPDH was used as negative control.

## CONCLUSION

Our new scaffold functionalized with hyaluronan is well-adapted to MSC adhesion and proliferation. In the presence of a chondrogenic medium, it allows MSC to differentiate into mature chondrocytes with deposition of a hyaline cartilaginous matrix. Our biomaterial is thus a good candidate for cartilage tissue engineering.

### INTRODUCTION

Multipotent mesenchymal stem cells (MSC) are a promising source for cell based therapies. Cultivation conditions can have a strong impact on differentiation characteristics of MSC. Three-dimensional (3D) culture systems have the basic idea of a higher similarity to the physiological environment of cells in the body than conventional two-dimensional (2D) cultures, as the cells can undergo increased cell-cell and cell-matrix interactions. Moreover, spheroids do not adhere to cell culture surfaces and are thus injectable without pre-treatment.

In this study we characterized 3D-spheroids of human MSC from adipose tissue (adipose tissue-derived MSC/adMSC) compared to adMSC in 2D grown on tissue culture polystyrene. The characterization was done non-stimulated as well as under specific osteogenic and adipogenic stimulation. Furthermore, the two different cell culture models were examined for the release of the pro-inflammatory cytokine interleukin-6 (IL-6), the basic fibroblast growth factor (bFGF) and the vascular endothelial growth factor (VEGF).

### EXPERIMENTAL METHODS

We used human adMSC in passage 4 and cultivated them under 2D (standard cultivation) and 3D/spheroid cultivation conditions. Seeding density was 20,000 cells/cm<sup>2</sup> for 2D- and 12,5000 cells/cm<sup>2</sup> for 3D-culture. Spheroid formation was attained by seeding in low attachment plates (Corning). Cultivation was performed for a period of up to three weeks.

Specific stimulation of differentiation was induced by standard reagents (osteogenic stimulation: dexamethasone, ascorbic acid, glycerophosphate; adipogenic stimulation: dexamethasone, indomethacin, IBMX, insulin).

Characterization of osteogenic differentiation potential was by detection of alkaline phosphatase activity and mineralization. Adipogenic differentiation was examined by oil red O. Cytokines and growth factors were quantified by ELISA (R&D-Systems).

### RESULTS AND DISCUSSION

Spheroid formation occurred within 1-2 days after seeding (Fig. 1). Whereas unstimulated (US) and osteogenically stimulated (OS) spheroids disintegrated within the period of observation for the most part, adipogenically stimulated (AS) spheroids were stable (Fig.1).

Adipogenic differentiation after specific stimulation took place in 2D and 3D culture (Fig. 2). The comparative quantification of lipid amount is pending.

The release of bFGF was upregulated in 3D cultures whereas the release of VEGF was downregulated in 3D compared to 2D (Table 1). Quantification of the pro-

inflammatory IL-6 revealed a downregulation in 3D spheroids (Table 1), which might be an important feature for the use of spheroids in regenerative medicine.

Fig. 1: Phenotype of spheroids after 2 and 16 days of cultivation under non-stimulated (US), osteogenically stimulated (OS) and adipogenically stimulated (AS) conditions (scale bar: 200 µm).

Fig. 2: Lipid detection in 2D and 3D culture after 21 days of adipogenic stimulation (scale bar: 50 µm).

Table 1: Growth factor and cytokine quantification in cell culture supernatants after 2 and 7 days in unstimulated (US) and adipogenically stimulated (AS) 2D and 3D cultures of adMSC.

time/stimulation		b-FGF		VEGF		IL6	
		2D	3D	2D	3D	2D	3D
		[µg/ml]		[µg/ml]		[µg/ml]	
2 d	US	-	29.46	266.59	-	2201.64	189.82
	AS	-	-	108.41	-	1067.09	84.36
7 d	US	-	23.75	1084.77	-	1778	494.36
	AS	-	65.18	435.68	-	1230.73	370.73

### CONCLUSION

Due to the successful adipogenic differentiation of spheroids and the clear reduction of pro-inflammatory cytokine release in 3D, spheroid cultures should be further examined for future application in cell-based therapies and tissue engineering.

# Investigation of the Effect of Different Velocities and Surface Treatments on hMSCs Seeding Efficiency and Mechanical Characterization of 3D Insert PCL Scaffolds Undergoing Compression Loading

Marzia Brunelli, Cecile M. Perrault, Damien Lacroix

INSIGNEO Institute for in silico medicine, Department of Mechanical Engineering, University of Sheffield, UK  
[mep12mb@sheffield.ac.uk](mailto:mep12mb@sheffield.ac.uk)

## INTRODUCTION

The study of mechanically-induced cell differentiation in a scaffold requires a preliminary understanding of the cellular distribution in the scaffold and the distribution of the mechanical load throughout the structure. A good cell seeding efficiency and distribution can be achieved by dynamically perfusing cells at appropriate rate<sup>1</sup> or statically seeding cells on structures modified by surface plasma<sup>2</sup> or collagen bulk treatments<sup>3</sup>. The objectives of this study were (1) to study the bioreactor conditions of a custom microfluidic system in term of surface/bulk treatments and flow rate in order to achieve uniform cell distribution in 3D PCL scaffolds seeded statically and dynamically, and (2) to measure the compressive mechanical properties of 3D PCL scaffolds and test their suitability in bearing cyclic loads.

## EXPERIMENTAL METHODS

**Microfluidic system.** Devices were developed using polydimethylsiloxane (PDMS) and drilling holes to accommodate 3 scaffolds in series. Air plasma treatment was applied to achieve glass-PDMS bonding. hMSCs were pumped at 0.01 and 0.1 mm/s and DNA assay was performed after 1, 2, 3 and 24 h.

**PCL scaffold seeding.** Air plasma was applied. Treated and non-treated 3D Insert PCL scaffolds (3D Biotek, USA) were seeded by dropping 20  $\mu$ l of cell suspension with or without collagen bovine 1 (Gibco). Presto Blue and DNA assays were performed after 24 h.

**PCL mechanical properties.** Scaffold area (A) was calculated as  $A = a \cdot (h/h + d)$  where  $h$  is the initial height,  $a$  is the area calculated as  $h = 1.5$  mm, and  $d$  is the displacement. A 14% compressive strain was maintained constant for 150 min. Then, samples were loaded with cyclic ramps at 5% strain and apparent modulus ( $E$ ) was calculated as average stress over strain at 25, 30 and 37°C.

## RESULTS AND DISCUSSION

Scaffolds seeded at 0.1 mm/s showed low attachment with an initial peak of 14% reduced to 6% after 24 h. The microfluidic system at low velocities is subject to the gravitational action requiring a pre-cycle at 0.1 mm/s before setting a constant velocity of 0.01 mm/s in order to obtain the same seeding efficiency among samples. Static seeding showed enhanced attachment on treated scaffolds due to a more active surface (Fig.1A). Collagen allows a steep increase of efficiency up to 60%. Scaffolds present a high variability for strain above 2.5% suggesting a strong dependence of the mechanical properties on scaffold orientation and fiber alignment (Fig.1B). For strain values below 1%, the change in slope due to contact and stabilization of the structure is noticeable. Between 1 and 2.5% strain

scaffolds show a linear behaviour resulting in an apparent modulus of  $5.5 \pm 1.5$  MPa at 25°C.  $E$  decreases progressively with temperature up to  $2.5 \pm 1.1$  MPa at 37°C. The maximum stress at 37°C acting on samples loaded with 5% strain amounts to  $0.31 \pm 0.09$  MPa.

Fig.1: (A) Viability of plasma treated (PCLt), collagen embedded (cPCL) and treated collagen embedded (cPCLt) samples after 24 h; (B) Loading stress/strain curve of PCL scaffolds.

## CONCLUSION

The multi-chamber perfusion system presents a uniform distribution of cells at high flow rates but the excessive shear stress prevents a significant seeding efficiency. At low flow rates, gravity prevents a uniform cellular distribution among scaffolds and applying high rate pre-cycles have negative effects on cell adhesion capabilities. A simple configuration based on a single chamber is preferred to minimize the effect of gravity and flow variability between the chambers. Static seeding is improved by embedding collagen within plasma treated scaffolds as the viscosity of the gel prevents cells from drifting out the structure and the plasma treatment allows uniform spreading of collagen and cells. Following relaxation, PCL scaffolds do not show significant viscoelastic effects. The stiffness measured on this PCL scaffold show consistent values with repeated cyclic compression and are of sufficient magnitude to provide an initial stabilization for osteochondral or bone repair applications.

### INTRODUCTION

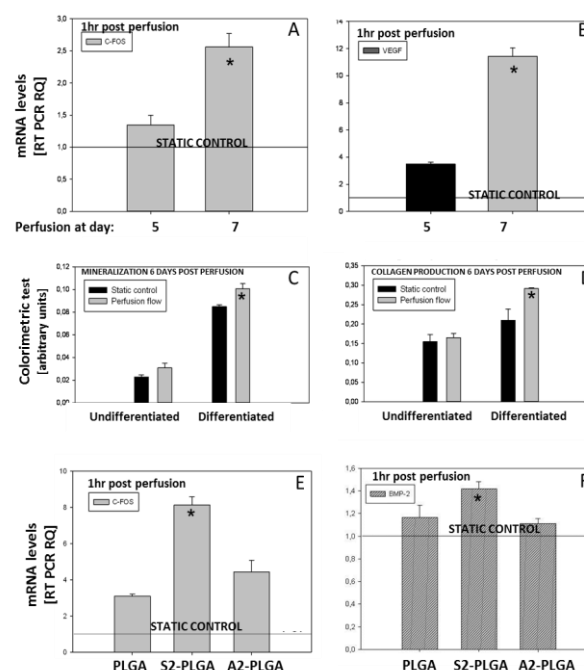

Perfusion of culture media through cell-seeded 3D scaffolds may provide several benefits to cells growing within the scaffold pores. Recently, Keogh et al. showed that a short flow perfusion effectively stimulates osteogenesis in 3D osteoprecursors culture<sup>1</sup>. We have examined whether a short, one-directional media perfusion through porous 3D scaffolds can enhance *in vitro* osteogenesis of human bone marrow-derived osteoprogenitor cells (hBMSC). hBMSC are commonly used in cell-based bone therapies and hBMSC dynamic cultures become an important part of bone tissue engineering with these cells. We show that a short, steady, one-directional media perfusion through the scaffold pores may enhance hBMSC osteogenic response, but this depends on cell culture and cell differentiation stage as well on scaffold chemistry.

### EXPERIMENTAL METHODS

hBMSC<sup>2</sup> were seeded on either gelatine-coated polyurethane (PU)<sup>3</sup> or on composite scaffolds made of PLGA and gel-derived bioactive glass (i.e. high silica S2 or high calcium A2)<sup>4</sup>. Cells were stimulated with osteoinducers (i.e. dexamethasone or rhBMP-2) or left untreated. Some hBMSC were pre-treated with osteoinducers in 2D cultures (differentiated) and compared to undifferentiated cells. Media perfusion was applied at 2.5ml/min for 2h in EBERS 1000TEB bioreactor. Perfusion stimulated cultures were compared to corresponding static controls. Data were collected in triplicates. Statistical analyses were performed in Sigma 11.0 software and  $p \leq 0,05$  was considered significant.

### RESULTS AND DISCUSSION

We found that a single perfusion session is sufficient to enhance hBMSC response, but this depends on a culture stage the perfusion is applied. Perfusion at day 7 resulted in increased *c-Fos* and *VEGF* mRNA levels compared to perfusion at day 5 (Fig. 1A, B). This suggested increased mechanical and angiogenic response of hBMSC, respectively. Perfusion at day 7 also enhanced mRNA levels of *RUNX-2* and *BMP-2* that are important for initiation of osteogenesis (data not shown). When hBMSC were pre-differentiated in 2D cultures, the effects of perfusion were more profound compared to respective static controls. Perfusion applied at day 7 of 3D cultures significantly enhanced collagen deposition and matrix mineralization in differentiated (Fig. 1C, D). Finally, when hBMSC were

cultured on bioactive composite scaffolds, the scaffolds chemistry seemed to determine their response to perfusion. hBMSC cultured on

composite S2-PLGA scaffolds and subjected to perfusion, expressed significant mRNA levels of mechanoresponsive *c-Fos* and pro-osteogenic *BMP-2* compared to PLGA or A2-PLGA (Fig 1E, F). Thus, the chemical composition of the scaffolds should be taken into account when dynamic culture is applied.

### CONCLUSIONS

Our data indicate that a short stimulation of 3D hBMSC cultures with media perfusion may find a broad application in bone tissue engineering on either bioinert or bioactive scaffolds, but culture conditions and cell delivery constructs must be carefully optimized to achieve beneficial perfusion effects.

## INTRODUCTION

Prebiotic chemistry is the study of the chemistry associated with the origin of life<sup>1</sup>. HCN derived polymers have been studied for many years in this context as possible sources for the precursors of proteins and nucleic acids<sup>2</sup>. However, the application of these polymers in the field of materials science has not been reported. Here, we have investigated the polymerization of the HCN trimer aminomalononitrile as a simple generic surface coating method. Our results suggest that the resulting rich surface chemistry is highly suitable for biomedical applications<sup>3</sup>.

## EXPERIMENTAL METHODS

Aminomalononitrile p-toluenesulfonate (AMN) was used as a precursor material. PBS buffer solutions containing AMN were adjusted to pH 8.5 using sodium hydroxide to initiate polymerization. Copolymerization reactions were carried out both during coating formation and via secondary immobilization reactions, while metallization experiments were carried out after coating deposition. Surface analysis was carried out XPS, AFM, SEM and contact angle measurements. Cell culture experiments were carried out using L929 mouse fibroblasts. Biofilm assays were carried out using *S. Epidermidis* and *P. Aeruginosa* strains.

## RESULTS AND DISCUSSION

Aminomalononitrile polymerizes spontaneously to give a brown protein-like polymer. We found that this polymerization reaction, when carried out in simple aqueous buffer solutions, can be used to produce adherent coatings on a wide range of organic and inorganic substrate materials (Figure 1).

Figure 1. Contact angles determined on a range of materials before and after AMN coating deposition.

We also demonstrated that the robust, non-cytotoxic AMN coatings provide cell attachment equivalent to tissue culture polystyrene (TCPS), thereby providing access to a range of biomedical applications (Figure 2).

Figure 2. L929 cell attachment after 24 h on Corning Ultra-low attachment surface (ULA) before and after AMN coating in comparison to TCPS.

In addition, the nitrogen-rich coating chemistry allows the covalent immobilization of compounds carrying suitable complementary functional groups such as aldehydes both during coating formation and via secondary immobilization reactions. Furthermore, AMN coatings can be used for metallization. This can be exploited for the formation of antimicrobial coatings via the release of silver ions (Figure 3).

Figure 3. AMN polymer coatings are effective in preventing the formation of biofilms after electroless silver deposition.

## CONCLUSION

We have demonstrated that prebiotic chemistry inspired coatings derived from AMN can be deposited on a wide range of substrate materials. These coatings combine excellent biocompatibility with a rich surface chemistry, allowing the immobilization of bioactive signals and the complexation of metal ions. Combined with an extraordinarily simple coating process, it is expected that these coatings will be translated into a number of biomedical applications.

### INTRODUCTION

Over the last three decades, the envisaged strategies to develop biocompatible vascular materials have considerably evolved. Nowadays, several research group objectives are targeted towards the development of bioactive materials. It is expected that these materials would promote specific interactions with the endothelial progenitors cells. The main strategy used in our work is the co-immobilization of two different bioactive molecules onto biomaterial surface in order to improve cell recruitment, adhesion and differentiation. Accordingly, sitagliptine<sup>1</sup> and RGDS peptide are covalently conjugated on PET to recruit these cells and promote their adhesion, respectively. They were micropatterned by photolithography process<sup>2</sup> to mimic the extracellular matrix. This technique consists of the transfer of a specific pattern to a photosensitive material (a photoresist) by selective exposure to a radiation source. This allows enhancing the biocompatibility of the so-called biomaterial<sup>3</sup>. The present work focuses on characterizing the grafting of these bioactive molecules on PET.

### EXPERIMENTAL METHODS

Sitagliptine, was from Biovision, Milpitas, CA. RGDS and RGDS-TAMRA peptides were purchased from Genecust, Luxembourg.

#### Bioactive molecule grafting:

PET films were subjected to ethanol washing under sonication before use. The first grafting step consisted in hydrolysing PET ester groups to get carboxylic acid moieties onto the polymer surface<sup>4</sup>. These –COOH groups were then converted into activated esters through reaction with NHS and EDC grafting. This step allowed further peptide grafting. Fluorescent peptide (RGDS-TAMRA) was used in order to characterize the homogenous and patterned functionalization of PET.

#### Characterization:

All the samples were analysed with XPS, AFM (data not shown). Epifluorescence microscopy (Leica DM5500B, Germany) was used to characterize

grafting of RGD-peptide. Optical profilometer (VEECO NT9080) was used to study size and spacing of the lines of pattern (Fig3). Various patterns will be used. After the reaction, the amount of COOH grafted onto the film was determined using the toluidine blue-O method. The density of the carboxyl groups is determined with a calibration plot containing several samples with different carboxyl group concentrations.

### RESULTS AND DISCUSSION

As we expected the experiment shows (Fig 4) that the density of carboxyl groups increase with the oxidation step, which is normal because of the breakage of the polymer chains it expose more COOH groups on its surface. The

Fig4 : Carbonyl group density of the different steps of functionalization of PET

decreasing of COOH density after NHS grafting proves NHS is covalently grafted by COOH functions onto PET surface. The PET sample functionalized with the peptide shows a higher density due to carboxyl groups in its structure. Fluorescent microscopy permitted to validate homogeneous RGDS peptides (Fig5) grafting onto PET surfaces, and patterned RGDS peptides and sitagliptine grafting

Fig5 : RGDS-TAMRA peptides homogeneously grafted onto PET surfaces (1) RGDS-TAMRA peptides and sitagliptine patterned on PET (2)

### CONCLUSION

Bioactive molecules were successfully grafted onto the surface of PET. These molecules were selected to promote the recruitment of endothelial progenitor cells as well as their adhesion, proliferation, and differentiation. Further experiments will be done in order to study the recruitment effect of sitagliptine on EPCs and adhesive properties of RGD peptide. Impact of surface grafting homogeneously and patterned with different geometry will be study on endothelial progenitor cell.

## INTRODUCTION

Titanium (Ti) and Ti alloys are largely used in different clinical areas for example in orthopaedics, craniofacial, dental and bone replacement<sup>1</sup> due to their exceptional mechanical properties tensile strength, stiffness, fracture toughness and corrosion resistance<sup>2</sup>. It is well known that Ti and their alloys have an amphoteric oxide layer<sup>3</sup> and by increasing the thickness of this oxide layer can improve adsorption of biomolecules<sup>4</sup>. Synthetic peptides are developed to be used as non-pathogenic and -cytotoxic scaffolds for drug delivery, tissue repair and engineering<sup>5</sup>. In this study a peptide aptamer is electrostatically adsorbed onto modified Ti surfaces. The interaction of a range of peptide aptamer sequences with modified Ti6Al4V surfaces of different roughness is explored. The aim is the formation of a stable and homogeneous layer of peptide aptamers, to explore the possibility of adding functionalities to Ti-based medical surfaces.

## EXPERIMENTAL METHODS

Solid-phase peptide synthesis (SPPS) principles were used to synthesise the Ti-hydroxyapatite (Ti-HA) aptamer KKLPDAKKLPDAEEEEEEEEEE labelled with 5(6)-carboxyfluorescein (5-FAM) for posterior tracking. Ti6Al4V plates of medical grade and of dimensions 0.01m x 0.01m were dip coated in PBS buffer pH 7.4 with 1, 5 and 10 $\mu$ M of peptides and without peptide as control. The surfaces were characterized by SEM, white light interferometry, and fluorescence microscopy.

## RESULTS AND DISCUSSION

The TiO<sub>x</sub> layer obtained after different chemical treatments with 30wt% aqueous H<sub>2</sub>O<sub>2</sub> was analysed by SEM (Figure 1). The roughness was measured by interferometry to investigate the effect of etching time on the topography of the samples (Table 1).

**Table 1.** Surface roughness of titanium plates after etching with H<sub>2</sub>O<sub>2</sub> 30 wt% aqua solution for 0, 1, 3, 6, 13, 24 and 48 hours.

Etching time (h)	S <sub>a</sub> (average roughness, nm)	S <sub>y</sub> (peak to valley, $\mu$ m)
0	13 $\pm$ 9	0.22 $\pm$ 0.08
1	37 $\pm$ 3	1.14 $\pm$ 0.14
3	29 $\pm$ 1	1.57 $\pm$ 0.12
6	78 $\pm$ 4	1.23 $\pm$ 0.04
13	33 $\pm$ 3	2.6 $\pm$ 0.31
24	197 $\pm$ 7	2.38 $\pm$ 0.37
48	128 $\pm$ 2	3.35 $\pm$ 0.41

Etching with H<sub>2</sub>O<sub>2</sub> increased electrostatic interactions according with the literature<sup>4</sup>. An increase in roughness also had an effect on the electrostatic interactions and quality of the Ti-HA peptide coating as shown clearly in Figure 2. This observation is in good agreement with previous work<sup>4</sup>. This suggests that both the roughness and composition of Ti surfaces are important for improved bioactivity<sup>1-4</sup>.

**Figure 1.** Micrographs of (a) Ti mirror polished surface, (b) Ti mirror polished surface etched for 1h, (c) 3h, (d) 6h, (e) 13h, (f) 24h and (g) 48h.

**Figure 2.** Fluorescence intensity of (a) control (b) 1 $\mu$ M Ti-HA peptide on etched Ti6Al4V, (c) 5 $\mu$ M Ti-HA peptide on etched Ti6Al4V and (d) 10 $\mu$ M Ti-HA peptide on etched Ti6Al4V.

## CONCLUSION

Ti6Al4V was etched with H<sub>2</sub>O<sub>2</sub> to increase hydroxyl groups on the surface. The oxide layer became thicker with increasing the etching time resulting in a simultaneous increase in roughness that allowed better adsorption of peptide aptamers on the Ti surface. A homogeneous surface coating was achieved.

### INTRODUCTION

Recently, the most commonly used materials for bone-implants are titanium and its alloys. It is due to their good biocompatibility, high strength to weight ratio and an excellent corrosion resistance [1]. Unfortunately, there are some drawbacks connected with titanium implants, such as their inertness and long-term osseointegration via the natural oxide (TiO<sub>2</sub>) existing on Ti surface. Therefore, nanoporous materials on Ti surfaces become a novel solution for bone implants [2]. One of the materials proposed as a potential nanostructured material for that purpose are nanoporous anodic titanium dioxide (ATO) layers on Ti formed by electrochemical anodization [3]. The main advantage of such materials is a direct growth of TiO<sub>2</sub> on Ti surface, using a simple and cost-effective method of anodic oxidation. Anodization allows to precisely control nanopore size and structure porosity, which have a great impact on cell growth [4]. Nanoporous layer guarantees an excellent inertness of its surface, allowing it to readily heal into the bone tissue. Such surfaces may be also modified with antibacterial and anti-inflammatory compounds, that could help with the healing process.

### EXPERIMENTAL METHODS

ATO layers on Ti foil were prepared via a three-step anodization in glycol ethylene based solutions under a constant voltage of 40 V and temperature 20 °C. As-prepared ATO layers were then annealed at two different temperatures in order to obtain polymorphic structures of TiO<sub>2</sub> (anatase and a mixture of anatase and rutile). Some of the TiO<sub>2</sub> layers were modified with Ag nanoparticles for increased antibacterial properties. Moreover, two kinds of drugs, ibuprofen and gentamicin, were loaded inside ATO pores. The drug release profiles were made. Afterwards, non-modified and modified samples were used for cell and microbial growth examinations. The MG63 osteoblast cell line was used for cell viability and proliferation tests. *Staphylococcus aureus* and *Pseudomonas aeruginosa* bacteria were used for evaluation of the inhibition of microorganisms growth and possibility of a biofilm formation on various nanoporous TiO<sub>2</sub> surfaces.

### RESULTS AND DISCUSSION

ATO layers on Ti substrate formed by anodization process allow to obtain a well-organized nanoporous structure with a well-defined pore diameter and oxide thickness. Furthermore, the presence of porous structure enables to load small compounds inside the pores. Both,

silver nanoparticles and drug compounds were successfully loaded inside pores. ATO layers enriched with either ibuprofen or gentamicin exhibits an extended release profiles. This may suggest that ATO layers may be used as a drug delivery systems, especially in implantology. Microbiological tests showed that gentamicin completely inhibits growth of bacteria on TiO<sub>2</sub> surface. Silver nanoparticles also show antibacterial properties but to a lesser extent. The cell growth on ATO layers is enhanced. Dependently on a crystallographic structure, osteoblast like cells grow differently. The best surface for cell growth seems to be an anatase phase.

### CONCLUSION

ATO layers presents a new and promising alternative for the osteoblast like cell growth. Due to the presence of the nanoporous dioxide on Ti substrate, there is a possibility to enrich ATO layers with antibacterial and anti-inflammatory compounds. Nanoporous TiO<sub>2</sub> on Ti foil enhances cell growth and at the same time inhibits bacteria expansion.

## INTRODUCTION

Glycosaminoglycans (GAGs) are main building elements of the extracellular matrix where they act in synergism with proteins and are equally critical for the development, growth, function or survival of an organism[1]. GAGs are anionic linear polysaccharides made of repeating disaccharide units, whose negative charge is due to the presence of sulfate groups. These charge units have a crucial role in GAG interaction with proteins and therefore in key biochemical/signalling processes related to cell functionality and survival. In a previous work we have developed a platform that is based on self-assembled monolayers (SAM) and allow precise control on the surface exposed sulfonic groups (-SO<sub>3</sub>H)[2]. We proved that those surfaces are reliable tools to study GAGs interactions with proteins (basic fibroblast growth factor, FGF-2) or cells[2, 3]. Herein, we have used the same SAM platform to investigate the influence of sulfonic functional groups on the interactions with fibronectin and the impact of these interactions on the adhesion and morphology of human adipose derived stem cells (ASCs).

## EXPERIMENTAL METHODS

SAMs were prepared by adsorption of HS(CH<sub>2</sub>)<sub>11</sub>OH or HS(CH<sub>2</sub>)<sub>11</sub>SO<sub>3</sub>H on gold coated glass slides or QCM crystals to obtain -OH or -SO<sub>3</sub>H functionalised surfaces respectively. The interaction between these surfaces and fibronectin (FN) was studied in situ by quartz crystal microbalance with dissipation (QCM-D). Live-imaging and QCM-D were used to follow in situ the cell adhesion on SAMs surfaces with or without adsorbed fibronectin. Immunofluorescence was employed to assess the effect of surface chemistry and protein adsorption on cell morphology.

## RESULTS AND DISCUSSION

FN has an acidic isoelectric point and thus, we were expecting some repulsion between the negatively charges sulfonic groups on -SO<sub>3</sub>H surfaces and this protein. However, QCM-D data showed that more FN adsorbs on -SO<sub>3</sub>H surfaces in comparison to the uncharged -OH functionalised ones. Unexpectedly, the adsorbed protein had negative influence on the cell adhesion: ASCs adhere significantly faster on -SO<sub>3</sub>H surfaces in the absence of FN (Fig. 1A). Opposite effect was observed for the -OH surfaces: adsorbed FN shortens significantly the adhesion time in this case. Different cell morphology was also observed: cells spread after 7h on -SO<sub>3</sub>H surfaces and on -OH surfaces when coated with FN (Fig. 1B). The analysis of cell motility (Fig. 1C) showed that cells have longer

migration paths on -OH surfaces suggesting weakest ASC adhesion on those surfaces.

**Figure 1.** Time of adhesion (A), morphology (B) and migration paths (C), obtained from the live imaging analysis (A and C) and immunofluorescence (B).

These results suggested different mechanism of adhesion on both studied surfaces. Live-imaging analysis and QCM-D confirmed this hypothesis. The presence of fibronectin causes an opposite effect on the studied surfaces – it delays cell adhesion on -SO<sub>3</sub>H functionalised surfaces and accelerates it on -OH ones. The protein causes formation of ASCs clusters on -SO<sub>3</sub>H surfaces, i.e. the cell adhesion depends on previous adherent cells on the surface.

## CONCLUSION

Based on these results, we propose a model according to which positively charged amino acids from FN interact electrostatically with the underlying -SO<sub>3</sub>H groups causing both passivation of the surface by neutralisation of its charge and irreversible change in the conformation of the protein. As a result the protein is not active in further interactions with cells. The FN adsorption on -OH is based on weaker interactions that do not restrict the protein flexibility in the following interactions with ASCs.

## INTRODUCTION

Natural polymer derived scaffolds for use in tissue engineering of heart valves have been seen as the ultimate devices proposed by heart surgeons for replacing diseased heart valves. Interpenetrating polymer networks (IPNs) can provide an even better way of building natural polymer based TEHVs with properties matching those of native heart valves. The characteristic interlocking structure of two polymers in an IPN is expected to enhance the mechanical integrity and in-vitro degradation resistance of resulting TEHVs. Collagen and glycoaminoglycans (GAGs) are the most abundant polymers found in human heart valve accounting for 60% and 20% by weight respectively [1]. Hyaluronic acid (HA)-collagen system has found applications in reconstruction of different tissues in the body such as skin and eye etc [2-4]. In the current study, the fundamentals of this approach have been extended to utilize HA-collagen for the development of novel TEHVs.

## EXPERIMENTAL METHODS

HA-Collagen based full IPNs were prepared by combining different proportions of HA and collagen hydrogels. Parent hydrogels (i.e. HA and collagen) with varying crosslinking densities were synthesized using freeze drying method followed by carboiimide crosslinking chemistry. In the next stage, collagen hydrogels (primary network) were penetrated by HA chains (secondary network) followed by HA chain crosslinking in the presence of collagen network. HA hydrogel, collagen hydrogel and resulting IPNs were characterized by Fourier transform infrared spectroscopy (FTIR), nuclear magnetic resonance (NMR) and scanning electron microscopy (SEM) to estimate the effect of crosslinking on chain structure and pore size. The effect of concentration of crosslinking agent on crosslinking densities and swelling ratio were studied. Degradation behaviour of hydrogels was studied in Phosphate buffer saline (PBS) at 37°C. To assess the biocompatibility of IPNs, scaffolds were cultured with cardiosphere derived cells (CDCs) from rats.

## RESULTS AND DISCUSSION

Peak analysis performed on FTIR spectra of hydrogels confirmed the modified polymer chain structure. Degree of modification was calculated around 30% for HA hydrogel. Swelling studies indicated that swelling ratio decrease with increase in concentration of crosslinking agent for both HA and collagen hydrogels. Image analysis of SEM micrographs revealed that pore size tends to decrease with an increase in crosslinking density for primary networks i.e. Collagen. The

degradation profile of HA hydrogels at pH4.0 and pH 7.4 indicates that crosslinking density contribute significantly to the degradation resistance. For instance, HA hydrogels showed higher weight loss (50% wt) in neutral media as compared to acidic media (30% wt). However, in contrast, Collagen did not show any appreciable weight loss under different conditions. This feature can be manipulated for tailored degradation rates of IPNs under physiological conditions. HA hydrogels only respond to specific cell receptors such as CD44, when combined with collagen which is capable of interacting with wide spectrum of cells, cell attachment can be enhanced on HA-collagen IPNs. Percentage reduction in AlmarBlue assay on CDCs cultured cross-linked collagen hydrogels suggested that degree of cell attachment decreases with increase in crosslinking density and the rate of cell proliferation was found to be independent of the extent of crosslinking density.

Figure showing scanning electron micrographs (SEM) of (a) HA hydrogel (b) Cross-linked collagen network at 100X.

## CONCLUSION

HA and collagen could be the ideal natural polymers for the construction of TEHV. A unique experimental route based on a chemical crosslinking technique to fabricate the HA-collagen based full IPN structures has been demonstrated. The emerging 3D constructs have shown great potential for mimicking the healthy heart valve in terms of mechanical and in-vitro biological compatibility.

### INTRODUCTION

During the past decade, multicompartiment and anisotropic assemblies with complex architectures have received significant attention due to their novel morphologies and diverse potential applications<sup>1</sup>. Microassemblies with complex architectures are more desired due to their unique properties such as anisotropic responses to external force, large surface area and building blocks for hierarchical superstructures formation. For the biological and medical areas, shape-controlled biocompatible and biodegradable hydrogel microassemblies can be applied as drug delivery<sup>2</sup> and cell immobilization<sup>3</sup> systems.

We firstly describe microfluidic devices for the generation of monodisperse anisotropic microparticles and microfibers based on plant or marine polysaccharides. Secondly, we demonstrate the ability of these renewable resources microassemblies to control the release of a model protein.

### EXPERIMENTAL METHODS

Low-methoxyl citrus pectin was purchased from Cargill France SAS. Alginate was obtained from FMC biopolymer (U.S.A.). HE800 exopolysaccharides (EPS) was produced by *Vibrio diabolicus* hydrothermal bacterium by fermentation process<sup>4</sup>. Gel formation was set by the ability of cross-linking between the carboxylic groups of uronic acids present in these polysaccharide structures and divalent cations. Flow-focusing devices were designed to structure pectin, alginate or HE800 into complex anisotropic microparticles (Janus and rose-shape morphologies) or microfibers. Polysaccharide gelation was initiated in the chip by diffusion-controlled ionic cross-linking. Morphological characteristics were studied by confocal scanning laser microscopy (CSLM) and scanning electron microscopy (SEM). Encapsulation of fluorescein isothiocyanate labelled bovine serum albumin (BSA-FITC) was investigated. The distribution of labelled BSA was studied by CSLM and/or fluorescence spectrophotometry.

### RESULTS AND DISCUSSION

In a first step, microfluidic technology was applied to elaborate microassemblies based on natural polysaccharides, namely pectin and alginate. Janus microparticles made of pectin-pectin (homo Janus) and pectin-alginate (hetero Janus) of perfectly controlled size and composition were produced. The microparticles of a high monodisperse diameter of 90µm were shown to be stable in calcium solution. The

efficiency of formation of the two hemispheres was then investigated by CSLM. The Janus structure was also confirmed by subjecting each microparticle hemisphere to specific enzymatic degradation. As a proof of concept, free labelled-BSA or labelled-BSA grafted with dextran, were encapsulated in each hemisphere of the hetero Janus microparticles<sup>5</sup>.

In a second step, microfluidic was used for the first time to structure HE800 EPS. This polysaccharide displays an interesting glycosaminoglycan (GAG)-like structure and can thus be considered as an innovative compound to design biomaterials for tissue engineering. We took advantage of microfluidic tool to generate either stable cylindrical stream or emulsion to elaborate, respectively, microfibers and microparticles. Microfibers of 1-5 mm in length and 90 µm in diameter were structured in layers with a smooth surface. The convective intermixing inside the droplets led to microparticles of rose-shape structure composed of rolled up layers. Microparticles had a diameter of 90µm. Both microassemblies were shown to be stable in copper solution. In order to evaluate the potential of the microassemblies formed as delivery systems, encapsulation of labelled-BSA was assessed. The protein release was studied in different buffers and culture media.

### CONCLUSION

This study demonstrates the use of microfluidic to generate complex microassemblies based on natural polysaccharides, which can further be used as controlled release systems. Microfluidic tools offer high control, of the size, the shape and the composition of microassemblies. The encapsulation using microfluidic devices is highly advantageous since all active compound is integrated within microassemblies formed.

### INTRODUCTION

Glycosaminoglycans (GAGs) are a class of anionic polysaccharides, most of them being more or less sulfated<sup>1</sup>. GAGs perform many structural and physiological functions such as regulating hemostasis, morphogenesis and immune response, and take part in a multitude of pathological processes. They are also anatomical components of many structures on different levels, e.g., cellular receptors, extracellular matrix (ECM), cartilage, tendons, cornea, and many others.

### RESULTS AND DISCUSSION

In our studies GAGs played three different roles:

**1. GAGs as biomaterials.** Using the LbL technique we have obtained ultrathin multi-layered cell culture supports<sup>2</sup>. The polycation used to fabricate the supports was diazoresin while heparin, chondroitin sulfate and hyaluronic acid (the only nonsulfated GAG) were used as polyanions. Irradiation of the supports resulted in photocrosslinking of the multilayer and increased its stability. We found that human mesenchymal stem cells (hMSC) grew on these supports much faster than on the commercial tissue culture plastic (TCP) supports. Moreover, the hMSC monolayers spontaneously detached from the support so that no trypsinization was necessary. The supports could be regrown by new cell layers relatively early during culture indicating that the supports were not modified by the growing cells.

**2. GAGs as drugs.** Heparin is a GAG commonly used as an anticoagulant in thrombotic disorders and cardiac surgeries. In emergency (e.g., hemorrhage), its anticoagulative action has to be interrupted by the administration of protamine, which is, however, a hypotensive and immunogenic protein and may trigger life-threatening reactions. Therefore, searching for a safer heparin antidote, we have obtained a series of cationic polymers, both synthetic and of natural origin, which have been proved to inhibit heparin both *in vitro* and *in vivo*<sup>3</sup>. Some of them have been found to be superior to protamine.

**3. GAGs as pathogens.** As mentioned above, GAGs are essential components of human body. However, the disorders in their metabolism may result in serious diseases, such as the Sanfilippo disease, a rare genetic and so far incurable disease caused by the excessive storage of heparan sulfate in all body cells, ultimately leading to death in the second decade of life. Some isoflavone compounds, such as daidzein, are known to

decrease level of GAGs. Unfortunately, poorly soluble daidzein shows very low bioavailability. To overcome this problem we have developed drug delivery systems based on the complex of cationized  $\alpha$ -cyclodextrin with daidzein. The cationic cyclodextrin was shown to be efficiently taken up by murine nervous cells and by normal human dermal fibroblasts (HDFs) and its complex with daidzein decreased the level of GAGs in HDFs<sup>4</sup>. Moreover, the cationic cyclodextrin was found to be mucoadhesive suggesting the possibility of its oral administration.

### CONCLUSIONS

Glycosaminoglycans are an important yet apparently underappreciated class of biopolymers. A better understanding of their structure, physicochemical properties and mechanism of action is needed to fully exploit their great potential as biomaterials and drugs and to treat GAG-related pathologies.

## INTRODUCTION

PLA and related polymers are widely used materials in medical devices because of their biocompatible and biodegradable properties. The history and changes of such polymers after implantation as medical devices should be characterized since they condition their tissue repair functions by providing mechanical and/or scaffolding properties.

In this study, PLA degradation has been investigated, in particular, in terms of molecule transformation and crystallinity evolution, after subcutaneous implantation in rabbits. The extent and mapping of PLA degradation within selected medical devices was documented by a novel approach combining FTIR spectroscopy and image analysis, from tissue explant sections.

## MATERIALS AND METHODS

18 New Zealand White male rabbits were included in this study. Each rabbit received 8 subcutaneous implants: 4 PLLA test meshes and 4 control meshes (TIGR® Matrix Surgical (made of copolymers of lactic acid, glycolic acid and trimethylene carbonate - Novus Scientific). The follow-up period was 4, 26 and 52 weeks (n=6 animals per time-period). Both the test and control meshes were implanted in 3 configurations: original state, partially pre-degraded and highly pre-degraded state in terms of residual molecular weight, gravimetric mass and manipulability by controlled accelerated hydrolysis. The tissue explants were paraffin-embedded and the glass slide histological sections (9 µm thickness) were prepared before dewaxing.

FTIR (Fourier Transform Infra-Red) measurements were made directly on the tissue sections using Spotlight 400 (Perkin-Elmer) microspectrometer. FTIR mapping was performed in ATR (Attenuated Total Reflection) mode using the ATR-imaging accessory with Ge crystal. The scanned area was 400 x 400 µm<sup>2</sup> with lateral resolution of 1.56 µm. The MCT (?) detector covered the range from 720 to 4000 cm<sup>-1</sup> with a spectral resolution of 8 cm<sup>-1</sup>.

Standard histology staining on serial tissue sections were carried out in parallel.

## RESULTS

FTIR analysis of reference PLA fibers (non-degraded PLA and PLA pre-degraded during 120 h) revealed peak shifts and intensity changes for bands at 1209 cm<sup>-1</sup> and 1130 cm<sup>-1</sup> (Fig. 1). These bands are related respectively to the asymmetric C-O-C stretching ( $\nu_{as}COC$ ) and asymmetric CH<sub>3</sub> rocking ( $\nu_{as}CH_3$ ) vibrations<sup>1</sup>. The intensity of these bands is linked to the crystallinity of PLA, increasing with lower

molecular weights of PLA as a result of hydrolysis progression.

FTIR maps of PLA fibers from tissue explant sections have been processed and the ratio R1 (1209 cm<sup>-1</sup> band intensity / 1181 cm<sup>-1</sup> band intensity) was imaged in false colors, in the overall tissue sections (≈10 x 20 mm<sup>2</sup>) as illustrated in Fig. 2.

Fig. 1. FTIR spectra of non-degraded (blue) and degraded PLA (red).

Fig. 2. FTIR mapping of the PLLA mesh 26 weeks post-operatively. In red, degraded PLA (high R1 ratio) and in blue non-degraded PLA (low R1 ratio).

## DISCUSSION AND CONCLUSIONS

FTIR microscopy has been used to image the degradation of PLA from explanted tissues. It precisely mapped out the progression of degradation of PLA and related polymers in meshes and inside yarns. This helped in better understanding the foreign body reaction kinetics and tissue repair throughout the in vivo life of the degradable polymers, by confronting FTIR and standard histology results.

## Possible Approach to Improve Systemic Gene Delivery to Tumour Using Polyplex Nanoparticles

Mikhail Durymanov<sup>1</sup>, Alexei Yarutkin<sup>2</sup>, Andrey Rosenkranz<sup>1,2</sup>, and Alexander Sobolev<sup>1,2</sup>

<sup>1</sup> Laboratory of Molecular Genetics of Intracellular Transport, Institute of Gene Biology of the RAS, Russia

<sup>2</sup> Department of Biophysics, Lomonosov Moscow State University, Russia

[mdurymanov@gmail.com](mailto:mdurymanov@gmail.com)

### INTRODUCTION

Systemic nanoparticle gene delivery has a great potential for cancer therapy but its application still limited mostly due to low efficacy of gene delivery<sup>1</sup>. Basing on our previous data<sup>2</sup>, we hypothesized that low transfection is a result of poor extravasation and permeation of gene delivery nanoparticles. In an attempt to improve the tumour accumulation of PEI-PEG-based polyplexes, their *in vivo* application was combined with three different physiologically active agents including nitroglycerin (generates NO which causes disruption of adherens junction between endotheliocytes and improves tumour vasculature leakiness<sup>3</sup>), losartan (inhibits angiotensin signaling in cancer-associated fibroblasts that leads to suppression of collagen I production and enhancement of extracellular matrix permeability<sup>4</sup>) and angiotensin-II (induces mild hypertension and increases convective influx<sup>5</sup>).

### EXPERIMENTAL METHODS

**Intravital microscopy.** Murine Cloudman S-91, clone M-3 or B16F1 melanoma cells were inoculated subcutaneously in DBA/2 and C57 black mice bearing dorsal skinfold chamber (DSC), respectively. For intravital microscopy, mice (3 per group) were anesthetized and stably mounted onto a platform above the objective (10x) of Zeiss LSM 510 microscope. Blood vessels were visualized by 0.5 mg of 150 kDa FITC-dextran i.v. injected, and polyplexes (80 µg of quantum dot labeled plasmid DNA per mouse) were injected i.v. immediately after FITC-dextran. Sequential 3D 96-µm stacks were obtained for up to 4 hours after polyplex administration.

**Polyplex application and gene expression analysis.** M-3 or B16F1 mouse melanoma tumours were established in female DBA/2 or C57 black mice, respectively. Polyplexes containing firefly luciferase as a reporter gene under CMV promoter were i.v. injected when tumour size was 200 mm<sup>3</sup>. The mice were treated with three different physiologically active agents (5 mice per group): nitroglycerin (NG), angiotensin-II (AT-II) and losartan (LS). NG ointment was applied locally onto the skin overlying tumour at doses of 0.5-1.0 mg/tumour 20 min before polyplex injection. For AT-induced hypertension, AT-II was continuously infused at a rate of 3 µg/kg/min immediately after polyplex injection and maintained for 30 min. The last group of mice was treated with LS (30 mg/kg i.p.) each day for 7 days before polyplex administration. Control mice were injected with the same polyplexes without any treatments. At 24 hours post-injection tumours were harvested and luciferase activity was measured.

### RESULTS AND DISCUSSION

Mixing plasmid DNA with PEI-PEG-MC1SP (at N/P=20) resulted in formation of positively charged ( $\zeta$ -potential 22.7±1.0 mV) polyplex nanoparticles with average hydrodynamic diameter of 41.2±4.0 nm. Previously, it has been shown that the major part of extravasated polyplex nanoparticles reside in close proximity to the blood vessels<sup>2</sup>. We have found that LS potentiates systemic gene delivery in a greater extent than other physiologically active agents (Figure 1) and causes 3-6-fold increase in reporter gene expression. Visualization of fluorescently labelled polyplex distribution using intravital microscopy has shown that enhanced gene expression turned out to be a result of improved polyplex extravasation.

Figure 1 shows luciferase activity in B16F1 and Cloudman S91 (clone M-3) melanoma tumours at 24 hours after polyplex i.v. injection combined with physiologically active agents. Results are means ± S.E.M.

### CONCLUSION

Our results have shown that polyplex accumulation in tumour tissue may be enhanced using safe physiologically active agents resulting in superior systemic gene delivery.

### INTRODUCTION

The challenge for cardiovascular tissue engineers is to design hemocompatible biomaterials that promote neo-tissue formation. Despite many years of intensive research materials used to fabricate synthetic implants still cause formation of clots in the bloodstream, which can have fatal consequences for the patient. Under physiological conditions, the process of blood clotting is controlled by endothelial cells. These cells constantly and actively prevent thrombosis by releasing a number of substances. Synthetic materials are not able to release certain substances due to limited capacity. Thus, the most promising strategy to fabricate non-thrombogenic materials is covering the implant surface with a layer of endothelial cells.

### EXPERIMENTAL METHODS

The aim of this research was to improve hemocompatibility of polyurethane (PU) surface by REDV peptide sequence immobilization. The study included REDV peptide chemical immobilization to the polyurethane surface, peptide presence on the material confirmation and the material hemocompatibility analysis. Peptide presence was confirmed by BCA assay and contact angle measurement. Hemocompatibility analysis included anti-fibrinogen ELISA assay and SEM observation (platelet adhesion). Endothelial cells adhesion was also evaluated.

### RESULTS AND DISCUSSION

Studies have shown that the modified materials have a higher wettability compared to the unmodified PU. BCA assay confirmed successful immobilization of the peptide molecules. Modification resulted in decrease in serum-derived fibrinogen (fig.1). SEM analysis confirmed decreased adhesion of platelets to the peptide-modified surface compared the non-modified one. Hypothesis that REDV peptide immobilization improves hemocompatibility of polyurethane materials has been confirmed.

Fig. 1: Surface-adsorbed fibrinogen on unmodified polyurethane (PU) and polyurethane modified with REDV peptide (PU-REDV 0.5, PU-REDV 5).

Fig. 2: Growth of endothelial cells on polyurethane modified with REDV peptide.

### CONCLUSION

Hypothesis that REDV peptide immobilization improves hemocompatibility of polyurethane materials has been confirmed.

### **INTRODUCTION**

*Helicobacter pylori* (*H. pylori*), a gram-negative bacterium, is the only known organism able to survive and colonize the human gastric mucosa, infecting over 50% of the world's population and causing several gastric disorders from gastritis to gastric cancer.<sup>1</sup> Current treatments rely on antibiotic-based therapies, but are still inefficient in 20% of the cases, thus leaving around 140 million patients worldwide without alternative treatment.<sup>2</sup> Chitosan microspheres have recently been proposed as a promising *H. pylori*-binding system, mainly due to their antimicrobial/mucoadhesive properties.<sup>3,4</sup> After oral administration, these particles should bind *H. pylori* present in the mucosa and remove them through the gastrointestinal tract. Chitosan particles with 170  $\mu\text{m}$  can adhere to *H. pylori*<sup>3</sup> in the mucus layer, but are too big to penetrate the human gastric foveola (stomach invaginations) where *H. pylori* is also present, which are around 70  $\mu\text{m}$  wide. This work aims to produce smaller chitosan particles (diameters < 50  $\mu\text{m}$ ), characterize them and evaluate their interaction with *H. pylori* and mice and human gastric mucosa.

### **EXPERIMENTAL METHODS**

Chitosan microparticles (Mics) were produced by ionotropic gelation into a sodium tripolyphosphate solution using an aerodynamically assisted spraying system, varying parameters such as chitosan degree of acetylation (DA) (6% and 16%), concentration (0.5 and 1% (w/v)), flow rate (0.25, 0.33, 0.5 and 1ml/min), air pressure (205 and 525mbar) and nozzle diameter (0.25 and 0.5mm). Mics were then crosslinked with genipin (10mM, 45min) to avoid dissolution in gastric pH, followed by lyophilisation. Particles size, morphology and area were evaluated using laser diffractometry (Mastersizer, MS), high-throughput microscopy (IN Cell Analyzer, ICA) and imaging flow cytometry (ImageStream, IS).

Mics ability to adhere *H. pylori* was assessed by confocal microscopy (CM) and IS after incubating Mics with FITC-labelled *H. pylori* ( $1 \times 10^7$  CFU/ml) at pH 6.0 for 2h. The ability of Mics to enter into gastric foveolae was evaluated by incubating Mics with fresh mice (C57BL/6) and human stomach samples at pH 6.0. Gastric mucosa was either labelled with CellMask™ Deep Red plasma membrane stain and immediately assessed by CM or frozen in OCT medium, cryosectioned into 50 $\mu\text{m}$  slices and analysed by ICA.

### **RESULTS AND DISCUSSION**

Mics size was found to decrease with increase of chitosan DA and air pressure and with decrease of chitosan concentration and nozzle diameter; flow rate did not influence particle size. The optimization of the production process revealed 6% DA chitosan at 0.5% (w/v), flow rate of 0.5 ml/min, 525 mbar and 0.25 mm nozzle diameter as the optimal conditions to obtain particles with the required size.

Size distribution was obtained by MS, which revealed that 50% of Mics (Dv50) presented a diameter below 55.2  $\mu\text{m}$ . The lyophilisation process was found to reduce the particles size and to make them more irregular: ICA showed a reduction in the circular diameter from 43.8  $\mu\text{m}$  to 29.8  $\mu\text{m}$ , in the maximum chord from 55.8  $\mu\text{m}$  to 43.3  $\mu\text{m}$  and in the area from 1725.6  $\mu\text{m}^2$  to 786.9  $\mu\text{m}^2$ . IS corroborated this reduction in the particles size.

CM and IS showed the ability of FITC-labelled *H. pylori* to adhere throughout the surface, although not inside Mics.

Regarding *ex-vivo* Mics penetration studies, both CM and ICA revealed the presence of Mics in different depths of the mice and human gastric mucosa, thus indicating their ability to enter into gastric foveola.

### **CONCLUSION**

Chitosan microparticles with 29.8  $\mu\text{m}$  circular diameter were successfully produced using an extremely fast system that can be used for large scale production. These Mics are able to adhere *H. pylori* and penetrate the foveola from mice and human gastric mucosa, revealing to be very promising to fight *H. pylori* infection and thus potentially preventing gastric cancer.

## INTRODUCTION

The clinical application of cell-based therapeutics is ever accelerating with an emergence of approved cell therapy products (CTPs) to the market. One of the major bottlenecks for CTPs, however, is in the short-term storage of cells for quality, safety and efficacy testing, and their distribution from the donor or bank, to sites of processing, and back to the clinic<sup>1</sup>. To meet this need, we have developed an alginate-based encapsulation system for cell storage at hypothermic temperatures (0–32°C) allowing the preservation of cell viability and function for extended time periods, obviating the need for cryogenic storage.

## EXPERIMENTAL METHODS

**Cell encapsulation.** Human adipose-derived stem cells (hASCs) ( $0.5 \times 10^6$  cells/mL) were encapsulated in 0.5mL 1.2% calcium alginate discs as previously described<sup>2</sup> before transferring to sealed cryovials containing medium and storing for up to 3 weeks at a specified temperature (see figure 1 for schematic).

**Assessment of viable cell recovery.** Cells were extracted from alginate discs and viable cell number was assessed by Calcein-AM staining before counting using a Countess II FL automated cell counter.

**Assessment of cell attachment.** Cells were seeded at 20,000 cells/cm<sup>2</sup> and incubated for 24 hours at 37°C, 5% CO<sub>2</sub> before assessing the attached cell number by methylene blue staining as previously described<sup>3</sup>.

**Statistical analysis.** Differences between groups were assessed by unpaired T-test (viable recovery) and one-way ANOVA (cell attachment) analyses.  $n = 3$ .

**Figure 1. Encapsulation of cells in alginate discs.** A: Discs were formed in filter paper moulds saturated in calcium chloride. Two filter paper rings were placed upon a filter paper disc (i) before pipetting 500µL cell/alginate suspension into the aperture (ii). A second filter paper disc was placed on top of the mould to allow initial gelation before transfer to a calcium chloride bath to complete gelation. B: Alginate disc for cell storage.

## RESULTS AND DISCUSSION

Alginate encapsulation improved viable cell recovery following 72 hours storage at a range of temperatures. These included 4 and 17°C where encapsulation affected a significantly higher viable cell recovery compared to control (non-encapsulated cells) at both temperatures.

Viable cell yield was, however, temperature dependent with 15°C storage resulting in a greater number of viable cells compared to 4°C in all samples, with encapsulated samples yielding 86±6% of viable cells loaded (figure 2). The protective effect of alginate encapsulation was observed for up to 3 weeks of storage.

**Figure 2. The protective effect of encapsulation at multiple storage temperatures.** hASCs were stored for 72 hours at either 4°C or 15°C. Values are expressed as means ± SEM (\*\* $p < 0.01$ ; \* $p < 0.05$ ;  $n = 3$ ).

As well as promoting viability, alginate encapsulation also preserved cell function following release from storage, including the ability for cells to attach and proliferate. Whilst control samples exhibited a significant decrease in attached cell number compared to the non-stored control (NSC), encapsulated cells exhibited no significant decrease, rather a significantly higher number of attached cells were apparent compared to the control with normal morphological characteristics (figure 3). Subsequently, cells regained metabolic activity, proliferative potential, and differentiation capacity.

**Figure 3. Preservation of cell attachment by encapsulation.** hASCs were stored for 5 days at 15°C before assessing attachment 24 hours after seeding. NSC, non-stored control. Values are expressed as means ± SEM (\*\* $p < 0.01$ ; \* $p < 0.05$ ;  $n = 3$ ). Scale bars = 500µm

## CONCLUSION

We present a simple and cost-effective method to preserve stem cell viability and function during hypothermic storage which could be of great benefit in counteracting the short time windows associated with cell-based therapeutic manufacture and distribution.

### INTRODUCTION

Dental plaque is a biofilm that causes dental caries, gingivitis and periodontitis. Most of the studies in antibacterial coatings have been conducted by *in vitro* single-species biofilm formation but oral biofilm involves more than 500 different bacterial species that are able to interact.<sup>1,2</sup> Therefore, new studies are focused on *in vitro* multispecies biofilm model that mimic *in vivo* biofilms.<sup>3,4</sup> This work has two main goals: (1) to investigate the efficiency of five antibacterial coatings on titanium and (2) to compare the antibacterial properties of these coatings on single species and multispecies oral biofilms.

**Figure 1.** Schematic representation of the applied surface treatments.

### EXPERIMENTAL METHODS

Smooth titanium (Ti) samples were coated with five different conditions: silver electrodeposition, TESPSA silane coating, hLf1-11 peptide binding with CPTES silane and polymer brush based (ATRP) peptide binding with two different chemical routes. Surfaces were characterized by contact angle measurements, white-light interferometry and X-ray photoelectron spectroscopy (XPS). Cellular viability and proliferation were studied by LDH assay with human fibroblasts. The *in vitro* antibacterial properties of the modified surfaces were tested with single biofilm and oral plaque biofilm by means of bacterial adhesion assay at 2 h and evolution of biofilm formation after 24 h, 1, 2 and 3 weeks.

### RESULTS AND DISCUSSION

The success of each coating process was evaluated by means of XPS studies. Silver was deposited onto titanium surfaces and silanization with covalent attachment of the Lhf1-11 onto Ti was successfully performed. Surface roughness was not affected by these treatments. Cell viability and proliferation evaluated with LDH assays were not affected by the modified surfaces. The treated titanium samples displayed a promising reduction in bacterial adhesion. Overall, the results showed a reduction of bacterial attached on all

modified surfaces, thus confirming the efficacy of the antibacterial coatings.

Finally, the focus in the experiments was placed on the long-term antibacterial properties and biofilm formation onto modified coatings (**Figure 2**). These experiments showed that after 4 weeks of incubation the treated surfaces still showed a reduction in bacterial viability. These results are of great interest because they demonstrate that distinct mono-species biofilms show differences in bacterial adhesion and long-term biofilm evolution. Besides, disparities are also obtained when oral plaque biofilm was used. Thus, bacterial strains exhibit different sensitivities to the activity of antibacterial and/or antifouling treatment.

**Figure 2.** Live/dead staining of *S. sanguinis*, *L. salivarius* and oral plaque after 4 weeks of incubation at 37°C. (A) Ti, (B) Ti\_Ag, (C) Ti\_N\_TSP, (D) Ti\_N\_CM\_Lf, (E) Ti\_ACoI\_Lf and (F) Ti\_BCoI\_Lf

### CONCLUSION

Two different *in vitro* biofilm models were used to study the antibacterial properties of five different titanium surface coatings. A higher decrease was measured when a single-species bacteria model was used, especially for *S. sanguinis*. The *in vitro* multispecies biofilm model is a promising strategy to study the properties of antibacterial coatings because it more realistically mimics the complex microflora of peri-implantitis.

## INTRODUCTION

In current bone tissue engineering strategies the obtaining of sufficient angiogenesis during tissue regeneration is still a major limitation in order to attain construct integration and tissue functionality. This drawback is further relevant when considering large bone defects, where the amount of oxygen required for cell survival is limited to a diffusion distance between 150-200  $\mu\text{m}$  from the supplying blood vessels. Several strategies have been described to tackle this problem, mainly by the use of angiogenic factors or endothelial progenitor cells. However, when facing a clinical scenario these approaches are inherently complex and present a high cost. As such, more cost effective approaches are awaited. We have recently demonstrated that the increased local concentration of calcium ions ( $\text{Ca}^{2+}$ ) could induce the migration, maturation and organization of endothelial progenitors<sup>1</sup>. Moreover, a composite biomaterial of poly(lactic acid) (PLA) and Ca phosphate glass has shown to elicit proangiogenic and chemotactic properties on endothelial precursor cells *in vitro*<sup>2</sup>. Here, we tested electrospun PLA fiber-based materials, containing different ratios of calcium phosphate glass nanoparticles, subcutaneously in mice. These distinct formulations allowing different  $\text{Ca}^{2+}$  release kinetics to the vicinity of the matrix expect to improve vessel formation into the biomaterial.

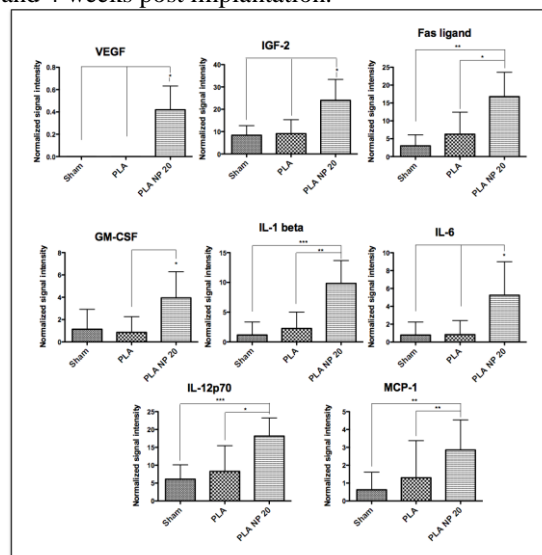

## EXPERIMENTAL METHODS

Aligned electrospun PLA nanofibers containing glass ceramic nanoparticles (CaP) at a mass ratio of 0, 10, 20 and 30% (i.e. PLA, NP10, NP20 and NP30, respectively) were prepared as previously described<sup>3</sup>. One cm diameter membrane disks were cut and sterilized by UV. The biomaterials were implanted subcutaneously in the dorsal pouch of swiss strain female mice (3 month, n=6). At 1 and 4 weeks post implantation animals were sacrificed and materials, together with the surrounding tissue, were recovered. Samples were fixed in 4% paraformaldehyde for 24 hrs at 4°C and then processed for cryosection. Sequential 8  $\mu\text{m}$  sections were performed; samples were then processed for HE staining or immunohistochemistry for CD31 and the assessment of the macrophage density and phenotype. The same implantation procedure was equally performed for 3 weeks of implantation, samples were recovered, snap frozen and homogenized for total protein extraction. A dot blot array of angiogenic factors (Abcam) was used to assess the different composites.

## RESULTS AND DISCUSSION

All constructs tested showed augmented cellular penetration with increased time of implantation. An increase on microvessel formation was observed in the

case of the constructs containing glass ceramic nanoparticles, when compared with PLA alone, at both 1 and 4 weeks post implantation.

**Figure 1-** Relative quantification of angiogenic factor expression within the tissue of the implanted matrices of electrospun poly(lactic acid) (PLA) alone, containing 20% of calcium phosphate nanoparticles (NP) or sham operated animals, at 21 days (n=4, average $\pm$ SD).

Additionally, this effect was shown to correlate with their mass ratio and their  $\text{Ca}^{2+}$  release profile. Angiogenic factor array assessment, at 3 weeks post implantation, revealed an increased expression of key pro-angiogenic and chemotactic factors for the 20% composite materials in comparison with PLA alone or sham-operated animals (Fig.1). Macrophage density and profile evaluation allow us to postulate on a mechanism of chemotaxis mediated by the released  $\text{Ca}^{2+}$ , leading to the mediation of endothelial cell recruitment and increased angiogenesis. Additionally, the evaluation of selected materials in a bone orthotopic site in a rat critical size defect model is underway and will shed light on their impact for bone regeneration strategies.

## CONCLUSION

The developed composite materials have the ability, *in vivo*, to increase the vessel formation into the implanted structures. This approach, due to its simplicity, presents an attractive strategy for clinical musculoskeletal repair.

### INTRODUCTION

Current tissue engineering strategies are focused on the restoration of pathologically altered tissue architecture by transplantation of cells in combination with supportive scaffolds and biomolecules. In recent years, considerable attention has been given to chitosan (CS)-based materials and their applications in the field of orthopaedic tissue engineering. Interesting characteristics that render chitosan suitable for this purpose are a minimal foreign body reaction, an intrinsic antibacterial nature, and the ability to be molded in various geometries and forms such as porous structures, suitable for cell ingrowth and osteoconduction. Due to its favourable gelling properties chitosan can deliver morphogenic factors and pharmaceutical agents in a controlled fashion [1]. Here, we reported the possibility to compare two different approaches based on inorganic and organic bioactive signals used to obtain biomimetic chitosan scaffolds.

### EXPERIMENTAL METHODS

Chitosan scaffolds were prepared by using a foaming method based on physical foaming combined with microwave curing. In the first step of the process, a stable physical foaming was induced using a surfactant (i.e. Pluronic) as blowing agent of a homogeneous blend of Chitosan (CS) and Polyethylene glycol diacrylate (PEGDA700) solutions. In the second step, the porous structure of the foaming was chemically stabilized by radical polymerization induced by homogeneous heating of the sample in a microwave by using a thermoinitiator (TI). The biomimetic scaffolds were obtained by using two different approaches based on inorganic and organic compounds, respectively. The first one was based by treating the scaffolds with a supersaturated SBF solution (5SBF); the treatment is able to create an hydroxyapatite coating on the surface and into the porous wall in few days (7days). The second approach is based by using a bioactive peptide of Bone Morphogenetic Protein (BMP-2). The 67-87 residue of the “knuckle” epitope of hBMP-2 (NSVNSKIPKACCVPTLSAI) was synthesized by microwave-assisted Fmoc solid phase peptide synthesis (SPPS). The physicochemical, morphological and mechanical properties of materials, before and after treatments, have been evaluated. Furthermore, biological analysis by using hMSC cells to estimate the effect of the two different biomimetic approaches on cellular behaviour were performed.

### RESULTS AND DISCUSSION

In this study, the combination of foaming method and

biomimetic approaches has a great potential as process of production of chitosan based scaffold for bone tissue regeneration. The *in vitro* degradation tests showed a gradual dissolution of the foam over time, but maintaining their 3-D morphology and integrity even after 6 week of incubation. The surface morphology of the scaffolds after biomimetic treatment was observed using SEM-EDS analyses that demonstrated the presence apatite coating after few days of treatment. This data was confirmed by ATR-IR that also demonstrated the interactions between the polymeric matrix and peptide sequence. The kinetic release showed a sustained release in the time with a good effect on osteogenic differentiation of hMSC.

The biological tests performed in basal medium without osteogenic factors demonstrated that the cell proliferation increases with time during the *in vitro* culture period suggesting that the materials are nontoxic, not affecting the cell proliferation and showed good biocompatibility. Moreover, for scaffold materials after inorganic and organic biomimetic approaches, an early osteogenic differentiation was observed, demonstrating that a layer of apatite and/or BMP-2 peptide are bioactive solid signals for cells.

Fig.1 SEM images of Chitosan scaffold after 7days of SBF treatment (A) and after 21days of hMSC cell culture (B).

### CONCLUSION

This study has demonstrated the possibility to generate biomimetic structures with an highly interconnected and homogeneous structure with pores of different size in agreement with the dimensional characteristics required for bone regeneration scaffold. The presence of bioactive signals on the scaffold surface allows to obtain an osteoinductive effect on hMSC, making chitosan a promising candidate scaffold material for bone tissue regeneration.

## INTRODUCTION

Hydrogels are three-dimensional, hydrophilic, polymeric networks that have the ability to retain substantial amounts of water/biological fluids that typically exhibit physico-chemical properties reminiscent of the cell microenvironment. Thus, hydrogels can provide essential cues to cells and form an important class of biomaterials for tissue engineering. However, single hydrogel networks are mechanically weak and exhibit large dimensional changes on fluid uptake that has led to several new platform technologies, such as formation of multi-component, interpenetrating and double-networks and some nanocomposite hydrogels<sup>1</sup>.

Polymer blending of polyvinyl alcohol (PVA) and sodium alginate (SA) have been attempted to combine mechanical and biological properties. Although high water absorption and hydrophilicity are important parameters this also limits cell adhesion. In this study we report the formation of dual networks PVA and SA to elucidate the effect on mechanical properties and swelling behaviour. Furthermore, these hydrogel networks can be designed to entrap fluids such as platelet rich plasma, growth factors, blood, cells, marrow and proteins, which make them potential candidates for tissue engineering.

## EXPERIMENTAL METHODS

Briefly a solution of PVA 10%(w/v) was prepared and subjected to 1, 2, and 3 cycles of freeze thawing (FT) in a (VirTis SP Scientific) freeze dryer at -59.4°C, vacuum 17mT for 24hrs. The FT-PVA xerogels were swollen in SA until equilibrium and chelated with calcium chloride. The gels formed were then subjected to 1 cycle of FT or air-drying (AD) and FT (AD+1FT). Hydrogels were characterised by FTIR, EWC, mechanical testing and thermal properties determined using a differential scanning calorimetry (DSC).

## RESULTS AND DISCUSSION

PVA-alginate dual networks were successfully formed and the methodology optimised. FTIR spectra of the dual networks exhibited characteristic peaks corresponding to the stretching of the hydroxyl group along with alkyl groups in PVA, and carboxylate groups present in both the guluronic and mannuronic acid units in alginate. The EWC of dual networks was significantly lower than that of PVA hydrogels ( $P < 0.001$ ), indicating the formation of a tight network, which consisted of the PVA network with the entangled alginate fibrils that was chelated with calcium chloride (Table 1). It was interesting to note that 3FT PVA used for dual network formation did not lower EWC or enhance UTS, which may be attributed to the limited ingress of the alginate fibrils in the first network. The PVAFT/alg-1FT derived from the 2FT-PVA cycles

exhibited significantly higher UTS than the other dual networks ( $P < 0.001$ ) (Table 2) and much higher than PVA-alginate ( $\sim 0.19\text{MPa}$ )<sup>2</sup> blends.

Hydrogel system	PVA Freeze-thaw cycles	EWC (%)	Degree of swelling
PVA	1	$82.07 \pm 0.47$	$4.58 \pm 0.15$
	2	$76.80 \pm 1.02$	$3.32 \pm 0.18$
	3	$74.27 \pm 0.40$	$2.89 \pm 0.06$
PVAFT/alg-1FT	1	$53.63 \pm 2.56$	$1.16 \pm 0.12$
	2	$56.89 \pm 2.01$	$1.32 \pm 0.11$
	3	$53.86 \pm 1.96$	$1.17 \pm 0.09$
PVAFT/alg-AD+1FT	1	$55.59 \pm 1.64$	$1.25 \pm 0.08$
	2	$57.49 \pm 2.08$	$1.36 \pm 0.11$
	3	$57.74 \pm 0.59$	$1.37 \pm 0.03$

Table1: EWC and degree of swelling of PVA, PVA/Alg hydrogels subjected to different cycles of freeze thawing as well as AD+1FT

Hydrogel system	PVA: Freeze thaw cycles	Ultimate tensile strength (MPa)	Glass transition Tg(°C)
PVAFT/alg-1FT	1	$0.45 \pm 0.07$	$155.2 \pm 3.0$
	2	$0.73 \pm 0.12$	$164.3 \pm 4.6$
	3	$0.48 \pm 0.08$	$158.7 \pm 5.8$
PVAFT/alg-AD+1FT	1	$0.58 \pm 0.06$	$169.3 \pm 2.2$
	2	$0.48 \pm 0.09$	$176.6 \pm 2.6$
	3	$0.50 \pm 0.10$	$177.4 \pm 2.3$

Table 2: Glass transition (Tg) and Ultimate tensile strength (UTS) of PVA, PVA/Alg hydrogels with the 1<sup>st</sup> PVA network subjected to different cycles of freeze thawing and a FT or AD+1FT post alginate chelation

The Tg of the dual networks, also indicated the dense network formation and the influence of the second network formed within the first network.

## CONCLUSION

Insoluble dual networks were formed with PVA and alginate resulting in a dense network structure with reduced swelling, EWC and good mechanical properties, which suggest that the hydrogel maybe better suited to cell adhesion and be explored as orthobiologic bone grafts.

### INTRODUCTION

Despite improvements in the management of coronary artery disease, a need exists to develop procedures to repair damaged heart tissue. Intensive research has recently been conducted in our group towards creating tailor-made 3D scaffolds, based on Collagen (Col) and Gelatin (Gel), for myocardial tissue repair and regeneration. Biopolymer scaffolds, mimicking the function of ECM, should not only possess the appropriate morphology, physical properties and mechanics, but also supply correct signals for cell activity<sup>1</sup>. Studies of cell attachment to collagen-based materials often ignore the details of the binding mechanisms - be they integrin mediated or non-specific. In this work we have used a range of cells which express different integrins and have measured cell adhesion in order to probe the nature of integrin binding sites as a function of collagen type, degree of crosslinking, composition and two or three dimensional architecture of the substrate.

### EXPERIMENTAL METHODS

Protein scaffolds (Col, Gel and Col/Gel=50/50) were obtained by freeze-drying, and cross-linked (XL) with carbodiimide (EDC) in combination with succinimide. EDC concentration 11.5mg/ml was taken as standard (100%) and was varied in the interval 1 – 200%. Films of ~8µm thickness were prepared by drying the corresponding 0.5% suspension of protein directly in 96-well plates used for cell attachments. Treated surfaces were obtained by deposition of 1µg/well of different types of Col (I, II or III) or Col-Gel compositions from 10µg/ml solutions. Studies of cell adhesion were made on the following cell lines: HT 1080 (fibroblast from human sarcoma, expressing  $\alpha_2\beta_1$  integrin), RUGLI (derived from a rat glioma, expressing  $\alpha_1\beta_1$ ), C2C12 (mouse myoblast, expressing  $\alpha_v\beta_3$  and  $\alpha_5\beta_1$ ) and L3, transfected C2C12- $\alpha_2+$ , which in addition expresses  $\alpha_2\beta_1$  integrin. Cell adhesion in the presence of  $Mg^{+2}$  (integrin mediated) and EDTA (non-specific) was assessed by calorimetric assay.

### RESULTS AND DISCUSSION

Static adhesion on treated surfaces showed very similar behaviour for HT1080 and Rugli cells for all Col types (I, II and III) and for all Col-Gel-based compositions. Examples of adhesion profiles of HT1080 are displayed in (Fig.1a). Adhesion was integrin-dependent and increased linearly with initial cell concentration (from 0.5 to  $2 \times 10^5$  cells/ml) for all systems studied. The incorporation of Gel to Col decreased adhesion of both cell lines. It is known that Col possesses the high affinity triple-helical motif GFOGER which interacts with cells via specific  $\beta_1$ -integrins, especially  $\alpha_1\beta_1$ ,  $\alpha_2\beta_1$ ,  $\alpha_{10}\beta_1$ ,  $\alpha_{11}\beta_1$ . Gel's main recognition motif is RGD

which signals to integrins, mainly  $\alpha_5\beta_1$  and  $\alpha_v\beta_3$ . The presence of Gel should decrease the cell receptor sites and, hence, cell adhesion. Adhesion values of HT1080 and RUGLI cells similarly depend on Col type: Col I  $\approx$  Col II > Col III, possibly due to the different affinity of Col motifs to  $\alpha_2\beta_1$  and  $\alpha_1\beta_1$  integrins. C2C12 cells did not adhere to any type of Col or to mixed surfaces due to lack of Col binding integrins in these cells. L3, transfected with  $\alpha_2\beta_1$  integrin, showed the same adhesion behaviour as HT1080 and Rugli cells.

Fig.1 HT1080 cell adhesion on surfaces (a) and scaffolds (b)

Static adhesion on films and scaffolds depends on composition and XL status. For films, adhesion decreased with increase in XL due to decrease in cell-binding sites consumed in EDC-mediated bond-formation. Surprisingly, EDC treatment significantly increased adhesion of all cell lines studied on all scaffolds (Fig.1 b), suggesting that 3D properties and mechanics (spatial structural strength) strongly influence cell behaviour. Cell adhesion on 100%-XL matrices depends on composition and cell lines: a decrease with increasing of Gel content for both HT1080 and RUGLI cell lines; similar values shown for Col and Gel for L3 and maximum values for Gel for C2C12. These results may be explained by availability and affinity of cell-binding sites on the scaffolds of different compositions.

### CONCLUSION

Focusing on the nature and extent of integrin binding in cell adhesion, studies on treated surfaces, 2D films and 3D scaffolds provides a simple and effective way of assessing separately the influence of the availability of cell binding sites, material properties and 3D architecture on cell adhesion. This assessment should assist in the tailoring of the biological activity of scaffolds for specific TE applications.

[selcen.alagoz@metu.edu.tr](mailto:selcen.alagoz@metu.edu.tr)

## INTRODUCTION

In this study, poly(3-hydroxybutyrate-co-3-hydroxyvalerate), PHBV, a biodegradable, natural polymer, was used as an alternative for the petroleum based polyesters to fabricate a wet spun scaffold for bone tissue engineering. VEGF and an elastin like recombinamers (ELR) with REDV sequences specific for endothelial cells<sup>1</sup> were introduced to the scaffold to make it attractive for endothelial cells so that it can be vascularized as needed in a thick implant which otherwise cannot maintain the viability of the cells that have penetrated deep into the scaffold.

## EXPERIMENTAL METHODS

PHBV scaffolds prepared by wet spinning were characterized under compression, and fiber morphology and porosity were determined by SEM and micro CT. Surface of the fibers was coated with ELR by exposing PHBV film with oxygen plasma (50 W, 5 min) and then immersing into ELR solution. Toluidine Blue staining and FTIR-ATR analysis were used to show of protein on the surface. AFM was used to study the influence of the treatments used in the binding process. PHBV nanocapsules loaded with BSA were produced by the double emulsion. BSA was used as a model protein instead of VEGF. Size distribution of PHBV nanocapsules was determined by using the Zeta Potential and Mobility Measurement System. These PHBV nanocapsules were incorporated to scaffold fibers by adsorption from a solution. Scaffold was examined with fluorescence microscope and SEM to study final form ready for in vitro studies.

## RESULTS AND DISCUSSION

The ultimate compressive strength of dry scaffolds under compression (5 mm/min) was  $4.65 \pm 0.69$  MPa, which showed compressive strength adequate for substituting human cancellous bone ( $\sim 2$ -12 MPa) not the native human cortical bone ( $\sim 100$ -230 MPa)<sup>2</sup>. The average fiber diameter was about 90  $\mu\text{m}$  and porosity of scaffolds was measured as 75% by using both SEM micrographs processed with NIH Image J program and micro CT data (Figure 1). Blue spots on the surface of ELR attached PHBV films were observed after Toluidine Blue staining. FTIR-ATR showed that upon treatment with O<sub>2</sub> plasma new peaks at around 1530 cm<sup>-1</sup> and 1650 cm<sup>-1</sup> was observed due to stretching of carbonyl groups. After ELR attachment, these peaks became more intense. This was probably due to the amide I and amide II groups of ELR attached onto the PHBV film<sup>3</sup>. AFM micrographs showed that surface roughness decreased upon oxygen plasma treatment

from 343.4 nm to 160.0 nm and increased to 280.3 nm after ELR attachment.

Figure 1: SEM image of the PHBV scaffold

PHBV capsules were found to have an average diameter of 340 nm, with particle size in the range 190-530 nm. SEM images showed that PHBV nanocapsules were attached on PHBV fibers (Figure 2).

Figure2: SEM image of PHBV fibers and VEGF loaded PHBV nanocapsules

## CONCLUSION

In this study a biological polyester PHBV, which is an alternative to petroleum based polyesters was used to design a novel cell carrier. It was treated with an endothelial cell attractive ELR and VEGF loaded nanocapsules were attached. Thus, a novel multifunctional scaffold with appropriate mechanical and physical properties could be prepared.

### INTRODUCTION

Traumatic or disease-caused bone defects, account annually for at least 2.2 million procedures worldwide. At present mainly autografts and allografts are used during surgeries, but the interest towards synthetic grafts has constantly grown. Synthetic bone substitutes not only avoid risks of rejection and of disease transmission, but might also degrade gradually and be replaced by natural bone when they are resorbable (such as calcium phosphates, CaP). At the moment, however, these resorption phenomena (including both acellular and cellular related aspects) are still partially unclear. In the same way, although several kinds of metal ions-doped CaP have been investigated, the consequences of these chemical modifications have been evaluated in terms of their impact on cell vitality and differentiation, more than on the resorption process of the material itself. The aim of the present work is, therefore, to develop an experimental method to assess mechanisms and kinetics of degradation of some CaP bone substitutes (some of which doped).

### EXPERIMENTAL METHODS

$\beta$ TCP ( $\beta$ -tricalcium phosphate,  $\beta$ -Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>) dense samples, pure and doped (5% mol. Mg), were produced in cylindrical shape ( $\varnothing$ =9 mm, h=4 mm). The initial powders were first uniaxially, then isostatically pressed (by means of Cold Isostatic Pressing) and finally sintered at high temperature (1050°C). *In vitro* cellular tests were performed with the aim of evaluating the influence of Mg-doping on the resorption process. For this purpose murine RAW 264.7 cells were cultured in RPMI medium enriched with growth factors (MCSF and RANKL) and then seeded on the surface of the  $\beta$ TCP and Mg- $\beta$ TCP samples. After 2-4-7 days respectively, samples and cells were fixed and analysed (SEM, fluorescence, TRAP staining, WST).

Another part of the study was devoted to assess the relationship between acellular degradation, mechanical, physico-chemical and structural properties. For this purpose micro-porous  $\beta$ TCP and DCPD (dicalcium phosphate dihydrate, CaHPO<sub>4</sub>·2H<sub>2</sub>O) samples underwent dissolution tests *in vitro* (PBS and TRIS-buffer solutions, static and dynamic conditions, from 30' to 2 months). Particular attention was paid to the mechanical properties which were assessed by the use of a "non-conventional" micro-indentation technique<sup>1</sup>.

### RESULTS AND DISCUSSION

Preliminary tests have shown how RAW 264.7 cells grown directly on  $\beta$ TCP samples hardly differentiate into osteoclast-like cells. This behaviour, also according to previous studies<sup>2</sup>, could be caused by the strong release of Ca ions induced by  $\beta$ TCP. In order to overcome this problem, in the present work, RAW 264.7 cells were not directly seeded on the samples, but first incubated for some days in well-plates with growth factors (RANKL, MCSF). The first results have showed no substantial differences between cells incubated on  $\beta$ TCP and Mg- $\beta$ TCP. Cell viability and morphology, in fact, seemed to be comparable in both cases.

The dissolution tests performed on micro-porous  $\beta$ TCP and DCPD samples, have displayed how the chosen medium and conditions (static/dynamic) influence the degradation phenomena and the precipitation of new CaP phases. Although with differences, both for  $\beta$ TCP and DCPD, the degradation process seemed to start at the interface between liquid and sample and induced a gradient of properties between the surface and the inner part of the specimen. Thanks to the use of micro-indentation it was possible to assess a strong decrease of mechanical properties localised on the outer part of the specimen, while only smaller changes were measured in the inside.

### CONCLUSION

All in all this study showed that the Mg doping didn't seem to affect radically the cellular behaviour.

As far as acellular tests of dissolution were concerned, the evolution of mechanical properties was correlated both to the changes observed in the chemistry (precipitation of new CaP phases, mostly on DCPD) and in the microstructure (increase of porosity, above all in  $\beta$ TCP) of the samples.

# Induction of Endothelial Cell Sprouting by Poly ( $\epsilon$ -Lysine) Dendron Tethered with an Angiopoietin-1-mimicking Peptide

Maria Elena Verdenelli, Steven Meikle, Gary Phillips, Matteo Santin

BrightSTAR Group, School of Pharmacy and Biomolecular Sciences, University of Brighton, UK

[M.E.Verdenelli@brighton.ac.uk](mailto:M.E.Verdenelli@brighton.ac.uk)

## INTRODUCTION

Coronary heart disease and stroke are leading causes of mortality in Europe, resulting in a loss of function of the affected tissue<sup>1</sup>. The challenge is to restore the tissue functionality using growth-factors mimicking peptides to stimulate the development of pre-existing blood vessels and enhance tissue regeneration.

In this research, poly ( $\epsilon$ -lysine) dendrons of different branching generations (Gx) will be used as molecular scaffold to present, at their uppermost branching generation, the Angiopoietin-1 (Ang-1) mimicking peptide, QHREDGS, previously shown to be able to promote blood vessel formation and stabilisation<sup>2</sup>.

## EXPERIMENTAL METHODS

G2 and G3 dendrons were synthesised by solid-phase peptide synthesis (SPPS) with a manual method. G2 and G3 were designed starting from a molecular root of two phenylalanine residues (FF) and branching up the molecule by addition of lysine monomers to expose either 8 (G2) or 16 (G3) active amino groups. Finally, G3 and G2 dendrons were functionalised, using the same SPPS method, with the bioactive peptide sequence, QHREDGS, mimicking Ang-1. Non-functionalised and functionalised dendrons were analysed by both analytical HPLC and micro-time-of-flight mass spectrometry (TOF-MS). The *in vitro* cytotoxicity effect of G2 and G3 functionalised with the Ang-1-mimicking peptide was evaluated as cell viability in a 2D culture model using human umbilical vein endothelial cells (HUVEC). Cells were seeded at  $22 \times 10^3$  cells  $\cdot$  well<sup>-1</sup> using 1 mL of F12 K medium supplemented with 10 vol% of foetal bovine serum, 0.05 g  $\cdot$  mL<sup>-1</sup> heparin and 0.1 g  $\cdot$  mL<sup>-1</sup> ECG. A linear QHREDGS sequence was used as control. After 24 hours in culture, cells were stained for their vitality with Hoerscht Propidium Iodide and for their cytoskeleton organization by Rhodamine-Phalloidin staining. HUVEC were analysed by confocal microscope.

## RESULTS AND DISCUSSION

Generation two and three poly ( $\epsilon$ -lysine) dendrons were characterised successfully: peaks (G2  $MH^+ = 402.30$ ; 549.37 and G3  $MH^+ = 914.69$ ; 970.74) generated through MS analysis correspond to different dendron generation and HPLC chromatograms showed that the increased molecular weight led to a decrease in peak retention time from 9 min to 8min. Laser confocal images with Phalloidin-Rhodamine staining show the effect of the linear and branched Ang-1-mimicking peptides. Indeed, while in the control cells grew as a monolayer (Fig. 1 A); the QHREDGS linear peptide appeared to induce their organization into 2D branched patterns (Fig. 1B). The spiking with non-functionalised

G2 dendron generated more dense branched 2D patterns (Fig. 1C), but the Ang-1 peptide-functionalised G2 dendrons clearly induced the formation of a network of endothelial sprouting where cells appeared to establish connections also in a 3D fashion (Fig 1,D). The results shown in Fig 1, C and D seem to demonstrate the synergistic action played by the dendron branched structure and by the QHREDGS sequence in guiding the 3D organization of the endothelial sprouting. G3 dendrons presenting a higher number of QHREDGS led to the formation of small 3D cell clusters unable to sprout (data not shown).

**Fig.1.** Effect of linear Ang-1 peptide and dendron Ang-1 on HUVEC in a 2D model at 24h. (A) Control, (B) linear Ang-1 peptide, (C) G2 dendron, (D) dendron Ang-1.

## CONCLUSION

The present study for the first time unveils a novel biomaterial approach to stimulate angiogenesis through nano-structured biomaterials and emphasise the need for a finely spaced presentation of the relevant peptide sequence to obtain established endothelial sprouting.

## Sustained Release of Adipose-Derived Stem Cells by Thermosensitive Chitosan-Gelatin Hydrogel for Therapeutic Angiogenesis

Nai-Chen Cheng<sup>1</sup>, Tai-Horng Young<sup>2</sup>

<sup>1</sup> Department of Surgery, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan

<sup>2</sup> Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan

[naichenc@gmail.com](mailto:naichenc@gmail.com)

### INTRODUCTION

Recent studies showed that adipose tissue exhibits mesenchymal stem cells, referred as adipose-derived stem cells (ASCs). These cells are multipotent and can be applied for tissue engineering or regenerative medicine. However, transplantation of isolated ASCs frequently resulted in cell death quickly, so a good carrier is required to deliver these cells *in vivo*. The carrier is expected to have good biocompatibility and easy to handle. Because thermosensitive hydrogels are liquid at room temperature or 4°C, ASCs can be mixed with the gels and delivered by injection in a minimally-invasive fashion. Once *in vivo*, the hydrogels solidify and retain the injected ASCs in the target area.<sup>1</sup> This study aimed to develop a thermosensitive hydrogel capable of sustained releasing ASCs for therapeutic angiogenesis.

### EXPERIMENTAL METHODS

We blended gelatin in the chitosan/glycerophosphate hydrogel system, and we estimated the release pattern of gelatin *in vitro*. Human ASCs were then encapsulated in the chitosan-based temperature-sensitive hydrogels and perform *in vitro* culture. The characteristics of ASCs encapsulated in hydrogels, including proliferation activity, were investigated. *In vitro* migration assay and *in vitro* tube formation assay were performed. Moreover, the chick embryo chorioallantoic membrane (CAM) assay,<sup>2</sup> a well-established *in vivo* assay for studying angiogenesis, was performed by injecting ASC-encapsulated hydrogels into chick embryos.

### RESULTS AND DISCUSSION

We were able to add gelatin in the mixed solution of chitosan/glycerophosphate and maintained the temperature-sensitive property. By immersing chitosan-gelatin hydrogels into PBS, sustained release of gelatin from the composite hydrogel was found. After ASC encapsulation, we also detected sustained release of ASCs from the chitosan-gelatin hydrogel. By performing live/dead assay, death of a significant portion of the encapsulated cells was observed in pure chitosan hydrogel, but the cell survival improved significantly after blending gelatin in the chitosan/glycerophosphate hydrogel (Fig 1).

Moreover, *in vitro* wound healing could be significantly facilitated by co-culturing fibroblast (Hs68) with ASCs encapsulated in chitosan-gelatin hydrogel. In terms of angiogenesis, co-culturing endothelial cells (SVEC4-10) with ASC-encapsulated chitosan-gelatin hydrogel revealed SVEC4-10 cells forming tube-like structures, indicating the potential of the hydrogel in promoting angiogenesis. In the CAM assay, quantification of the capillary density in the chorioallantoic membrane showed that ASC-encapsulated chitosan-gelatin

hydrogel significantly promoted angiogenesis comparing to pure chitosan hydrogel (Fig 2).

Figure 1. After 5 days of *in vitro* culture, more live cells (green) were observed if gelatin was mixed in the chitosan/glycerophosphate hydrogel.

Figure 2. The CAM assay revealed significantly larger area consisting of capillary when chitosan-gelatin hydrogel was injected. (\* $p < 0.05$ )

### CONCLUSION

Chitosan-gelatin-based temperature-sensitive hydrogel not only can provide a niche to maintain ASC survival, it also enables sustained release of ASCs for application in therapeutic angiogenesis.

## Cobalt Doped Proangiogenic Hydroxyapatite for Bone Tissue Engineering Application

Senthilguru Kulanthaivel, Krishna Pramanik, Indranil Banerjee\*

Department of Biotechnology and Medical Engineering, National Institute of Technology,  
Rourkela-769008, Odisha, India.

[senthilgurubt@gmail.com](mailto:senthilgurubt@gmail.com), [Indraniliti@gmail.com](mailto:Indraniliti@gmail.com)

### INTRODUCTION

In bone tissue engineering success of any implant is ensured by early angiogenesis after implantation. Angiogenesis is crucial for active transport of oxygen and nutrients to the cells where the implant size is considerably larger than diffusional limit (150-200  $\mu\text{m}$ ) of solutes<sup>1</sup>. Existing methodologies involve the application of growth factors like Vascular Endothelial Growth Factor (VEGF)<sup>2</sup> and other micro-patterning techniques to induce angiogenesis which may limit the processing and commercial availability of implant. Interestingly, cobalt bivalent ions can induce angiogenesis through Hypoxia Inducible Factor 1 alpha (HIF-1 $\alpha$ ). Synthetic hydroxyapatite, a well known biomaterial for decades has more flexibility and stability over incorporation of bivalent metal ions. The present study describes the synthesis of cobalt doped HAp and its physico-chemical and biological characterisation.

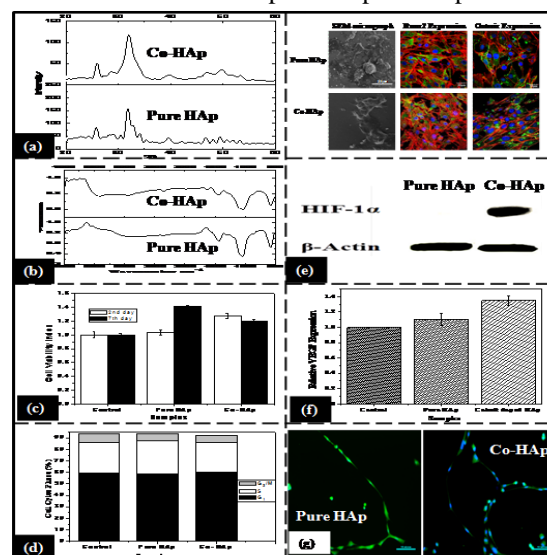

### EXPERIMENTAL METHODS

Cobalt doped hydroxyapatite (Co-HAp) (different doping percentage) were prepared by the ammoniacal precipitation method. X-ray Diffraction (XRD) and FT-IR (Fourier transformed infrared spectroscopy) analysis were performed to study the structural properties of doped HAp. Extent of doping and release of Co<sup>2+</sup> ions were estimated by ICP-OES analysis. Osteogenic property of doped HAp were accessed by performing analysis pertaining to cell proliferation (cell viability assay), Cell cycle progression (Flow cytometry) and expression of differentiation markers (Runx2 and Osterix) (Immunocytochemistry) in MG-63cells cells. Angiogenic property of the material was analyzed by checking the expression of HIF-1 $\alpha$  (Western blot analysis) and VEGF (ELISA) in MG-63 cells<sup>3</sup>. Finally, tube formation assay was performed with human umbilical vein endothelial cells (HUVEC) to confirm the pro-angiogenic potential of the material.

### RESULTS AND DISCUSSION

Hydroxyapatites, doped with varying concentration of cobalt were successfully prepared by ammoniacal precipitation method and extent of doping was measured by ICP-OES. Crystalline structure of doped hydroxyapatite was confirmed by XRD (Fig. 1a) and FTIR (Fig. 1b) studies which showed slight deformation in the patterns with respect to doping nature. Analysis pertaining to the effect of doped hydroxyapatite on cell proliferation (Fig. 1c) and cell cycle progression (Fig. 1d) of MG-63cells revealed that the doping of cobalt supported the cell viability and proliferation up to a threshold limit. Such level of doping also induced differentiation of osteoblast cells, which was evident from the higher expression of differentiation markers (Runx2 and Osterix) and better nodule formation (SEM study). Western blot analysis (Fig. 1e) in conjugation

with ELISA study (Fig. 1f) confirmed that the doped HAp samples significantly increased the expression of HIF-1 $\alpha$  and VEGF in MG-63 cells. Tube formation assay (Fig. 1g) well supported the western blot and ELISA analysis, where the doped HAp samples induced better tube formation compared to pure HAp.

**Fig. 1 Characterization of cobalt (Co<sup>2+</sup>) doped HAp**

### CONCLUSION

The present study confirmed that doping of HAp with bivalent cobalt ions imported an excellent angiogenic property. These studies clearly proved that bivalent cobalt ion doped HAp may be a potential alternative to the prevailing methodologies for inducing angiogenesis in bone tissue engineering. Furthermore, *in vivo* studies and HAp desorption profiling in the presence of osteoclast are required to confirm the pro-angiogenic and osteogenic properties of cobalt doped hydroxyapatite.

### INTRODUCTION

One of the greatest challenges currently faced in Tissue Engineering (TE) is the incorporation of vascular networks within tissue engineered constructs. Generally, TE grafts thicker than 400  $\mu\text{m}$  will need the presence of vasculature for avoiding necrosis and allowing diffusion of nutrients and gases<sup>1,2</sup>. Knowledge of the major factors that drive vascular ingrowth is key to overcoming this hurdle.

**AIM** To develop a technique for producing a perfusable, cell friendly model of vascular structures which can be used to study the factors affecting angiogenesis.

### EXPERIMENTAL METHODS

Electrospun mats were produced by dissolving PHBV in a mixture of dichloromethane (DCM) and methanol. Optimal concentrations of 10% w:w of PHBV (containing 10% w:w of methanol) was prepared and electrospun for 1 hour using four 5 ml syringes with 0.6mm ID blunt tip at a rate of 40  $\mu\text{l}/\text{min}$  and a voltage of 17 kV. Using these parameters nanofibres with diameters of  $0.70 \pm 0.05 \mu\text{m}$  were obtained. Alginate paste was printed on top of the mat by placing inside a syringe barrel attached to a dispensing system whilst a 3D printer was used to hold the dispensing arm and print the alginate at a feed rate of 8.3cm/s and extrusion rate of 0.025cm<sup>3</sup>/s. Electrospinning was then carried out again to cover the alginate. To remove the alginate the scaffolds were submerged in 0.5M EDTA solution overnight. Removal of the sacrificial substrate was studied by both SEM and fluorescence microscopies. The suitability of the constructs as synthetic vascular networks was then explored by seeding the structures with proliferating human dermal microvascular endothelial cells (HDMECs) alone and in combination with human dermal fibroblasts (HDFs). Briefly,  $0.5 \times 10^6$  HDMECs were infused through a cannula into the hollow structures and allowed to attach overnight at 37°C. The scaffolds were then flipped and this process was repeated before culturing for 5 days. To observe the effect of HDFs as a potential 'helper' cells this process was repeated but this time  $0.5 \times 10^6$  HDFs were seeded onto both sides of the scaffold and cultured for 5 days. Samples were fixed, cryosectioned and stained for CD31 and DAPI.

### RESULTS AND DISCUSSION

Upon removal of the alginate substrate nanofibrous hollow networks ranging from 0.5-2mm were created (Fig. 1). These networks were perfusable which enabled the recellularisation of the hollow channels. Both HDMECs and HDFs were found to adhere well to

Figure 1. Image of PHBV artificial electrospun vascular network (a); High magnification SEM image of PHBV fibres in the vascular construct (b); SEM image of vascular conduit containing the alginate sacrificial substrate (c); Fluorescence image of alginate loaded with Eosin-Y after printing (d); Fluorescence image of alginate loaded with Eosin-Y after spinning (e); SEM image of vascular conduit after removing the alginate sacrificial substrate (f).

the PHBV material attaching to both the curved and flat surfaces. When the channels were reseeded with HDMECs alone, cell coverage was found to be irregular. However when using a co-culture of HDMECs and HDFs coverage was found to be continuous throughout the internal channel (Fig. 2) implying the need for a 'helper' cell.

Figure 2 – Fluorescence image showing CD31 positive cells (red) with DAPI counterstaining (blue) throughout a cross section of the scaffold using a co-culture of HDMECs and HDFs.

### CONCLUSION

We have developed a technique for the fabrication of bespoke constructs with applications in the study of angiogenesis. We have demonstrated that HDMECs attach uniformly to our constructs when co-cultured with HDFs and that we can tune our scaffolds in terms of chemical nature, size and morphology.

## INTRODUCTION

Enhanced vascularisation is critical for the treatment of ischemic tissues and the engineering of new tissues and organs [1]. Paracrine factors from Wharton's Jelly-derived Mesenchymal Stromal cells (WJ-MSCs) could act as a stimulant for the vascular formation [1, 2].

In this study we report on the strong adhesion of Human Umbilical Vein Endothelial Cells (HUVECs) on a chitosan-graft-poly ( $\epsilon$ -caprolactone) (CS-g-PCL) copolymer [3], which is used as a biodegradable matrix for the formation of angiogenic sprouting induced by the Conditioned Medium (CM) from WJ-MSCs.

We investigate the cellular adhesion and viability of HUVECs, as well as the production of Platelet Derived Growth Factor (PDGF BB), a characteristic marker of endothelial "tip cell" which leads the angiogenic sprouting [1,3].

## EXPERIMENTAL METHODS

The copolymer was synthesized by grafting the modified PCL-COOH onto a chitosan backbone as described previously [4]. Spin-coated films of the grafted copolymer were prepared on round glass substrates. We investigated the cellular adhesion of HUVECs on the films by means of Scanning Electron Microscopy (SEM), their viability by the AlamarBlue® assay, and their focal adhesion points by confocal microscopy. We examined the expression of secreted PDGF BB by means of indirect ELISA after incubation with CM from WJ-MSCs.

## RESULTS AND DISCUSSION

Successful seeding of HUVECs on CS-g-PCL surfaces led to strong adhesion and cellular proliferation (Fig. 1). Treatment of the cells with CM from WJ-MSCs resulted in higher cell viability and increased the expression of the characteristic angiogenic marker PDGF BB (Fig. 2). Ongoing experiments focus on the expression of the angiogenic genes DLL4, VEGFR2, ANGPT2, SPROUTY2, PDGFBB and MMP2 by means of semi-quantitative PCR.

Figure 1: Optical microscopy images illustrating the viability of HUVECs on CS-g-PCL substrates on day 1 (left), and their growth after 3 days (right) using Endothelial Growth Medium+2% FBS

Figure 2: Higher levels of PDGF BB are secreted by HUVECs cultured on CS-g-PCL with CM after 2 and 4 days compared to the control medium. Bars represent averages of triplicates with standard deviation.

## CONCLUSION

We show that the copolymer CS-g-PCL strongly supports the adhesion and proliferation of HUVECs, which is increased in the presence of the Conditioned Medium from WJ-MSCs. Moreover, HUVECs angiogenic response is significantly induced in the presence of the CM, suggesting the potential of the copolymer as an inductive substrate for blood vessel regeneration and vascularized tissue.

## INTRODUCTION

The prospect for patients with chronic ulcers is challenging, they face protracted treatment and management of underlying primary pathology to attain wound healing by secondary intent. Recent gains in understanding wound pathologies and the introduction of an increasingly diverse range of advanced wound and synthetic skin technologies has resulted in only marginal improvements in healing rate and health economic benefits<sup>1</sup>

Bio-intelligent biomaterial scaffolds are an integrative modality which can provide cell adhesive signals, a reservoir of activators and or signals for, or modulators of, tissue reconstruction, a proteolytic environment, a source of cryptic or released regulators, or delivery system for complex biological therapies.

This work investigates the potential for fibrin-based materials to be used in stem cell therapy for chronic wounds.

## EXPERIMENTAL METHODS

Fibrin/alginate scaffolds were prepared from a foam mixture by glutaraldehyde cross-linking, reduction, washing and lyophilisation. Adipose-MSC were used with permission to assess cell infiltration in vitro. Samples were fixed, stained with Texas red-X phalloidin/To-Pro3(white) for laser confocal microscopy visualisation against green scaffold autofluorescence at each scaffold depth (xz section). Integration of scaffolds was assessed in porcine acute full thickness or delayed partial burn excision defects, by punch biopsy histology over a 6 week time course. Histology was stained for vWF to observe vascularisation. Collagen based materials, Integra and Matrigel, were used as controls.

Figure 1. SEM of fibrin alginate scaffold and pore size distribution. Scalebar = 500 um.

## RESULTS AND DISCUSSION

Fibrin alginate scaffolds form an hierarchical interconnected pore structure from fibrin nanofibre mesh (Fig 1). 24 h infiltration of MSC occurs throughout the depth of the fibrin scaffold whereas MSC density is heavily polarised to the seeding surface of Integra scaffold (fig 2) with similar cell viability.

Figure 2. MSC ingress into fibrin/alginate & Integra.

In acute wounds fibrin/alginate scaffolds gave rapid cellularisation & neovascularisation via vasculogenesis through the scaffold depth within 7 days. This allowed single step reconstruction with a split thickness overgraft. Matrigel integrated via rapid resorption without vasculogenesis (fig 3). In the delayed wound model, tissue scaffolds increased the healing response and achieved integration at 7 days. The fibrin/alginate scaffold resulted in greater neo-dermal organisation.

Figure 3. vWF staining of tandem 7d wound biopsies.

Fibrin-alginate scaffolds were designed to optimise porosity to support rapid cellular vascularisation, tissue formation and subsequent remodelling. Support of MSC corroborates previous data on fibroblasts<sup>2</sup>. This material may be additionally suited to cell therapy potentiation.

## CONCLUSION

This work demonstrates an emergent scaffold design with pro-vascular integration properties, with potential for accelerating delayed wound healing.

### INTRODUCTION

Chitosan-siloxan porous hybrids prepared via sol-gel method have high potential as scaffolds as for the several tissues [1-3]. In addition, the incorporation with calcium chloride into the hybrids deposited hydroxyapatite on their surface into the simulated body fluid (SBF) [1]. However, the hybrids must wash with sodium hydroxide solution before soaking in SBF because neutralization of the remained acetic acid in to their matrix. Recently, we have tried to soak the hybrids into alkaline phosphate solution to deposit apatite and remove the acid simultaneously. In this study, we report that the apatite formation of the hybrids into alkaline phosphate solution and implantation them into the skull defect, named “bull hole”.

### EXPERIMENTAL METHODS

Chitosan (0.5 g, high molecular weight, deacetylation: 79.0%, Aldrich®, USA) was dissolved in aqueous acetic acid (0.25 M, 25 mL). GPTMS (Lancaster, Lancashire, UK) and calcium chloride (Nacalai Tesque, Kyoto, Japan) were added to give a molar ratio of chitosan to GPTMS (ChG) of 1:0.5 or chitosan to GPTMS :to CaCl<sub>2</sub> (ChGCa) of 1.0 : 0.5 : 1.0. The mixtures were stirred for 1 h at room temperature and a fraction of each resultant sol was poured into a polystyrene container and frozen at -20°C for 24 h. The frozen hybrids were then transferred to a freeze dryer (FDU-506, EYELA, Tokyo, Japan) for 12 h until dry. The resultant porous ChG and ChGCa hybrids were then washed with NaOH (0.25 M) and distilled water to neutralize remaining acetic acid and were again lyophilized. Some ChGCa hybrids were instead soaked in aqueous Na<sub>2</sub>HPO<sub>4</sub> (0.01 M, pH8.8) at 80°C for 3 days (ChGCa\_HAp). The hybrids were then washed with distilled water and lyophilized.

The surface analyses of the samples were examined by thin film X-ray diffraction (TF-XRD), Fourier transform infrared spectroscopy (FT-IR) and scanning electron microscopy (SEM).

The hybrids were sterilized with  $\gamma$ -ray irradiation. Adult female beagles were used for in vivo animal test. Four 14-mm burr holes were created to evacuate the liquefied hematoma and then the hybrids were inserted into each burr hole. The commercial bone cement was also implanted as a control. After implantation period, specimens of the parietal bones including the cranioplasty were harvested and examined histologically.

### RESULTS AND DISCUSSION

The low crystalline hydroxyapatite deposited on the hybrids surfaces in alkaline phosphate solution. Their porous structure was maintained after apatite deposition.

The hybrids fitted the burr holes and blood infiltrated the pores, but did not overflow. Following implantation, all beagles survived with no wound infection or automutilation. The chitosan-siloxane porous hybrid induced new bone formation in their matrix. Every hybrid degraded and disappeared within 12 months of implantation. In the case of ChG, many osteoblasts were on the hybrid and many blood vessels with havers canals formed in the new tissue. There are some reports that a pore sizes smaller than 100  $\mu$ m is not sufficient for cell migration; however in this work, the chitosan-siloxane hybrids induced new bone and blood vessel formation even at a pore size of around 100  $\mu$ m.

Incorporation of calcium ions (ChGCa) and modification of hydroxyapatite (ChGCa\_HAp) accelerated bone formation. Osteoblasts were also present at the interface of the pre-existing bone and newly formed osteoid tissue. Calcifications were found in the osteoid tissue easily. In particular, Azan staining showed the strong calcifications in the osteoid tissue. In the present work, we could not find osteoclasts around the new bone. In this case, we observed them only 12 months after implantation and the hybrids had already disappeared. The osteoclasts may be present in the early stages after implantation.

### CONCLUSION

After 12 months implantation, no inflammation occurred and the hybrids were degraded and disappeared completely. In the hybrid groups, the new bone formation occurred the site of the implantation and there were many osteoblast and blood vessels with havers canals. Hydroxyapatite coating accelerated the calcification. The chitosan-siloxane porous hybrids are useful for the new scaffold of “burr holes” in cranioplasty.

### INTRODUCTION

Chronic wounds are susceptible to infection and are increasing in prevalence. 14 days application of topical antiseptic is the initial recommended treatment.<sup>1</sup> An antiseptic eluting wound dressing which could deliver active antiseptic to the wound bed over two weeks would greatly aid in this bioburden management.

Chlorhexidine (CHX) is a topical antiseptic widely used in wound care due to its broad spectrum antimicrobial effect, rapid mechanism of action and low cytotoxicity.<sup>2</sup>

The purpose of this study is to investigate the feasibility of encasing novel antiseptic CHX-hexametaphosphate nanoparticles (CHX-NPs)<sup>3</sup> within an alginate matrix – widely used in wound dressings – to provide a sustained release of CHX and the impact this may have on the bioburden of a chronic wound.

### EXPERIMENTAL METHODS

#### CHX-NPs synthesis<sup>3</sup>

10 mM aqueous solutions of CHX digluconate and sodium hexametaphosphate were combined (1:1 ratio).

#### CHX-NPs alginate nanocomposite

Powdered alginate was dissolved in the diluted CHX-NPs to give doping of 6, 3 & 0 wt%. These solutions were cast (55g alginate per m<sup>2</sup>), and the water allowed to evaporate (RT, 3 days). These thin films were cross-linked in CaCl<sub>2</sub> (aq) (0.18 M) for 25 min, washed with distilled water and air dried. Disks (ø = 10 mm) were cut from this material and used in subsequent work.

#### CHX elution

One alginate disk was immersed in distilled water (2.25 mL) and the [CHX]<sub>(aq)</sub> monitored ( $\lambda = 255$  nm) over two weeks (n=15 for each CHX-NPs doping; 6, 3 & 0 wt%).

#### Microbial growth inhibition

Single alginate disks were placed on an agar plate seeded with a bacterium (methicillin-resistant *S. aureus* (MRSA), *P. aeruginosa*, *E. coli*, *K. pneumoniae* or *A. baumannii*) by the spread plate method. The zone of inhibition was measured following 24 h incubation at 37°C (n=9 for each CHX-NPs doping; 6, 3 & 0 wt%).

#### Bioluminescent imaging<sup>4</sup>

Single alginate disks were placed on a petri dish seeded with *E. coli*, modified with the *Photobacterium luminescens lux* operon, by the spread plate method. Light output across the petri dish was recorded for 16 h using an Andor iXon EM+ DU-897 back-illuminated EMCCD camera with a Tamron SP AF 17-35 mm F/2.8-4 lens.

### RESULTS AND DISCUSSION

CHX elution was sustained over two weeks with the material tailorable with respect to delivery dose (Fig 1).

**Fig 1.** Alginate nanocomposite thin films at two CHX-NPs dopings sustain CHX elution for two weeks.

The initial CHX release (25.5 & 62.6 µmoles m<sup>-2</sup> for 3 & 6 wt% CHX-NPs respectively at 21 h) was found to be effective against five common wound infecting microorganisms (Fig 2).

**Fig 2.** Inhibition zones (MRSA) produced by alginate thin film disks (ø = 10 mm) containing a wt% CHX-NPs

Video imaging of bioluminescent *E. coli* allowed visualisation of the antiseptic effect in real time *in situ*.

### CONCLUSION

CHX-NPs impregnated alginate facilitates the tailorable release of antiseptic at therapeutic concentrations, effective against common infecting microorganisms. *In vitro* cytotoxicity studies are planned on fibroblast cell lines which will provide an indication of any effect upon the healing pathways of a wound.

Timothy.Douglas@UGent.be

### INTRODUCTION

Antibacterial properties are highly desirable for materials for bone regeneration. Hence, biomaterial enrichment with antimicrobial agents is advantageous. Polyphenols are organic chemicals containing phenol structural units. Phlorotannins are a subset of polyphenols occurring in brown seaweeds such as *Ecklonia cava*. They possess antibacterial<sup>1</sup> and anti-inflammatory activity<sup>2</sup>. Brown seaweed extracts such as Seanol® are widely used as food supplements thanks to their antioxidant properties, but their use as biomaterial components to endow antibacterial activity remains unexplored. Seanol® is an *E. cava* extract of which <95% consists of polyphenols. In this study, Seanol® was incorporated into hydrogels consisting of gellan gum (GG), which were enzymatically mineralized with calcium phosphate (CaP) using alkaline phosphatase (ALP) as in previous work<sup>3</sup> in order to further improve their suitability for bone regeneration. It was hypothesized that Seanol® would inhibit biofilm formation of Methicillin-resistant *Staphylococcus aureus* (MRSA) on hydrogels, both before and after mineralization with CaP.

### EXPERIMENTAL METHODS

Hydrogels containing 0.7% GG (sterilized by ethylene oxide) and 0.03% CaCl<sub>2</sub> (w/v) with Seanol® and ALP concentrations described in Table 1 were fabricated as described in Figure 1 under sterile conditions. Hydrogel cylinders of diameter 6 mm and height 10 mm were incubated in a 0.1 M CaGP solution-suspension for 7 d to induce mineralization with CaP in GG/S2.5/ALP samples. To evaluate ability of Seanol®-loaded GG hydrogels to inhibit biofilm formation, 6 cylinders of GG/S2.5 and GG/S2.5/ALP were placed on a silicone disc and incubated with 10<sup>4</sup> Colony Forming Units (CFU) of MRSA. After 24 h incubation at 37°C, the number of sessile bacteria present on both the silicone disc and the hydrogel cylinders were determined by plating. Physicochemical characterization was also performed. Dry mass percentage (mass percentage attributable to polymer and CaP and not water) served as a measure of CaP formed. Compressive modulus was determined. For all measurements, n = 3.

Table 1: Composition of sample groups

Sample group	Conc. Seanol®	Conc. ALP
GG/S2.5	2.5 mg/ml	0 mg/ml
GG/S2.5/ALP	2.5 mg/ml	2.5 mg/ml

### RESULTS AND DISCUSSION

Both GG/S2.5 and GG/S2.5/ALP samples strongly inhibited biofilm formation on hydrogel samples (Figure 2). Inhibition of biofilm formation on silicone discs was similar (data not shown). Hydrogel incubation

in 0.1 M CaGP caused a reduction in antibacterial activity, presumably due to release of Seanol®.

Figure 1: Schematic description of hydrogel production

However, biofilm formation on GG/S2.5/ALP samples was significantly lower than on controls, indicating retention of antibacterial activity. This may be due to CaP formation, inhibiting complete loss of Seanol®. Seanol® also increased CaP formation and compressive modulus: values for GG/S2.5/ALP samples were significantly higher than those for GG/ALP samples.

Figure 2: Biofilm formation on hydrogels, which were either incubated in 0.1 M CaGP for 7 days prior to testing or unincubated. \* p<0.05 compared to CTRL (GG hydrogels without ALP or Seanol®).

### CONCLUSION

Incorporation of Seanol® in GG hydrogels inhibits MRSA biofilm formation, even after mineralization.

### ACKNOWLEDGMENTS

### INTRODUCTION

The surgical disciplines involved in the bone replacement (osteolysis, osteosarcoma) raise multiple problems, in particular infection (1-2%), which can lead to dramatic consequences for the patient (re-interventions, amputation, fistulisation, *etc.*); and the need of vascularisation. Hydroxyapatite (HA) is largely used for bone tissue regeneration due to its excellent biocompatibility, bioactivity and osteoconduction properties<sup>1,2</sup>. Chitosan is a biopolymer known for its antibacterial, haemostatic properties and its ability to form hydrogel networks, *i.e.* through the reaction with an anionic polymer (*e.g.* cyclodextrin) to form a polyelectrolyte complex. The aim of this project is to develop an antibacterial spongy hybrid (chitosan/HA), obtained by the physical gelation of chitosan and polymer of cyclodextrin. After freeze-drying, the rheological and biological properties of this hybrid material were determined, and the antibiotics release profile and antibacterial properties were assessed by loading the ciprofloxacin on the hybrid.

### EXPERIMENTAL METHODS

The hydrogel was prepared by dissolving chitosan (CHT, 3% w/v, 75-85% deacetylated), and polymer of cyclodextrin (PCD, 3; 5 or 10% w/v) in an acetic acid solution (1% v/v) with or without HA particles (80  $\mu$ m; 30% w/v). At the end of the process, the hydrogels were freeze dried (-60°C, 0.06mbar) and stored at room temperature. Their swelling ratio was determined by immersing 20 mg of hybrid in 10 mL of ultrapure water and/or phosphate buffer saline (PBS, 0.1M; pH 7.4).

Cell vitality was evaluated by the Alamar blue method with pre-osteoblast cells (MC3T3/E1) according to the ISO 10993-5 standards. Scanning electron microscope (SEM, S-4000 Hitachi, Krefeld, Germany) was used to observe the microstructure of the sponge. Rheological studies were carried out on rheometer (MCR301-Anton-Paar). The storage modulus ( $G'$ ) and loss modulus ( $G''$ ) of the hydrogels were carried out with a controlled shear stress ( $\gamma=1\%$ ,  $T=25^\circ\text{C}$ , and  $\omega=10\text{s}^{-1}$ ). For drug sorption and drug release studies, 20 mg of sponge was impregnated in 10 mL of ciprofloxacin (CFX, Kabi®, 200 mg/100 mL) at room temperature. The drug loading was then determined by UV spectrophotometer at 271 nm by desorption of drug in NaOH 0.1 N overnight. The release profile of CFX was determined under dynamic condition with a USP4 apparatus (Sotax®, 37°C, 30 mL/min). Finally the antibacterial activity of the CFX-loaded sponge was determined by Kirby-Bauer method

### RESULTS AND DISCUSSION

Fig. 1 shows that the swelling rates increase to reach a maximal value (up to 800%), and then decreased and stabilized after 120 minutes. Increasing PCD ratios in the formulations provoked the decrease of the swellability of gel.

**Figure 1:** Swelling behaviour of the hydrogel at different proportion of PCD in PBS (0.1M, pH7.4)

After impregnation of the sponge in CFX solution, the drug sorption (25 mg/g) did not increase with the PCD ratio, but the release profile was prolonged with decrease of PCD ratio. These results were also confirmed by the microbiological evaluation, which revealed antibacterial activity on *E. coli* and *S. aureus*. Rheological studies of the gel displayed the elasticity of the gels the storage modulus  $G'$  was always superior to the loss modulus  $G''$ , the ratio  $G'/G'' \approx 2$ . The evaluation cell vitality test showed an excellent cytocompatibility (>80% of osteoblast vitality).

**Figure 2:** Kinetic release of CFX in mg/g of hydrogel at different proportion of PCD in PBS(0.1M, pH7.4)

### CONCLUSION

We demonstrated the prospect of preparing a well characterized HA incorporated CHT/PCD spongy hybrid. The gel structure can be fine-tuned by varying the ratio of PCD to CHT. Increasing PCD resulted in the stiffer gels, but didn't improve the reservoir property. The HA particles can improve osteoblastic proliferation on the hydrogel and PCD could carry CFX to prevent infections. Moreover, other therapeutic agents could also be applied in future.

### INTRODUCTION

Corneal bandage lenses have an important role to play in the treatment of corneal infection and disease<sup>1</sup>. Corneal ulcers are of particular interest as current treatment involves the topical administration of antibiotics, of which only 1 - 7 % is absorbed to the site of infection<sup>2</sup>. This inefficiency allows a lot of scope to improve the delivery of drugs to the surface of the eye.

This study aimed to investigate the natural antimicrobial activity of a novel hydrogel as well as observing differences in activity when compounds such as additional poly-ε-lysine (Pεk) and penicillin G (pen G) were covalently or ionically coupled to the hydrogel.

### EXPERIMENTAL METHODS

Peptide gels were synthesised from poly-ε-lysine and crosslinked with suberic acid with a density of 0.071 g/cm<sup>3</sup> and 45%, 60% or 75% crosslinking. Some of the hydrogel surfaces were modified to bind additional poly-ε-lysine using an EDCI/NHS mediated crosslinking technique and/or the β-lactam antibiotic penicillin G by soaking in an ionic solution of the antibiotic. Hydrogel samples were incubated with *E.coli* or *S.aureus* inoculum ( $5 \times 10^5$  cells/ml) for 2 h, 4 h and 18 h before being removed and washed in PBS (x5). An alamar blue metabolic assay coupled with serial dilution plate counts were used to determine the bacterial burden on the surface of the hydrogel materials.

### RESULTS AND DISCUSSION

The degrees of crosslinking had no significant difference on alamar blue reduction between the hydrogels and performed similarly to the LB agar control which suggests the variation in amine groups at these concentrations had little effect on antimicrobial activity. A significant difference in antimicrobial activity was obtained by altering the surface properties of the hydrogel material with either additional poly-ε-lysine or penicillin G compared to the LB agar control. The *S.aureus* experiment control (28 % resazurin after 18 h) was significantly less ( $P < 0.001$ ) than values for poly-ε-lysine (90 %), penicillin G (96 %) and poly-ε-lysine + penicillin G (96 %) (figure 1). Results for *E.coli* were similar, the resazurin in the control was significantly ( $P < 0.001$ ) reduced (30 % resazurin after 18 h) when compared to values for poly-ε-lysine (80 %), penicillin G (99 %) and poly-ε-lysine + penicillin G (99 %) (figure 2). These data demonstrate

the potential to modify the hydrogel material in such a way that enables an increase in antimicrobial activity. This may allow for the tailoring of the hydrogel to target other pathogens utilising alternative antimicrobial compounds bound to the surface.

Figure 1: Metabolic Activity of *S. aureus* Newman Incubated with the Hydrogel Variants

Figure 2: Metabolic Activity of *E. coli* MC1061 Incubated with the Hydrogel Variants

### CONCLUSION

Crosslinked poly-ε-lysine hydrogel alone was not antimicrobial to *E.coli* or *S.aureus* however binding poly-ε-lysine or penicillin G to the free amine groups on the crosslinked hydrogel caused a significant antimicrobial effect. These modified hydrogels could have a role as bandage contact lenses in the treatment of corneal ulcers.

## Ephemeral Biogels to Control Anti-Biofilm Agent Delivery

Véronique Larreta-Garde, Elodie Lefebvre, Damien Seyer

Biology Department/ERRMECe, University of Cergy-Pontoise, France

[veronique.larreta-garde@u-cergy.fr](mailto:veronique.larreta-garde@u-cergy.fr)

### INTRODUCTION

Over the past 15 years, the impact of biofilms on persistent infections and their potential role on chronic wounds have been extensively documented<sup>1</sup>. However, up to now, no efficient system to deliver anti-biofilm agents has been described<sup>2</sup>.

The aim of this study was to create a biogel system entrapping and releasing various agents to allow eradication of bacteria in biofilms. The anti-biofilm strategy combined destruction of bacteria and disruption of the biofilm matrix, expecting a biomass decrease by at least 5 log. The biomaterial here elaborated was conceived to control the delivery of active compounds and tested on monospecies and mixed biofilms from *Pseudomonas aeruginosa* and *Staphylococcus aureus*.

### EXPERIMENTAL METHODS

**Biogels:** Gelatin 5 to 7% (W/V) solutions containing PHMB (from  $5 \cdot 10^{-2}$  to  $8 \text{ mg.mL}^{-1}$ ), EDTA (20mM) without and with Esperase ( $6$  to  $9 \text{ U.mL}^{-1}$ ) are turned to gels under the action of transglutaminase ( $1 \text{ U.mL}^{-1}$ ). The mechanical properties of the biogels are measured through rheology.

**Biofilms:** *Pseudomonas aeruginosa* and *Staphylococcus aureus* biofilms were grown for 24h, then treatments (contact with the active biogel) were applied for 24 to 48 h and the viable biofilm bacteria quantified on agar.

### RESULTS AND DISCUSSION

The combination of a commercial antiseptic (PHMB, low concentration), and an ion chelator able to inhibit MMPs (EDTA) in solution was first tested on biofilms. The mixture was proven efficient with a very high anti-bacterial effect ( $> 99.999\%$ ) against both *P. aeruginosa* and *S. aureus* biofilms. The addition of EDTA potentialized the effect of PHMB, showing an efficient synergistic effect of the two compounds.

The two active compounds were then entrapped together into a 5% gelatin gel. Unfortunately, the efficiency of this gel against biofilms was largely reduced compared to the antiseptic solution. The PHMB concentration was then increased to  $8 \text{ mg.mL}^{-1}$ , but this induced a large decrease of the mechanical properties of the gel. The 5% gelatin gel entrapping PHMB was 7 times less elastic than the control gel. Using a more concentrated gelatin solution (7%) allowed obtaining satisfactory elastic properties, the gel containing the antiseptic compounds being handeable.

However, in these conditions, a diffusion limitation of the chosen antiseptic was evidenced. Only 4% of the

initial PHMB concentration included in the gel diffused in the surrounding medium within 24h, limiting its efficiency against biofilms.

To overcome this diffusion limitation, an innovative drug delivery system, developed in our laboratory<sup>3</sup> and allowing a gelatin gel formation followed by a controlled-time resolubilization was elaborated. This gel is based on the action of two antagonistic enzymes, one generating and the other cleaving covalent bonds, respectively a transglutaminase and a protease. The use of this ephemeral gel, named Enzgel leads to enhanced and controlled molecular release<sup>4</sup>.

Thus, a protease, Esperase, was added to the gelatin solution containing the treatment; a gel was first formed which later re-solubilized. The network hydrolysis was complete after about 2 days. This system promoted molecule diffusion from the gel to the surrounding medium allowing their anti-biofilm activity to express. After 24 h contact, the biomass was reduced by 5 logarithms for *S. aureus* biofilm and by 7 logarithms for *P. aeruginosa* biofilm, an improvement of 40 and 11 times compared to the gel without protease. After 48h contact, both monospecies biofilms and a mixed biofilm were totally eradicated. The efficiency rates fixed in the project were thus largely overcome.

### CONCLUSION

In the United States, 8 million people are affected by chronic wounds which lead to a cost of 20 billion dollars per year. The presence of biofilm may extend the healing delay. Our strategy to limit or eradicate biofilms was based on two major points: destabilize the biofilm and its matrix and eliminate pathogenic bacteria by the use of an antiseptic. In this study, we have conceived and elaborated an active biogel, able to control the bacteria level in various biofilms. This biomaterial is very promising for wound care and will be developed in the near future.

[haritz.sardon@ehu.es](mailto:haritz.sardon@ehu.es)

**In this study, a new family of broad-spectrum antimicrobial polycarbonate hydrogels has been successfully synthesized and characterized. *In vitro* antimicrobial studies revealed that quaternized hydrogels exhibited broad-spectrum antimicrobial activity against *Staphylococcus aureus* (Gram-positive), *Escherichia coli* (Gram-negative), *Pseudomonas aeruginosa* (Gram-negative), and *Candida albicans* (fungus).**

### INTRODUCTION

Wound treatments have a major impact on quality of life. It is believed that the treatment of chronic wounds will become an important challenge to healthcare systems worldwide due to an aging society. Despite these urgent needs, wound dressing technology still has a long way to go probably due to the intrinsic complexity of the wound healing process.<sup>1</sup>

In the last decade, polymeric hydrogels have been studied and used as alternative to gauze dressing materials in wound dressing applications. Hydrogels have the ability to maintain wound occlusion, creating a more conducive environment for tissue regeneration than exposed wounds. The main problem in using hydrogels for wound care is the high risk of infection as the moist environment in the hydrogels allows pathogen to proliferate and colonize. The goal of this study is to design a hydrogel that fast degrades and prevents bacterial infection. In this sense, aliphatic polycarbonates were chosen not only due to their ability to degrade fast under physiological condition but also their activity against multidrug resistant bacteria.<sup>2</sup>

### EXPERIMENTAL METHODS

**Synthesis of polycarbonate hydrogels** A 20 mL glass vial containing a magnetic stir-bar was charged with monomer 1, monomer 2, PEG<sub>1500</sub> in DCM. DBU was added and the solution was stirred for 24 h.

DBU was quenched with an excess of benzoic acid. The resulting hydrogel was washed by immersion in DCM to remove catalyst and soluble fractions, and dried under vacuum. (Yield: 0.40 g, 89 %) Finally, the gel was immersed in methyl iodide (CH<sub>3</sub>I) for 48 h at room temperature under N<sub>2</sub>. (Scheme 1)

**Antibacterial activity** The quaternized hydrogel was cut into 5 x 5 mm square and placed into a 1.7 mL micro-centrifuge tube. TSB or YMB (100  $\mu$ L) was added into the tube before an equal volume of microbe suspension ( $3 \times 10^5$  CFU/mL) was added. After the hydrogel treatment, the samples were taken for a series of tenfold dilution, and plated onto agar plates. The plates were incubated for 24 h at 37 °C for bacterial samples or 42 h at room temperature for *C. albicans* before the number of colony-forming units (CFU) was counted.

### RESULTS AND DISCUSSION

The antimicrobial activity of different hydrogels was evaluated against Gram-positive bacteria *S. aureus*, Gram-negative bacteria *E. coli* and *P. aeruginosa*, and fungi *C. albicans*. After treating the microbes with the hydrogels, the growth of the microbes was completely suppressed with killing efficiency of at least 99.999%. Furthermore, the CFU counts after 18 h of treatment showed that the hydrogels were bactericidal to a wide range of microbes. There was a 6 – 10 log reduction in colony counts. Meanwhile, the unquaternized gels did not show any significant activity towards the microbes. All hydrogels demonstrated similar antimicrobial activity against all microbes tested. These hydrogels were chemically cross-linked as thin transparent films, making them desirable for wound healing applications.

### CONCLUSION

Quaternized polycarbonate hydrogels exhibited high ability to kill Gram-positive and Gram-negative bacteria as well as fungi. Therefore, these materials have potential applications in wound healing and medical implants for the prevention of infections.

## Injectable Gellan Gum-Based Nanoparticle-Loaded System for the Local Delivery of Vancomycin in Osteomyelitis Treatment

Urszula Posadowska<sup>1\*</sup>, Monika Brzychczy-Włoch<sup>2</sup>, Elżbieta Pamuła<sup>1</sup>

### INTRODUCTION

Conventionally elimination of pathogens from musculo-skeletal environment involves surgical removal of necrotic tissue, osseous repair and antibiotherapy for 4 – 6 weeks<sup>1,2</sup>. The procedure applied is often inefficient and harmful to the patients. Alternative solution that seems to be less complicated and more accurate is the usage of drug releasing degradable implants placed exclusively into the infected tissue (preferentially via non-invasive way<sup>3,4</sup>). Thus, here we present application of gellan gum-based biomaterial enriched with nanoparticles loaded previously with antimicrobial agent (vancomycin) for local elimination of musculoskeletal infection that leads to chronic bone disease, i.e. osteomyelitis.

### EXPERIMENTAL METHODS

Vancomycin was encapsulated in poly(L-lactide-co-glycolide) (PLGA, 85:15, Mn = 80 kDa, d = 1.8) nanoparticles (Vanc-NPs) via double-emulsification. Vanc-NPs were characterized with dynamic light scattering (DLS), capillary electrophoresis, atomic force microscopy (AFM); fluorescence spectroscopy (OPA assay) was used to assess loading and encapsulation efficiencies. In order to obtain injectable drug delivery system, Vanc-NPs were suspended in gellan gum (Gelzan<sup>TM</sup>) and cross-linked with Ca<sup>+2</sup> (GG-Vanc-NPs). The systems obtained were evaluated with respect to injectability, rheology, drug release and morphology (SEM). Then, they were studied *in vitro* via an indirect way. Extracts performed to cell culture medium (37 °C, 24 h) were examined on osteoblast-like MG-63 cells. Cells were evaluated with respect to their metabolic activity (Alamar Blue test), viability (live-dead test) and morphology. For the antimicrobial activity agar-diffusion tests via Kirby-Bauer method were conducted. Bone inhabiting pathogens causing osteomyelitis *Staphylococcus spp.*, both referential strains and strains isolated from infected joints were used.

### RESULTS AND DISCUSSION

DLS studies showed that size of Vanc-NPs was in nanometric range (250 – 380 nm). Analysis of morphology by AFM showed their spherical shape. Laser electrophoresis demonstrated negative zeta potential connected with the ionized carboxyl end group of PLGA. Results of solubilization revealed encapsulation efficiency of 55.2 ± 0.5% and drug loading of 8.4 ± 0.1%. Injectability studies performed in

compression mode (cross-head speed 50 mm/min) showed that extrusion force from the standard 18G needle was lower than 15 N and the force increased upon Vanc-NPs addition. Rheological evaluations showed that despite Vanc-NPs addition gellan gum matrix had good mechanical properties ( $G'$  - storage modulus 7.4 kPa,  $G''$  - loss modulus 0.4 kPa). The  $G'$  and  $G''$  moduli were lower than for unloaded system. The structure exhibited ability to self-organize after disruption by strain sweep deformation. Drug release studies of GG-Vanc-NPs showed short burst release followed by long sustained release phase. Regarding *in vitro* studies, comparable values of Alamar Blue reduction by MG-63 cells were obtained when cells were incubated in culture medium or in GG-Vanc-NPs extracts. Incubating *S. aureus* and *S. epidermidis* with GG-Vanc-NPs resulted in inhibition of microbes growth. The inhibition zones had diameters in the range 24 – 29 mm, what indicated sensitivity of the tested strains.

### CONCLUSION

Our systems based on vancomycin loaded nanoparticles suspended in gellan gum matrix: i) were found to be syringeable and easy to administer (injectable), ii) reassembled their structure after disruption by strain sweep deformation, iii) ensured local vancomycin delivery, iv) did not affect osteoblast-like cells viability, and v) demonstrated antimicrobial activity against *Staphylococcus spp.* referential as well as the clinical isolates. The results show the promising potential of developed injectable systems for the local elimination of microbial infections leading to osteomyelitis.

## Long-Term and Bioinert Labeling of Mesenchymal Stem Cells with Polymeric-Gd Conjugates and MRI Monitoring of the Cell Behaviour in Ischemic Rats

Tetsuji Yamaoka\*, Yoichi Tachibana

Department of Biomedical Engineering, National Cerebral and Cardiovascular Center Research Institute, Japan  
[yamtet@ncvc.go.jp](mailto:yamtet@ncvc.go.jp)

### INTRODUCTION

There is an increasing interest in stem cell transplantation therapy, and autologous mesenchymal stem cells (MSCs) have received much attention in treating limb ischemia, infarcted myocardium, brain injury, and so on. Although the detailed mechanisms of MSC actions in vivo remain unclear, recent studies have focused on paracrine mechanisms. It is also reported that the transplanted MSCs decrease within 2 to 3 weeks according to the histological analysis, that is a semi-quantitative method and cannot distinguish whether the cells died or migrated elsewhere. To clarify the behaviour of transplanted MSCs quantitatively, we have developed novel magnetic resonance imaging (MRI) cell tracking system. There are two important factors to achieve long-term cell tracking; the stable retentivity of the contrast agent in the cells and the elimination of the free contrast agents when they leak out of the cells upon cell death.

We have been studying the water-soluble gadolinium (Gd)-based MRI contrast agent for cell labeling and tracking for the first time<sup>1-4</sup>. Gd-chelate molecules were conjugated to the side hydroxyl groups of water soluble carrier such as poly(vinyl alcohol) (PVA) or dextran. The novel polymeric-Gd, was delivered under a mild condition system to various types of cells. In the present study the migration and survival of MSCs in rat ischemia model will be discussed.

### EXPERIMENTAL METHODS

Polymeric-Gd was synthesized by recently reported method<sup>5</sup>. First, rMSCs were cultured at a concentration of  $5 \times 10^5$  cells/dish for 1 day, washed with PBS three times, and suspended in culture medium without serum. Polymeric-Gd or low molecular weight contrast agent ProHance® at a final Gd concentration of 10 mM was added to the culture medium. Electrical pulses were applied to cells using a CUY-21 electroporator (NEPPA GENE, Tokyo, Japan). Rectangular electrical pulses (field strength, 300 V/cm; number of pulses, 10; pulse duration, 5 ms) were applied to cells using two parallel electrodes with a 5-mm gap, resulting in the cell labelling with the Gd with very low cytotoxicity.

Male rats (8 weeks old) were anesthetized with isoflurane (1.5% in air) and the left femoral artery and vein and their branches were ligated and completely excised through a skin incision. The Gd-labeled MSCs were injected intramuscularly.

MR imaging was conducted using T1-weighted images obtained with a 1.5-T compact MRI system (MRmini, Dainippon Sumitomo Pharma, Osaka, Japan)

with a repetition time (TR) of 2000 ms and an echo time (TE) of 9 ms.

The recovery of blood flow in ischemic limbs 輪 measured by using a Laser Doppler Perfusion Imager (LDPI). The amount of [Gd(III)] retained in the cell, accumulated in the tissue, and excreted to the urine was measured by the inductively coupled plasma atomic emission spectroscopy (ICP-AES) (Model 7510, Shimadzu Co., Kyoto, Japan).

### RESULTS AND DISCUSSION

Polymeric-Gd did not show any cytotoxicity in the tried condition and did not affect the growth or differentiation of the MSC, indicating that they are safe and could be translated for use in clinical cell therapy

Polymeric-Gd was retained in the cytosolic compartment of MSCs higher than 90% at 1 month post labelling. In vivo T1-weighted images of rMSCs revealed that rMSCs are eliminated with time from the site of transplantation within two weeks even when the stem cells are seeded and trapped in the porous gelatin scaffold, Spongel®.

### CONCLUSION

Our system is very effective to quantify the cell survival by noninvasively visualizing them with MRI. These cell tracking system will be a powerful tool for studying the lifespan of transplanted cells and developing the most effective transplantation methods for stem cell therapy.

## INTRODUCTION

Fluorescent probes are widely used for imaging in cell biology. Increasingly, they are also being utilized as chemosensors to diagnose specific pathological conditions and report on cellular events<sup>1-3</sup>. There is considerable interest in designing nanoparticles that report on physiologically relevant species such as hydrogen ions<sup>4,5</sup> because such sensors provide attractive cell and tissue uptake kinetics and distribution.

## EXPERIMENTAL METHODS

Monomers, Nile Blue methacrylamide (NBM) and Nile Blue 2-(methacryloyloxy)ethyl carbamate (NBC) were prepared from Nile Blue (NB). pH-responsive diblock copolymers based on (2-(methacryloyloxy)ethyl phosphorylcholine) [MPC] and 2-(diisopropylamino)ethyl methacrylate [DPA], PMPC-PDPA labelled with Nile Blue derivatives were synthesised using Atom Transfer Radical Polymerisation (ATRP). Polymer toxicity on HDF cells was assessed using an MTT assay. Uptake and intracellular distribution of polymer nanoparticles was studied on Human Dermal Fibroblast (HDF) cells using confocal microscopy and conventional subcellular markers. 3D Multicellular tumour spheroids (MCTS) of MDA-MB-231 breast cancer cells were cultured according to literature<sup>6</sup>. Hypoxia-induced pH change of live spheroids was monitored using an optical microscope and the results were compared to results obtained using a control marker for hypoxia (Glut-1). Full experimental details can be found in reference 7.

## RESULTS AND DISCUSSION

Absorption and emission properties of two Nile Blue derivatives were found to be pH-sensitive around physiological pH. These dyes were found to attach themselves to polymers through a radical mechanism. PMPC-PDPA diblock copolymers were easily labelled with NB, NBM or NBC (Figure 1B). The resulting polymers were found to exhibit pH-responsive absorption characteristics as shown in Figure 1A. The pH-responsive absorption was used to monitor hypoxia in tumours (see Figure 1C). In addition, such polymers are known to be rapidly incorporated into many different cell types and are distributed inside intracellular organelles<sup>8</sup>. Therefore, it was possible to simultaneously monitor lysosomes and early endosomes by exploiting the pH-induced change in the fluorescence emission wavelength.

## CONCLUSION

PMPC-PDPA-based pH-responsive nanoparticle probes

report clinically-relevant pH-changes in tumors and cell organelles thus enabling pH sensing both at the interstitial level and also at the sub-cellular level.

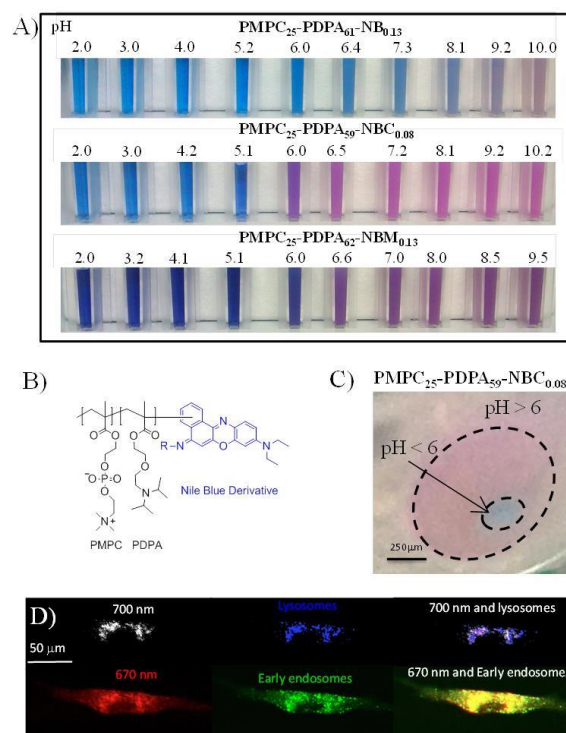

Figure 1: A) pH-dependent absorption of three PMPC-PDPA block copolymers labelled with NB dyes. B) Structure of PMPC-PDPA. C) Picture of an MCTS treated with PMPC-PDPA-NBC. D) Confocal fluorescence microscopy pictures of HDF cells treated with PMPC<sub>25</sub>-PDPA<sub>59</sub>-NBC<sub>0.08</sub> measured at 700 nm and 670 nm.

[l.plawinski@cbmn.u-bordeaux.fr](mailto:l.plawinski@cbmn.u-bordeaux.fr)

## INTRODUCTION

Circulating platelets and blood cells (leucocytes, red cells) as well as endothelial cells are capable of releasing membrane microvesicles under the influence of a variety of stimuli (fig 1). Variations in the relative amount of one or the other microvesicles may be characteristically found in specific pathologies including atherosclerotic vascular disease, diabetes, cancer, rejection of cardiac transplants and inflammatory diseases<sup>1</sup>.

In addition to exposure of phosphatidylserine at the surface of the membrane, microvesicles convey surface identity antigens and/or contain biomolecules that allow their identification and functional characterization. Accordingly, detection of microvesicles and their specific functional properties open new horizons for clinical applications including patients' follow-up and treatment monitoring. Here, we propose a chemosensor capture assay based on recognition of phosphatidylserine at the surface of microvesicle by two type of functionalized synthetic dinuclear zinc complexes (fig 2).

**Figure 2:** Schema of synthetic dinuclear zinc complexes with varying tail length.

## EXPERIMENTAL METHODS

To prove the concept, we first immobilized two types of chemosensors by activated 96 well-plates with polyglutaraldehyde. Secondly, microvesicles of human endothelial cell origin were incubated for 1h at room temperature. At last, the captured microvesicles were revealed by 2 techniques: immunoassay (using antibodies directed against CD105 present at the endothelial-derived microvesicle membrane) and enzyme analytic assay. This one is based on the ability of microvesicles to activate 1μM of plasminogen in the presence of a chromogenic substrate selective for plasmin (CBS 0065). Plasminogen is converted in plasmin by plasminogen activators bound at the surface of microvesicles. Thus, plasmin cleaves the chromogenic substrate and the released p-nitroaniline is detected by measuring A405nm as a function of time.

## RESULTS AND DISCUSSION

**Antigenic detection.** In fig 3, we observe a dose-dependent response, using an increasing number of microvesicles for our two types of chemosensors.

However, we observed a signal saturation with the first chemosensor (short tail; dark bar).

**Figure 4:** Detection of microvesicles fibrinolytic activity by the immobilized complexes

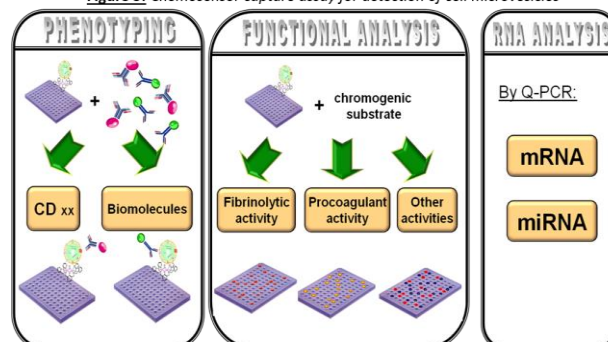

**Functional detection.** Two types of chemosensors were tested with plasminogen chromogenic assay. Fig 4 shows a better functional detection of captured microvesicles with the second chemosensor (long tail; grey bar).

## CONCLUSION

The innovation of the technology we propose is that we have identified a novel synthetic ligand (dinuclear zinc complex) for phosphatidylserine that **allows capture, origin identification** (using specific antibodies) **and functional analysis** (including fibrinolytic activity) **of microvesicles**. Our experimental development indicates no interaction of the immobilized complex with added antibodies or reagents thus ensuring specific signal detection and high sensitivity. This is a major advance as there is currently no technological procedure that may allow this versatility. The expected product (fig 5) is a kit assay in a 96-well microplate format where the functionalized complex allows (i) capture of microvesicles from plasma or other biological fluids, and (ii) their identification and characterization with provided reagents. This will be the first test assay<sup>2</sup> available for routine clinical practice that allows microvesicle characterization and can thereby be applied to the study of a number of pathologies where microvesicles are implicated.

## INTRODUCTION

Porosity and polymer network architecture are very important properties for hydrogels in tissue engineering and cell culture applications as cell proliferation, migration and nutrient diffusion are all dependent on pore structure<sup>1</sup>. If hydrogel is transparent, optical methods can be used for analysis of physical properties and pore structure.

In previous work, we have compared the diffusion properties of bioamine cross-linked gellan gum (GG) hydrogels using confocal microscopy technique fluorescence recovery after photobleaching (FRAP)<sup>2</sup>. The spermine (SPM) bioamine is an attractive choice to replace  $\text{Ca}^{2+}$  as cross-linker, due to the reduced interference with cellular electrophysiology. In this work we use optical projection tomography (OPT)<sup>3</sup> in the fluorescent mode to image the fluorescent dextran-FITC molecule mass transport through GG hydrogel. This technique can be used to study diffusion in mesoscopic scale to complement the more local diffusion measurement done with FRAP<sup>2</sup>.

## EXPERIMENTAL METHODS

GG and cross-linker stock solutions were made in 10 % sucrose water solutions and sterilized by filtration. The used cross-linker concentrations are 0.6 & 1.1 % -w/w SPM and 2.5 mM  $\text{Ca}^{2+}$ . The hydrogel samples were made by mixing the reagents at +37 °C inside disposable polystyrene cuvettes.

The penetration of dextran inside the hydrogel was imaged using fluorescence emission illumination mode of an in-house built OPT-system<sup>3</sup>, using only one projection. The samples were excited using a collimated LED with 470 nm (M470L3, Thorlabs) and the detection system consisted of a 5x objective, a band pass filter with center wavelength of 520 nm, tube lens and a sCMOS camera (ORCA-Flash 4.0, Hamamatsu). Images were collected every minute with an exposure time of 0.04 seconds. Dextran-FITC with molecular weights 20 kDa and 2000 kDa, 10mg/mL, were used as model diffusing agents. The imaged area is the upmost 3 mm of the hydrogel with 100  $\mu\text{L}$  of dextran solution applied on top and image acquisition started 1 min before applying the dextran. The image acquisition time was 120 min for 20 kDa and 250 min for 2000 kDa.

## RESULTS AND DISCUSSION

In Figure 1 (a), (b), and (c) can be seen the penetration of 2000 kDa dextran at 1, 111 and 250 min time points. In parallel sample Figure 1 (d), the detected fluorescence is not uniform throughout the hydrogel,

indicating that the diffusion is affected by the pore structure and the heterogeneity showed by the hydrogel.

Figure 1. From a) to c): time series of dextran-FITC spreading inside the GG- $\text{Ca}^{2+}$ -hydrogel, d) example of uneven penetration at 250 min in parallel sample. Scale bar is 500  $\mu\text{m}$ .

The change in average pixel intensity at ~1.5 mm depth is plotted in Figure 2, showing penetration of dextran deeper into the hydrogel. The  $\text{Ca}^{2+}$  cross-linked GG has the highest diffusion speed and 1.1 % SPM the lowest, so their pore structure is hypothesized to be different.

Figure 2. Normalized average pixel intensity along the middle pixel row of the image over time, a) 20 kDa, b) 2000 kDa.

The different diffusion properties can be due to different pore number, size and interconnectivity, which can also be interpreted as the density of the microstructure of the polymer network. Diffusion of the largest dextran also varies between parallel samples, indicating a threshold molecular weight, which can pass through this hydrogel easily, to be lower than 2000 kDa.

## CONCLUSION

Our study demonstrates that fluorescent molecules of known size can be used for studying the mass transport and porosity of hydrogel in an OPT setup. In this study we show how used cross-linker and its concentration affect diffusion of differently sized dextran molecules.

## INTRODUCTION

Hyaluronan (HA) is an important component in the extracellular matrix of cartilage and other tissues. It is widely used as a scaffold material and can be found in many synthetically engineered forms. Here, model HA surfaces were developed for biomolecular and cell interaction studies using surface sensitive techniques.

## EXPERIMENTAL METHODS

Biotinylated HA was immobilized to streptavidin-modified sensors compatible with quartz crystal microbalance with dissipation monitoring (QCM-D) and surface plasmon resonance (SPR).<sup>1</sup> The obtained HA surfaces were subjected to either hyaluronidase or aggrecan under liquid flow and changes of properties at/near the surface were detected by QCM-D or SPR. Hyaluronidase degradation was also studied using high-performance liquid chromatography (HPLC). QCM-D and light microscopy were combined using a dedicated measurement module to study cell attachment of chondrocytes to biotinylated HA.

## RESULTS AND DISCUSSION

HA of different degree of biotinylation was tested for enzymatic degradation by hyaluronidase with QCM-D (Fig. 1):

**Fig. 1:** Hyaluronidase degradation of biotinylated HA bound in a side-on (dashed, solid) or end-on (dotted) orientation. -1 to 0 in normalized  $\Delta f$  is equivalent to complete degradation.<sup>2</sup>

The HA biotinylation procedure was crucial for retained biofunctionality of the immobilised HA, where only the end-on orientation allowed for almost complete degradation. This dependency on biotinylation degree was also verified separately in bulk degradation by HPLC.

The end-on biotinylated HA was further used for cell interaction studie, including chondrocytes from human cartilage (Fig. 2):

**Fig. 2:** QCM-D  $\Delta f$  and  $\Delta D$  shifts for the addition chondrocytes (marked by \*) to immobilized HA. (i) Addition of streptavidin, (ii) addition of HA. Top row: the suggested degradation process and microscopy images taken during the QCM-D experiment during incubation with cells and after rinsing with media.<sup>3</sup>

In Fig. 2 the addition of chondrocytes induced a positive  $\Delta f$  equal to removal of the HA layer. By simultaneous microscopy it could be verified that the cells were present on the sensor. Thus, QCM-D could be used to study the cell-interface interactions without the disturbance of the relatively large cellular mass.

## CONCLUSION

Control of the degree of biotinylation is crucial for retaining the functionality of surface grafted HA. End-on biotinylated HA was proven to have the most retained biofunctionality with respect to enzymatic degradation by hylauronidase. Taking a QCM-D based approach to study chondrocyte-HA interaction, it was shown that the cells degrade HA in a similar way as for the hyaluronidase study.

### INTRODUCTION

Two- and three- dimensional scaffold fabrication technologies (e.g. electro-spinning, fibre extrusion, isoelectric focusing and imprinting) have been at the forefront of scientific and technological research and innovation to recapitulate native tissue extracellular matrix (ECM) supramolecular assemblies. Although fibrous constructs can maintain permanently differentiated cell phenotype and to differentiate stem cells towards specific lineages *in vitro* and to induce acceptable regeneration in preclinical models, none of these technologies offers precise control over the spatial distribution of the fibres. Imprinting technologies, on the other hand, have demonstrated a diverse effect on a range of permanently differentiated and stem cell functions, including adhesion, orientation, secretome expression and lineage commitment. Despite these advancements, a comprehensive study on the influence of surface topography over different scales, ranging from nano- to micron-level, on cell function *in vitro* and on tissue response *in vivo* has yet to be elucidated.

### EXPERIMENTAL METHODS

In the present study, we employed imprinting lithography technologies to create anisotropically grooved substrates with constant width and spacing and varying depth and we subsequently assessed the influence of anisotropic topography, as opposed to isotropic topography, on tenocyte (1) and on osteoblast (2) function *in vitro* and on host tissue response *in vivo*.

### RESULTS AND DISCUSSION

**Figure 1:** DAPI (blue) and rhodamine conjugated phalloidin (red) indicates that tenocytes aligned parallel to the substrate topography on substrates with groove depths of ~317 nm and ~1988 nm. A random morphology was observed on isotropic substrates and substrates with groove depth of ~37 nm (A).

**Figure 2:** Only substrates with groove depth of ~2046 nm induced aligned mineralised matrix by day 21 (A). No significant difference between the groups was observed in calcium deposition (B). At day 7, ALP activity was significantly increased on ~35 nm and

~2046 nm in groove depth substrates, as compared to ~306 nm in depth, control and isotropic substrates (C). At day 14 and 21, no significant difference was observed in ALP activity between all structured substrates and the control, isotropic, substrate (C).

### FUTURE WORK & CONCLUSION

Topographical features in the middle nano-range (~300 nm) and low micron-range (~2000 nm), rather than in the low nano-scale (~30 nm) groove depth, induce cellular and matrix alignment and upregulation of tenogenic / osteogenic markers *in vitro*. However, these topographical features did not translate *in vitro* contact guidance, directional cell growth and matrix alignment into enhanced interfacial integration and directional neotissue formation *in vivo* in a tendon model in a bone model and in a subcutaneous study.

### INTRODUCTION

Hybrid 3D scaffolds in regenerative medicine are used to combine the organic phase as a mechanical supporting constituent and the inorganic phase to promote bioactivity. Their potential is very promising, although several studies report some dramatically weak points, such as the fragile interaction between components which can lead to an undesirable collapse of the structure. Another problem is that the bioactive phase is often masked by the organic matrix, leading to inefficient contact with cells<sup>1</sup>.

Recently, our group found that calcium ions released by the degradation of glasses are effective angiogenic promoters because of their stimulation of a cell-membrane calcium sensing receptor (CaSR)<sup>2</sup>. Based on this, other focused tests on angiogenesis have found that Bioglasses® also have potential as angiogenic promoters even with high contents of silicon (80%); however, their slow degradation is still a problem, as the levels of silicon cannot be decreased any lower than 45%<sup>3</sup>. In this work, we propose a new generation of hybrid organically modified glass coatings (ormoglasses) that allows the Si content to be reduced, therefore speeding up the degradation process, the direct contact with cells and efficient polymer-ormoglass contact, thanks to a covalent bond. Using electrospinning as an accurate way of mimicking the extracellular matrix (ECM), we successfully produced hybrid fibrous mats with different Si, Ca and P contents and thus different calcium ion release rates and degradation.

### EXPERIMENTAL METHODS

PLA nanofibers were made by the electrospinning technique. Ormoglass nanoparticles were prepared using two composition ratios within the system SiO<sub>2</sub>:CaO: P<sub>2</sub>O<sub>5</sub> (60 S60 and 40% Si S40) by a partial hydrolyzed sol-gel method using alkoxide precursors. PLA nanofibers were coated with ormoglass nanoparticles using APTES as coupling agent. Material characterization included EDS, FE-SEM, Z-potential, contact angle, FTIR, tensile-strain assays, AFM, TGA, DSC and Ca<sup>2+</sup> release and pH evaluation. Biological characterization involved rMSCs and rEPCs adhesion and proliferation assays.

### RESULTS AND DISCUSSION

The production of different PLA coatings with two different ormoglass composition was successful. Mechanical properties, surface roughness and

hydrophilicity of coated samples increased compared to pure PLA samples, as Si content was increased.

The coated samples induced successful rMSCs and rEPCs adhesion. The 40% Si sample showed the best results in agreement with the previous blending results published by our group<sup>4</sup>. The lower the Si content, the higher the release rate of calcium and the more constant the sustained decrease at higher time points. 40% Si sample showed the best cell-material interaction (figure 1). However, the proliferation was slightly increased when the Si content was increased.

Figure 1: Adhesion after 1 day

### CONCLUSION

The total exposure of the bioactive phase to the media is possible using this novel hybrid-coating protocol. Controlling the Si content in ormoglasses allows the tailoring of important parameters such as the mechanical properties, degradability, surface roughness and layer thickness, modulating cell response.

## INTRODUCTION

Thin films formed *via* the Layer-by-Layer (LbL) assembly of oppositely charged macromolecules are finding widespread application in energy, sensing, and biomedicine. LbL films are particularly attractive for applications involving cell-material contact, as they are easy to fabricate, can be used to modify the surface of many types of materials, irrespective of shape, and possess physicochemical properties that are readily controllable.

A key goal in the engineering of thin films is to direct the cell behavior of contacting cells. Biocompatibility and bioactivity can be improved through surface-adsorbed or film embedded macromolecules. Of particular interest is to recreate the cell micro-environment through the surface modification or functionalization with components of the extracellular matrix. Fibronectin (Fn) is an extracellular matrix protein known to play a key role in cell adhesion, spreading, migration, differentiation and proliferation<sup>1</sup>. Previous studies have demonstrated that multilayer films can be functionalized via the adsorption of Fn on a positively charged terminated layer, and promote cell adhesion and spreading<sup>2</sup>.

Here we investigate the direct incorporation of Fn as the anionic polymer during film assembly, in order to generate a thin film enriched in Fn that could better mimic the extracellular environment. We investigate the influence of Fn on a (PLL-Fn) film construction and physicochemical and mechanical properties, as well as the influence on pre-osteoblastic cells.

## EXPERIMENTAL METHODS

Film assembly is achieved by alternate dipping in polyelectrolyte solutions of opposite charge. The polyelectrolytes are poly-L-Lysine (PLL) as the polycation, and either poly-L-glutamic acid (PGA) or Fn as the polyanion (Fn is net negatively charged under near-neutral pH).

Film assembly is followed by ATR-FTIR and Quartz Crystal Microgravimetry (QCM). Information about the surface charge (zeta potential) is assessed using an electrokinetic analyzer for solid surface. Pre-osteoblastic MC3T3-E1 cells attachment and proliferation are observed by LCSM and cell counting. Fn reorganization is observed by LCSM using fluorescently labeled Fn.

## RESULTS AND DISCUSSION

The buildup process of (PLL-Fn) is followed by ATR-FTIR and QCM-D. The amide I' band area (FTIR-ATR) and the mass (QCM-D) are observed to increase with layer number, confirming the layer-by-layer growth of PLL-Fn thin films. However, film growth

appears to stall after a few layers (Figure 1). Cessation of layer-by-layer assembly is unusual – multilayer films generally follow either linear or exponential growth<sup>3</sup>.

Figure 1 : Evolution of the amide I' band measured by ATR-FTIR during (PLL-Fn)<sub>10</sub> film

Our finding may suggest a new growth mechanism, with a terminated-growth regime.

Layer-by-layer assembly generally involves a charge overcompensation following each layer placement. Here we find that after a few

layers, the surface charge is not modified after PLL or Fn adsorption, comforting the hypothesis of a terminated growth for (PLL-Fn) films.

We next assess the influence of PLL-Fn thin films on pre-osteoblastic cells behavior, compared to a simple Fn monolayer. Fn coatings are known to enhance cell adhesion, spreading and proliferation. PLL-Fn films are seen to exhibit similar initial adhesion, and enhanced cell proliferation, compared to the Fn monolayer (Figure 2).

Using fluorescently labelled Fn, we find cells are able to reorganize Fn into fibrils in both

Figure 2 : Cell adhesion and proliferation monolayer coatings and PLL-Fn films. Interestingly, fibrils consume all the Fn within a monolayer following 48h, whereas unassembled Fn remains in the (PLL-Fn)<sub>5</sub> thin film even after 7 days.

## CONCLUSION

We demonstrate here the possibility of thin films enriched in Fn by direct incorporation of Fn during layer-by-layer assembly. These films present a novel growth regime that can be described as terminated growth.

Fn-based films show enhanced cell proliferation, possibly due to the extended availability of Fn for fibril formation.

Hyaluronic acid (HA) is a major intracellular component of connective tissues where it plays an important role in cell differentiation and growth. Although it has been widely used for tissue engineering applications, it does not support cell attachment and spreading and needs chemical modification to support cellular adhesion. In the present study, polyelectrolyte multilayer films of HA and Poly-L-lysine (PLL) were built up by layer-by-layer method, which is of particular interest for tissue engineering and surface functionalization. The principle is based on the assembly of polyanion/polycation constituting a layer pair [1-2]. The main objective was to optimize the polyelectrolyte multilayer film growth and controlled cytokine release via controlling the crosslinking of HA component. The aim is to decrease the implant and medical device failure due to adverse immune reactions by developing an innovative immunomodulatory system.

Hyaluronic acid (HA), HA-Tyramine derivative and HA-Aldehyde were produced and characterized by CONTIPRO. HA contains functional groups along its backbone that can be used to introduce functional domains. HA-Tyramine has been synthesized with tyramine moiety attached to the polymer backbone via aliphatic linker; it could be crosslinked to amino groups by a horseradish peroxidase mediated reaction. HA-aldehyde is crosslinked by hydrolytically labile imine bond between amino groups of one polymer and aldehydic derivative of HA. The polyelectrolyte (PLL/HA's) films were built by consecutive deposition of oppositely charged polyelectrolytes with a dipping robot system.

The build-up process of the multilayered films was monitored *in situ* by quartz crystal microbalance-dissipation. In first approximation, changes in the resonance frequency can be associated with a variation of the mass adsorbed on the crystal. The evolution of the thickness and of the adsorbed mass with the number of deposited layers is exponential for all of the films (Fig.1).

Confocal laser scanning microscope section images of (PLL/HA)<sub>24</sub>PLL-FITC-HA multilayer deposited on glass slides are presented in Figure 2. Confocal sections demonstrated a homogeneous fluorescence of PLL-FITC throughout the entire film thickness for all the obtained films. This may be attributed to the diffusion of mobile PLL-FITC chains in and out of the film due to interlayer mixing of HA and PLL-FITC.

In order to study the release behavior of the multilayered films, the FITC-labeled bovine serum albumin (FITC-BSA) was loaded on the top of the

films. By confocal analysis, it was observed that there is no difference on FITC-BSA adsorption for the PLL/HA's films. However, the kinetics of FITC-BSA release from the multilayered films, investigated by fluorimetry, seem to be dependent on the film crosslinking. A rapid release was observed for PLL/HA-tyramine crosslinked. On the other hand, PLL/HA-aldehyde, which presents the most rigidity property (Young Modulus ~ 38kPa), is the one that presents the lowest amount of FITC-BSA released. This is hypothesized that it is due to the denser nature of the PLL-HA-aldehyde films.

The cytocompatibility of the films has been checked with a human monocytic cell line (THP-1). HA derivatives did not cause any significant cytotoxic effect compared to PLL/HA controls.

Figure 1 - Buildup (PLL/HA)<sub>6</sub> multilayer film on a SiO<sub>2</sub>-coated crystal followed by QCM-D.

Figure 2 - Confocal cross-section image of a (PLL/HA)<sub>24</sub>PLL-FITC-HA multilayer.

The results confirmed the hypothesis that polyelectrolyte multilayer made of PLL and HA-derivatives can be successfully deposited onto the biomaterials surface. Biofunctionalization of these films can be envisioned by introducing bioactive molecules. Moreover, drug release behavior could be modulated in function of the physical property of the films. Our current focus is to use the controlled release capacities for the delivery of immunomodulatory cytokines such as IL-4 and quantification of its effect on primary macrophages.

## Biointerfaces through Continuous Electrojet-Writing

Zhaoying Li<sup>1</sup>, Xia Li<sup>1,2</sup> and Yan Yan Shery Huang<sup>1</sup>

<sup>1</sup>Department of Engineering, University of Cambridge, UK

<sup>2</sup>Department of Physics, University of Cambridge, UK

[yysh2@cam.ac.uk](mailto:yysh2@cam.ac.uk)

**We report continuous electrojet writing (cEJW) of geometrical cues for guided cell motility. cEJW allows direct-writing commonly used tissue cultureware material into controlled architectures over tens of centimetres squared. The fibre resolution can be tuned crossing three orders of magnitude, from 100nm to 100s of microns, where the combination of resolution and process flexibility is unique amongst existing bio-microfabrication.**

### INTRODUCTION

The complex, but well-defined extracellular matrix consists of topographical and adhesive features ranging from nanometres to micrometres [1]. Leveraging the control of nano- micro-topography in a biointerface, which recapitulates the intricate ECM features, opens up numerous possibilities: these range from investigating the fundamentals of mechanobiology, to elucidating cancer drug targets under well-defined laboratory conditions. However, fabricating biointerface geometries in a scalable and adaptable manner remains a challenge [2] which critically limits the translation of interface engineering for the use in day-to-day cell culture studies.

### EXPERIMENTAL METHODS

Our configuration of cEJW is processed under two distinct jetting modes for depositing fibres based on polystyrene, a standard cultureware material. Fibre deposition is achieved by a stable jet string initiated from an electrified droplet of solution material at a syringe tip. The cross-sectional profile can be controlled to either circular using N,N-Dimethylformamide (DMF) or ribbon-like using tetrahydrofuran (THF) under room temperatures and humidity. A 1D fibril-guided cell migration assay and a 3D cell scaffold were demonstrated.

### RESULTS AND DISCUSSION

#### 1. cEJW

With a continuous jet initiation mechanism, cEJW achieves large area patterning by mitigating solvent drying at the jetting nozzle. Interface patterning is facilitated over areas of tens of centimeters, even for fast-solidifying solutions. Two distinct jetting modes yield two types of building blocks: a fibril structure with a nano-wrinkled surface and a ribbon structure with a smooth surface. The 1D fibrils show both topographical and mechanical mimicry to the naturally occurring type-I collagen fibrils. The 3D scaffolds are formed by interconnected ribbon structures. The associated framework exhibits high optical transparency, providing a high quality platform for evaluating cellular behavior at different sample depths.

#### 2. Culture Models for Cancer Niche

The cellular migration on the 1D polystyrene fibrils was found to exhibit a persistent migration speed of  $\sim 65 \mu\text{m/hr}$ ; in comparison to  $\sim 36 \mu\text{m/hr}$  found for the migration taken place on a featureless PDMS surface. Compared to studies performed by Doyle *et al.* [3], who showed that fibroblasts interfacing with tracks of fibronectin less than  $2 \mu\text{m}$  width would induce a 1D migratory behavior resembling 3D, our data suggests that a similar phenotype can also be spontaneously triggered by the polystyrene fibril topology with non-specific adhesion. It may be plausible that the nano-wrinkled surface texture may have enhanced the cell-fibril interaction.

The 3D ribbon scaffold has an ultrastructure providing inter-connected channels for cell migration and penetration. Using MB231 cancer cells as a model, we observed cell attachment to the ribbon surface, as well as cell-bridging between the layer inter-space. Closer study of the cancer cells presented in different layers in show strikingly different cellular morphologies. The images also indicated a vastly heterogeneous vinculin expression across different cells within the same layer.

Figure 1. (a) Fibril guided cell migration; (b) a cancer niche supported by interconnected ribbons. Scale bar=100 $\mu\text{m}$ .

### CONCLUSION

In this work, we have demonstrated cEJW as a versatile and precise technique for biointerface engineering in the size regime critical for cellular geometry and topography sensing. Using polystyrene as a scaffold material, tailored architecture can be designed for different *in vitro* studies compatible with conventional culturing techniques.

## INTRODUCTION

Elucidation of the cues that control fate decisions of stem cells is critical in the understanding of normal development and repair, and can be utilized in tissue engineering and regeneration applications that require stem cells to be directed towards specific cell fates [1].

In fact, both biochemical and physical cues in the natural extracellular matrix (ECM) are known to play important roles in directing the differentiation of mesenchymal stem cells (MSCs) [2], [3].

In this study, we focus on how MSC adhesion and differentiation are influenced by nanohelices (with the same periodicity as Collagen I functionalized or not with RGD and BMP-2 mimetic peptides and grafted onto glass surfaces. Nanohelices presenting different lengths were used in this work.

## EXPERIMENTAL METHODS

Chiral structures with nanometric periodicity are synthesized by silica transcription of organic precursors made by auto-assembly of enantiomerically pure gemini surfactant tartrate and functionalized or not with cell adhesion peptide (RGD peptides) or/and BMP-2 mimetic peptides (Figure 1). Human mesenchymal stem cells are cultivated on these substrates and examined using scanning electron and fluorescence microscopy. Materials without peptide and/or helices act as reference surfaces.

(functionalized or not with RGD and BMP-2 mimetic peptides) and grafted onto glass surfaces.

Figure 2: SEM image of helical ribbons without peptide functionalization grafted onto glass surface. Scaling bar 1  $\mu$ m.

## CONCLUSION

Helices mimicking the periodic geometry of collagen have been synthesized and functionalized. Materials grafted with these helices were synthesized.

Perspectives: Future work is going to include the evaluation of the impact of MSC differentiation using bare glass, peptide-grafted glass and helices with and without peptide functionalization grafted onto glass.

The present study also provides a tool to promote hMSC osteogenic capacity, which may be exploited in a 3D scaffold for bone tissue engineering and repair.

Figure 1: Grafting of unfunctionalized (left) and RGD peptide functionalized (right) helices to glass surfaces.

## RESULTS AND DISCUSSION

Each surface type was characterized by AFM, XPS, fluorescent microscopy using fluorescent peptides and SEM to validate our grafting process. Successful grafting of helical ribbons (periodicity 63.5 nm) without (Figure 2) and with peptide functionalization [4] was confirmed by fluorescence microscopy and SEM. Ongoing work focusses on the behaviour of MSC seeded on nanohelices presenting different lengths

### INTRODUCTION

The established treatment of trans-femoral amputees is the use of a socket-prosthesis. Mismatch in the fit between the socket and the remaining stump is a frequent problem. A solution would be to transfer the loads directly to the remaining skeleton rather than via the soft tissues. In the dental field, osseointegrated titanium implants are regarded as a routine treatment and could potentially be used in orthopaedic applications. A prospective study of 51 patients treated with an osseointegrated titanium fixture for the anchorage of an amputation prosthesis in the residual femoral limb has shown promising results.<sup>1</sup> To date, more than 100 patients have been treated with good results both in terms of function and quality of life.<sup>2</sup> In order to understand the maintenance of osseointegration in high load applications and long-term use, analysis of clinically retrieved materials is required.

### CASE HISTORY

The current case,<sup>3</sup> a female patient born 1960, suffered a high transfemoral amputation due to tumor at the age of 17. At the age of 33 she was enrolled for treatment using bone anchored prosthesis (Fig 1A). The titanium fixture suffered a fracture in 1998, however, as the majority of the fixture remained stable, a custom-made abutment was fitted to the fixture and the patient could continue to use the prosthesis. In 2004, the fixture suffered yet another fatigue fracture and it was decided to remove it. The fixture was removed with a thin collar of bone by trephine burring and immersed in formalin. The patient received a new fixture.

### EXPERIMENTAL METHODS

After formalin fixation, the sample was dehydrated and plastic embedded. A ground-section was prepared for histology and histomorphometry, and the remaining block was used for ultrastructural evaluation by scanning electron microscopy and micro-CT.

### RESULTS AND DISCUSSION

Large amount of cortical bone tissue was observed around the implant (Fig 1B-E), while predominantly trabecular bone was seen in the hollow apical region. The histomorphometric quantification of bone showed a bone-implant contact of 81% and bone area of 87% when averaging for the 29 intact threads of the ground-section. The results showed morphological evidence of osseointegration of the titanium implant from a patient

with trans-femoral amputation and demonstrates similar high amount of bone implant contact as previously observed for oral<sup>4</sup> as well as in the upper extremity.<sup>5</sup> This shows that the concept of osseointegration could be transferred to the lower extremity as well. This taken together with published studies on the quality of life for patients treated with osseointegrated amputation prosthesis<sup>6</sup> suggests that osseointegration is a promising long-term treatment option for amputees.

Figure 1: A) Clinical x-ray of the patient. B) Overview of the ground-section. C) Two threads filled with bone in light optical microscopy. D) One thread filled with bone in BSE. E) Segmented micro-CT image of bone surrounding the implant.

### CONCLUSION

These observations support that the osseointegration concept could be extended from the head and oral cavity to high load femoral sites, for long-term treatment of amputees.

### INTRODUCTION

Approximately 30% of breast cancers overexpress HER2 receptor that contributes to the metastatic potential and resistance to many drugs. Additionally, actual cancer therapies are highly toxic and, therefore, research is focused on the development of new treatments that selectively target cancer cells. In this sense,  $\alpha$ -TOS is considered a potent mitocan (mitochondrially targeted anticancer compound) that selectively induces apoptosis of tumor and proliferating cells [1]. For that reason, the main objective of this project was the synthesis, characterization and biological evaluation of new multi-targeting polymeric nanovehicles based on  $\alpha$ -TOS that target specifically the mitochondria of cancer cells (figure 1).

Figure 1: Scheme of new multi-targeting polymeric nanovehicles

For this purpose, block copolymers of a hydrophilic segment (PEG) and a hydrophobic segment (based on a methacrylic derivative of vitamin E, MTOS) were obtained by RAFT polymerization. The amphiphilic nature of the macromolecules and their structural homogeneity allowed to obtain self-assembled NP. Additionally, specific functional groups (triphenyl phosphonium TPP, heptamethine NIR dye IR-780 or peptide ligand LTVSPWY) were incorporated in the molecular structure of the polymers in order to target the mitochondria of HER2-positive breast cancer cells.

### EXPERIMENTAL METHODS

NP bearing targeting molecules were prepared by Self-Organized Precipitation method (SORP). These self-assembled NP were characterized by Dynamic Light Scattering and microscope techniques. Fluorescence properties of IR780-NP were measured using a microplate reader ( $\lambda_{exc}$  = 770 nm and  $\lambda_{emis}$  = 810 nm). HER2-positive breast cancer cells (MDA-MB-453) were cultured following the instructions of the manufacturer. Cell viability (Alamar Blue) in the presence of NP was tested in order to evaluate the effect of the modifications with different targeting molecules.

The endocytosis of coumarin-6 loaded NP was monitored and co-localization of NP into the mitochondria of cancer cells was performed using mitotracker green. *In vivo* biodistribution of NP was evaluated on orthotopic mammary MDA-MB-453 cells growing in athymic nude mice.

### RESULTS AND DISCUSSION

Nanoparticles bearing different targeting molecules were successfully prepared by SORP with sizes between 80 and 200 nm. TPP and IR780 modified NP had positive charge, crucial to target mitochondria. IR780-NP were fluorescent with excellent optical properties for *in vitro* and *in vivo* applications.

Figure 2: Comparative biodistribution [Ratio(Tumor/all Tissues)] of NP unmodified or bearing peptide ligand (PEP) and TPP.

*In vitro* biological results demonstrated a higher activity of the targeting NP in comparison to unmodified NP. Additionally, TPP and PEP decorated NP entered the cells faster than unmodified NP and preferentially localized in the mitochondria. Finally, *in vivo* biodistribution results indicated that NP with TPP and PEP had a higher accumulation in tumor in comparison to unmodified NP (figure 2).

### CONCLUSION

New block copolymers based on PEG and MTOS were obtained and multi-micellar nanoparticles were prepared with targeting moieties (TPP, IR-780 and peptide) attached to the PEG segment. Targeting molecules significantly increased *in vitro* biological activity of the NP and significantly enhanced *in vivo* NP accumulation in orthotopic breast tumor. Moreover, IR780-NP allowed visualization of NP *in vivo*.

### INTRODUCTION

Traditionally, surgery has been the only cure for tumour. Technological advances have catalysed a shift from open surgery towards less invasive techniques, such as radiotherapy, laser ablation and high intensity focused ultrasound (HIFU)<sup>1,2</sup>. The clinical applications of photodynamic therapy (PDT), however, have been frustrated because laser cannot reach deep tissues in the body<sup>3</sup>. Ultrasound, being widely used for diagnostic imaging, has emerged as the therapeutic modality in combination with drugs. Particularly, since ultrasound is non-invasive and permeable to the deep tissue. In this study, we designed hydrophilized TiO<sub>2</sub> nanoparticle (HTiO<sub>2</sub> NPs) which could be activated by HIFU to generate reactive oxygen species (ROS) *in vivo*. We have shown that our system can suppress the tumor growth in liver tumour model. These results prove the feasibility of using TiO<sub>2</sub> nanoparticles as sonodynamic agents for non-invasive cancer surgery.

### EXPERIMENTAL METHODS

HTiO<sub>2</sub> nanoparticles were prepared in two steps; dopamine was dissolved in deionized water (0.192 mg/ml). TiO<sub>2</sub> anatase nanoparticles were dispersed in formamide (10mg/5ml). 100 µl of dopamine solution was added and the suspension was stirred for 6 hr and purified by centrifugation and washing with formamide. For the activation of carboxylic acid group, 200 mg of carboxymethyl dextran (CMD) was dissolved in 20 ml of formamide to which 76.7 mg 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide and 57.5 mg N-hydroxysuccinimide were added and stirred overnight. The activated CMD was added into 2 ml of dopamine TiO<sub>2</sub> solution and stirred for 10 hr. The HTiO<sub>2</sub> NPs were obtained after dialysis against sodium borate buffer (pH 8.6) and deionized water for 48 hr.

### RESULTS AND DISCUSSION

HTiO<sub>2</sub> NPs have a hydrodynamic radius of 188.6±39.4 nm with a zeta potential value of -15.8 mV. The TEM image and the FT-IR data confirm the presence of polymer coating around the nanoparticles. Even after 24 hours incubation in presence of fetal bovine serum, the HTiO<sub>2</sub> NPs did not show drastic increase in the size. The HIFU treated HTiO<sub>2</sub> NPs produce ROS in dose-dependent manner *in vitro*. And also, the long circulating HTiO<sub>2</sub> NPs were activated by HIFU to generate ROS *in vivo* (Figure 1). The HIFU activated HTiO<sub>2</sub> nanoparticles can up-regulate the pro inflammatory cytokines to several folds and

significantly suppress the tumour growth in a dose-dependent manner. Also, we evaluated the effectiveness of our system in treating tumor in deep region. The HIFU activated HTiO<sub>2</sub> nanoparticles can suppress the tumor growth by at least 15 folds in liver tumour model when compared with the controls (Figure2).

Figure 1. *In vivo* ROS generation with SDT.

Figure 2. Anti-tumour efficacy in liver tumour model.

### CONCLUSION

In this study, we demonstrated extensive evaluation of sonodynamic cancer therapy using HTiO<sub>2</sub> NPs for the first time. Sonodynamic therapy could be a potential alternative for cancer photodynamic therapy, especially for treating deeply set tumours. With our HTiO<sub>2</sub> NPs can activate the immune-response to cancer and destroyed the tumour vessels. These results make the HTiO<sub>2</sub> NPs a suitable candidate as sonosensitizer for non-invasive cancer surgery.

### INTRODUCTION

A microfluidic device such as Kima Pump and Vena8 biochip is able to realize functions that are not easily imaginable in conventional biological analysis, such as highly parallel, sophisticated high-throughput analysis and single-cell analysis in a well-defined manner [1].

Cancer cell tracking within the microfluidic model will be achieved by grafting fluorescent label probe Fluorescein-5(6)-isothiocyanate (FITC) to dendrimer nanoparticles allowing cell visualization by immunofluorescent staining followed by fluorescence microscopy. In this study, synthesis and physicochemical characterization of Carboxymethyl-chitosan/poly(amidoamine) dendrimer nanoparticles (CMChT/PAMAM NP's) were performed[2]. Several cancer cell lines such as a HeLa (cervical carcinoma cell line), HTTC-116 (Colon Carcinoma) and Glioblastoma cell line (GBM) were exposed to different concentrations of CMChT/PAMAM dendrimer nanoparticles over a period of 7d. After finding the adequate NP concentration, the internalization efficiency was tested, as well as cellular trafficking, in static and dynamic conditions (Kima Pump bioreactor).

### EXPERIMENTAL METHODS

CMChT/PAMAM NP's were synthesized and labelled with fluorescein isothiocyanate (FITC) according to Oliveira *et al.* [3].

To access internalization efficiency, semi-automated microfluidic platform, Vena8 Endothelial+ biochips (Cellix®, Dublin, Ireland) was used to mimic physiological flow conditions. Biochips were coated with fibronectin (Sigma, Germany) into each microchannel and placed at 4°C for overnight coating, followed by cell seeding. A solution of FITC-CMChT/PAMAM NP's at a concentration of 0.4 mg.mL<sup>-1</sup> was prepared in a complete culture medium and then transferred to Kima Pump. Perfusion was performed for 24 hrs and 48 hrs at a flow rate of 2 µL/min for 2 min. (Period I) followed by 20 min of pause (Period II).

### RESULTS AND DISCUSSION

CMChT/PAMAM NP's were successfully synthesized as shown by <sup>1</sup>H-NMR analyses. Moreover, they exhibited good physicochemical properties, with a consistent nanosphere-like shape and a diameter of ~30 nm, as shown by TEM, DLS and AFM analysis. Fluorescent-probe labelled CMChT/PAMAM NP's were found to be internalized with high efficiency by all cell types, either in conventional static conditions and when seeded and

grown in a biochip under perfusion with Kima Pump. It was found that the best flow rate was 2 µL/min (Period I), followed by a pause of 20 min. (Period II). Kima Pump bioreactor permits reaching cell confluence in dynamic conditions in just 3 hours consisting in a faster way to perform assays with lower consumption of reagents. Fluorescent probe labelled nanoparticles were found to be internalized with high efficiency in several cancer cell lines (Fig.1), either in conventional static conditions and when seeded and grown in a biochip under perfusion with Kima Pump.

Figure 1 - Fluorescence microscopy images of HTTC-116 cells (B), GBM (D) and HeLa (F) in the presence of FITC-labelled CMChT/PAMAM NP's 0.4mg.mL<sup>-1</sup> (green) in dynamic conditions. A), C) and E) represent the same cell lines cultured in complete DMEM medium.

### CONCLUSION

CMChT/PAMAM NP's were successfully synthesized. The microfluidic platform allowed investigating the uptake of the CMChT/PAMAM NPs by different tumour cells (2D cultures) and monitor its fate in real-time. Another feature to be considered is high-resolution, real-time imaging and the possibility of *in vitro* analysis of biochemical, genetic and metabolic activities of living cells in the tumor context. The promising results encourages us to develop relevant 3D models of disease on a chip for both TE and cancer research.

### INTRODUCTION

Superparamagnetic Iron Oxide Nanoparticles (SPIONs) are in biology and medicine utilized mostly as biocompatible contrasting and tracking agent for organs, single cells or even implanted material. For most preparations only minimal effects on cellular physiology have been reported (mainly increased oxidative stress). Hyaluronan based polymeric micelles loaded with SPIONs intended for theranostic development showed in vitro specific antitumorigenic properties on several cancer cell lines while primary cells remained viable<sup>1</sup>. For this reason mechanism of this effect was studied and gene expression analysis brought interesting results in both cancer (HT-29 cell line) and normal primary cells (dermal fibroblasts).

### EXPERIMENTAL METHODS

SPION loaded polymeric micelles (HA-SPION) were prepared by previously described method<sup>1</sup>. MTT assay and flow cytometry was used for cytotoxicity and cell death analysis. Whole human genome expression microarray (Agilent) was used for the differential analysis in control and HA-SPION treated samples. Statistical analysis was done with R (R Development Core Team) using package limma. Gene ontology terms of the significantly changed transcripts were investigated in online annotation database DAVID.

### RESULTS AND DISCUSSION

Occurrence of necrosis in cancer cells after HA-SPIONs treatment correlated with previously published data<sup>1</sup>. Normal fibroblasts showed no significant effects in both viability and cell death frequency. No effect of SPIONs themselves and HA derivatives on either cell type viability was observed. This finding is in agreement with general knowledge about iron nanoparticles, which are considered significantly less damaging to cells than for example gold nanoparticles<sup>2</sup>.

At the cellular level one of the adverse effects of iron nanoparticles might be oxidative stress. In both normal and cancer cells no increase of the concentration of ROS was detected. Interestingly, overall gene expression of proinflammatory genes (including CXCL1, IL6, CXCL2 and CCL8) even decreased in fibroblasts. Only small number of upregulated genes was detected in normal cells. Cancer cells, on the other hand, showed upregulation in lipid and steroid synthesis and metabolism (including genes like HMGCR,

CYP51A1, SCD, UGCG, ACACA, HMGCS1, LSS, SREBF1, LDLR, INSIG1, PCSK9 and ABCA1). However, these changes might be attributed to oleyl chains in HA-SPION composition. The most significant decrease was in genes of metal metabolism (metallothioneins MT1L, MT2A, MT1E, MT1B, MT1H, MT1X and MT1F) and DNA replication and repair (histons, RFC5, RPA3, PRIM1, MSH6, DTL, UNG, TIPIN, MLH1, GTF2H5, TTC5, RAD54L, RAD51, NSMCE1, RAD54B, PARP1, CCNO, NTHL1 and RTEL1).

Figure 1. Different effect of SPION loaded HA polymeric micelles (HA-SPIONs) on gene expression pattern in normal and cancer cells

### CONCLUSION

Cytotoxic effect of HA-SPIONs on cancer cells is accompanied by gene expression changes in both metal binding and DNA replication and repair. This suggests that HA-SPIONs cause the impairment of iron homeostasis, crucial for DNA processing enzymes, which results in significant reduction of viability of the rapidly proliferating cells.

### INTRODUCTION

CD44, a transmembrane glycoprotein, is the major cell surface receptor for hyaluronic acid (HA).<sup>1</sup> HA is a negatively charged polysaccharide composed of repeating disaccharides of D-glucuronic acid and N-acetyl-D-glucosamine and is a naturally occurring glycosaminoglycan. It has been studied as a targeting motif in drug delivery systems for cancer therapy because several tumor cells are known to overexpress CD44.<sup>2</sup> CD44 cell surface marker is reported to have increased expression in AGS and MKN-45 gastric cell lines.<sup>3</sup> The influence of HA molecular weight (Mw) on the HA-CD44 interaction has been reported for solubilized HA.<sup>4</sup> However, this Mw influence has not been reported for surface immobilized HA, e.g. by Layer-by-Layer (LbL). In this study, the adhesion of AGS and MKN-45 cells and the influence of the HA Mw on the CD44 expression were evaluated on LbL constructs obtained through the sequential adsorption of HA and Poly-L-Lysine (PLL).

### EXPERIMENTAL METHODS

**LbL construction and CD44 adsorption:** the sequential adsorption (10 layers) of HA (6.4 kDa, 752 kDa or 1.5 MDa) and PLL (30-70 kDa), as well as the subsequent adsorption of recombinant CD44 (onto the constructs presenting HA as top layer) was monitored using Quartz Crystal Microbalance with Dissipation (QCM-D). Surpass Electrokinetic Analyzer were used to measure the Zeta potential of the complete LbL systems. **Immunostaining:** AGS and MKN-45 cells were cultured onto the LbL constructs presenting different HA Mws in the surface and the cellular CD44 expression was evaluated. Nuclei were counterstained with DAPI. **Statistical Analysis:** Shapiro-Wilk normality tests followed by Kruskal-Wallis with Dunn's Post hoc test. \*\*\* Significant differences (<0.001).

### RESULTS AND DISCUSSION

We evaluated the LbL deposition, the stability of the systems, and their capacity to adsorb CD44 as a function of HA Mw. The QCM-D data shows that the CD44 adsorption is directly dependent on the HA Mw (higher adsorption observed for higher Mws, Fig. 1b). The adhesion of MKN-45 and AGS cells to the LbL constructs (produced with the different HA Mws) presents significant differences in the number of adherent cells after 24h (Fig. 2a). Surprisingly, and in contrast with the QCM-D adsorption study, the cellular CD44 expression and the number of adherent cells was

higher for the surfaces presenting HA with lower Mw, i.e. 6.4kDa, for both AGS and MKN-45 cell lines.

Fig. 1. LbL buildup executed using different HA Mws (a); and quantification of CD44 adsorption as a function of the HA Mws on the surface of the LbL constructs (b).

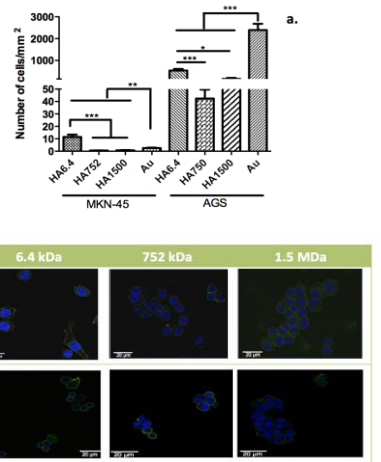

Fig. 2. Adhesion of AGS and MKN-45 after 72h (a). Immunostaining for CD44 expression (blue - nucleus; green - CD44) (b).

### CONCLUSION

Adhesion of AGS and MKN-45 cells is affected by HA Mw. AGS cells adhere faster than MKN-45, but AGS spread more in contact with 6.4 kDa HA. In the surfaces that present higher Mws the adhesion of AGS and MKN-45 depend on previously adhered cells, resulting in the formation of clusters and round-shaped cells, as well as, in a delayed CD44-independent cell adhesion.

## INTRODUCTION

Conventional cancer treatment strategies, such as chemotherapy, radiotherapy, hormone therapy and surgery, result in severe side-effects including systemic toxicity or damage to healthy organs<sup>1</sup>. There is a need for less invasive cancer treatment technologies with significantly reduced side effects. A promising therapeutic procedures for the management of a variety of tumors is photodynamic therapy (PDT). PDT relies on the cytotoxicity of singlet oxygen (<sup>1</sup>O<sub>2</sub>) and other reactive oxygen species like O<sub>2</sub><sup>•-</sup>, OH<sup>•</sup> or HO<sub>2</sub><sup>•</sup> generated upon light-induced activation of photosensitizers. Most of the photosensitizers with established utility in PDT are macrocyclic compounds from the class of porphyrins, chlorins and corroles (e.g. Photofrin, Tookad, Foscan, Purytin, Lutrin and Levulan). Recently, photosensitizers that belong to the class of phthalocyanines (Pcs), attracted considerable attention. Phthalocyanines are organic dyes structurally related to the porphyrins. Pcs are well known for their distinct physicochemical properties such as: absorption of light in the range 600 – 700 nm, high molar extinction coefficient, usually good photochemical/chemical stability, as well as, the ability to photogenerate singlet oxygen and other reactive oxygen species (ROS).

## EXPERIMENTAL METHODS

MgPcI<sub>4</sub> was prepared from 4-iodophthalonitrile. ZnPc(t-Bu)<sub>4</sub>I<sub>4</sub> was prepared from 6-*tert*-butyl-4-iodo-1,3-diiminoisoindoline, while ZnPc(t-Bu)<sub>4</sub>(CF<sub>3</sub>)<sub>4</sub> was obtained from 5-*tert*-butyl-3-(trifluoromethyl) phthalonitrile. Compounds were characterized by <sup>1</sup>H-NMR, <sup>13</sup>C-NMR, UV-Vis, IR, MALDI-TOF-MS and elemental analysis. The quantum yield of singlet oxygen formation (Φ<sub>Δ</sub>) was determined by two methods, viz. by measuring time-resolved phosphorescence at 1270 nm and by using chemical quenchers. The interaction between Pcs and lipid bilayer in an aqueous liposomal suspension was studied using a laser scanning confocal microscopy, fluorescence technique and the atomic-scale molecular dynamics.

## RESULTS AND DISCUSSION

Challenges associated with the synthesis of Pc photosensitizers will be discussed along with spectroscopic characterization. Moreover, photophysical properties of the synthesized Pcs that are

important from the PDT perspective were evaluated and presented in Table 1. Photostabilities and photosensitization efficiencies were determined.

**Table 1.** Summary of photophysical and photochemical data of photosensitizers (in DMF).

Compound	$\lambda_{abs}$ (nm)	$\epsilon$ (M <sup>-1</sup> cm <sup>-1</sup> )	$\Phi_f$	$\Phi_\Delta$	$\tau_T$ ( $\mu$ s)	$\tau_f$ (ns)
MgPcI <sub>4</sub>	678	223 872	0.063	0.95	-	-
ZnPc(t-Bu) <sub>4</sub> I <sub>4</sub>	689	295 177	0.015	0.76	3.3	-
ZnPc(t-Bu) <sub>4</sub> (CF <sub>3</sub> ) <sub>4</sub>	664	157 881	0.139	0.63	131	2.5

In view of potential clinical applications, the photosensitizers were encapsulated in the liposomal carriers. The position and orientation of the Pcs molecules within the lipid bilayer and their tendency to migrate from one leaflet to the other were assessed by atomic-scale molecular dynamic simulations.

## CONCLUSION

Novel photosensitizers were developed and studied as potential PDT active agents. The halogen substituents present in the structure of Pcs induced efficient singlet-to-triplet intersystem crossing (heavy atom effect), which resulted in high quantum yields of singlet oxygen (Φ<sub>Δ</sub>). MgPcI<sub>4</sub> is among the Pcs with the highest Φ<sub>Δ</sub> ever reported for this class of compounds, viz. 0.95 ± 0.01. MgPcI<sub>4</sub> possesses limited photostability, which is advantageous in PDT therapy of cancer as rapid breakdown and clearance of photosensitizers from the patient's system after treatment is desirable<sup>2</sup>. All synthesized Pcs can be administered in liposomal formulations.

## INTRODUCTION

Artificial scaffolds mimicking the morphology, mechanical properties and biochemical complexity of natural tissues are of vital importance for tissue engineering applications. Tendonous tissues are comprised of aligned collagen fibrils providing topographical guidance for cells and mechanical strength; however, an often-overlooked physical property of collagenous tissues is an inherent piezoelectric response, which is speculated as having a functional role in musculoskeletal homeostasis<sup>1,2</sup>.

Piezoelectric materials can exploit the loading capacity of tendon tissue to produce stimulating current, which, is important for tissue repair. In this study, a piezoelectric fibrous scaffold is developed from Poly (vinylidene fluoride-co-trifluoroethylene) P(VDF-TrFE), a material capable of generating electrical charges under mechanical loading in physiological conditions to maintain cell tenogenic phenotype. In addition, fiber alignment for adequate topographic guidance of the cells and piezoelectric properties are controlled through the incorporation of Boron Nitride Nanotubes (BNNT) which have same structure as MWCNT but present piezoelectricity.

## EXPERIMENTAL METHODS

P(VDF-TrFE) is dissolved in DMF/Acetone and electrospun into fine fibers by changing the voltage, mandrel rotation speed and the distance between tip and collector with a constant flow rate. To improve the mechanical and electrical properties, BNNT are coated with amphiphilic polyvinyl pyrrolidone (PVP) using an ultrasonication process and incorporated into the matrix. The scaffold morphology is observed by FESEM and the electrical properties in response to cyclic loading are assessed with piezoresponse microscopy (PFM) and an in-house oscilloscope/dynamic loading system. Primary Human Tenocytes are isolated and cultured for 1, 3, 7 and 14 days onto the scaffolds under static and mechanical loading conditions. Samples are stained for focal adhesions (FA) using an anti-vinculin antibody. The number of FA and its length is counted using confocal microscopy and analyses by means of software (ImageJ 1.49c). Proliferation of cells is assessed via Alamar blue® and gene expression is evaluated by RT-PCR using different markers such as Osterix, Osteocalcin, Collagen Type I and GAPDH.

## RESULTS

PFM measurements show that the incorporation of 0,1% w/w of BNNT result in an increase on the piezoelectric behaviour. Thus, the coercive voltage after

incorporation of BNNT is 3,8 V rather than 1,2 V for pristine polymer. The results show that PDVF-TrFE/BNNT scaffolds have no cytotoxicity and stimulate differentiation; attachment and growth of tenocytes on scaffolds. In addition, the results show that cell morphology and focal adhesion distribution in cells cultured on composite scaffold are distinctly different from those on pristine scaffold. Tenocytes grown on the composite scaffolds exhibited a more elongated and spread morphology while cells on pristine scaffolds are not well-spread.

Figure 1 a) show PVDF-TrFE scaffold guiding cells b) Hysteresis loop showing higher coercive voltage for PVDF-TrFE/BNNT sample.

## CONCLUSION

This study shows that the physical properties of piezoelectric PVDF-TrFE/BNNT fibers can be readily controlled by incorporation of BNNT by electrospinning. Moreover, the tenocyte phenotype is maintained up to 14 days under mechanical loading on these fibres.

## INTRODUCTION

The cornea is the most exterior protective barrier of the eye and serves as the principal optical element of the eye by refracting 70% of the incoming light<sup>1</sup>. Cornea has a layered structure consisting of 200-400 lamellae that are orthogonal to each other forming a plywood-like structure<sup>2</sup>. It is very difficult to mimic the natural organization with the various approaches tested until now due to the thickness and orthogonal arrangement which is not possible with sheets or fibers<sup>3</sup>. This study aims to construct a cornea by combining cell sheet engineering to mimic the natural micro environment of the cornea by using thermo-responsive surfaces created by poly(N-isopropylacrylamide) (pNIPAM) with tissue engineering approach by using photoresponsive methacrylated gelatin (GelMA) hydrogels to surround the aligned cell sheets for higher stability and integration. Micropatterned NIPAM-HEMA films were used as the micropatterning tool for the cell sheets produced and swelling properties against temperature were studied. Methacrylated gelatin was synthesized and gelation under UV in 1 min. was achieved.

## EXPERIMENTAL METHODS

Micropatterned NIPAM-HEMA films were prepared by UV crosslinking in the presence of ethylene glycol dimethylacrylate (EGDMA) as the crosslinker and azobisisobutyronitrile (AIBN) as the photoinitiator onto a micropatterned silicon wafer with ridge-valley patterns (Figure 1). Micropatterns were clearly visible under the stereomicroscope. The temperature response (swelling) of the pNIPAM-pHEMA discs were studied in the temperature range 20-37 °C gravimetrically. Methacrylated gelatin (GelMA) was synthesized from type A porcine skin gelatin by dissolving in PBS and crosslinking under UV in the presence of photoinitiator (2-(hydroxyl)-4-(2-hydroxyethoxy)-2-methylpropiophenone).

**Figure 1:** Template for patterned films. A) Schematic representation of the surface of the template and B) dimensions of the template.

## RESULTS AND DISCUSSION

In order to produce micropatterned pNIPAM films various isopropanol:water ratios (1:1 to 9:1) were used. Pattern sharpness was enhanced when isopropanol proportion was increased and 9:1 ratio yielded the best patterns but made them brittle. In order to improve the handling and strength of the film poly(2-hydroxyethyl

methacrylate) (pHEMA) (1 to 5% wrt NIPAM) was added to the composition. Higher pHEMA decreased the water contents of the hydrogels (Figure 2) but did not affect the diameter change. The swelling difference was almost 14 fold with pure NIPAM and the lowest change was 8 fold with NH5 at RT. The rate of change from hydrophilic to hydrophobic was not very rapid. All the samples reached equilibrium swelling within 60 min. With higher pHEMA content suturability was better but flexibility was lower. As a result NH3 was chosen as the optimum property product. Meanwhile, to be used at the final step of production of cornea substitute to cover the aligned cell sheets, methacrylated gelatin was synthesized. Gelation took place in 1.5 min for 5% and in 8% GelMA hydrogels in PBS. Results were promising in the way of creating a full thickness cornea.

**Figure 2:** Degree of swelling of the pNIPAM-pHEMA films at different temperatures. pHEMA fraction in the composition was shown as NH1 to represent 1% HEMA and so on.

## CONCLUSION

In this current study it was aimed to construct a cornea by using tissue engineering and cell sheet engineering approaches. Temperature responsive NIPAM-HEMA surfaces were created to obtain cell sheets. Characterization of these surfaces showed that increasing pHEMA concentration in the composition leading to decreased swelling properties but enhanced the durability of the hydrogels as understood from the suturability tests. To cover the aligned cell sheets GelMA hydrogels were created 1 min crosslinking times was achieved under UV with 8% GelMA.

## Macromolecular Crowding in Corneal Fibroblasts Culture Accelerates the Production of Extracellular Matrix-rich Supramolecular Assemblies

Pramod Kumar, Abhigyan Satyam, Kyriakos Spanoudes, Abhay Pandit and Dimitrios I. Zeugolis

Network of Excellence for Functional Biomaterials, National University of Ireland Galway Ireland

[dimitrios.zeugolis@nuigalway.ie](mailto:dimitrios.zeugolis@nuigalway.ie)

### INTRODUCTION

Therapeutic strategies based on tissue engineering by self-assembly put forward the notion that functional regeneration can be achieved by utilising the inherent capacity of cells to create highly sophisticated supramolecular assemblies similar to the native tissue. However, very few products have reached the clinic, due to the prolong culture time required to develop an implantable device<sup>1</sup>. Corneal stromal cells require 35-84 days in culture to build a cohesive stromal substitute, which is poor in extracellular matrix (ECM) and thinner than the native tissue<sup>2,3</sup>. Macromolecular crowding (MMC), the addition of inert macromolecules in culture media, can significantly accelerate the cell specific ECM deposition within two days of culture, without any phenotypic changes<sup>4</sup>. Herein, the role of MMC on human corneal fibroblasts (HCFs) culture was assessed.

### EXPERIMENTAL METHODS

HCFs cultured under MMC (100  $\mu$ g/ml dextran sulphate (DxS); 37.5mg/ml Ficoll™ 70 and 25mg/ml Ficoll™ 400; and 75  $\mu$ g/ml Carrageenan (CR)) for 2-6 days. ECM deposition was analysed by SDS-PAGE, immunocytochemistry (ICC), atomic force microscopy (AFM) and proteomic analysis. Gene expression was assessed using the qRT-PCR. Intact HCFs cell sheets were developed using NIPAAM/n-tert butyl acrylamide (65% + 35%) thermal responsive polymer and characterised using van-Geison/Masson's trichrome staining, ICC and absorbance assay at visible light.

### RESULTS AND DISCUSSION

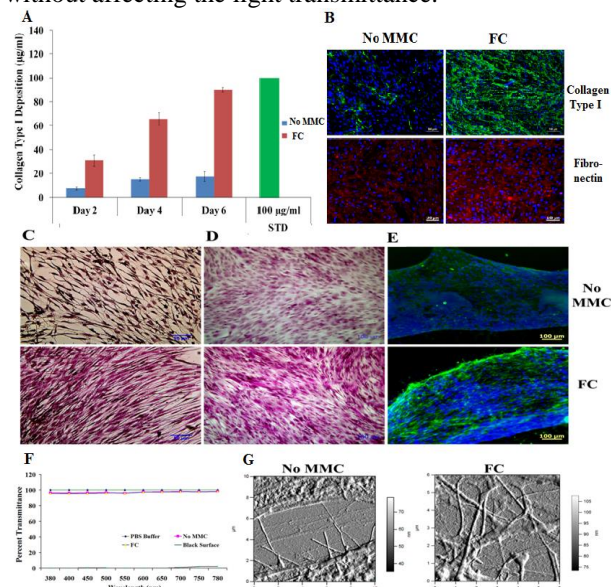

ECM is one of the most vital elements of tissue engineering and plays an active role of scaffold and growth factor reservoir in scaffold free cell based therapy. The MMC of HCFs with DxS, CR and FC significantly increase the collagen type I deposition ( $p < 0.005$ ). The immunofluorescence further confirmed the more aligned organization of ECM in the presence of MMC. The higher ECM deposition also promotes the development of cell sheet which show good light transmittance behaviour. Thus, the deposited ECM does not compromise the transmittance of the cell sheet<sup>5,6</sup>.

**Table 1:** Significant increase in several ECM peptides and total proteins deposition was observed at day 6 of FC treatment, whilst,  $\alpha$ -SMA, a myofibroblast marker remains unchanged.

Peptides	Change
Total proteins, Histone H4, Fibronectin, Collagen $\alpha$ -1(I), Collagen $\alpha$ -2(I), Collagen $\alpha$ -3(VI), Collagen $\alpha$ -1(VI)	Significant increase
$\alpha$ -SMA, Vimentin	No change

**Figure 1:** Densitometric analysis of SDS-PAGE (A), immunocytochemistry (B, E), van-Geison staining (C) and Trichrome's staining (D) demonstrate enhanced ECM deposition in the presence of MMC.

Light transmittance assay (F) and AFM analysis (G) confirmed the ECM rich nature of developed cell sheet without affecting the light transmittance.

**Figure 2:** No change in mRNA expression for collagen type I, fibronectin or  $\alpha$ -SMA was evidenced up to day 6 of FC treatment, confirming phenotype maintenance.

### CONCLUSIONS

MMC significantly accelerates corneal specific ECM deposition and favours the development of ECM rich HCFs cell sheets. Thus, MMC provides an alternative approach in the field of cell-based therapies for corneal stromal repair with considerable clinical implications.

### INTRODUCTION

Recent studies have demonstrated the benefits of polymeric 3D scaffolds seeded with various cell types for the regeneration of heart<sup>1</sup>, kidney<sup>2</sup> and liver<sup>3</sup>. Since the past decades, there is a growing interest in the use of bone marrow mesenchymal stem cells (MSCs) to regenerate tissues after acute and chronic diseases through the secretion of paracrine factors<sup>4</sup>. MSC delivery to the targeted organ via a 3D biomimetic scaffold may present several advantages in comparison with direct cell injection, including cell retention on the injury site and improved viability and secretion. The success of this therapeutic strategy lies on the scaffold design, as its biocompatibility and architecture influence host's reaction and implanted cells fate. In this context, we describe here the design of alginate foam scaffolds specifically tailored for MSC immobilization and improvement of their therapeutic effects on soft tissues.

### EXPERIMENTAL METHODS

Alginate foams were produced by mixing alginate solution with a pore-forming agent and various surfactants acting as foam stabilizers. After cross-linking, rinsing and lyophilisation, macroporous sponges were obtained and characterized by Fourier-Transformed Infra-Red spectroscopy (FTIR), scanning electron microscopy (SEM) and micro-computed tomography (micro-CT). Their mechanical and rheological properties were also studied in order to evaluate their accordance with soft tissue characteristics. Cell seeding within scaffolds and quantification of cell metabolic activity was evidenced by Live/Dead<sup>®</sup> and AlamarBlue<sup>®</sup> assays, respectively. Finally, cell secretion function was investigated by the quantification of HGF, FGF-2 and VEGF released in the supernatant of MSC-loaded scaffolds.

### RESULTS AND DISCUSSION

Whatever the formulation tested, highly interconnected porous scaffolds (fig. 1A) were obtained, with pore sizes suitable for 3D cell culture (100-230  $\mu\text{m}$  on

surface and in cross-section, determined by micro-CT). All scaffolds exhibited storage moduli higher than their loss moduli, thus confirming a well-structured polymeric network. Their mechanical properties were in the range of the elastic moduli of soft tissues (alginate foams: 10-27 kPa; soft tissues: 1-20 kPa). FTIR analysis confirmed the efficacy of the rinsing steps, warranty of alginate scaffolds' preserved biocompatibility. The generated porosity allowed an efficient cell seeding in-depth (fig. 1B), and the metabolic activity of the seeded MSCs was maintained during 14 days showing the good in vitro biocompatibility of all the scaffolds. In addition, the MSC secretion level measurements revealed that growth factors release was globally improved in comparison with control alginate scaffolds (VEGF:  $p < 0.05$ ; HGF and FGF2:  $p > 0.05$ ).

### CONCLUSION

Our work presents for the first time a comparative study of the use of various surfactants associated with alginate to generate highly porous (foam-based) scaffolds with tunable properties for soft tissue engineering with MSCs. By varying the surfactant type, various microarchitectures were generated, together with different secretion profiles of the seeded MSCs, which could give rise to different biological effects in vivo. Associating MSCs with alginate foam-based scaffolds appears as a promising strategy to improve soft tissues cell therapy.

[royi@wmin.ac.uk](mailto:royi@wmin.ac.uk)

### INTRODUCTION

Polyhydroxyalkanoates (PHAs) are water-insoluble storage polymers which are polyesters of hydroxyalkanoic acids, produced by a variety of bacterial species<sup>1</sup>. They are biodegradable and biocompatible, exhibit thermoplastic properties and can be produced from renewable carbon sources<sup>1</sup>. In this work we have focussed on the use of PHAs in cardiac tissue engineering applications. Myocardial infarction (MI) and congestive heart failure (CHF) are the main cardiovascular diseases. Cardiac patches aim to facilitate the normal functioning of the heart muscle by providing repair and support to the infarcted tissue; post MI. The main objective of this study was to fabricate cardiac patches using Poly(3-hydroxyoctanoic acid), P(3HO), which would be able to mimic the structure and functionality of the cardiac muscle.

### EXPERIMENTAL METHODS

The production, characterisation and production of P(3HO) solvent cast films were carried out as in Rai *et al.*, 2010<sup>2</sup>. Surface functionalized porous patches were developed using the particle leaching method and electrospinning. Cell culture involved the use of the specific cell line and proliferation was measured using the MTT Assay.

### RESULTS AND DISCUSSION

**Production and characterisation of P(3HO):** P(3HO) was successfully produced, extracted and purified. GC-MS and NMR results confirmed that the PHA produced was Poly(3-hydroxyoctanoate), i.e. P(3HO).

#### Material Characterisation:

The  $T_g$  and  $T_m$  for P(3HO) were  $-34.86^\circ\text{C}$  and  $45.62^\circ\text{C}$  respectively. The Young's modulus, % elongation at break and the tensile strength, was  $3.7 \pm 0.3\text{MPa}$ ,  $299 \pm 29\%$  and  $2.8 \pm 0.1\text{MPa}$ , respectively. Porous patches and surface functionalised patches with electrospun fibres, VEGF and RGD peptide were produced.

#### Biocompatibility Studies:

*In vitro* studies using C2C12 cells were conducted on these patches. The porous patches containing random fibres on the surface showed the highest cell proliferation rate. Also, the % proliferation of C2C12 cells in the VEGF and RGD peptide modified P(3HO) patches was found to be much higher as compared to only VEGF or only RGD peptide containing patches.

**Figure 1:** P(3HO) (A) neat patch (B) with fibres (C) C2C12 cells proliferation on the P(3HO) patch

Adult ventricular cardiomyocytes were seeded on P(3HO) films, the cells survived well and their contractile parameters were maintained.

**Figure 2:** Contraction amplitude of adult ventricular cardiomyocytes stimulated to beat at different intervals on glass and P(3HO).

Human induced pluripotent stem cells derived cardiomyocytes (hiPSC-CM) were seeded on P(3HO) and gelatin (control). The cardiomyocytes were live and healthy on the P(3HO) constructs. The beating rate on the control was  $33 \pm 1.53$  beats/min while that on P(3HO) construct was  $42.0 \pm 2.52$  beats/min.

**Figure 3:** Immunohistochemistry analysis for P(3HO)

Immunohistochemistry analysis for F-actin, MHC and nuclei showed similar results for both gelatin and P(3HO).

### CONCLUSION

In conclusion, the MCL-PHA, P(3HO) has been confirmed as a new emerging material with great potential in cardiac tissue engineering.

### INTRODUCTION

Hydrogels are polymeric materials with a wide range of advantages such as: good biocompatibility, high water content, adjustable architecture, high permeability etc...<sup>1</sup> These properties make them ideal materials for tissue engineering applications<sup>2</sup>. However single polymeric systems are not able to mimic all tissue properties, for example poly(ethylene glycol) is cell repellent in spite of being highly biocompatible<sup>3</sup>. Therefore, combination of synthetic and biological polymers can overcome limitations of single polymer hydrogels and it can be a solution for the design of functional scaffolds.

In this study a novel biosynthetic hybrid scaffold comprised of poly (ethylene glycol) and chitosan was obtained by UV polymerization. Their physicochemical properties were studied and analyzed for their potential use as skin substitute.

### EXPERIMENTAL METHODS

**Synthesis of biosynthetic hydrogel scaffold.** First, a microwave-assisted method was used to obtain poly(ethylene glycol) dimethacrylate (PEGDM). Briefly, linear PEG polymer (MW = 4000 g.mol<sup>-1</sup>; Polioles, MX) and methacrylic anhydride (Sigma-Aldrich, USA) were mixed, then acrylation was carried out for 6 minutes (700 Watts). Biosynthetic Hydrogel was fabricated by free radical polymerization of a homogenous solution of PEGDM, chitosan (Sigma-Aldrich, USA) and a UV initiator (Sigma-Aldrich, USA) in a PTFE mold. Samples were washed with de-ionized water several times in order to remove any unreacted initiator.

**Physicochemical characterization.** Chemical structure of the biosynthetic scaffold was analyzed by FTIR, the test was done by triplicate. Swelling behavior was studied by gravimetry of previously dried cylindrical samples of (n = 12) until equilibrium was reached in a phosphate buffer saline solution (PBS; pH = 7.4). Scanning electron Microscopy (SEM) was used to analyze pore structure of samples.

### RESULTS AND DISCUSSION

PEG hydrogels are widely used because of their lack of toxicity, however the non-adhesive properties of its polymeric chains are a drawback for tissue engineering applications. For this reason, a chitosan polymer, well known for its adhesive characteristics, was combined with a PEG network in a simultaneous way. Physicochemical properties were compared for both: the single PEG network and the PEG-Chitosan biosynthetic hydrogel. It was shown, that maximum swelling ratio (Qw) of biosynthetic hydrogel (3.90±0.09) has a lower value than the PEG network by

its own (5.60±0.78). The PBS uptake in the biosynthetic scaffold decreases due to the introduction of chitosan polymeric chains. Although the PEG-Chitosan hydrogel has a lower Qw compared with the PEG network, it still can uptake 3 fold their own weight in PBS (Fig. 1) and it can provide a moist environment in skin wounds.

SEM analysis shows an average pore size of approximately 30 µm in previously lyophilized samples of biosynthetic hydrogel (Fig.1). For regeneration of adult mammalian skin a pore size between 20–125 µm have been reported to be the optimal, therefore this material can be expected to promote cell proliferation of fibroblast.

Figure 1. A. Weight swelling behavior in PBS of dried cylindrical samples at room temperature (n=9, sigmoidal fit:  $R^2=0.99$ ), B. PEG-chitosan hydrogel y C. SEM micrograph of biosynthetic hydrogel of PEG-Chitosan.

### CONCLUSION

Physicochemical characterization is the first step to assess performance of tissue-engineered scaffolds. Although, it does not replace other studies such as cell or animal models, it helps to have a better prediction of their *in vivo* behaviour. Here, the swelling and pore structure indicates that the biosynthetic material has potential use as skin substitute.

### INTRODUCTION

In-stent restenosis (ISR) is induced by an uncontrolled smooth muscular cells (SMC) proliferation after stent implantation. It is associated with recurrence of symptoms and additional health costs. Drug-eluting stents have demonstrated efficiency on ISR, but induce a high risk of late acute thrombosis due to a delayed struts reendothelialization<sup>1</sup>. Polydopamine (PDA), a biocompatible polymer inspired from mussels byssus, has been reported to promote endothelial cells (EC) and SMC proliferation *in-vitro*<sup>2,3</sup>, thus suggesting a potential pro-healing effect on the vascular wall. This study aimed to evaluate the impact of a pro-healing PDA-coated stent on in-stent restenosis (ISR) and on the quality of the struts re-endothelialization *in-vivo* using a rat model.

### EXPERIMENTAL METHODS

Chemical oxidation of Cobalt-Chromium (CoCr) plates was achieved using a “piranha” solution mixture. PDA coating was performed by dip coating in a 2mg/mL dopamine solution, followed by rinsing in deionized water and thermal treatment at 150°C<sup>4</sup> for one hour. Surface morphologies were assessed on PDA-coated CoCr plates by scanning electron microscopy (SEM). Ten Wistar rats received the implantation of 2.5mm CoCr coronary stent in aortic position (5 bare metal stents (BMS), 5 PDA stents, prepared according to the same protocol) and then sacrificed on the 28<sup>th</sup> day. Eight rats were used to estimate ISR in optic microscopy with quantification of the neointima/media (n/m) ratio after eosin/hematoxylin coloration<sup>5</sup>. Quality of the struts reendothelialization was analyzed in the two remaining rats with transmission electron microscopy (TEM).

### RESULTS AND DISCUSSION

Visual aspect of PDA-coating appears smooth and homogeneous, however SEM analyses with a scratch test revealed a rough surface of around 50 nm in depth (Figure 1).

Figure 1: Typical aspect of PDA-coated CoCr plates after thermal treatment (a) and PDA coating aspect in SEM (b).

On the ten rats, one died of bleeding complications after stent implantation in the BMS group. The aspect of rats aortas is presented in Figure 2. PDA stents demonstrated a significant reduction in ISR compared to bare metal stents (ratio n/m = 0.48 (+/- 0.26) versus 0.83 (+/- 0.42),  $p < 0.001$ ). TEM analyses confirmed the presence of neointima surrounding the struts in each group, and revealed a thinner neointima layer in the PDA-stent group compared to BMS (Figure 2), with similar ultrastructures of the cells facing the arterial lumen.

Figure 2: Morphology of the aortic wall 28 days after stent implantation of BMS (a) and PDA-stents (b) with optic microscopy. TEM analyses confirmed re-endothelialization of BMS (c) and PDA-stents (d). The neointima layer appeared thinner with PDA-stents (or in the PDA-stent group).

### CONCLUSION

The pro-healing effect expected of PDA-coating on the arterial wall seems to be confirmed in this *in-vivo* model. This biocompatible polymer could intrinsically limit in-stent restenosis. Additionally, it also offers the possibility to immobilize many relevant drugs on its surface through amine functions providing potential synergistic effects.

### INTRODUCTION

In recent years, there is a growing interest in the immobilization of bioactive molecules on the surface of biomaterial implants<sup>1</sup>. In this regard, the coating of stents with bioactive sequences to prevent restenosis after percutaneous transluminal angioplasty is of particular therapeutic relevance<sup>2</sup>. For this purpose, it is essential that the stent enhances the adhesion of endothelial cells to facilitate healing of the blood vessel and also prevents restenosis and thrombosis. However, the optimal sequences and their combinations remain to be elucidated. We aimed to investigate the biological effects of bioactive CoCr surfaces on endothelial cells adhesion, vascularization, pro-thrombosis and anti-thrombosis processes through gene expression studies<sup>3</sup>. A further step is presented here with the study of platelet cell adhesion response to evaluate anti-thrombogenic effects.

### EXPERIMENTAL METHODS

CoCr alloy (ASTM F90) polished discs were etched with 5M NaOH 2h to activate the surface, previous to silanization with 3-chloropropyltriethoxysilane, and functionalized with cell adhesive peptides –containing the active sequences RGDS (RGD), YIGSR (Lam) - with aminohexanoic acid as spacer units - and their combination (Mx). Plain surfaces were used as control (CT). Real time polymerase chain reaction (RT-qPCR) gene expressions for selected genes of adhesion (ICAM-1, VCAM-1), vascularization (VEGFA, VEGFR-1, VEGFR-2), pro-thrombogenic (vWF) and anti-thrombogenic (eNOS, TPA) in HUVEC cultured on the different surfaces for 24h, 48h and 72h were determined.  $\beta$ -actin was used as housekeeping gene. Thrombogenicity was evaluated through platelet adhesion and aggregation, by circulating human blood onto TCPS coated surfaces - RGD, Lam and Mx - using a flat chamber perfusion at 75 ml/min during 5 min and 37°C to then, stain by immunofluorescence. ANOVA tables with Fisher's multiple comparison tests were obtained to determine statistically significant differences ( $p < 0.005$ ).

### RESULTS AND DISCUSSION

CoCr surface functionalized with RGD, Lam, or Mx sequences influenced the expression of anti-coagulatory genes of HUVECs and the adhesion and aggregation of platelets. Moreover, differences have been detected if the biomolecules are simply adsorbed or covalently adhered to the surface. HUVEC cells cultured on CoCr surfaces with the peptides RGD, Lam or Mx physisorbed did not show differences in the expression

of ICAM-1 (Figure 1) and VCAM-1 genes after 24h and 72h. Conversely, gene expression was enhanced on RGD and Lam silanized CoCr surfaces after 72h where Mx surfaces overexpressed ICAM-1 and VCAM-1. This can be explained by the higher immobilization of peptides RGD, Lam and Mx onto CoCr surfaces via silanization compared to physisorption, which effectively guides cell adhesion response.

Figure 1. Gene expression of ICAM-1 on all different surfaces by RT-qPCR

vWF factor, related to pro-thrombogenic events, decreased its gene expression over time in all studied surfaces, thereby suggesting a lower blood clot formation on the mentioned surfaces.

Interestingly, tPA and eNOS were overexpressed on silanized Mx CoCr series after 72h compared to all surfaces, indicating lower thrombogenic properties on this surface and a better prevention of platelet aggregation. A blood *in vitro* assay confirmed this behaviour, where all CoCr surfaces with immobilized bioactive sequences presented a lower platelet adhesion and aggregation compared to CT surfaces. This effect was noticeable for RGD and Mx coated surfaces, which resulted in a lower thrombogenicity.

### CONCLUSION

Coating of CoCr surfaces with the combination of RGDS and YIGSR bioactive sequences influences HUVEC's adhesion and inhibits platelet adhesion and aggregation. These biomaterials may have a great potential for arteries recover.

## INTRODUCTION

Continuous glucose monitoring is an efficient method for the management of diabetes and in limiting the complications induced by large fluctuations in glucose levels. For this, intravascular systems may be useful in producing more reliable and accurate devices. However, biocompatibility remains the key issue to be addressed for optimal performance<sup>1</sup>. In particular, inflammation and neo-vascularization are key factors to be addressed. Currently, the most commonly used method to overcome these obstacles is the use of drug releasing implants<sup>2</sup>. We believe that this paradigm should be reconsidered in view of their limited lifetime. In this scope, the perennial modification of the surface of a gold-based implant with pro-angiogenic and/or anti-inflammatory principles holds some promise. Gold is widely used in medical devices due to its excellent biocompatibility.

The objective of this study is to investigate the impact of surface modified with the anti-inflammatory molecule  $\alpha$ -Melanocyte Stimulating Hormone<sup>3</sup> ( $\alpha$ -MSH) as well as the pro-angiogenic peptide sequence GDSVVYGLR<sup>4</sup> on Human Umbilical Vein Endothelial Cell (HUVEC) behavior *in vitro*.

## EXPERIMENTAL METHODS

**Functionalization** – Our model is based on self-assembled monolayers (SAMs) of thiol-bound carboxyethyl terminated hepta(ethylene oxide) (EO<sub>7</sub>-COOH) on gold. Following this,  $\alpha$ -MSH is grafted using a thiol-maleimide bond, thus yielding EO<sub>7</sub>-MSH surfaces, while GDSVVYGLR is coupled by peptide linkage to obtain EO<sub>7</sub>-SVV surfaces. Peptide surface density was quantified using XPS and PM-IRRAS.

Schematic diagram of the bioactive modified gold surfaces used in this study.

**Biological studies** – HUVEC proliferation was investigated after 96h. To discriminate the effect of surface grafted SVVYGLR from Vascular endothelial Growth Factor (VEGF), experiments were performed in cell culture media containing either 0.1% or 0% VEGF. Finally, ERK1/2 signaling was investigated.

HUVEC inflammatory response was assessed by quantifying the impact of the EO<sub>7</sub>-MSH surfaces on the production of the pro-inflammatory cytokine IL-6. A

comparative study of the effect of soluble versus immobilized  $\alpha$ -MSH on IL-6 production was also performed.

## RESULTS AND DISCUSSION

**Surface characterisation** – Using XPS and PM-IRRAS we found that the EO<sub>7</sub>-COOH surfaces are compact, homogeneous and have a structure analogous to crystalline poly(ethylene oxide). EO<sub>7</sub>-SVV and EO<sub>7</sub>-MSH were successfully produced with surface densities of SVVYGLR and  $\alpha$ -MSH of 1.6 and 3.5 pmol/mm<sup>2</sup> respectively.

**Proliferation** – HUVECs proliferated more on the EO<sub>7</sub>-SVV surfaces, regardless of VEGF concentration. Importantly, in VEGF deprived conditions, surface grafted SVV was able to maintain adhesion and proliferation *via* activation of the ERK1/2 signaling pathway.

**Inflammation** – We observed that IL-6 production was significantly reduced on the EO<sub>7</sub>-MSH surface. In addition surface bound  $\alpha$ -MSH was found to be as efficient as physiological levels of soluble  $\alpha$ -MSH in reducing IL-6 expression.

## CONCLUSION

**Summary** – Bioactive gold surfaces with controlled surface density were produced and characterized. These were used to assess HUVEC response with regards to proliferation and inflammation. We found that HUVECs respond to the presence of bioactive molecules by proliferating on surfaces presenting the SVVYGLR peptide, *via* activation of a pro-angiogenic pathway. We also observed that surface bound  $\alpha$ -MSH is beneficial in limiting HUVEC inflammation and that it is as potent as equivalent levels in solution in reducing inflammation.

**Perspectives** – Future work includes simultaneously modifying gold surfaces with both anti-inflammatory and pro-angiogenic molecules and to test their effect on cell behavior *in vitro*, with ultimately the prospect of an *in vivo* study.

### INTRODUCTION

Cardiovascular diseases, including ischemic heart disease and stroke, are collectively responsible for 25% of all deaths worldwide. Globally, their prevalence continues to increase, in spite of enormous progress in diagnostics and therapy. For therapeutic and regenerative purposes, biomaterials constitute a solution with multiple advantages over synthetic materials. In this work, we focus on the directions for the current and future development of (nano)biomaterials for cardiovascular applications.

### EXPERIMENTAL METHODS

The current literature regarding (nano)biomaterials for cardiovascular medicine was reviewed based on the Medline bibliographic database.

### RESULTS AND DISCUSSION

**Vascular grafts:** One of the most addressed, but thus far unanswered needs in cardiovascular tissue engineering is the development of small-diameter vascular grafts which would mimic anti-thrombogenic effect of an autologous vessel. Promising results were recently obtained with biodegradable polymers (e.g. poly (caprolactone) (PCL); poly(lactic-co-glycolic) acid (PLGA)) and their blends with proteins (silk fibroin, elastin, collagen, gelatin) electrospun to fabricate tubular scaffolds with nanometer-range fibre diameter mimicking native-like topology. To improve endothelialisation and prevent thrombosis, surface modifications of nanofibres, as well as incorporation of cell attachment-supporting peptide sequences or nitric oxide donors into the scaffolds were proposed<sup>1</sup>. Aspirin-loaded electrospun PCL tubular scaffold were also suggested as anti-thrombotic drug-releasing graft for small-diameter vessel replacement. Apart from electrospinning, several rapid prototyping techniques, including submerged bioprinting, have been recently developed to improve the mechanical stability of the biofabricated tubular constructs.

**Vascular bioresorbable stents:** Recent advances in bioresorbable metal and polymer materials enable the design of stents, which are aimed at scaffolding the vessel only temporarily after coronary interventions. Following revascularization and restoration of vessel function, the stents are progressively resorbed to eliminate the drawback of an unnecessary permanent metallic implant. This new concept of vascular regenerative therapy utilizes nanoparticulate drug delivery systems in combination with bioresorbable polymers (e.g. PLA, PLGA), or bioabsorbable metal stents based on iron or magnesium alloys that use a controlled corrosion by body fluids as mechanism of degradation<sup>2</sup>.

**Cardiac patches:** Abnormal heart formation or heart tissue damage often require placement of a cardiac patch to repair the defect, but the available polymeric materials obstruct the transfer of electrical signals between cardiomyocytes, which can cause arrhythmias. Novel myocardial patches based on hydrogels containing conductive nanoparticles (e.g. alginate hydrogels with gold nanowires, or chitosan/gelatin-hydrogels with single-walled carbon nanotubes) are now proposed that provide the native-like extracellular matrix environment for cardiac cells, but also support the electrical conductivity necessary for cardiomyocyte function.

**Nanoparticles for cardiovascular imaging and drug delivery:** PLGA<sup>3</sup> and chitosan are commonly used as nanocarriers, due to their favourable safety profiles. To highlight but a few novel biomaterial-based nanosystems with the best potential for use in clinical applications<sup>4</sup>, glycol chitosan-gold nanoparticles were successfully tested in mice as contrast agents for thrombus detection with CT. Chitosan nano-tPA gene plasmids and urokinase-coated, self-assembled chitosan and tripolyphosphate nanoparticles were used to prevent thrombus formation in dog and rabbit models respectively. Nanoparticulate drug-delivery was also proposed for the regeneration of myocardial infarction-induced injury, utilizing e.g. chitosan-alginate nanoparticles loaded with cardioprotective placental growth factor, or PLGA nanoparticles conjugated with insulin-like growth factor-1. PLGA nanoparticles containing active superoxide dismutase were also tested in an animal model of stroke, showing considerable protection against ischemia and reperfusion injury.

### CONCLUSIONS

The potential clinical impact of tissue-engineering, biofabrication and nanotechnology in terms of cardiovascular disease management is enormous. Clinically-driven needs give the precise directions for further improvement of existing, and development of novel nano(bio)materials that can be translated into the clinical trials.

## INTRODUCTION

Biofilm formation leads to a 1000 times increase in antibiotic tolerance compared with planktonic bacteria and is associated with 80% of hospital acquired infections. New materials that prevent biofilm formation would offer enormous benefits to the health industry and improve patient welfare. However, the limited understanding of bacteria-material interactions restricts the rational design of such materials. Polymer microarrays are a key enabling technology for the discovery of new biomaterials<sup>1</sup> and have been utilised to identify novel polymers that resist bacterial attachment.<sup>2,3</sup> The hundreds of polymer-bacteria interactions observed on a microarray can be used to elucidate the structure-function relationship underpinning the ability of a material to resist bacterial attachment.<sup>4</sup>

## EXPERIMENTAL METHODS

Polymer microarrays were formed using a XYZ3200 pin printing workstation (Biodot) onto poly(hydroxyethyl methacrylate) coated slides. Printing was carried out using slotted metal pins. Polymerisation solution was composed of 75% (v/v) monomer, 24% (v/v) DMF and 1% (w/v) photoinitiator 2,2-dimethoxy-2-phenylacetophenone. After printing polymers were UV cured and vacuum extracted. A bacterial attachment assay was developed using green fluorescing protein (GFP) tagged bacterial strains (*Pseudomonas aeruginosa* PAO1, *Staphylococcus aureus* 8325-4, Uropathogenic *Escherichia coli* (UPEC)) where the attachment of bacteria to each material was quantified by measuring the fluorescence after incubation.

## RESULTS AND DISCUSSION

Polymer microarrays were used for the discovery of novel materials that resist bacterial attachment. A multi-generation approach was used to search the chemical space represented by polymerised commercially available acrylates. First generation arrays were designed to represent a large chemical diversity whilst subsequent generations utilised copolymers to explore 'hit' formulations in greater detail. Using this approach over 1200 unique materials were screened to identify a hit formulation that was able to reduce bacterial attachment by up to 99% compared with silicone.<sup>2,3</sup> The 'hit' material was able to reduce infection *in vivo* on subcutaneous implants within a mouse model (Fig. 1). The materials with the lowest bacterial attachment were homologues as they each contained a hydrophilic ester group, associated with the acrylate functionality, and a bulky hydrophobic pendant group. Each of the materials was, thus, amphiphilic.

To explore structure-function relationships, a new array

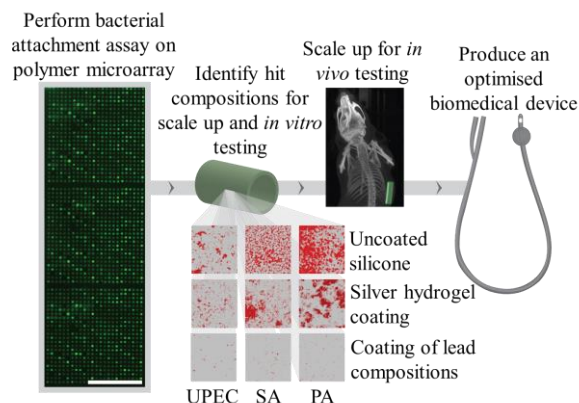

Figure 1 – Summary of high throughput method to discover a material resistant to bacterial attachment, from the polymer microarray to *in vivo* application.

was prepared containing copolymers with pendant groups derived from the *tert*-butyl cyclohexyl moiety. Bacterial attachment to these materials was found to correlate with a composite parameter representing both molecular flexibility and hydrophobicity (Fig. 2).

Figure 2 - For weak amphiphiles, bacterial attachment was found to correlate with the combination of a rigid hydrophobic pendant group.

## CONCLUSION

Polymer microarrays were successfully applied to discover new materials resistant to bacterial attachment. This was achieved without the requirement for a comprehensive understanding of the underlying material-biological interactions, however, this understanding was developed subsequently from the biological responses observed on microarrays.

## INTRODUCTION

Silver nanoparticles as antibacterial agent in biomedicine with unfortunately a rather narrow therapeutic window<sup>[1-3]</sup> and biologically inert gold nanoparticles for the use in tumor therapy, drug delivery or imaging applications<sup>[4,5]</sup> recently became a prominent subject in scientific studies. Alloyed silver-gold nanoparticles are promising candidates to combine and tune the properties of both metals, e.g. their optical characteristics or their toxicity towards cells or bacteria.

## EXPERIMENTAL METHODS

The alloyed Ag:Au nanoparticles with different compositions of silver and gold were prepared in aqueous media by co-reduction of silver nitrate and tetrachloroauric acid with a mixture of citrate and tannic acid and subsequently functionalized by the addition of polyvinylpyrrolidone (PVP).<sup>[6]</sup> For comparison, pure gold and silver nanoparticles were synthesized with the same reaction parameters. After colloidal stabilization and physicochemical characterization, the nanoparticles were purified by multiple ultracentrifugation steps for further cell-biological experiments with HeLa cells and human mesenchymal stem cells.

## RESULTS AND DISCUSSION

The presented synthesis is well suited for the generation of monodisperse bimetallic Ag:Au nanoparticles with different molar compositions (with the molar ratios of Ag:Au ranging from 90:10 to 10:90). Characterization with X-ray powder diffraction (XRD), transmission electron microscopy (TEM), differential centrifugal sedimentation (DCS), UV-Vis and atomic absorption spectroscopy (AAS) showed spherical monodisperse and colloiddally stable silver-gold nanoparticles with diameters of ~7 nm (see Fig. 1) with the actual molar metal compositions very close to the theoretical values.

**Figure 1:** Representative transmission electron micrographs (TEM) of synthesized Ag:Au-30:70 (left) and Ag:Au-60:40 (right) nanoparticles with an average particle diameter of 7 nm.

Examination of the nanoparticle cytotoxicity towards HeLa cells and human mesenchymal stem cells (hMSCs) showed that the toxicity increases non-linearly with increasing silver content. Nanoparticles with a molar Ag:Au composition of 80:20 showed the highest cytotoxicity. It is possible that a passivating effect from the alloyed gold is responsible for this effect.

## CONCLUSION

The presented one-pot synthesis of alloyed Ag:Au nanoparticles in aqueous medium can easily be modified to gain size control over the final particle diameter and the stabilizing agents without affecting the resulting purity or stability. The cytotoxicity towards HeLa cells and hMSCs increases with growing silver fractions in the nanoparticles with a maximum at Ag:Au=80:20. This may permit to reduce the dose of silver for the antibacterial action.

## INTRODUCTION

Biofilm-forming bacteria are a major treat to hospitalized patients and the main cause of chronic obstructive pulmonary disease and pulmonary infections, which are the third cause of death worldwide. There is an urgent necessity for novel therapeutic approaches, since current antibiotic delivery fails to eliminate biofilm-protected bacteria. Biomaterial carriers designed to improve such drug release need to overcome the biological barrier that is the biofilm extracellular matrix (ECM), a mesh made of proteins, polysaccharides and extracellular DNA (eDNA)<sup>1</sup>. In this work we propose to target bacterial ECM with enzyme-activated NPs, able to disassemble the biofilm matrix and boost the efficacy of antibiotic treatment. Polylactic-co-glycolic acid nanoparticles (PLGA NPs) loaded with ciprofloxacin (CPX) were prepared and coated with DNase to degrade the eDNA that stabilizes the biofilm structure. Such NPs were evaluated against established *P. aeruginosa* biofilm, under static and dynamic conditions.

## EXPERIMENTAL METHODS

NPs were prepared co-dissolving 1.5% w/v PLGA (Purasorb PLG 5010, Purac) and 700 µg/mL CPX in the green solvent ethyl lactate. The mixture was added to a water bath, and NPs formed by nanoprecipitation. Polylysine (PL)-coated NPs were obtained adding 70 µg/mL of PL to the water bath. DNase-coated NPs were produced grafting DNase I on the ε-aminogroups of PL via carbodiimide chemistry. NPs size and surface charge were studied by dynamic light scattering, and their morphology by scanning electron microscopy. DNA degradation by DNase-NPs was quantified via gel electrophoresis. CPX content and release kinetics at 37°C were measured by high performance liquid chromatography. Cytotoxicity was tested on J774 murine macrophages. Antimicrobial activity of NPs was first assessed against planktonic *P. aeruginosa* PAO1 and the minimum inhibitory concentration of each NPs type was determined. NP efficacy against 48h-old mature *P. aeruginosa* biofilm was evaluated *in vitro*. NP treatment was applied either once or repeatedly (1 dose/day for 3 days) and surviving biofilm-forming bacteria were counted. NP antibiofilm activity was also studied under dynamic conditions in a microfluidic flow chamber. 96h-old biofilms were subjected to a single dose NP treatment, stained (LIVE/DEAD assay), and analysed by confocal laser scanning microscopy.

## RESULTS AND DISCUSSION

Spherical and monodispersed NPs encapsulating CPX,

were synthesized with a size between 200 and 300 nm. Z-potential can be tuned as PLGA NPs had negative surface charge and PL-coated NPs (with and without DNase) showed a positive charge. PL-coating also enabled a simple way to graft bioactive molecules on the NPs surface. For all NPs formulations CPX release kinetics had a biphasic behaviour, with an initial burst in the first hour, followed by a slower sustained release. NPs were non-cytotoxic for mammalian cells, enhanced CPX antimicrobial activity against planktonic *P. aeruginosa* and prevented biofilm formation. More importantly, administration of DNase-NPs delivering CPX concentrations as low as 0.0078 µg/mL against 2-days old mature biofilms successfully reduced the living bacteria by >95%, outperforming free-soluble CPX (cell reduction <40%). Higher doses of DNase-coated NPs, as well as repeated administrations over 3 days, were able to completely eradicate the established biofilm, which was not possible with CPX alone or uncoated NPs. In the flow chamber assay, a model closer to the *in vivo* milieu, DNase-NPs kept their activity also under dynamic flow. Both living biomass density and biofilm thickness were reduced, indicating the contextual disassembly of the biofilm ECM and bacteria elimination due to the improved antibiotic delivery (Fig. 1).

Figure 1: Flow chamber biofilm (A) untreated and (B) after DNase-NPs treatment. Bacterial cells: green (live), red (dead)

## CONCLUSION

PLGA NPs encapsulating CPX, with size suitable for airway delivery, were successfully prepared and endowed with functional DNase activity as smart drug delivery devices that target and disassemble the biofilm ECM. Such NPs enhance antibiotic penetration into the biofilm and eradicate persistent infections *in vitro*. Enzyme-activated NPs are proposed as novel antimicrobial agents, and these results provide fundamental clues to design the next generation of drug delivery devices to treat biofilm infections.

## INTRODUCTION

*Helicobacter pylori* (*Hp*) colonizes the stomach of more than 50% of the World's population<sup>1</sup>. *Hp* infection recommended treatment is based in a combination of two antibiotics and a proton pump inhibitor<sup>2</sup>. However, this therapy fails in 20% of patients especially due to bacterial resistance<sup>3</sup>. Therefore, it is urgent to develop new antibacterial agents that can effectively eradicate *Hp* with minimum drug resistance. We have previously demonstrated that docosahexaenoic acid (DHA), a polyunsaturated fatty acid present in fish oil, has antibacterial activity against *Hp* growth *in vitro* in a dose-dependent way and inhibits mice gastric colonization *in vivo*. However, up to 40% of infected mice remain colonized by *Hp* after DHA treatment<sup>4</sup>. This might be explained by low residence time of DHA on mice stomach and/or low penetration of DHA through the stomach mucus layer, leading to insufficient concentration of DHA to eradicate *Hp* at the infection site. The main goal of this work is to develop a DHA gastric delivery system to improve its efficacy in the treatment of *Hp* infection.

## EXPERIMENTAL METHODS

DHA (0, 1, 2 and 2.5% v/v in solution) was incorporated into nanostructured lipid carriers (NLC) by hot homogenization technique using a mixture of solid lipids/liquid lipid/stabilizer<sup>5</sup>. Nanoparticles were characterized in terms of size and  $\xi$ -potential by electrophoretic light scattering and DHA incorporation was quantified using UV-Vis spectroscopy (200-400nm) after dissolution in ethanol. Nanoparticles physical stability was evaluated by examining changes of mean particle size and charge during storage conditions for 1 month at RT.

The effect of DHA-NLC (prepared with 2% v/v) on *Hp* J99 strain growth ( $\sim 1 \times 10^7$  bacteria/ml) was evaluated in Brucella broth (150rpm, 37°C) with different concentrations of NLCs and DHA-NLCs (10, 25, 50, 100, 500  $\mu$ M). DHA in solution was used as control. Samples of bacteria cultures were collected every 3h for 24h and plated on *Hp* selective medium. Number of viable bacteria was determined by colony forming units (CFU) counting.

Cytotoxicity of different concentrations of NLCs and DHA-NLC (10, 25, 50, 100  $\mu$ M) towards MKN45 gastric carcinoma cell line ( $\sim 5 \times 10^5$  cells/well) was performed using LDH and MTT assays by measuring optical density at 490 and 630 nm and at 590 and 630 nm, respectively, using a microplate reader.

## RESULTS AND DISCUSSION

The maximum of DHA incorporation into nanoparticles was obtained using at least 2% v/v DHA in solution ( $2.0 \pm 0.2$  mM/ml). After incorporation of DHA, the size of NLCs increased from  $151 \pm 16$  nm to  $214 \pm 31$  nm, independently of DHA concentration. All nanoparticles have a negative  $\xi$ -potential ( $\sim -30$  mV), demonstrating that DHA did not change the particle charge. All nanoparticles were stable during storage conditions at room temperature.

Encapsulation of DHA improves its bactericidal effect against *Hp*, since all DHA-NLCs used, even at lower concentration (10  $\mu$ M) are bactericidal in opposite to DHA in solution that did not kill *Hp* at concentrations lower than 100  $\mu$ M. Also, NLCs without DHA have an inhibitory effect on *Hp* and are able to kill it after 12h. Cytotoxicity studies revealed that all nanoparticles tested are non-cytotoxic for gastric cells at concentrations that kill *Hp*.

**Figure 1.** Effect of soluble DHA, NLCs and DHA-NLCs (25  $\mu$ M) on *Hp* J99 growth during 24 hours.

## CONCLUSION

The inhibitory and bactericidal activity of unloaded and DHA-loaded NLCs nanoparticles, respectively, in treating *Hp* infection, was demonstrated. These nanoparticles are not cytotoxic against gastric cells at bactericidal concentrations. DHA-loaded NLC should therefore be considered as an alternative to the current treatment of *Hp*.

## INTRODUCTION

Dental implants are a common solution to overcome the problem of tooth loss. Despite their high rate of success, however, such implants can fail due to different factors, e.g. poor quantity and quality of the bone, defective implant placement, or infection. Among them, infection has been described to play a key role in mid- and long-term implant failure<sup>1</sup>. Thus, different approaches to avoid peri-implant infection have been studied, including loading of antibiotics, antibacterial polymeric coatings or immobilization of antimicrobial peptides (AMPs).

In this study, a combination of an antifouling coating (polyethylene glycol, PEG) and an AMP has been developed on Ti surfaces. Two different AMPs have been tested: Lactoferrin 1-11 (LF1-11) and Magainin-2 (MG-2), to compare the biological performance of the coatings in terms of biocompatibility and bacterial adhesion.

## EXPERIMENTAL METHODS

Samples of polished titanium (Ti) grade 2, cleaned with ethanol, acetone and water were activated with argon plasma (0.40mbar, 100W, 5min).

PEG-amine electrodeposition was done with an electrolyte containing 2% PEG-amine and 0.3M of NaCl. The potential was applied with a constant sweep rate of  $-0.1\text{Vs}^{-1}$  and maintained at  $-5.0\text{V}_{\text{SCE}}$ . Process optimization was studied for electrodeposition time (5, 15, 30min) and pulsed or non-pulsed regime.

Amine-functionalized PEG (PEG-amine) surfaces were treated by either crosslinking with N-Succinimidyl 3-maleimido-propionate (SMP) or carboxylic acid activation with EDC/sulfo-NHS to bond the AMP to the PEG. Coatings were characterized by sessile drop contact angle, white light interferometry, ATR-FTIR and XPS. Bacterial adhesion assays were done by immersion of the samples in culture medium with bacteria (*Staphylococcus aureus* and whole dental plaque) for 2h. Bacteria presence was measured by seeding and CFU counting, as well as by staining with a life/dead kit and analysing with a confocal fluorescence microscope. Cell adhesion and cytotoxicity LDH assays were done with human fibroblasts. Polished titanium surfaces were used as controls.

## RESULTS AND DISCUSSION

Water contact angle measurements showed an increase in the surface hydrophilicity due to the presence of the PEG-amine coating. ATR-FTIR measurements showed the presence of PEG-amine and peptide in all the samples.

Based on the XPS results (table 1), a higher amount of

carbon, nitrogen and sulphur was detected on the samples coated with AMPs, sign of a successful immobilization process.

Table 1. Atomic concentration of the control and treated samples

	C 1s	O 1s	N 1s	Ti 2p	S 2p
Ti	23.4±1	59.6±1	0.6±0	16.3±0	0.0±0.0
PEG-amine	28.1±1	47.1±1	0.9±0	34.5±0	0.0±0.0
LF crosslinker	49.1±7	33.1±6	11.9±1	5.2±2	0.7±0.0
MG crosslinker	51.4±6	32.8±5	9.6±1	5.6±1	0.5±0.0
LF (EDC/NHS)	51.4±6	33.7±3	8.3±1	6.3±1	0.2±0.0
MG (EDC/NHS)	50.2±9	35.9±5	7.4±1	6.2±4	0.1±0.0

Cytotoxicity assays showed a cell survival rate higher than 80%, demonstrating the biocompatibility of the coating *in vitro*, while the cell adhesion was not significantly affected by the presence of PEG or PEG plus AMP.

Bacterial adhesion assays (figure 1) showed a decrease on the bacterial adhesion with the presence of PEG-amine. This antibacterial effect was further increased with the presence of the AMP. In this regard, a similar behaviour was observed between MG-2 and LF1-11.

Figure 1. Bacterial adhesion on the treated samples

## CONCLUSION

Titanium surface has been functionalized with a PEG-amine antifouling coating by an electrodeposition method. This coating has been used as a platform for the immobilization of AMP as antibacterial agents. The bonding of AMP to PEG-amine was successfully established with both SMP and EDC/NHS. The coatings showed a good biocompatibility and a significant decrease on the bacterial adhesion.

[leislal@gmail.com](mailto:leislal@gmail.com)

### INTRODUCTION

In hospitals, nearly 20% of patients use a urinary catheter, which increases the risk of developing a urinary tract infection (UTI)<sup>1</sup>. Health care related UTIs are due to the formation of a bacterial biofilm on the surface of the catheter<sup>2</sup>. In this study, modified poly(vinyl chloride) urinary catheters, with a binary graft of acrylic acid and poly(ethylene glycol) methacrylate, were submitted to cytocompatibility testing, drug loading and release studies, and bacterial inhibition and adhesion tests, to see whether the binary graft could successfully prevent the formation of a biofilm.

### EXPERIMENTAL METHODS

Ciprofloxacin loading and release studies were carried out using pieces of pristine and modified catheters (1 cm). The samples were left to swell in an aqueous ciprofloxacin solution and the amount of drug absorbed was calculated by monitoring the solution's absorbance at 271 nm. The drug-loaded catheters were then placed in an artificial urine solution, and the drug release was calculated by monitoring the absorbance at 273 nm. Cytocompatibility tests were conducted *in vitro* using BALB 3T3 mouse fibroblast clone A31 cells (ATCC<sup>®</sup> CCL-163<sup>™</sup>, Manassas, VA, USA) following the ROCHE© protocol. All experiments were carried out in triplicate. For the bacterial inhibition tests, drug-loaded catheters (1 cm) were placed in an agar Petri dish that had been seeded with *Staphylococcus aureus* (ATCC 25923) or *Escherichia coli* (ATCC 11229). The plates were kept at 37°C for 24 h, and then the inhibition rings were measured. For the bacteria adhesion tests, the samples were placed in 2 mL of an *Escherichia coli* solution in trypticase soy broth ( $8 \times 10^8$  CFU/mL) and cultured at 37°C for 3 h under static conditions. Afterwards, the samples were washed with phosphate buffer (PBS), placed in 2 mL of a sterile PBS, and sonicated for 5 min. The suspensions were then spread on TSA plates, and the colony forming units (CFUs) were measured after 24 h of incubation at 37°C.

### RESULTS AND DISCUSSION

Catheters grafted with PEGMA or the binary graft improved the cell viability and had better cytocompatibility for longer periods of time (Table 1).

Table 1: Cytocompatibility of pristine and modified catheters after 24 and 48 h.

	Cell viability (%)	
	24 h	48 h
PVC	94 ± 7	73 ± 4
PVC-g-PEGMA(40%)	99 ± 1	83 ± 8
PVC-g-AAc(44%)	67 ± 5	69 ± 2
[PVC-g-PEGMA(10%)]-g-AAc(14%)	98 ± 16	92 ± 8

The catheters that were grafted with AAc were able to absorb ciprofloxacin; however, catheters grafted solely with PEGMA did not significantly absorb the drug, as was the case with pure PVC (Fig 1).

Fig 1: Ciprofloxacin absorbed by PVC, PVC-g-AAc, and PVC-g-PEGMA.

The catheters grafted with PEGMA proved better than PVC-g-AA and binary grafted catheters at preventing bacterial growth (not shown) and adhesion (Fig 2).

Fig 2: CFU/mL of *Escherichia coli* upon pristine and modified catheters that were loaded with drug (shaded region) and not loaded with drug (white).

### CONCLUSION

Catheters grafted with PEGMA could prevent bacteria growth and adhesion better than PVC, PVC-g-AAc, or the binary grafted catheters.

#### INTRODUCTION

Over the past several years, the development of sophisticated laboratory-grown skin substitutes containing dermal and epidermal components has gained intensive interest in skin tissue engineering. In particular, plasma-based skin equivalents<sup>1</sup> have been used extensively for the treatment of extensive skin injuries since they can be produced as complete autologous scaffolds. However, limitations in the process of skin generation such as the use of specialized personnel combined with a high demand of artificial skin, necessitate the development of new methods that allow the automation and the reduction of production costs of the entire process. In this sense, 3D bioprinting, has emerged as a flexible tool in regenerative medicine and provides a platform to address these needs. 3D bioprinting allows for the construction of artificial tissues or organs, either autologous or allogeneic by printing cells, soluble factors and biomaterials in a desired pattern with the help of high-precision Cartesian robots. In this approach, we were able to build 400 cm<sup>2</sup> of functional skin in 45 - 60 min.

#### EXPERIMENTAL METHODS

Skin equivalents consisted of two layers, the inner layer (dermis) which was composed by human fibroblasts embedded in a plasma-derived fibrin matrix and the upper layer (epidermis) which was formed by human primary keratinocytes seeded on the top of the fibrin scaffold. These equivalents were deposited using a bioprinter in two different ways: six transwells prepared to differentiate in the incubator (*in vitro* test) and a p100 cell culture dish to be transplanted into a mouse (*in vivo* test). When the process was carried out *in vivo*, the upper layer of keratinocytes differentiated in the mouse. In this case, the equivalents were manually detached from the p100 cell culture dish and placed on the backs of athymic mice (4 immunodeficient *nu/nu* female mice). To characterize the *in vitro* and *in vivo* differentiated printed skin, biopsies from the *in vitro* equivalents and grafted mice were collected. It was performed histologies and immunofluorescence analysis using human specific antibodies against markers of epidermal differentiation (K5, K10, vimentin).

#### RESULTS AND DISCUSSION

***In vitro* test:** The histological staining of printed skin equivalent was able to give rise to all the different strata

found in a normal skin. The histology obtained from these equivalents was very similar to the real skin (Fig. A). The immunostaining also showed that all the cells and the main layers of the skin were in the bioengineered final tissue (Fig. B and C).

***In vivo* test:** The quality recovery of the epidermal phenotype was analyzed (Fig. D). There was a strong suprabasal expression of keratin K10 as it is found in the normal mature skin (Fig. E). The correct epidermal-dermal junction of the skin was confirmed by labeling with an anticollagen VII antibody (Fig. F).

**Histology of engineered human skin reconstructed by bioprinting differentiated *in vitro* 17 days (A,B,C) and on an immunodeficient mouse 6 weeks postgrafting (D,E,F).** A: Hematoxylin and eosin staining. B: Human K10 immunofluorescence (green). C: Human vimentin (red). D: Histologic appearance of the regenerated human skin. E: Human K10 immunofluorescence (red). F: Human vimentin (red) and collagen type VII (green).

(These are only a sample of the obtained results).

#### CONCLUSION

In this work, a new method to print human skin equivalents has been developed. It was also demonstrated that these equivalents maintained a similar functionality compared to the real human skin.

# A New Laser-Based Approach for Native Silk Structuring

Anastasia Brif<sup>1</sup>, Chris Holland<sup>2</sup> and Frederik Claeysens<sup>1</sup>

<sup>1</sup>Department of Materials Science and Engineering, The Kroto Research Institute, North Campus, University of Sheffield, Broad Lane, Sheffield, S3 7HQ, UK

<sup>2</sup>Department of Materials Science and Engineering Sir Robert Hadfield Building, Mappin Street, Sheffield, S1 3JD, UK  
[abrif1@sheffield.ac.uk](mailto:abrif1@sheffield.ac.uk)

## INTRODUCTION

Silk is undergoing a renaissance, especially garnering researcher's interest in the fields of biomaterials and tissue regeneration [1]. Applications of silk-based biomaterials range from templating controlled crystal growth [2] to complex drug delivery systems [3] and even a substrate for transient biodegradable electronics [4]. Yet despite this impressive diversity of applications the manufacturing processes for silks are yet to be fully exploited and call for the development of simple, fast and low-cost silk structuring routes. Currently, most of the silk structuring techniques involve a complex multi-stage process of silk solution production, prior to any structuring [5]. In this research, we present a more direct route for laser silk structuring using photocurable *Bombyx mori* native silk feedstock. Microfabrication techniques including direct laser writing (DLW) and Digital Micromirror Device (DMD) based micro-stereolithography ( $\mu$ SL) were used for the fabrication of various microstructures down to a few microns in scale.

## EXPERIMENTAL METHODS

**Photocurable silk solution preparation:** Native silk feedstock was extracted from posterior section of the middle division of the silk glands from final instar *B. mori* silkworms and diluted in Type II water silk so that the concentration varied from 0.3 to 1.5 wt%. Photocurable silk solution was produced by addition of 1 wt% of Rose Bengal (Sigma-Aldrich) for DLW  $\mu$ SL or of 0.02 wt% Riboflavin (Sigma-Aldrich) for the DMD-based  $\mu$ SL as required.

**Preparation of silk structures by DLW  $\mu$ SL:** A passively Q-switched DPSS Nd-YAG microchip laser with integrated second harmonic generator, with a sub-ns pulse duration was used. This laser emits at wavelengths 1064 and 532 nm (45 kHz repetition rate, Alphas laser). The laser output was expanded by Galilean beam expander to  $\sim 8$  mm beam diameter, reflected by a silver mirror and focused through a 10 $\times$  objective lens (NA 0.3) into a sample holder mounted on a high precision xyz stage. 10  $\mu$ l of the silk solution was dispersed on a glass slide. The patterns were written *via* focusing the laser just above the glass-silk interface.

**Preparation of silk structures by DMD  $\mu$ SL:** A 405 nm violet diode laser was used (150 mW, Vortran laser technology). The laser output was expanded to a 5 mm diameter beam and was reflected from a DMD. The reflected image was directed by a silver coated mirror onto a glass slide covered with photocurable silk solution. The laser power was 100 mW and projection time varied from 10 sec to 10 min.

## RESULTS AND DISCUSSION

The results of this research clearly indicate that native silk solution down to 0.3 wt% can be laser structured by combining with Rose Bengal and Riboflavin photo-

absorbents. By applying a  $\mu$ SL fabrication technique, micrometre-sized complex silk structures were produced by DLW (fig. 1a) and DMD (fig. 1c). In addition, we noticed alignment of silk structures *outside* sections exposed by the laser writing direction. This created an additional sub-micron grooved pattern (fig. 1b) which may have potential use for tissue engineering.

Figure 1: Native silk structuring by a,b) DLW and c) DMD  $\mu$ SL

To better understand the mechanism of silk photocuring, silk structures were analysed by ATR-FTIR. A clear shift in the amide I peak position [6] confirmed the partial structural conversion/solidification of the silk solution (fig. 2). A methanol wash of the structured silk resulted in a full conversion of native silk to cocoon-like structure.

Figure 2: ATR-FTIR spectra of native silk conversion under laser illumination

## CONCLUSION

The innovative results of this study indicate that native silk conversion can be achieved by laser light illumination. Complex structure were fabricated by laser structuring techniques for various biomedical and tissue engineering application.

## INTRODUCTION

Non-spherical microparticles, as for example micro-cylinders, have presented interesting features such as a high surface area to volume, sustainable drug release<sup>[1]</sup>, reduced immune clearance<sup>[2]</sup> and good internalization by cells<sup>[3]</sup>, making them suitable for drug delivery and tissue engineering applications. Such structures can be developed using physical processes such as lithography, stretching techniques and cryo-sectioning of microfibers or chemical-based strategies. Compared to the other approaches, the chemical-based strategies present the advantages as a lower cost, more mild conditions and a better control of the properties present in the final product. A promising chemical approach to produce micro-cylinders is aminolysis, by which an amine reagent reacts with the polymeric material, e.g. polymeric microfibers, resulting in their controlled sectioning<sup>[4]</sup>. More importantly primary amine groups are attached to its surface, leading to an increase in hydrophilicity and serving as linking points to the immobilization of different compounds.

The aim of this work is to produce micro-cylinders that present a high porosity, surface area to volume and are functionalized with reactive amine groups at their surface. In order to achieve such goal electrospun Poly(L-lactic acid) (PLLA) microfibers were subjected to an aminolysis process.

## EXPERIMENTAL METHODS

PLLA fibers were prepared by dissolving the polymer in different solvents; hexafluoro-2-propanol (HFIP), a dichloromethane (DCM)/chloroform mixture or a dichloromethane/water emulsion and subjected to electrospinning. Micro-cylinders were prepared by an aminolysis procedure, using a 5% ethylenediamine solution, and further characterized by Scanning Electron Microscopy (SEM), X-Ray Diffraction (XRD), Fourier Transform Infrared Spectroscopy (FT-IR), nitrogen adsorption BET method, Differential Scanning Calorimetry and Thermogravimetric Analysis (DSC-TGA) techniques. Primary amines present in the micro-cylinders were quantified by a TNBS (2,4,6-trinitrobenzene sulfonic acid) colorimetric assay. Statistical evaluation of the results was performed using two-way analysis of variance (ANOVA) significance test.

## RESULTS AND DISCUSSION

Morphological evaluation has shown that the use of HFIP generated fibers with a smooth surface while the use of DCM as a solvent lead to the formation of porous fibers after electrospinning (Fig 1a and b). Porosity of the fibers increased by using a DCM and water emulsion (Fig 1c).

After aminolysis the porous morphology of the different materials was maintained (Fig 1d, e and f). Micro-cylinders with different dimensions were obtained, being their length dependant of the time of aminolysis.

The results obtained from the morphological evaluation and XRD analysis show that aminolysis lead to the sectioning of the fibers and that such process occurs mainly in their amorphous regions, resulting in the maintenance of the more crystalline domains in the final product.

Quantification of primary amines detected the presence of such groups in the samples subjected to aminolysis, being their amount proportional to the time of aminolysis.

**Fig 1** Electrospun fibers prepared with a) HFIP b) DCM/Chloroform c) DCM+H<sub>2</sub>O. Microcylinders after 3 hours of aminolysis (d; e and f).

## CONCLUSION

The results obtained suggest that the structural and morphological properties of PLLA electrospun fibers can be modified using different solvents. Micro-cylinders of different porosity and lengths were obtained by tuning the aminolysis treatment conditions. Primary amines immobilization was achieved, enabling the functionalization of these structures with compounds relevant for biomedical applications.

## INTRODUCTION

The usage of laser 3d printers is very perspective in fabrication of solid and porous implants from various polymers, metals and its alloys. The Selective Laser Melting (SLM) process, where consolidated powders are fully melted on each layer, gives possibility of fabrication structures with interconnected pores like scaffolds for bone tissue engineering basing on CAD model. During SLM fabrication on 3d printer, depending on used system, there is possibility for setting amount of energy density [ $\text{J}/\text{mm}^3$ ] transferred to the consolidated powders thus controlling contact angle and roughness of created implants surface. In this study, we are controlling energy density delivered to titanium powder by setting various laser power, exposure time and exposure point distance. This study allowed us to determine the optimal laser parameters for cell proliferation on CP titanium alloy substrates.

## EXPERIMENTAL METHODS

The sets of disks with dimensions of 12 mm diameter and 2 mm thickness were fabricated from CP titanium powder on Realizer SLM50 3d printer. The average size of titanium powder was  $40\text{ }\mu\text{m}$ . The energy density used for powder consolidation was in range from 4 to  $45\text{ J}/\text{mm}^3$ . The energy density values were changed by laser power, exposure time and point distance in range 1000-1800 mA, 20-80  $\mu\text{s}$  and 20-60  $\mu\text{m}$  respectively. The selectively laser melted disks morphology was observed using Scanning Electron Microscope (Hitachi SU8000). The surface roughness was measured using optical profilometer (Wyko NT9300), contact angle was measured using Contact Angle System OCA, the Archimedes method and Radwag XA 110 were used for theoretical density calculations. The proliferation of human mesenchymal stem cells (hMSC, Lonza, passage 4) on discs fabricated with various parameters was evaluated by means of MTS assay after 24h and 7 days of culture.

## RESULTS AND DISCUSSION

The cells proliferation after one-day incubation was similar for all samples irrespectively from parameters used during fabrication. The differences in cells proliferation were clearly seen after 7 days incubation (Fig. 1). We have observed that growing energy density from 4 to  $23\text{ J}/\text{mm}^3$  had positive influence on cell proliferation. Higher values of energy density, delivered for powder consolidation, than  $23\text{ J}/\text{mm}^3$  caused proliferation decrease. The cells proliferation had the lowest value for samples with fully hydrophilic or close to hydrophobic surface. There was not found Ra parameter influence on samples cell adhesion. Samples Ra parameter was in range from  $6.2$  to  $37\text{ }\mu\text{m}$  and there

was no direct connection between Ra parameter and cell proliferation. In our study we report also that hydrofluoric (HF) acid treatment, positive for unmelted titanium particles removal, had negative influence on cell proliferation on fabricated samples. The titanium surface treatment with hydrofluoric acid concentration from 1 to 5% decreased cell proliferation more than 50% in comparison to untreated surfaces.

Fig. 1. The Energy density [ $\text{J}/\text{mm}^3$ ] and HF treatment influence on cells proliferation on selectively laser melted CP titanium implants.

## CONCLUSION

The cell proliferation on titanium implants fabricated by laser 3d printer can be controlled by amount of delivered energy density [ $\text{J}/\text{mm}^3$ ]. The energy density should be set carefully by various laser work parameters (laser power, exposure time, point distance) to avoid obtaining a fully hydrophilic or hydrophobic surface. Unmelted fully particles should be removed in as low as possible hydrofluoric acid concentrations to avoid cell proliferation decrease.

## INTRODUCTION

Therapeutic proteins have a high potential for pharmaceutical applications. Drug delivery systems are needed to protect these proteins from *in-vivo* degradation. Furthermore, the proteins can induce unwanted side effects, e.g. an immunogenic response. A local administration close to the diseased area and a slow drug release can minimize these effects. Hydrogels are well suited as drug delivery systems. To investigate the relation between network structure and release hydroxyethyl starch modified with polyethylene glycol-methacrylate was used to obtain bulk hydrogels or injectable hydrogel microspheres.

**Figure 1:** Hydroxyethylstarch derivatives can be used to prepare bulk hydrogels or injectable hydrogel micro-particles

## EXPERIMENTAL METHODS

Hydroxyethylstarch was modified with polymerizable methacrylate groups via ester or carbonate linkers, respectively (see Figure 1), and with different degrees of substitution.<sup>1</sup> These prepolymers can be cross-linked as aqueous solutions in the presence of proteins using photoinitiators and encapsulate proteins with high efficiency. By a water-in-water emulsion technique microgels are accessible.<sup>1</sup> Several model proteins e.g. green fluorescent protein (GFP), but also antibody fragments have been incorporated. The release and mobility of the proteins was studied. Furthermore, nanogel suspensions were prepared by ionotropic gelation of chitosan with a degree of deacetylation of 58% with tripolyphosphate in the presence of bone morphogenetic protein 2 (BMP-2). The suspensions were used to coat implants. The coatings were investigated *in-vitro* and *in-vivo*.

## RESULTS AND DISCUSSION

Green fluorescent protein (GFP) loaded hydrogels have been analyzed by fluorescence methods with two-photon excitation.<sup>2</sup> Via fluorescence anisotropy the inner rotational motions can be studied. The results suggest an unrestricted GFP rotation within the hydrogel (see Figure 2).<sup>2</sup> Fluorescence recovery after photo-bleaching gives information about the

translational diffusion. Here the data indicate that translational mobility of GFP is strongly restricted in the hydrogel.<sup>2</sup>

**Figure 2:** Decay of the fluorescence anisotropy of eGFP in solutions and hydrogels prepared with HES-P(EG)<sub>6</sub>MA<sup>2</sup>

The release of the proteins was investigated and correlated with the mesh size.<sup>1</sup> These *in-vitro* results were compared with *in-vivo* release experiments carried out with an *in vivo* imaging system (IVIS 200).<sup>3</sup> Entrapment of BMP-2 in chitosan and tripolyphosphate nanogels was highly efficient. Release is slow and depends on the degradation of the nanogel. The BMP-2 released from the nanogel shows biological activity *in-vitro* and *in-vivo*.<sup>4</sup>

## CONCLUSION

Hydrogels prepared from hydroxyethylstarch derivatives and chitosan/tripolyphosphate nanogels are systems well suited for the delivery of therapeutic proteins. The release can be adjusted by the crosslinking density and the degradability of the hydrogel as well as the interaction of the proteins with the polymer forming the hydrogel.

## INTRODUCTION

The potential of affinity binding peptide functionalized dendrimers to modulate the release and availability of growth factors important for musculoskeletal regeneration therapies, in combination with thermoresponsive hyaluronan hydrogels was assessed. Dendrimers were synthesized and characterized by HPLC, LC-MS and NMR. The BMP-2 and TGF- $\beta$ 1 released from injectable hydrogels were measured by ELISA assay in the presence and the absence of orthogonally synthesized dendrimers bearing BMP-2 or TGF- $\beta$ 1 affinity binding peptides.

## EXPERIMENTAL METHODS

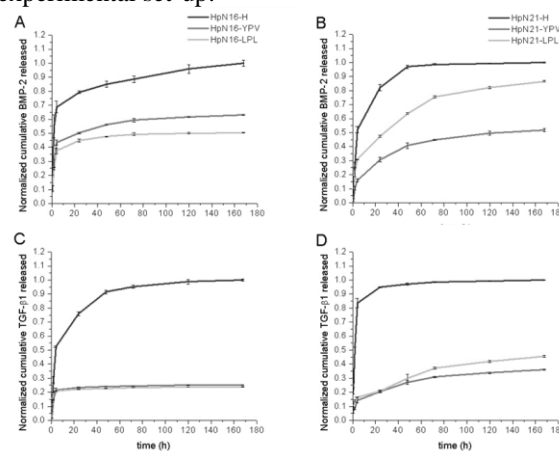

Thermoresponsive hyaluronan conjugates (HpN) were synthesized as reported with thermoresponsive segments, poly(*N*-isopropylacrylamide) (pN) of Mw equal to 16 and 21 kDa, and an identical degree of substitution 4.4 molar % measured by <sup>1</sup>H NMR [1]. Dendrimers bearing BMP-2 or TGF- $\beta$ 1 binding epitopes, YPV and LPL respectively, were synthesised, characterized and grafted onto hyaluronan as assessed by amino-acid analysis<sup>1</sup>. The purified and lyophilized polymers were reconstituted in PBS to 15% wt/vol (13% wt/vol Hyal-pN and 2% wt/vol dendrimer modified hyaluronic acid).

*In vitro* release studies of loaded hydrogels were quantified by ELISA. Statistical significance was calculated with a mixed design analysis of variance (ANOVA) model.

## RESULTS AND DISCUSSION

The dendrimers combined with poly(*N*-isopropylacrylamide) hyaluronan (HpN) conjugates do not significantly influence their gelation temperature 28°C  $\pm$  0.5°C and 30°C  $\pm$  0.5°C and elastic modulus at 37°C, 0.4 and 2 kPa respectively for HpN16 and HpN21 with and without dendrimers. In physiological mimicking conditions, the compositions loaded with either BMP-2 or TGF- $\beta$ 1 show that in the presence of dendrimers a statistically significant lower amount ( $p < 0.0005$ ) of BMP-2 and TGF- $\beta$ 1 is released (Figure 1). The peptide bearing dendrimers attenuate the protein release from HpN depots, causing a sharp decrease in the burst phase as well as a lower final concentration at 7 days. The specificity of the synthesized peptide epitopes was also performed by loading BMP-2 into depots containing TGF- $\beta$ 1 binding hyaluronan, and vice

versa. Interestingly in all scenarios, the dendrimers are at least similarly efficacious in retaining growth factors suggesting that the binding behavior of these peptides are not specific to BMP-2 and TGF- $\beta$ 1 in our experimental set-up.

**Figure 1.** Normalized cumulative protein release from loaded hydrogels showing the relative amounts of BMP-2 released from (A) HpN16 and (B) HpN21, and TGF- $\beta$ 1 released from (C) HpN16 and (D) HpN21.

## CONCLUSION

We have designed, developed and characterized unique nanoscale tools called dendrimers which have been augmented with terminal peptide binding sequences. We found that the peptide binding dendrimers attenuate the release of the GFs, but their binding was non-specific to either tested epitope. This study highlights the potential of incorporating these unique nanotools into a biomaterial platform with the goal to control the scaffold functionality with nanoscale precision.

### INTRODUCTION

The clinical use of glucagon like peptide-1 (GLP-1) is in the pipeline of type 2 diabetes Mellitus (T2DM) therapy. It acts in a glucose-dependent way stimulating insulin production [2]. Nevertheless, GLP-1 has to be administrated by parenteral route which is not well accepted by patients [3]. To achieve an efficient oral release and permeability of active GLP-1, GLP-1 was loaded into different nanoparticles (NPs).

### EXPERIMENTAL METHODS

Poly(lactic-co-glycolic acid) (PLGA) and porous silicon (PSi) NPs were prepared and coated with chitosan [3]. Cell-penetrating peptide conjugation was made using EDC/NHS chemistry. Afterwards, GLP-1 loaded NPs were coated with a pH-sensitive polymer HPMCAS-MF and loaded with DPP4 inhibitor using a microfluidics technique. The system was then characterized.

### RESULTS AND DISCUSSION

The particles presented a regular and round shape with the maintenance of their integrity at pH below 6.0 (gastric conditions). When the pH increased (small intestine conditions), the polymer degraded, and the NPs were released (Fig. 1).

**Fig. 1.** SEM images of the enteric-coated NPs in different pH conditions.

The *in vitro* release profiles of GLP-1 from the nanosystems were evaluated at pH 1.2 to mimic the gastric conditions and in fasted state simulated intestinal fluid (FaSSiF) (pH 6.8) to mimic the intestinal conditions. The release profiles showed that the enteric coating was successful, protecting the release of GLP-1 in acidic conditions, while in FaSSiF it reached 40% release after 6 h.

The cell viability studies showed that all nanosystems were compatible with the gastric AGS cells for 3 h and

with the intestinal cell lines HT29-MTX and Caco-2 for 12 h, presenting viability higher than 80% (results not shown). The interaction between the NPs and the intestinal co-culture cells showed that there was a clear increase in the interaction between the modified NPs with the cells, compared to the control and to the unmodified NPs.

The activity results of DPP4 enzyme after the contact with the inhibitor showed that its activity is extremely lower in comparison with cells without any contact with the inhibitor.

### CONCLUSION

A multisystem was developed using a microfluidic technique using modified NPs as a nanomatrix. These systems were sensitive to different pH, protecting the release of GLP-1 at low pH. They showed to be viable systems to interact in a closer way with intestinal cells and allow the co-delivery of two drugs in a single formulation. The very low activity of DPP4 enzyme is expected to prolong GLP-1's half-life, thus decreasing the blood glucose levels for a long time.

### INTRODUCTION

Injectable, self-setting calcium phosphate cements (CPCs) have been developed as synthetic bone substitutes in view of their similarity to the mineral component of bone. CPCs that maintain a high local concentration of drug would represent ideal therapeutic strategies<sup>1</sup> after tumor resection. During the last decade, nanotechnology has emerged as an additional tool to improve the efficacy of drug delivery for cancer therapies. Iafisco et al. (2012)<sup>2</sup> recently developed hydroxyapatite nanoparticles for local delivery of two chemotherapeutic platinum-bisphosphonate complexes<sup>3,4</sup>: (bis-{ethylenediamineplatinum(II)}-2-amino-1-hydroxyethane-1,1-diyl-bisphosphonate and bis-{ethylenediamineplatinum(II)}-medronate (Fig.1). Both complexes were developed to target traditional cisplatin-based drugs to bone tissue. The presence of bisphosphonate ligands allowed for efficient loading of these complexes onto hydroxyapatite nanoparticles. The results revealed a high loading capacity of hydroxyapatite nanoparticles for the complexes, while the release of chemotherapeutically active Pt was shown to proceed in a sustained manner. Nevertheless, drug-loaded nanoparticles cannot be injected directly into bone defects, due to the risk of excessive leakage of nanoparticles into the surrounding tissues.

**Fig.1:** Sketches of Complex A: bis-{ethylenediamineplatinum(II)}-2-amino-1-hydroxyethane-1,1-diyl-bisphosphonate and Complex B: bis-{ethylenediamineplatinum(II)}-medronate

Herein, we present a novel method to confine drug-loaded hydroxyapatite nanoparticles inside apatitic CPCs in an attempt to develop CPCs with a sustained chemotherapeutic efficacy.

### EXPERIMENTAL METHODS

Hydroxyapatite nanoparticles loaded with platinum-bisphosphonate complexes were added to the cement powder phase at different amounts ranging from 5–20wt% (Table 1). The morphology and crystal phases of the drug-loaded cements were studied using Scanning Electron Microscopy and X-Ray Diffraction, respectively. The release profiles of the complexes were investigated *in vitro* by soaking drug-loaded cements

into phosphate buffered saline (PBS) followed by quantification of Ca and Pt release for up to four weeks using Inductively Coupled Plasma-Optical Emission Spectroscopy (ICP-OES).

Abbreviations	$\alpha$ -TCP (wt%)	PLGA (wt%)	HA (wt%)
CPC1	55	40	5
CPC2	55	40	5 (+Complex)
CPC3	50	40	10 (+Complex)
CPC4	40	40	20 (+Complex)
CPC5	40	40	20
CPC6	95	-	5 (+Complex)
CPC7	80	-	20 (+Complex)
CPC8	95	-	5

**Table 1:** Abbreviations and compositions the various CPCs

### RESULTS AND DISCUSSION

ICP-OES results revealed that release of  $\text{Ca}^{2+}$  from all CPCs increased with incubation time, while Pt release increased with increasing the amount of drug-loaded HA NPs in CPC; however, the type of complex had a more significant effect (Fig.2). Furthermore, it was observed that incorporation of PLGA MPs into CPCs did not affect the release rate of Pt.

**Fig.2:** Cumulative release of Pt as a function of soaking time in Hepes buffer

### CONCLUSION

This study demonstrated that platinum-bisphosphonate complexes can be released in a sustained manner at rates which can be controlled by varying the hydroxyapatite-binding affinity of the complexes as well as the amount of drug-loaded hydroxyapatite nanoparticles.

### INTRODUCTION

Injuries to spatially-ordered tissues in the musculoskeletal system present unique challenges to the field of tissue engineering. The osteotendinous interface connects tendon to bone via a complex insertional zone. The inability to regenerate this interface after injury leads to poor healing and high re-failure rates. A long-term objective in our lab is to develop biomaterials that address current barriers to osteotendinous regeneration. Our efforts concentrate on collagen biomaterials to direct mesenchymal stem cell (MSC) differentiation down multiple osteotendinous lineages in a spatially-selective manner. Such a construct could be seeded with the patient's own stem cells then implanted to regenerate the interface. Here we describe a model collagen-GAG (CG) scaffold containing gradients of mineral content and structural alignment can locally modulate how MSCs respond to cyclic strain using an in vitro bioreactor. Further, given the mechanical strength of the scaffold is a critical design requirement for preclinical testing, we report the use of 3D printing to generate fiber-reinforced CG constructs to better balance strength and bioactivity requirements.

### EXPERIMENTAL METHODS

**Scaffold fabrication.** Single and multi-compartment scaffolds were fabricated from CaP-mineralized (CGCaP) and non-mineralized (CG) collagen suspensions via lyophilization. Directional solidification was used to create geometrically anisotropic scaffold.<sup>1</sup> ABS fibers (straight, 1 mm sinusoidal amplitude, 2 mm sinusoidal amplitude) were printed using a MakerBot Replicator 2X (MakerBot Industries, Brooklyn, NY). ABS fiber-reinforced scaffolds were created by embedding fiber variants into liquid CG suspensions prior to lyophilization. ABS fiber-reinforced scaffolds were characterized via mechanical tensile testing.

**Assessing bioactivity.** Scaffolds were subjected to strain by immobilization into plastic end blocks that were subsequently loaded into a custom built bioreactor. Scaffolds were then seeded with hMSCs and subsequently subjected to various levels of cyclic strain for up to 72 hours. Western blot, RT-PCR, ELISA, and histological analysis were used to evaluate hMSC differentiation and activity.

### RESULTS AND DISCUSSION

Uniaxial stretching of hMSC seeded scaffolds shows an immediate down-regulation in ROCK1 expression as well as a time-dependent relationship between the activation of ERK 1/2 and p38 MAP kinases. ERK 1/2, linked to cyclic strain-induced collagen production, is maximally activated within 10 minutes of strain, then decreases with activation of p38 MAPK by 30 minutes of strain. Short-term stretching was sufficient to induce

**Fig. 1.** (A) Model osteotendinous scaffold with integrated mineral (top) and aligned (bottom) zones. (B) 24-well tensile bioreactor. (C) Time-dependent ERK1/2 and p38 MAPK activation with 10% cyclic strain.

compartment specific mechanotransduction and integrin subunit ( $\beta 1$ ,  $\beta 3$ ) expression profiles. Increased expression of osteogenic genes (BSP, OCN) is seen in the mineralized compartment while expression of COL1 and the tendon marker SCX in the aligned non-mineral compartment is upregulated with the addition of strain.

The elastic modulus ( $\sim 70$ -fold;  $15.05 \pm 1.73$  MPa) and toughness ( $\sim 55$ -fold) of fiber-reinforced scaffolds increased significantly versus non-reinforced scaffold controls. Further, covalent immobilization of PDGF to the ABS fibers led to significant increase in cell viability within the fiber-scaffold composite.

**Fig. 2.** (A) Schematic of fiber reinforcement. (B) Stress-strain curves for fiber-reinforced scaffolds vs. control scaffold.

### CONCLUSION

We describe the use of uniaxial cyclic strain to elicit spatially and strain-dependent hMSC responses (activation and osteotendinous lineage specification) within a model CG scaffolds for osteotendinous repair. We report use of 3D printing to create scaffold-fiber composites with enhanced mechanical properties as well as the use of the fiber to present growth factors (PDGF) to enhance cell activity within the composite.

### INTRODUCTION

In this work, interconnected porous scaffolds have been obtained by an innovative foaming method based on the combination of both physical and chemical foaming stabilization. [1]. Microwaving curing allows the foam formation, employing short reaction times [2]. Current efforts are focused on improving the bioactivity and biological properties of cellulose scaffolds through the incorporation of bioceramics such as hydroxyapatite (HA). Here, we have used a facile biomimetic treatment with the aim to improve the bioactivity and biological properties on scaffold surface.

### EXPERIMENTAL METHODS

Different mixtures of sodium salt of carboxymethylcellulose (CMCNa) and polyethylene glycol diacrylate (PEGDA) were cured in a laboratory microwave oven into silicone vessels. Azobis(2-methylpropionamide) dihydrochloride was used as thermoinitiator (TI). CMCNa and PEGDA mixtures were prepared with different PEG/CMCNa ratios in order to investigate the effect of the concentration on the final material properties. The biomimetic scaffolds were obtained by treating the scaffolds with a supersaturated SBF solution (5SBF); the treatment is able to create an hydroxyapatite coating on the surface and into the porous wall in few days (7days). The rheological properties for each mixture before the curing process were evaluated by viscosity measurements (ARES Rheometric Scientific). The influence of different ratios of PEG/CMCNa in the final product was evaluated by different techniques. Firstly, chemical properties of each sample have been evaluated by spectroscopy analysis FT-IR, before and after curing in order to maximize reaction yield, and optimize the kinetic parameters (i.e. time curing, microwave power). The mechanical properties of the final product were evaluated by the calculation of the elastic modulus. Porous structure and surface analysis were characterized by SEM. Water absorption capacity and stability of materials was evaluated by means of in-vitro degradation test in PBS media. Finally, preliminary biological characterization was carried out with the aim to evaluate the effect of biomaterialization on cellular behaviour in terms of proliferation and early osteogenic differentiation.

### RESULTS AND DISCUSSION

During the foaming procedure, the solutions increased in volume at least by 100% of the initial volume after addition of Pluronic. All the foams with a lower PEG/CMCNa ratios are homogeneous and stables due

to an increased viscosity, resulting in more stable foam. Based on spectroscopy analysis FT-IR, it is evident that the reaction is not complete. Therefore it was added a post-cure in oven at 45°C for 12 h that has improved reaction yield. Mechanical properties of the foam increase by increasing the CMCNa concentration. This is mainly due to the presence of physical entanglements resulting in a higher degree of cross-linking. Fig. 1a shows the SEM image of a biomimetic foam. It is evident a hierarchical structure with open pores of different size and a presence of hydroxyapatite deposits on the scaffold surface.

The response of human mesenchymal stem cells cultured onto the cellulose scaffolds before and after biomimetic treatment showed that the materials are not cytotoxic and have good biocompatibility. The Fig.1B demonstrated a good proliferation. The potential of differentiation of hMSC cells were evaluated by expression of early marker of osteogenic differentiation like Alkaline Phosphatase (ALP) and our results showed that the hydroxyapatite deposits improve the differentiation in the early 3days of incubation evaluated by using a media without osteogenic factors. After 21 days, the majority of the areas of biomaterialized scaffolds were covered by layers of cells as demonstrated by SEM images (Fig.1B).

**Figure 1.** SEM images of biomimetic scaffold before (left) and after 21 days of hMSC cell culture (right).

### CONCLUSION

This work demonstrated that physical foaming followed by thermo-polymerization induced by microwave is a solid method to create structures with interconnected open porosity. The suitability to use a biomimetic treatment to increase the cell proliferation has been successfully evaluated. Moreover, the preliminary biological analysis demonstrated the excellent biocompatibility profile.

## INTRODUCTION

Silicones have been used in medical science for a variety of prosthetic applications, because of their unique properties, such as biocompatibility, weather resistance, low chemical reactivity, oxidation resistance and low toxicity. However, in some cases SR does not organically unite with tissues leading, in some cases, to inflammation and foreign-body reaction after long term implantation. Many attempts have been made to further improve SR's biocompatibility and bioactivity and to overcome the above drawbacks, including the incorporation of inorganic bioactive nanoparticles as a modifying additive<sup>1</sup>.

## EXPERIMENTAL METHODS

Polydimethylsiloxane (PDMS), composites reinforced with organically modified montmorillonite (OMMT: Cloisite 20A, Cloisite 30B), hydroxyapatite (HA), silica (Aerosil R972) nanoparticles and bioactive glass (Bonalive) particles were prepared using the sonication technique and subsequently characterized by differential scanning calorimetry (DSC) and thermogravimetric analysis (TGA), whereas their tensile and tear properties were also tested. An "in-vitro" assay of bioactivity was carried out by soaking PDMS hybrids in Simulated Body Fluid (SBF) at pH 7.4 for 7, 21 and 40 days<sup>2</sup>. The formation of hydroxyapatite was evaluated by FTIR-ATR spectroscopy and SEM/EDAX analysis.

## RESULTS AND DISCUSSION

The incorporation of reinforcement increases the rate of curing of PDMS, assessed by viscosity and DSC measurements, in all the examined systems. The introduction of all types of fillers used in this work, decreases the temperature of "cold" crystallization of PDMS, whereas the glass transition and melting temperatures remain intact.

The addition of Cloisite 20A to polysiloxane leads to higher increase in tensile strength compared with that of composites with bioactive glass, silica and Cloisite 30B while hydroxyapatite does not present any reinforcing effect (Table 1).

Table 1. Mechanical properties of PDMS and 5 phr loaded PDMS composites.

Material type	Tensile strength MPa	Mod. of elastic. (MPa)	Tear strength (Nt/mm)
PDMS	0.32	1.27	0.114
CI20A/PDMS	0.92	1.79	0.274
CI30B/PDMS	0.53	1.51	0.261
Silica/PDMS	0.63	1.48	0.122
HA/PDMS	0.34	1.30	0.103
BG/PDMS	0.70	1.27	0.147

The modulus of elasticity increases by the incorporation of the two types of montmorillonite as well as with silica, but remains almost stable by the addition of hydroxyapatite and bioactive glass. Resistance to tearing was increased in almost all the examined composites except those reinforced with hydroxyapatite (Table 1).

After 21 days and especially after 40 days of immersion in SBF, a large number of microparticles were detected on the surface of all the examined specimens by SEM. Using the EDAX technique, the percentage weight of Ca and P and then the molar ratio of Ca/P were calculated (Table 2). Ca and P are present at low percentage up to 21 days and their presence become significant after 40 days of immersion. Within this period of immersion, the Ca/P ratio is close to 1.67, which corresponds to hydroxyapatite. Deviations from this value were attributed to the formation of some defects during apatite growth.

Table 2. The quantitative results using EDAX analysis on the examined PDMS composites (5 phr), after 40 days immersion in SBF.

Material type	w% Ca	w% P	Ca/P
PDMS	28.14	13.6	1.60
CI20A/PDMS	30.24	14.16	1.65
CI30B/PDMS	11.17	7.34	1.18
Silica/PDMS	29.87	14.52	1.59
HA/PDMS	28.84	13.68	1.39
BG/PDMS	28.24	16.70	1.31

## CONCLUSION

The use of the appropriate type of montmorillonite (Cloisite 20A) as biomedical silicone filler might ensure high mechanical strength as well as biocompatibility similar to that provided by other bioactive fillers (hydroxyapatite and bioactive glass).

Bioactive glass (BG) is a new alternative for the modification of biomedical prosthetic silicone elastomers and despite the fact that it does not significantly improve the mechanical behaviour, seems to enhance biocompatibility of polysiloxane matrix.

## INTRODUCTION

Hydrogels-inorganic particle composites are gaining interest as materials for bone regeneration. Enrichment with inorganic particles improves hydrogels' mechanical properties and mineralizability and biological properties, e.g. bioactivity and adhesion, proliferation and differentiation of bone-forming cells, while maintaining injectability. Knowledge of the size and distribution of particles/particle agglomerates in the hydrogel is desirable. High-resolution techniques (e.g. SEM) require drying. Distribution in the dry state is not representative of the wet state. Techniques in the wet state (histology,  $\mu$ CT) are of lower resolution.

In this study, self-gelling, injectable composites of Gellan Gum (GG) hydrogel and bioactive glass (bioglass) particles were analysed in the wet state using Synchrotron X-ray radiation to determine size and spatial distribution of bioglass particles with high resolution. To our best knowledge, this is the first report on use of this technique to study hydrogel-particle composites in the biomaterials field.

## EXPERIMENTAL METHODS

Bioglass preparation S2 was produced by a sol-gel technique (1) (see Table 1 for composition). Self-gelling GG-bioglass composites (1% w/v bioglass, 0.7% w/v GG) were generated as in previous work (2). Cylindrical composite samples of height 1 cm and diameter 6 mm in 0.5 ml vessels filled with water to prevent evaporation were subjected to X-ray imaging at the Topo-Tomo beamline, ANKA light source facility, Karlsruhe Institute of Technology, Germany. From the spectrum of the bending magnet (white beam) 10 keV monochromatic X-ray beam was selected by a double multilayer monochromator. The detector system consisted of Andor Neo camera (sensor size 5.5 megapixels, 6.5  $\mu$ m pixel size), BAM microscope 3.6x and the scintillator LAG 50  $\mu$ m thickness resulting in the effective pixel size of 1.8  $\mu$ m and field of view of 10x6.7 mm. Volumes were obtained by X-ray computed tomography: 1501 projection images were taken over an angular range of 360° with an exposure time of 2 ms per projection. Dark current of the camera and reference images without sample were taken to reduce artefacts.

S2 particles were also suspended in water for zeta potential and particle size distribution measurements.

Table 1: composition of bioactive glass S2

component	SiO <sub>2</sub>	CaO	P <sub>2</sub> O <sub>5</sub>
Molar %	80	16	4

## RESULTS AND DISCUSSION

A 3D reconstruction of the GG-S2 composite is presented in Figure 1. Predominantly, homogeneously distributed agglomerations of approximate diameter 90  $\mu$ m were observed. Larger agglomerations were also seen. Analysis of particle size distribution confirmed this. The most commonly occurring agglomerates were of volume 20000  $\mu$ m<sup>3</sup>, corresponding to an approximate diameter of 90  $\mu$ m. Numerous agglomerations with approximate diameters in the range 90-240  $\mu$ m were detected. The largest agglomerations had an approximate diameter of 900  $\mu$ m. Flow cytometry revealed that the average diameter of S2 particles in solution is 1  $\mu$ m, proving that agglomeration took place. Zeta potential was -4.25 mV. Agglomeration might be caused by both particle-particle interactions and hydrophobic interactions with the negatively charged GG polymer.

Figure 1: Image showing distribution of S2 bioglass (red) in GG hydrogel based on synchrotron X-ray data.

## CONCLUSION

Synchrotron X-ray radiation is a novel and powerful tool to visualize size and spatial distribution of inorganic particles in hydrogel biomaterials. Bioglass particles aggregate upon incorporation in GG hydrogels.

## INTRODUCTION

Significant differences in degradation behaviour of similar composites made from biodegradable polymer (poly- $\alpha$ -hydroxy-acids) and calcium-based ceramic (tricalcium phosphate, hydroxyapatite) have been reported<sup>1,2</sup>. The simultaneous phenomena and the interactions of the different factors affecting the degradation are not yet fully understood. In the present study a combined computational-experimental approach is used to investigate the degradation behaviour of CaCO<sub>3</sub>-PLGA composites and gain insight into the degradation mechanisms.

## EXPERIMENTAL METHODS

### Computational model

The computational model was implemented in C++ based on an existing degradation model for TCP composites<sup>3</sup>. The model uses three sets of equations: a set of differential equations to characterize the polymer, another set for the ceramic and a third set to represent the interactions between both. The model outputs amongst other things the evolution of the average molecular weight of the polymer and the ceramic content.

### Composite material

Composites were fabricated with 50:50 molar ratio poly(D,L-lactide-co-glycolide) (trade name PLGA50:50 5E) from Lakeshore Biomaterials<sup>TM</sup>, Evonik Industries as matrix and calcium carbonate cubic particles of 80 nm and 150 nm from Shiraishi Calcium Kaisha, Ltd.

The CaCO<sub>3</sub> particles and the polymer were stirred separately in acetone. Then both mixtures were blended and stirred further. The composite mix was cast in shallow moulds. The resulting films were injection moulded into rods. The rods were cut into cylinders with a diameter of 3 mm and a height of 2 mm. Pure injection-moulded polymer was used as control for the degradation study. The degradation protocol has been previously reported in literature<sup>4</sup>.

## RESULTS AND DISCUSSION

**Figure 1:** Predicted evolution of the average matrix Mn (number-averaged molecular weight) during the degradation study.

Figure 1 depicts an example of the computational predictions. It shows a reduction in hydrolytic degradation rate due to the buffering effect of the ceramic particles and the influence of the CaCO<sub>3</sub> quantity in the reduction. These predictions agree with experimental data published in the literature<sup>5</sup>.

Figure 2 illustrates the size consistency of the CaCO<sub>3</sub> particles and figure 3 shows the good dispersion of the particles in the composite.

**Figure 2:** SEM of two sizes of CaCO<sub>3</sub> cubic particles (a) cubes of 155 nm ± 28 nm (b) cubes of 84 ± 19 nm (mean ± standard deviation).

**Figure 3:** 3D micro-CT reconstructions of a section of the injection-moulded rod.

## CONCLUSION

The use of a combined computational and experimental approach is a promising tool to gain insight into the degradation behaviour of the composites. The comparison between the predicted and the actual behaviour will highlight the depth of the actual understanding and will point new factors to be considered for the degradation process.

### INTRODUCTION

In recent years, fabrication of inorganic–organic composites mimicking the composite nature of bone has attracted research interest in the field of bone regeneration<sup>1</sup>. Over the last decade, nanosized and nanocrystalline apatite (Ap) has been of special interest to dentistry, the orthopedic industry and nanomedicine because of their excellent performance<sup>2</sup>.  $\epsilon$ -Polylysine ( $\epsilon$ -PL) is non-toxic, biodegradable, water soluble natural homopolymer with potential applications in medicine<sup>3</sup>.  $\epsilon$ -PL is a cationic surface active agent due to its positively charged amino group in water. In last decade experimental work has been done investigating the interactions of various macromolecules of acidic amino acids with hydroxyapatite<sup>4</sup>. In this study, novel bioactive nanostructured composites for bone tissue engineering were developed based on  $\epsilon$ -PL and apatite (Ap). This composite biomaterial would combine the chemical and biological functionality of  $\epsilon$ -PL and bioactivity of Ap.

### EXPERIMENTAL METHODS

Ap/ $\epsilon$ -PL containing nanostructured composites were processed by spray drying technique using slurry of *in situ* synthesized Ap in 5% (w/v)  $\epsilon$ -PL aqueous solution. *In situ* synthesis of Ap was realized by precipitation method using  $\text{Ca}^{2+}$  and  $\text{PO}_4^{3-}$  ions sources as starting reagents with molar ratio of  $\text{Ca/P} = 1.67$  in order to obtain spray-dried products containing Ap and  $\epsilon$ -PL at the 50/50 and 70/30 wt.%. The obtained slurry was spray dried by using a tabletop spray dryer with nozzle of 1.4 mm diameter at a temperature 200°C. The collected spray-dried composite powders were structurally characterized using X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FT-IR), Field emission-scanning microscopy (FE-SEM) and differential thermal analysis (DTA).

### RESULTS AND DISCUSSION

FE-SEM studies of obtained spray-dried products confirmed the formation of spherical composites with diameter in the range 2–8  $\mu\text{m}$  (Figure 1). FT-IR analysis demonstrated formation of Ca-deficient apatite which incorporates the  $\epsilon$ -PL macromolecules. The XRD

results suggested that *in situ* synthesis in  $\epsilon$ -PL produces a nanocrystalline apatite. Accordingly,  $\epsilon$ -PL influences apatite crystal nucleation and growth, allow for chemical functionalization of the inorganic phase.

Figure 1: FE-SEM micrograph of spray-dried spherical composites based on Ap/  $\epsilon$ -PL (50/50 wt.%).

### CONCLUSION

The development of bioactive nanostructured apatite and  $\epsilon$ -polylysine containing composites was done. Obtained spherical composites can be used as ideal carriers in drug delivery and bone fillers in tissue engineering.

## INTRODUCTION

Resorbable biomaterials play central roles in modern strategies for vascular tissue engineering (TE). Chitosan is a linear polysaccharide obtained industrially from deacetylation of chitin and particularly interesting for TE applications. We have shown that the physical and biological properties of chitosan physical hydrogels can be modulated by acting on chitosan concentration, acetylation degree (DA) and gelation route, inducing differential *in vivo* responses after subcutaneous implantation<sup>1</sup>. Here, these hydrogels were screened *in vitro* (direct contact of blood with chitosan, suture retention) and *in vivo* (arterial wall repair with chitosan patch) for hemocompatibility evaluation.

## EXPERIMENTAL METHODS

**Materials.** Chitosan (450,000 g/mol) was purchased from Mahtani Chitosan, purified and structurally characterized<sup>2</sup>. Hydrogels (Chitosan concentration 5%w/w and 10%w/w, Ch5% and Ch10% respectively both with 5% DA) were prepared following two physical gelation routes: the hydro-alcoholic and the aqueous routes, respectively<sup>1</sup>. Gel membranes were obtained.

***In vitro* testing.** According to standards ISO and ASTM, the following tests were performed after contact of Ch5% with human blood and in comparison with negative and positive controls: partial thromboplastin time (PTT), hemolysis, CH50 (complement consumption) and C5b-9 (final anaphylatoxin produced by both activation pathways). Suture retention (n = 3) was evaluated according to previous studies<sup>3</sup>.

***Surgical procedure.*** Procedure and animal treatment both complied with Principles of Laboratory Animal Care. Anesthetized sheep<sup>4</sup> underwent a common carotid artery exposure through a longitudinal incision in the mid neck. The arteries were cross clamped after a heparin bolus (0.5mg/kg) was administrated intravenously. A longitudinal 1 cm arteriotomy was performed on the anterior wall of the artery and then repaired with either a chitosan patch, or a polyester urethane (PU) vascular patch (control, n = 6) (B Braun, Germany). The patches were cut out from a hydrogel membrane or PU in a suitable shape and a slightly larger than the vascular wall defect then fixed with a Prolene 6/0 running suture. All surgical procedures were performed by the same 2 surgeons. Patency was assessed peroperatively and every 30 min by carotid doppler ultrasound (US) exam. Animals were sacrificed at 2h. Measurements of fibrinogen, cell counts, hematocrit and hemoglobin content were performed.

Tissues including patches were harvested for scanning electron microscopy (SEM) and histology.

## RESULTS AND DISCUSSION

***In vitro* testing:** a minimal contact activation of the intrinsic pathway of blood coagulation was observed in the presence of Ch5% (84% of negative control) and Ch 5% did not induce *in vitro* hemolysis, nor complement activation. Suture retention values were 51 and 162 gF for Ch5%, Ch10%, respectively, the latter being consistent with native vessels<sup>5</sup>. ***In vivo* testing:** the Ch5% patch (n = 3) was not strong enough to sustain the stitches and was partially lacerated by the thread. It is the reason why Ch10% was manufactured and implanted (n = 7), showing a greatly improved strength to sustain the suture. Time required to complete implantation was 25 and 7 min for chitosan and PU patches, respectively. Figure below shows fixed Ch10% *in situ* (1), Ch5% once harvested on luminal side (2), harvested control PU on external side (3) and luminal side (4).

US showed no flow obstruction inside carotids repaired by Ch5%, Ch10% or PU patches at 2h. SEM results indicated a lower fibrin deposition and platelet aggregation on Ch5% than on PU. Histology of Ch5% revealed an absence of thrombus in 2 out of 3 sheep.

## CONCLUSION

*In vitro* and *in vivo* results are promising for vascular TE. Blood flowing platelets are of great importance in inducing a thrombus, because of their immediate reaction<sup>5</sup>, they do not seem here to be activated after blood-material contact. Tube elaboration optimization as well as their endothelialization ability are ongoing.

### INTRODUCTION

Vascular calcification is a common finding in many cardiovascular diseases, such as hypertension, atherosclerosis, diabetes mellitus, chronic renal failure, prosthetic valve replacements, aortic stenosis, and aging (1). It causes decreased aortic compliance and elastic recoil, which, in severe cases, results in ischemia due to significantly impaired reverse arterial flow and organ perfusion (2). Blood vessels repair and replacement is one of the most challenging issues for biomedical research and, in particular, arterial bypass graft remains the primary surgical approach for patients with advanced cardiovascular diseases. Recently, decellularization of native tissue has gained a significant attention in vascular tissue engineering and this method is used to obtain biological scaffolds that are expected to closely mimic the complex three dimensional structure, preserving the biomechanical properties of the native tissues. After decellularization, the biological substitutes can be enriched with several molecules and be repopulated with different cell types and in order to optimize the repair, growth and remodeling *in vivo*.

Ghrelin is a 28-amino acid peptide present in two major forms: n-Octanoyl-modified Ghrelin and Des-Acyl Ghrelin (DAG). The two peptides differ for the third amino acid serine which is not acylated (3). Recently, Ghrelin role in cardiovascular functionality has been studied. Our work is focused on the effects of DAG on vascular smooth muscle cells (VSMCs) and endothelial cells (ECs). DAG has been even used for decellularized matrix enrichment and the biological effects have been studied. In particular, we focused on the role of DAG on cell proliferation, differentiation, with particular attention on the anti-calcifying effect on VSMCs.

### EXPERIMENTAL METHODS

VSMCs and ECs were isolated from porcine aorta and treated with  $10^{-7}$ M DAG. Western Blot analyses were performed in order to evaluate the expression of proliferation and differentiation cell markers (PCNA, Myogenin and eNOS). Moreover, a Real Time PCR was performed to evaluate the expression of Osteocalcin gene (BGLAP). The anticalcifying effect was also evaluated through a calcein assay on VSMCs cultured in calcifying medium with and without  $10^{-7}$ M DAG. Decellularized and enriched matrices have been characterized by XPS and FT-IR analysis. To evaluate the inflammatory response, decellularized and grafted materials were seeded with monocytes and a cytokine assay was performed. Also, materials were seeded with platelet and analyzed using scanning electron microscope. *In vivo* tests have been performed in order to evaluate the biological response of the decellularized matrices as tissue substitutes.

### RESULTS AND DISCUSSION

Western Blot analysis showed the ability of DAG in controlling VSMCs' proliferation while the expression of PCNA on ECs was not affected by DAG. VSMCs contractile phenotype was not affected by the presence of DAG while eNOS resulted up-regulated by the presence of DAG. The expression of BGLAP gene decreased in presence of DAG with respect to control. Calcein assay confirmed the results. These data show a role of DAG as anticalcifying agent on vascular cells. Decellularized enriched matrices show an excellent biocompatibility *in vitro* and *in vivo*.

Fig.1 eNOS expression is enhanced in ECs after 3 days of culture in medium with DAG  $10^{-7}$ M. ( $p < 0.05$ )

Fig. 2 A) Decellularized matrix after 28 days of intraperitoneal implant in mice B) Decellularized and enriched matrix after 28 days of intraperitoneal implant, no inflammatory response is present at the implant site.

### CONCLUSION

Our work showed that DAG has an anticalcifying effect on VSMCs and ECs.

Moreover, DAG can be grafted on a decellularized biological matrix and create innovative substitutes for vascular tissue engineering. Thus, enriched decellularized matrices may represent an excellent solution to guide tissue regeneration.

## INTRODUCTION

Nature continuously amazes the scientific world with its highly complex or straightforward solutions to a given problem. For example, mussels adhere to a wide range of surfaces (i.e. ship hulls, stones, wood and shells) independent of environmental media *via* the so-called mussel adhesion proteins (MAPs). Dopamine coatings<sup>1</sup> mimic the structure of MAPs and are capable of adhering to a variety of substrates including metals, ceramics and polymers upon incubation in aqueous alkaline media. The precise adhesion mechanism is not completely unravelled, but non-toxicity and non-inflammatory responses of dopamine-coated materials have already been reported in the literature, rendering them suitable for a vast range of applications in the biomedical field<sup>2,3</sup>.

Polyethylene terephthalate (PET) is an ideal candidate for medical use due to its good mechanical and thermal properties together with its inertness, but its poor surface properties induce poor cell-interactions and thrombus formation upon contact with blood<sup>4</sup>. In this study, we propose a straightforward biomimetic method suitable to covalently immobilize a cell-interactive protein (e.g. gelatin)<sup>5</sup> on PET for cardiovascular applications. A comparative study between these chemically and physically modified PET surfaces was initiated and preliminary haemo-compatibility and cell-interaction investigations were performed.

## EXPERIMENTAL METHODS

PET samples (0.5 cm x 2 cm, Goodfellow) were ultrasonically cleaned with disinfectol for 15 min prior to the surface modification. A dopamine-based coating procedure<sup>1</sup> (2g/L in Tris-HCl buffer, pH=8.5, 24h) was used to facilitate the subsequent covalent immobilization of gelatin type B (5 w%, GelB). In parallel with thus obtained chemically modified PET surfaces, physically modified surfaces were obtained by dip-coating procedures.

Gelatin-modified PET films were characterized in depth using static contact angle (SCA), atomic force microscopy (AFM) and X-ray photoelectron spectroscopy (XPS) combined with radiolabelling. Whole blood to assess preliminary haemocompatibility and HUVEC cells (passage 2-3) to investigate preliminary cell-biomaterial interactions were applied on all investigated samples.

## RESULTS AND DISCUSSION

The successful coating of PET was confirmed by XPS, AFM and SEM measurements. Improved homogeneity of the protein coating was observed for the chemical approach and the coating stability was investigated by an I<sup>125</sup> radiolabelling technique. Clear differences were observed after only 72 hours incubation (in PBS, at 37 °C), with remaining labelled protein amounts of 19 ng/mm<sup>2</sup> and 120 ng/mm<sup>2</sup> for physical and chemical immobilization respectively. Interestingly, minimal platelet activation was observed for chemically modified PET, while HUVEC cell adhesion tests demonstrated the importance of a stable coating (see Figure 1).

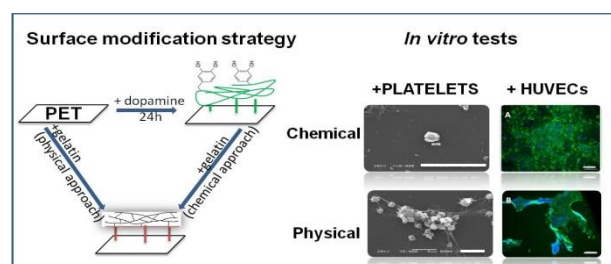

Figure 1. Overview of the surface modification strategy (left) and *in vitro* testing *via* platelet adhesion and HUVEC cell adhesion (right). The scale bars are 5  $\mu$ m for platelet images and 100  $\mu$ m for HUVEC immunostaining images. A clear delamination process can be observed for the latter.

## CONCLUSION

Stability and toxicity issues were avoided by using a 100 % organic solvent-free method inspired from nature in order to surface modify PET for cardiovascular applications. The importance of a covalent coating was shown to play an essential role in both haemo- and biocompatibility.

[p.basnett@my.westminster.ac.uk](mailto:p.basnett@my.westminster.ac.uk)

**INTRODUCTION:** An ideal tissue engineering scaffold (TES) is considered to have a (i) three dimensional, porous, inter-connected structure which facilitates cell growth, (ii) have biocompatibility and biodegradability properties that mimic the cell properties and (iii) possess surface topography that enhance cell attachment and proliferation<sup>1</sup>. Polymer fibres due to their high surface area have emerged as a new class of biomaterials for tissue engineering applications. In this project, we have used the pressurized gyration process (PGP) to produce polyhydroxyalkanoate (PHA) fibres. It is a robust, reliable, cost-effective and a novel method that produces fibres of desired properties<sup>2</sup>. PHA, which is the chosen polymer for this study, are hydrophobic storage polymers that are polyesters of 3-, 4-, 5- and 6-hydroxyalkanoic acids produced by bacterial species under nutrient-limiting conditions. They are biodegradable, biocompatible and exhibit thermoplastic properties<sup>3</sup>. In this study, we have focused on the production of PHAs, synthesis of random and aligned porous PHA fibres using PGP and their evaluation as TES.

**EXPERIMENTAL METHODS:** Production and characterisation of PHAs: PHAs were produced by bacterial fermentation of *Cupriavidus necator* in bioreactors using edible oil as a sole carbon source. The PHA produced was extracted, purified and characterised using Gas chromatography-Mass Spectrometry (GC-MS) and Nuclear magnetic Resonance (NMR). Synthesis and characterisation of PHA fibres: Purified PHA was used to generate fibres using PGP as described in Fig1.

**Figure 1:** Experimental set up of the pressurized gyration process. PHA fibres were viewed under the scanning electron microscope (SEM) to determine their size. In vitro biocompatibility studies: Human microvascular endothelial cells (HMEC-1) were seeded on to these fibres for 1, 3 and 7 days. Cell viability studies were carried out using MTT assay. Confocal imaging as well as the SEM was done after the Live versus Dead assay. These experiments were also carried out on the 5wt% PHA films for comparative study.

**RESULTS AND DISCUSSION:** Production and characterisation of the PHA produced: PHA was successfully produced, extracted and purified. GC-MS and NMR results confirmed that the PHA produced was poly(3-hydroxybutyrate) or P(3HB). Synthesis and characterisation of PHA fibres: P(3HB) fibres, both random and aligned were successfully synthesized

using PGP as shown in Fig 2. SEM images revealed interconnected porous fibres of  $9 \pm 2.6 \mu\text{m}$  and  $3.0 \pm 0.8 \mu\text{m}$  width for random and aligned fibres respectively.

**Figure 2:** SEM images of the (a) Aligned P(3HB) fibres (b) random P(3HB) fibres (c) P(3HB) film.

Cell proliferation studies: Results of these studies have been summarised in Fig 3. Cell attachment and proliferation was found to be the highest on the aligned fibres compared to the random fibres, the P(3HB) film and tissue culture plastic which was used as the positive control.

**Figure 3:** Cell proliferation study on P(3HB) fibres and film samples.

Live Vs Dead staining: Confocal images revealed that cells were alive at the end of the 7<sup>th</sup> day of incubation in both random and aligned fibres. However, the HMEC-1 cells on the aligned fibres grew in an aligned fashion.

SEM: SEM images further confirmed that the HMEC-1 cells attached, proliferated and grew in an aligned manner in contrast to that on the random fibres and the film as shown in Fig 4.

**Figure 4:** SEM images of HMEC-1 cells on (a) aligned fibres and (b) random fibres and (c) P(3HB) film.

**CONCLUSION:** Cell adhesion, proliferation and alignment were significantly higher on aligned fibres and hence, proved to be an ideal biomaterial for TE applications.

### INTRODUCTION

For the treatment of pulmonary air leaks and anastomotic sites between living tissues, surgical sealants have been widely used in clinical field. Fibrin sealant is a typical sealant which consists of human blood components and has excellent biocompatibility and versatile, however, it does not possess sufficient sealing effect because of its low interfacial bonding strength to tissues. Therefore, the molecular design of a tissue sealant is required for the sealant to adhere onto a living tissue and organs under wet environment during surgery. In our previous study, we have shown that tissue adhesives containing hydrophobically modified porcine-derived gelatins showed excellent bonding strength onto fresh vascular media compared with non-modified gelatin<sup>1,2</sup>. However, porcine-derived gelatin solution with high concentration has low fluidity at room temperature because of its high contents of imino acids and is required heat treatment before using sealant.

In this study, we have chosen cod-derived gelatins (cGltN) instead of porcine-derived gelatin as a base material for surgical sealants because it has low transition temperature due to its low contents of imino acids. We synthesized various hydrophobically modified cGltNs (Hm-cGltN) with different hydrophobic groups and introduction ratios and evaluated their sealing effects on wet tissues by combining Hm-cGltNs with polyethylene glycol-based 4-armed crosslinker (4S-PEG)<sup>3</sup>.

### EXPERIMENTAL METHODS

Modification of cGltN with hydrophobic groups was carried out by nucleophilic substitution reaction of the amino group with fatty acid chlorides (Hydrocarbon chain length : C3~18) in dimethyl sulfoxide. Modification ratio of hydrophobic groups was calculated by determination of residual amino group using trinitrobenzensulfonic acid. The measurement of burst strength for the porcine blood vessel was performed according to the method reported as ASTM (F2392-04). As shown in Figure 1, the sealant composed of Hm-cGltNs and 4S-PEG was fixed diameter and thickness. The burst strength was then measured by running a saline from the lower portion of the tissue at a flow rate of 2 ml/min at 37 °C.

Sealing effects for lung tissues were also evaluated by using rat lungs. The test sample was prepared by sealing on the air leak of a rat lung wound. Air leak pressures of Hm-cGltN-based sealants for rat lungs were measured by flowing air from the trachea at a flow rate of 1 ml/s.

Biodegradability of Hm-cGltN based sealants was observed by implanting in subcutaneous tissues of mice.

### RESULTS AND DISCUSSION

Hm-cGltNs were successfully synthesized by the method as we reported previously<sup>1,2</sup>. Propanoyl chloride (Pro:C3) and Hexanoyl chloride (Hx:C6), Lauroyl chloride (Lau:C12), Stearoyl chloride (Ste:C18) were used as fatty acid chlorides. By changing initial concentrations of fatty acid chlorides, each Hm-cGltN with three different modification ratios of hydrophobic groups was obtained.

The burst strengths of all Hm-cGltN-based sealants against blood vessel were higher than that of original cGltN (Org-cGltN)-based sealant. Highest burst strength of Hm-cGltN-based sealant was 10-fold higher than that of fibrin sealant and 3-fold higher than that of Org-cGltN-based sealant. This result indicated that the introduction of hydrophobic groups effectively enhanced the tissue penetration of sealants and, increased the interfacial strength between tissue and sealant. Furthermore, the burst strengths of Lau and Ste-cGltN-based sealant were higher than those of Pro and Hx-cGltN-based sealant. This result indicated that the bulk strength as well as interfacial bonding strength of sealants significantly affects the burst strength.

From the measurement of sealing effects of sealants against rat lungs, the burst strength of 9.6Ste-cGltN-based sealant was 2.1-fold higher than that of fibrin sealant and 1.6-fold higher than that of Org-cGltN-based sealant.

After subcutaneous implantation of sealants, 9.6Ste-cGltN-based sealant was completely degraded within 8 weeks. Cell infiltrations into 9.6Ste-cGltN-based sealants were also observed after 4 weeks.

### CONCLUSION

We developed surgical sealant which has a high interfacial strength by combining Hm-cGltN with 4S-PEG. Hm-cGltN-based sealant was completely degraded within 8 weeks in subcutaneous tissues. Therefore, our sealants can be applied in the field of thoracic surgery as well as cardiovascular surgery.

<sup>2</sup>Material Engineering Department (ME Dept.), Warsaw University of Technology (WTU), Poland  
[gosiag@frk.pl](mailto:gosiag@frk.pl)

## INTRODUCTION

The innovative implantable ventricular assist device, rotary blood pump called ReligaHeart ROT, has been developed in Poland<sup>1,2</sup>. An appropriate titanium surface engineering has to be developed, to reduce shear stress induced platelet activation on blood contacting pump elements.

The athrombogenic diffusive TiN layers have been applied for blood pump's house and rotor. The innovative process of plasma glow discharge technology and detail appropriate surface structure and topography has been developed and confirmed in laboratory testing<sup>3</sup>. The haemolytic properties as well as platelets activation and adhesion in the blood after contact with diffusive layers were analyzed in vitro, at high shear stress conditions.

## EXPERIMENTAL METHODS

The titanium nitride layers were formed in ME Dept. WTU (Warsaw, Poland). Different diffusive layers: TiN+Ti<sub>2</sub>N+αTi(N) and TiO<sub>2</sub>+TiN+Ti<sub>2</sub>N+αTi(N) were formed in plasma space within glow discharge on titanium samples. The process parameters were as following: temperature - 830°C (TiN) and 650°C (TiO<sub>2</sub>), treating time - 6 h, pressure - 2,5hPa (TiN) and 1,6hPa (TiO<sub>2</sub>). Titanium samples were polished before nitriding process to obtain different roughness: Ra=0,63μm, 0,16μm and 0,08μm.

The microstructure of diffusive layers was analyzed utilizing electron scanning microscopes, surface topography and morphology were analyzed using AFM microscope and optical scanning profile meter, wear resistance was examined in compliance with PN-83/H-04302 and tribological properties - PN-EN ISO 145771. Examinations were completed by ME Dept. WTU team. The special physical model, to evaluate the diffusive layers thrombogenic and hemolytic properties, was developed in AH Lab FCSD (Zabrze, Poland). The chamber with rotating biomaterial disk simulates the rotary pump rotor moving in close distance (0,05 to 0,3mm) to pump house wall. The shear stress exposed thrombocytes activity was determined in the dynamic conditions of different rotor-pump wall distance and disk rotation speed, under controlled blood flow through the chamber (1 to 15ml/min).

## RESULTS AND DISCUSSION

Tribological and mechanical tests showed that surface roughness and stoichiometric TiN presence are very important factors increasing material properties. TiN+Ti<sub>2</sub>N+αTi(N) layer formed in plasma space with the thicker TiN+Ti<sub>2</sub>N area has the best mechanical and tribological properties.

Surface topography of diffusive layers formed in

plasma space within glow discharge on titanium samples is more homogenous than surface of diffusive layers formed in cathode's potential. The best surface properties was achieved for layers produced on titanium polished at Ra level 0,08μm.

The experiments performed with fresh blood have confirmed the proper haemolytic properties of all examined diffusive layers. All tested diffusive layers have caused similar level of platelet aggregates on the biomaterial surface after contact with fresh blood under dynamic high shear stress conditions.

Fig.1. Hemolytic properties and platelets aggregates

Ref1 and Ref2 – titanium Grade 2 with Ra=0,08μm; A008A1 – TiN layer (cathodes' potential) with Ra=0,08μm; A016A2 – TiN layer (cathodes' potential) with Ra=0,16μm; A008A2 – TiN layer (plasma potential) with Ra=0,08μm; A016A1 – TiN layer (plasma potential) with Ra=0,16μm; A063A – TiN layer (plasma potential) with Ra=0,63μm

## CONCLUSION

The thrombogenicity and hemolytic examinations results analysis demonstrated that diffusive TiN+Ti<sub>2</sub>N+αTi(N) and TiO<sub>2</sub>+TiN+Ti<sub>2</sub>N+αTi(N) layer produced on titanium surface does not cause erythrocytes damage and platelets adhesion in the dynamic high shear stress conditions. Results obtained in reported research promise good properties of new developed layers for application in blood contacting elements of rotary blood pumps, where blood velocity and shear stresses are very high and increase the risk of thrombosis. The detail examinations will be done in order to choose the best diffusive layers for rotary blood elements implementation.

## INTRODUCTION

*In vivo* therapeutic potential of neurotrophic factors to modify neuronal dysfunctions is limited by their short half-life. A biomaterials-based intervention, which protects these factors and allows a controlled release, is therefore required. Fibrin as a biomaterial offers the advantage of being an autologous substrate where the rate of polymerization and degradation can be well controlled. The hypothesis of this study is to establish that template charge manipulation can lead to fabrication of hollow fibrin microspheres as a reservoir for controlled delivery of the neurotrophins *in vivo*. Specific objectives were to fabricate and characterize the fibrin based reservoir system, investigate interaction with cells, impact of neurotrophin encapsulation on its bioactivity and *in vivo* characterisation in rodent model.

## EXPERIMENTAL METHODS

Hollow fibrin microspheres were fabricated by template charge manipulation method<sup>1</sup>. The hollow microspheres were physically characterized and protein loading and release from the microspheres was demonstrated using NGF as a model neurotrophin. Impact of fibrin microspheres on rat mesenchymal stem cells (rMSCs), PC-12 and fetal ventral mesencephalon (VM) cells was shown using alamar Blue<sup>TM</sup> and live/dead assay. Bioactivity of released NGF was demonstrated by neuronal outgrowth assay in PC-12 cells followed by *in vivo* assessment for NGF release and host response. Statistical analysis was performed using two-tailed Student t-test ( $p < 0.05$ ).

## RESULTS AND DISCUSSION

Hollow fibrin spheres fabricated using the manipulation of electrostatic interactions showed high loading efficiency (>80%) with no adverse impact on cell viability. Neurotrophin encapsulation into the microspheres did not alter its bioactivity (Fig.1). Controlled release of NGF was observed from hollow fibrin spheres in the *in vivo* study (Fig. 2). The immune response obtained in response to NGF, spheres and NGF- loaded spheres was comparable.

## CONCLUSION

Fibrin hollow microspheres act as a suitable delivery platform for neurotrophic factors with tunable loading efficiency and maintaining their bioactive form after release. When tested qualitatively *in vivo*, fibrin spheres did not elicit any adverse immune response in the host and obtained a sustained release of NGF.

### INTRODUCTION

The clinical performance of artificial nerve guidance conduits (NGCs) is unsatisfying compared to the functional recovery obtained with the autologous gold standard<sup>1</sup>. With advanced bioengineered materials, topographical modifications and biochemical cues the next generation of NGCs is expected to mimic internal physiology to improve peripheral nerve repair<sup>2</sup>. Our gelatin-based conduits combine a natural, cell-adhesive polypeptide that is cross-linked by a multifunctional, tunable oligomer<sup>3,5</sup>. The composition allows for simple fabrication of artificial NGCs, adjustment of viscoelastic properties and chemical functionalization with biochemical factors or small amines that generate positively charged surfaces for improved neuronal outgrowth<sup>4</sup>.

### EXPERIMENTAL METHODS

The cross-linker oPNMAx was copolymerized from pentaerythritol diacrylate monostearate (P), N-isopropylacrylamide (N) and maleic anhydride (MA) in a molar feed ratio of P:(N+MA) = 1:(20-x)<sup>5</sup>. oPNMAx (x=7.5;10;12.5) were used to cross-link free amine functions of the collagen-hydrolyzate Collagel® (COL) (Gelita, Germany) to form a stable hydrogel network (cGEL)<sup>3</sup>. Hydrogel formation occurred when precursor solutions were mixed in presence of non-nucleophilic base (10% V/V) (triethylamine (TEA) or N-methylpiperidin-3-ol (NMPO)). The gelation step and resulting cGEL-discs were kinetically and mechanically characterized by oscillation rheology to identify suitable formulations for the fabrication of single-lumen cGEL conduits (cGEL-NGCs). A static mixing device and templating concept with tubular molds was developed to fabricate cGEL-NGCs of various lengths (≤50mm) and diameters (≤5mm). Furthermore, covalent derivatization of oPNMAx (x=7.5; 10; 12.5) in precursor solution was conducted prior to cross-linking. Predetermined equivalents of intact MA (MA<sub>eq</sub>=2.5) were amidated with N,N-diethylethylenediamine (DEED) for up to 4 h to produce a positively charged surface (cGEL<sup>+DEED</sup>). Evaluation of the derivatization was performed using established titration protocols and oscillation rheology<sup>3</sup>. Prenatal neurons from dorsal root ganglia (DRG) were used to examine neuronal outgrowth on cGEL- and cGEL<sup>+DEED</sup>-matrices.

### RESULTS AND DISCUSSION

The established gelation protocol was adopted with regard to gelation technique, base type and -concentration<sup>3</sup>. The fraction of TEA or NMPO was lowered from 10 down to 2% to promote slower gelation kinetic. This allowed for an injection-molding

technique and the reproducible fabrication of cGEL-NGCs. The tubes exhibited a high degree of flexibility, superior bending properties and elasticity. In the following step, chemical functionalization of oPNMAx was considered to promote neuronal outgrowth on cGEL<sup>+DEED</sup>-matrices. The initial coupling reaction was analyzed to quantify derivatization efficiency, constitution of MA and viscoelastic properties of resulting cGEL<sup>+DEED</sup>-matrices. The covalent incorporation of DEED and consumption of reactive MA groups decreased the cross-linking efficiency of oPNMAx resulting in reduced elastic modulus of cGEL<sup>+DEED</sup>. For oPNMAx x= 7.5 the cross-linking speed decreased over time; whereby for x=10 and 12.5 the gelation kinetic accelerated. We hypothesize that besides covalent cross-linking electrostatic forces contribute to the formation of cGEL<sup>+DEED</sup>-network. Based upon this, the derivatization time was reduced down to 2 h and oPNMA12.5 was preferred to fabricate cGEL<sup>+DEED</sup>-NGCs with sufficient mechanical properties complying with requirements for *in vivo* application. In addition, neurite-supporting behavior on cGEL- and cGEL<sup>+DEED</sup>-matrices was determined. Outgrowth of DRG neurons was found on cGEL<sup>+DEED</sup>. This validates the assumption that DEED-derivatization and occurring surface charge qualify cGEL<sup>+DEED</sup> as biomaterial for nerve repair.

### CONCLUSION

Tunable oPNMAx and base variations were used to modify cGEL fabrication and allow for a novel tubular injection-molding concept to produce flexible, elastic cGEL-NGCs. Pre-derivatization of oPNMAx with DEED was performed to functionalize cGEL-matrices to cGEL<sup>+DEED</sup>. Formulations were optimized for a suitable balance between cross-linking efficiency, mechanical properties and chemical composition through optimization of derivatization conditions. Preliminary results confirmed that neurite outgrowth was observed on cGEL<sup>+DEED</sup>-matrices, which makes these oligomer-cross-linked gelatin-based materials candidates for next generation NGCs.

### INTRODUCTION

Considerable advancements have been made using neural electrodes to minimise the effects of motor neurone disease, Parkinson's disease, epilepsy and to overcome paralysis<sup>1,2</sup>. These electrodes need to be implanted chronically (long-term) into the brain which has proven to be problematic, with most electrodes failing after 5-6 months<sup>3</sup>. Failure is mainly attributed to the formation of an inhibitory glial scar around the electrode, either due to the acute insertion-associated injury<sup>4</sup>, the chronic local inflammation of the neural tissue<sup>2</sup> or damage caused by micro-motion of the electrode<sup>2</sup>. The Trinity College Dublin (TCD) group is developing an alternative strategy using highly localized cooling paired with an MIT designed long term drug delivery system which we believe will significantly reduce the formation of a glial scar and extend the lifetime and efficacy of these probes.

### EXPERIMENTAL METHODS

Microfluidic channels of <100µm diameter were fabricated in a photocrosslinkable methacrylated gelatin (GelMA) hydrogel system and covered with a PDMS membrane with micropores. This system was dried (as it would be for insertion into the body) and reswollen. Drug and pro-healing cytokine diffusion rates were calculated using fluorescently labelled markers. The effects of the release of drugs and cytokines were tested *in vitro* on monocytes in order to determine macrophage behaviour over a period of 4 weeks. These monocytes were encapsulated in GelMA hydrogel crosslinked under UV light that was devised to have similar mechanical properties to brain tissue.

### RESULTS AND DISCUSSION

Microfluidic channels of <100µm diameter were successfully created in a hydrogel system using a sacrificial microfiber and maintained their integrity in a 37°C environment over a period of weeks.

Fig 1: Top view and cross-section of microchannel filled with dye and covered by PDMS porous membrane.

The hydrogel was optimised to have the desired mechanical properties and swelling ratios to reduce micromotion once inserted into the brain without causing undue pressure on the surrounding tissue. The hydrogel system was coupled with a PDMS membrane that was shown to slow down diffusion of particles into the *in vitro* brain model and reduce hydrogel degradation over time. As well as this, the PDMS allowed the anchorage of an inlet/outlet system that enabled the channels to be filled, emptied and refilled with a series of drugs and cytokines as required. These active particles significantly reduced the presence of inflammatory markers such as 27E10 and IL6 in monocytes and increased the presence of anti-inflammatory markers such as CD206 and CD163 which implies that a larger proportion of monocytes have differentiated to form M2 macrophages which are associated with healing. This implies that, in an *in vivo* environment, chronic drug delivery could potentially reduce the body's immune response against the implants and ensure they function better during long term implantation.

### CONCLUSION

The utilisation of a double layered coating system with incorporated microchannels allowed the controlled release of drugs from a biocompatible material with adequate mechanical properties. The swelling properties of the hydrogel were also shown to increase the stability of the implants and reduce micromotion. The release of anti-inflammatory drugs and cytokines from this system was shown to increase the presence of pro-healing macrophages in our *in vitro* brain model. This system could be repeatedly filled with different drugs or cytokines allowing for the design of an adaptable drug profile to reduce the formation of scar tissue. Combined with the use of cooling instead of electrical stimulation as a therapeutic method, this system could increase the long term efficacy of these implants in patients.

## INTRODUCTION

Tissue engineered electrodes<sup>1</sup> aim to stimulate neural tissues through synapse formation between cells within the tissue engineered electrode and those in target tissue. A major challenge in this research is to deliver functional neural networks capable of synapse formation. To address this issue, it is critical to understand the conditions required to support glia such as Schwann cells (SC), as they will in turn provide neurons with the appropriate niche. This study will examine SC encapsulation, survival and growth in a degradable biosynthetic hydrogel. Little research has been conducted on SC encapsulation from the point of view of developing SC into functional glia. Key design criteria for the supporting hydrogel include matching glial tissue stiffness (1-10 kPa) and delivery of appropriate biological cues to promote development and extracellular matrix (ECM) deposition by SC. Tyramine functionalized poly(vinyl alcohol) (PVA-tyr) supports covalent incorporation of non-modified tyrosine rich proteins within synthetic hydrogels<sup>2</sup> and can be tailored to mimic the biological environment while providing mechanical support. SC culture is well understood on two dimensional substrates, however there is little research on optimal three dimensional matrices that meet key design criteria. The aim of this research was to explore SC responses to encapsulation in PVA-tyr/sericin/gelatin hydrogels (PVA-T/S/G).

## EXPERIMENTAL METHODS

PVA-tyr (8 wt%) hydrogel was crosslinked with gelatin (1 wt%) and sericin (1 wt%) using previously described methods<sup>2</sup>. Gelatin was used to provide cellular attachment cues and sericin provided radical scavenging. Hydrogels were prepared with or without SC (SCL4.1/F7, 10 x 10<sup>6</sup> cells/ml). Samples were immunostained for S100 (mature SC marker), laminin (ECM deposition) and counterstained with bisbenzimidazole (nuclei). Cellular viability was tracked by live/dead staining. Hydrogel stiffness was measured by compression testing using a 50N load cell at a crosshead speed of 0.5 mm min<sup>-1</sup>. All the tests were performed at 1, 3, 5, 10 and 21 days. Hydrogel degradation was tracked to the point of reverse gelation.

## RESULTS AND DISCUSSION

Embedded cells remained viable at all the time points. S100 staining results showed that embedded SC were predominantly spherical at all the time points, however, cells localized at the upper surface of the gel were able to spread out processes. At day 21, embedded cells adopted bipolar morphologies and presented laminin on the cell surface (see Figure 1). These outcomes suggest that the PVA-T/S/G hydrogel provides sufficient support for SC differentiation.

Figure 1. SC embedded in PVA-T/S/G hydrogel at 21 days. A. Top view. B. Side view. Nuclei (blue). S100 (green), laminin (red), laminin/S100 overlap (yellow).

Hydrogel degradation produced ~10fold decrease in bulk stiffness from 41.5 ± 4.6 at 1 day to 4.83 ± 0.8 kPa at 21 days. The day 21 modulus is similar to glial tissue elastic modulus<sup>3</sup>. Hydrogels without cells were stiffer than those with cells at the 3-10 day time points. However, at 21 days, hydrogels with cells were significantly stiffer than those without (see Figure 2). These results suggest that although initial stiffness was similar in gels with and without cells, the presence of cells resulted in greater persistence of gel structure over extended time periods. Reverse gelation was observed at 27 days in gels without cells. Gels with cells had a modulus of ~2.7 kPa at the same time point.

Figure 2. Compressive modulus of gels with and without cells \*(p < 0.05). \*\*(p < 0.001).

## CONCLUSION

SC growth within hydrogels has an impact on hydrogel stiffness most likely mediated by changes in gel degradation kinetics and ECM formation. Future studies will test different mesh sizes and cellular densities to assess whether faster degradation or denser cell-cell interactions will enhance SC development resembling tissue *in vivo*.

## INTRODUCTION

Polyurethanes (PU) are used in a wide variety of implantable biomedical devices. A favorable aspect of PU chemistry is the broad range of physical and biological properties that can be achieved with this polymer<sup>1</sup>. A promising technology which permits direct fabrication of periodic micro structured surface patterns on solid materials such as PU is Direct Laser Interference Patterning (DLIP)<sup>2</sup>. Topographic patterns have been shown to induce cell alignment, a phenomenon called contact guidance<sup>3</sup>. In this study we evaluated cellular orientation in response to surface modifications produced by DLIP on vegetal oil based PU.

## EXPERIMENTAL METHODS

### *Vegetal oil based polyurethane and DLIP technique*

A high-power pulsed (pulse duration: 10 ns; repetition rate: 10 Hz), frequency quadrupled Nd:YAG (laser wavelength 266 nm) was used to fabricate periodic line like surface structures onto PU disc samples (5,6 mm of diameter and 1 mm of thickness). Spatial periods (distance between two ridges,  $\Lambda$ ) of 1  $\mu\text{m}$  and 10  $\mu\text{m}$  were achieved by adjusting the intercepting angle between the beams. The laser fluences chosen were 1000  $\text{mJ}/\text{cm}^2$  and 700  $\text{mJ}/\text{cm}^2$  to obtain high quality ridges with groove depth of 1  $\mu\text{m}$  ( $\Lambda$  1  $\mu\text{m}$ ) and 0,5  $\mu\text{m}$  ( $\Lambda$  10  $\mu\text{m}$ ) respectively.

### *Cell growth on DLIP modified PU*

Abdominal adipose tissue was collected from adult male Wistar rats and incubated with collagenase to obtain the stromal vascular fraction. After removal of blood and fat components, the remaining cells were cultured at 37 °C under static condition in a moisturized atmosphere with 5%  $\text{CO}_2$ . Following 5 subculture cycles, cells were seeded (140 cells/ $\text{mm}^2$ ) on control and DLIP-modified PU discs and incubated under the same culturing conditions as above ( $N = 3$ ; quadruplicates). The experimental groups were as follows: 1) unmodified PU (control), 2)  $\Lambda = 1 \mu\text{m}$  and 3)  $\Lambda = 10 \mu\text{m}$ .

### *Scanning electron microscopy (SEM)*

Three hours after the initial seeding cells were fixed with 4% paraformaldehyde and imaged with a Hitachi TM 3000.

### *Quantification of cell orientation*

SEM images of individual cells ( $n=100$ ) were analyzed using the *ImageJ* software (NIH). The angle between the major axis of the cell and the axis of the PU groove was obtained and cells considered aligned when this angle was less than 10°. For controls, the angle between

the major axis of the cell and the arbitrary image x-axis was measured.

### *Statistical analysis*

Statistical comparison between groups was performed by the Mann-Whitney Rank Sum Test. Statistical significance was accepted at  $P < 0.001$ .

## RESULTS AND DISCUSSION

Figure. Frequency distribution of orientation angles. Text boxes indicate mean values of three similar experiments carried out in quadruplicate for each group. SD = standard deviation. (\*) denotes statistical significance ( $P < 0.001$ ) versus control.

Various cell types display contact guidance when cultured on groove and ridge patterns with dimensions in the micrometer range<sup>3</sup>. The 1  $\mu\text{m}$   $\Lambda$  pattern showed higher cell alignment (88%) than the 10  $\mu\text{m}$   $\Lambda$  pattern (52%) ( $P < 0.001$ ).

## CONCLUSION

Our results show that high quality micrometer surface patterns can be produced by DLIP on PU surfaces. Also, the data reveal that line like micro structures generated onto PU surfaces by DLIP technique induced cell alignment along the groove direction which was dependent on fluence, groove depth and spatial period.

## INTRODUCTION

The structure of the blood vessel can be imitated by conventional surface engineering techniques, or haemocompatible coating by applying the concept of a tissue analogue, it means the substrate- promoting controlled angiogenesis process of proper blood vessels in tissue colonization. Bioactive materials should assist the body in regeneration of the natural hierarchical systems of cells to rebuild tissues. Angiogenesis is the process of creating new microvascular structures from existing vessels. This process is crucial in the embryonic development <sup>1</sup>. In healthy adult bodies the process is tightly restricted to a few organs <sup>2</sup>.

## EXPERIMENTAL METHODS

Porous coatings with varying degrees of rigidity modulated by the cross-linking were elaborated as a cell culture substrate. They were deposited using a layer-by-layer technique. Interaction of cells with the substrate was analysed for non-cross-linked and cross-linked EDC and NHS polyelectrolyte coatings with varying degrees of stiffness. The coatings were modified by physical vapour deposition in order to extend the life time duration and to improve biocompatibility. Rigidity of materials was determined by a micro hardness test using the Berkovich indenter geometry. Analysis revealed an effect of the temperature variation depending on stiffness of the porous coating. The performed bioassays used vascular endothelial cells. Materials were analysed in a dynamic system simulating the aortic flow of whole blood.

## RESULTS AND DISCUSSION

The temperature-dependent behaviour in polyelectrolyte multilayers was observed for native polyelectrolyte layers and layers subjected to the cross-linking in using confocal microscopy. The results are presented in Fig.1. The top polyelectrolyte layer was conjugated with FITC green fluorescent marker. A plot of fluorescence distribution along a line confirms that the is distributed not uniformly on the surface. Fluorescence intensity analysis confirmed local incensement in light fluorescence intensity for the non-cross-linked coating (native). On the surface endothelium was cultured as the natural layer to inhibit clot formation (Fig. 2). The more efficient growth of endothelial cells was observed on rigid, cross-linked coatings.

Fig. 1. Level of fluorescence a.) the surface of the non-cross-linked polymer materials b.) cross-linked polyelectrolytes

Fig. 2. The efficiency of endothelial monolayers formation a.) on non-cross-linked polymer materials b.) for cross-linked polyelectrolytes

Fig. 3. Blood material interaction in the function of the applied material with deposited endothelium

## CONCLUSION

Stiff coatings enabled the more efficient endothelial cell growth, which resulted better cell growth and faster confluent formation on the top of the coating thus the better inhibition of the coagulation system

## INTRODUCTION

Bone grafts are required for the treatment of injuries, tumors, infections and diseases such as osteoporosis and osteoarthritis. Bone is composed highly aligned collagen fibers and inorganic compounds which contribute to its tensile and compressive strength. In this study, microchannel patterned films of collagen and fibroin were prepared to guide anisotropic tissue formation. ELP was added to the blend to study accumulation of hydroxyapatite (HAP) owing to its functional DDDEEKFLRRIGRFG sequence [1]. The importance of cell type on the mechanical properties of microchanneled collagen – fibroin – elastin like recombinant polymer (ELP) blend films were investigated.

## EXPERIMENTAL METHODS

Stem cells derived from human adipose (ADSCs) and human osteoblasts (HOBs) were seeded on micropatterned films which were produced by solvent casting of collagen-fibroin-ELP solution on silicone elastomer mold. Protein films were crosslinked with 1-ethyl-3-[3-dimethylaminopropyl] carbodiimide hydrochloride (EDC) and *N*-hydroxysulfosuccinimide (NHS). In order to strengthen the films CaP was precipitated on the films using successive treatments with  $\text{NaNH}_4\text{HPO}_4$  and  $\text{CaCl}_2$  solutions. ADSCs were cultured in growth medium for 1 week and subsequently in osteogenic medium for 3 weeks. After 28 days ultimate tensile strength (UTS) of films ( $n=3-5$ ) were determined in wet state. Orientation of HOB and ADSC in microchannels were assessed using the SEM micrographs. Mineral deposition was analyzed with EDAX and calcium content of films was determined with o-cresol phthalein complexone and 8-hydroxyquinone assay. Statistical analysis was carried out for UTS, Young's modulus, elongation at break, and calcium determinations with ANOVA followed by Tukey's test and significant differences between groups were determined for  $p \leq 0.05$ .

## RESULTS AND DISCUSSION

CaP formed *in situ* on the protein films led to the highest UTS, Young's modulus and calcium amounts (Table 1). However, SEM results showed that ADSC was not found on the CaP precipitated surface after 28 days of cell culture. ADSCs covered native film surface and gave the second best mechanical strength and Ca amount. On the contrary, HOB seeded samples led to the lowest mechanical strength and highest elongation at break. Possible explanation can be matrix

metalloproteinase-2 (MMP-2) secretion by HOBs *in vitro* [2] while its downregulated during osteogenic differentiation of ADSCs [3]. Although mineral deposition was observed on each type of film, only *in situ* CaP formed films had Ca/P ratio close to tricalcium phosphate as shown by EDAX.

**Table 1.** Ultimate tensile strength (UTS) and Young's modulus (E) of unseeded (control) and cell seeded films (\* represents statistically significant difference between HOB seeded and other samples.).

Sample	UTS (MPa)	E (MPa)
HOB, day 28	$0.13 \pm 0.06$	$0.41 \pm 0.11$
ADSC, day 28	$0.32 \pm 0.15$	$1.21 \pm 0.42^*$
CaP/ADSC, day 28	$0.33 \pm 0.06$	$1.28 \pm 0.38^*$
Control, day 1	$0.18 \pm 0.05$	$0.58 \pm 0.13$
Control, day 28	$0.28 \pm 0.07$	$1.19 \pm 0.33^*$

**Fig. 1.** SEM micrographs of (a) unseeded film on Day 1, (b) unseeded film on Day 28, (c) HOB seeded film on Day 28, (d) ADSC seeded film on Day 28, and (e) CaP formed films with ADSC seeding on Day 28 (x5000). Scale bar: 20  $\mu\text{m}$ .

## CONCLUSION

Mechanical properties of blend film were improved by ADSCs growth unlike HOBs. *In situ* CaP deposition enhanced tensile strength but decreased cell adhesion.

## INTRODUCTION

Achieving vascularization of implanted materials is critical for an effective integration and the success of many regenerative medicine strategies. Typically, the angiogenic effect has been pursued through the delivery of cells and growth factors but these present significant limitations, such as sourcing issues, high cost of production, and regulatory challenges. Polyethylene glycol (PEG) hydrogels have emerged as promising biomaterials due to their structural similarity to extracellular matrices and the ability to functionalize them in precise and versatile ways. Recently, calcium phosphate based glasses (CaP) have shown to stimulate an angiogenic effect both *in vitro*<sup>1</sup> and *in vivo*<sup>2</sup>. The aim of this work was to test the angiogenic properties of a new material based on the combination of a PEG hydrogel and calcium phosphate particles.

## EXPERIMENTAL METHODS

**Material fabrication and characterization.** Two types of particles were fabricated with the sol-gel method: a CaP glass with fast calcium ( $\text{Ca}^{2+}$ ) release (FRP), and a glass-ceramic with slow release (SRP). The size of the particles was measured from FE-SEM images and their atomic composition with EDS.  $\text{Ca}^{2+}$  release into cell media was determined with a colorimetric method. The hydrogels were synthesized from 4-arm PEG-maleimide macromers (20 kDa, 4.5 polymer wt%) functionalized with the cell adhesive site RGD and a protease-cleavable cross-linker. Hydrogels containing 0.1%, 0.5% and 1% (w/v) of each particle were used.

**In vitro studies.** Cytotoxic effects were tested with hydrogels containing human mesenchymal stem cells (hMSC) in a live-dead assay. Angiogenic effects were studied through quantification of VEGF released in the media from hMSC embedded in the materials and a network formation assay with a co-culture of hMSC and human umbilical vein endothelial cells (HUVEC).

**In vivo study.** Vascularization *in vivo* was studied by implanting the gels containing luciferase-expressing hMSC in the epididymal fat pad (EFP) in immunocompromised mice. Three groups were examined: hydrogels + 0.5% SRP, hydrogels + VEGF (10 µg/ml) and empty gels. Six animals were used per condition with one precast gel implanted per fat pad. Bioluminescence was imaged with IVIS at several time points. Two weeks after material implantation, animals were injected fluorescently labelled lectin to stain functional vasculature and were humanely euthanized. Tissues were explanted and processed for histology and immunostaining.

## RESULTS AND DISCUSSION

SRP have a diameter of approximately 5 µm and a sustained daily release of Ca of 0.125 mM/mg for up to 8 days. FRP are 66.20 ± 11.41 nm in diameter and release  $\text{Ca}^{2+}$  in a burst of 2.25 mM/mg during the first 2h. No cytotoxic effects were observed for any of the conditions tested. Significant differences were detected in *in vitro* endothelial cell network formation for 0.5% SRP compared to cells in particle-free gels and regular media, but not for VEGF secretion into the media. IVIS images showed significantly higher signal for the hydrogel + 0.5% SRP compared to VEGF-containing and empty gels on days 2 and 7 post-implantation, indicating enhanced cell survival. Moreover, images taken on the EFP functional vasculature presented thicker vessels for the hydrogels containing 0.5% SRP and VEGF compared to empty gels (Fig.1). Detailed histological and immunostaining analyses are ongoing to confirm the presence of a more mature vasculature.

**Figure 1.** Vasculature of the fat pad tissue present in the area of implantation of the empty gel (A), the gel + 0.5% SRP (B) and the gel with VEGF (C) after lectin staining and tissue fixation.

## CONCLUSION

This study shows the fabrication of a new biomaterial based on the combination of a PEG hydrogel and glass-ceramic particles and its vasculogenic effect. The stimulation of the cells implanted in the hydrogel with the release of the particles promotes an angiogenic effect both *in vitro* and *in vivo*, although further studies should be performed to confirm this. The use of bioactive glasses instead of biological cues to stimulate angiogenesis in implanted materials can be a great contribution in tissue regeneration.

[h.yuan@utwente.nl](mailto:h.yuan@utwente.nl)

## INTRODUCTION

Due to the chemical similarity to the inorganic component of bone and bone bonding properties, calcium phosphate (CaP) ceramics are widely used as synthetic bone graft materials and many commercial CaP ceramics are available. It has been shown that the physicochemical properties (e.g. chemistry and surface structure) of CaP ceramics affect their bone forming ability and play an important role in their effectiveness in bone regeneration<sup>1</sup>. Since commercially available CaP ceramics have different physicochemical properties, their bone forming ability might vary. Using a well-established canine model<sup>2,3</sup>, we compared the ectopic bone forming ability of seven CaP ceramic products (i.e. BioOss, Actifuse, Bi-Ostetic, MBCP, OSferion, Vitoss and Chronos), as well as an experimental CaP ceramic (TCP-S).

## EXPERIMENTAL METHODS

Commercial CaP ceramics (Table 1) were purchased and used as supplied. The materials were subjected to XRD analysis and SEM observation. Mercury intrusion was used to evaluate strut microporosity (volume percentage of pores smaller than 10µm), micropore size and surface area. One cc of each material (n=4) was intramuscularly implanted in the dorsal muscle of 4 beagles for 12 weeks. Experimental osteoinductive (TCP-S) and non-osteoinductive tri-calcium phosphate ceramic (TCP-B) were implanted in cylinder form (Ø9x6mm) as positive and negative control<sup>2,3</sup>. TCP-S particles (1-2mm) were implanted to allow a comparison to commercial CaP ceramics in particulate form. After 12 weeks, the incidence and volume of de novo bone formation were investigated by histology and histomorphometry.

## RESULTS AND DISCUSSION

Table 1 and figure 1 show the main physicochemical characteristics of the different CaP ceramics. They are chemically different, have various surface structures (strut microporosity, micropore size and grain size) and different specific surface areas.

**Table 1. Physicochemical properties of CaP ceramics**

Materials	Supplier	Chemistry	Granules size [mm]	Strut Porosity [%]	Pore Size [µm]	Surface Area [m <sup>2</sup> /g]	Grain size [µm]
BioOss	Geistlich Pharma AG	HA	0.25-1.0	43.03	n/a	n/a	n/a
Actifuse	Apatech, Baxter	Si-HA	1-2	22.03	1.3	0.3	1.0±0.4
Biostetics	Berkeley Advanced Biomaterials	45HA/55TCP	1.4-2.8	53.67	1.5	2.7	1.8±0.3
MBCP	Biomatante	55HA/45TCP	0.5-1	40.53	0.4	1.4	1.4±0.4
OSferion	Olympus	TCP	1-3	51.90	0.9	1.4	2.7±0.9
Vitoss	Orthovita, Stryker		1-4	42.69	2.5	0.4	1.9±0.7
Chronos	Synthes		1.4-2.8	31.52	0.9	0.4	10.0±3.8
TCP-S granules	Xpand BV		1-2	45.09	0.5	1.4	0.8±0.2

The canine osteoinduction model was validated with the evidence of bone formation in TCP-S cylinders (bone in 4 out of 4 samples, 31.0±8.8%) and the absence of bone in all TCP-B cylinders. Ectopic bone formation in the commercially available CaP ceramics varied (Figure 2-3). No bone was formed in BioOss, Vitoss, Bi-Ostetic

and Chronos; limited amount of bone (<0.1%) was seen in 2 out of 4 Actifuse implants; whereas TCP-S granules (21.6±4.5%), OSferion (9.4±3.2%) and MBCP (2.1±1.4%) gave rise to bone formation in all 4 implants.

Due to the differences in chemistry, strut microporosity, micropore size, grain size and surface area, it is difficult to attribute the bone forming potential to a single physicochemical parameter, but literature indicates that grain size, micropore size and microporosity all play important roles in material-directed osteoinduction<sup>1</sup>.

**Figure 1.** SEM images showing the surface structure of the materials

**Figure 2.** Histological overview of implants (un-decalcified sections stained with methylene blue and basic fuchsin) harvested from dorsal muscle of canines after 12 weeks of implantation

**Figure 3.** Percentage of bone in the available space of the implants (12 weeks after the intramuscular implantation)

## CONCLUSION

These results show that commercially available CaP ceramics have different bone forming potentials in the canine ectopic bone formation model. Although these differences cannot be ascribed to one physicochemical parameter, we show that an experimental CaP can be developed with superior ectopic bone formation potential. This warrants the evaluation of its bone regeneration potential in large bone defects.

## **INTRODUCTION**

Synthetic bone-graft substitutes may provide a better alternative to autografts and allografts, as they eliminate donor-site morbidity and reduce immune response. Hydroxyapatite (HA) has been extensively investigated due to its excellent bioactivity, osteoconductivity and its similarity to the main mineral component of bone. However, its poor compressive strength and fatigue failure limits its applicability to low or non-load-bearing sites<sup>1</sup>. Polyurethane (PU) presents with desirable properties of greater elasticity, viscoelastic behaviour and higher mechanical strength associated with its versatile chemistry<sup>2,3</sup>. Although PU is a promising material for scaffold fabrication, the lack of bone-bonding bioactivity limits its use in bone. Therefore, the aim is to develop a biocompatible and osteoconductive PU-HA composite with optimal mechanical properties and beneficial bioactivity to enhance bone remodelling and growth.

## **EXPERIMENTAL METHODS**

Using a novel layer-by-layer particulate leaching technique, scaffolds were fabricated with 15%wt PU dissolved in 70/30 DMF/THF solvent and NaCl particles (~250 µm). Composite scaffolds with nano or micro hydroxyapatite particles were fabricated in a ratio of 3 PU: 1 HA. Scaffold morphology, pore size and pore interconnectivity were accessed with SEM and Micro-CT imaging, whereas chemical characterisation was done with Raman and PAS-FTIR spectroscopy. Scaffolds were mechanically tested in compression and biologically characterised *in vitro* with MLO-A5 osteoblastic mouse cells and assayed over a 21-day culture period for cell attachment, viability, depth penetration and matrix deposition. For *in vivo* biocompatibility studies, 36 rats were subcutaneously implanted with scaffolds and were sacrificed on Day 7 and 45 after implantation.

## **RESULTS AND DISCUSSION**

With an average pore size of  $190 \pm 75$  µm, composite scaffolds with nHA particles had the highest Young's Modulus and yield strength of  $0.671 \pm 0.080$  MPa and  $0.040 \pm 0.014$  MPa, respectively. These were significantly higher than that of PU scaffolds without HA (PU-only) which had the highest pore size of  $236 \pm 67$  µm. The presence of hydroxyl, phosphate and phosphate bending peaks in FTIR characterization confirmed the presence of HA in all composite scaffolds<sup>3</sup>, with Raman spectroscopy also confirming the presence of HA after autoclaving. Micro-CT imaging showed good pore interconnectivity in all

scaffolds, with a porosity of 89.38% for PU-only scaffolds being significantly higher than that of micro-HA composites at 83.19%. Confocal, SEM and histology demonstrated that all scaffolds supported cell attachment, proliferation and the deposition of calcified matrix. Interestingly, mHA composites with an average pore size of  $187 \pm 66$  µm had the highest cell viability and collagen matrix deposition. This was significantly higher than that of composites with nHA particles and PU-only scaffolds. After 45 days of *in vivo* studies, tissue in-growth was present in all composites with HA particles, but was not observed in PU-only scaffolds emphasising the need for HA in bone-matrix formation.<sup>1</sup>

Fig. 1: H&E staining of PU-only and HA composite scaffolds on Day 7 & 45 after *in vivo* implantation x360 (Above): Superficial Zone (Middle); Intermediate Zone (Below): Deep Zone

## **CONCLUSION**

We have developed novel PU-HA composites that mimic the composition of natural bone and have good mechanical properties in relation to their highly interconnected porosity. The fabricated scaffolds support bone matrix formation *in vivo* and *in vitro* and are promising constructs for bone-graft substitutes.

### INTRODUCTION

Bioactive glass nanoparticles (nBG) and mesoporous bioactive glass nanospheres (nMBG) have demonstrated to have improved bioactivity properties [1,2]. However, the use of these nanosized particles in bone tissue engineering (TI) requires their incorporation in suitable polymer scaffold matrices. Bionanocomposite scaffolds combine the bioactivity of nanoparticles with the supporting properties of the polymeric matrix. Biodegradable polyurethane (PU) are of particular interest in TI due its excellent mechanical properties. In this work, an *in situ* method for the preparation bionanocomposites based on biodegradable PU synthesized with non-toxic aliphatic diisocyanate, and nanosized BG particles is presented.

### EXPERIMENTAL METHODS

nBG was synthesized by using sol-gel technique following a modified procedure reported for us [1]. nMBG synthesis was carried according to the method reported by Wu et al. [2]. PU nanocomposites were prepared by adding dropwise a suspension of 13.2 mL of isophorone diisocyanate (IPDI) containing the BG nanoparticles to 24.3 mL of castor oil under constant stirring. Then, stannous octoate catalyst was added. Prepolymer was formed after 25 min at room temperature, after which 0.435 mL of butanediol and 0.6 mL of water were added. The foaming process was completed after 1 hour at 120 °C. Nanoparticles were characterized by high-resolution electron microscopy (HRTEM), X-ray diffraction and attenuated total reflectance with Fourier transform infrared spectroscopy (ATR - FTIR). Composites were examined by using scanning electron microscopy (SEM). Bioactivity was assessed in simulated body fluid (SBF) and citocompatibility by using alamarBlue® assay with fibroblast cultures.

### RESULTS AND DISCUSSION

The particle size of nBG and nMBG was of 70 and 100 nm, respectively (Fig. 1). nMBG exhibited the characteristic hexagonal close-pack array of nanopores of around 4 nm. nBG/PU scaffolds presented a more open macroporosity than those prepared with nMBG (Fig. 2). Microsized agglomerations of nMBG particles were also detected on the scaffold surface. Both, nBG and nMBG composites induced the formation of apatite on their surface after short time of immersion in SBF (3 days), which was not observed on the neat PU (Fig. 2)

Fig. 1 HRTEM images of nBG (a) and nMBG (b,c) particles.

Higher apatite crystallization was detected on the surface of nMBG/PU. Cell viability was not reduced when cultured in the presence of the nanocomposites. Previous works of PU impregnated with microsized BG report apatite formation after more prolonged incubation times [3]. In the current work, nanometric dimensions of BG particles having higher dissolution rate, accelerate the apatite crystallization process.

Fig. 2 Photograph of typical nanocomposite scaffold (a), and SEM images of nBG/PU (b) and nMBG/PU.

Fig. 3 XRD (a) and ATR-FTIR (b) analysis of neat PU and nanocomposites after immersion in SBF.

### CONCLUSION

Nanodimensional BG particles significantly improve the *in vitro* bioactivity of aliphatic PU scaffolds.

### INTRODUCTION

Biodegradable materials have received great interest in tissue engineering research. Usually these materials are synthesized into porous, fibre or film scaffolds, which can provide a biomimetic structure and biological functions as the extracellular matrix of several tissues. Polylactic acid (PLA) is one of these biodegradable materials commonly applied in surgery, medicine and tissue regeneration because it is biocompatible with bone tissue and its biodegraded products are nontoxic and could be absorbed by the body [1]. Degradation of PLA depends on the molecular weight, crystallinity, purity, pH, temperature, doped by nanoparticles, water permeability and the presence of terminal carboxyl or hydroxyl groups [2]. It occurs in two stages: the first one starts with the water diffusion into the amorphous zones of PLA, breaking the ester bonds. The second stage starts when the degradation of amorphous zones increases [3]. The aim of this study was evaluated the degradation behaviour of PLA scaffolds doped with hydroxyapatite nanoparticles prepared by air jet spinning, using three different concentrations of PLA 6, 7 and 10 % for bone tissue regeneration.

### EXPERIMENTAL METHODS

Hybrid fibers of poly(lactic-acid)-hydroxyapatite PLA-HA were synthesized by air jet spinning and subject to degradation test with PBS, Trypsin and collagenase enzymes at 1, 3, 5, 7, 14 and 21 days at 37 °C and with an atmosphere controlled with 5% of CO<sub>2</sub>. Characterization of hybrid fibres were carried out by infrared spectroscopy, X-ray diffraction and electron scanning microscopy. The results from degradation test were obtained by FITR and the pH was monitored during the test, for observe the changes as result from degradation of fibres.

### RESULTS AND DISCUSSION

PLA-HA fibers were obtained by air jet spinning; Figure 1 displays the hybrid fibre micrograph. It can see HA nanoparticles into the PLA fibres. Rugosity and diameter size of the fibres change when HA nanoparticles were incorporated into the fibres. HA nanoparticles contained into the PLA fibres could play an important role on the physic-chemical properties of the PLA and its degradation behaviour under some enzymes. First results obtained of the degradation test

showed that degradation accelerate on the fibres when they are subject to interaction with the trypsin, since, the fibres are complete solubilized at 5 days. While, with PBS and collagenase, they still are not complete degraded.

Figure 1. Micrograph of the PLA-HA hybrid fibres.

### CONCLUSION

Hydroxyapatite has an effect on PLA fibres scaffold and also the degradation test showed that trypsin enzyme accelerate the degradation behaviour of the scaffold. However, more studies are need for understanding the degradation process by the enzyme.

## INTRODUCTION

Multiple Sclerosis (MS) is an autoimmune inflammatory disease characterized by axonal demyelination in the central nervous system (CNS) and resultant neurological deficits. The autoimmune attack includes an imbalance between inflammatory auto-reactive T cells and tolerance inducing regulatory T cells which is mirrored in the dendritic cell (DC) phenotype. Biomaterial-based strategies are being pursued to 1) pre-program antigen-specific and immunosuppressive DCs *in vitro* for their delivery within an injectable polyethylene glycol (PEG) hydrogel or 2) *in situ* education of recruited DC precursors using controlled release of immunomodulators and antigen from an implanted agarose scaffold (AgSc). Applicability of these complementary approaches for MS attenuation is being considered in a murine Experimental Autoimmune Encephalomyelitis (EAE) disease model.

## EXPERIMENTAL METHODS

**PEG hydrogel for delivery of immunosuppressive DCs:** Murine bone marrow (BM)-derived DCs from C57BL/6 mice were obtained upon treatment with GM-CSF and IL-4 (6 days)<sup>1</sup>, followed by treatment with IL-10 (2 days), and EAE antigen conditioning using MOG<sub>35-55</sub>. Subsequently, DCs were incorporated into PEG hydrogel [5% (w/v) PEG-4MAL; 20 kDa MW; with 2 mM RGD] at a pH of 7.4, on ice, with 1 mM TEA buffer and hydrogel crosslinked via Michael-type addition using a cysteine-flanked protease-degradable peptide VPM<sup>2</sup>. **AgSc with gelatin microparticles (GelMPs) for immunomodulator delivery:** GelMPs (10 wt%, gelatin type B) were prepared by emulsification-solvent extraction, differentially crosslinked with glutaraldehyde and washed with 25mM glycine solution<sup>3</sup>. Freeze-dried gelMPs were diffusionally-loaded with rmGM-CSF (1.54µg/ml), DEX (24µg/ml), or PGN (120µg/ml) or without DEX/PGN but with rmIL-10 (4°C, 12 hr). Appropriate numbers of each type of loaded-gelMPs were mixed into 1.5% agarose solution which was frozen (-30°C, 1hr) followed by controlled rate thawing in a cryostat<sup>4</sup>. BM precursors were treated with AgSCs with gelMPs loaded separately with DEX and PGN (GM-CSF in culture medium) for 8 days. As needed, harvested DCs were treated with MOG<sub>35-55</sub> for antigen-specificity. Phenotype and functionality of derived DCs was assessed using flow cytometric analysis of surface markers, intracellular cytokine expression and an antigen presentation assay. **Amelioration of EAE:** PEG hydrogel-encapsulated

MOG-specific DC10s (1x10<sup>6</sup> in two 50 µl injections) were delivered to the flank or neck at the time of EAE induction and EAE disease scores recorded<sup>5</sup>.

## RESULTS AND DISCUSSION

Immunosuppressive DCs were derived upon treatment with soluble IL-10 (as used in PEG hydrogels) or upon treatment with DEX/PGN released from gelMPs in AgSCs (or soluble controls) as determined by surface marker expression and enhanced IL-10 and lower IFN-γ intracellular expression, compared to mature DCs. Using an MS antigen-specific presentation assay, DCs treated with soluble IL-10 or DEX+PGN or with DEX+PGN from GelMPs in AgSCs, resulted in lower levels of MOG-dependent proliferation of 2D2 T cells. Hydrogel delivery of pre-cultured MOG-specific

Fig. 1: Mean Clinical EAE scores for mice receiving hydrogel in two different sites with and without DCs (5 mice per group).

immunosuppressive DC10s attenuated EAE symptoms, particularly when delivered to the neck region (Fig. 1).

## CONCLUSION

Two biomaterial-based approaches demonstrate promise in adjusting the excessive pro-inflammatory autoimmune situation to tolerance through the delivery of antigen-specific immunosuppressive DCs or inducing their phenotype using controlled release technologies.

## INTRODUCTION

Healing of bone defects is a complex process which is regulated by internal and external factors. However, the knowledge about this process at the actual fracture site is still limited. This is caused by a general lack of methods for *in situ* sampling of such extracellular factors, metabolites, and proteins. Microdialysis is a minimally invasive method for continuously sampling cytokines, growth factors and other mediators from the site of injury.<sup>1</sup> In combination with proteomics this is one of the promising approaches to get comprehensive and time-resolved data to characterize the wound fluid in the fracture hematoma directly after the injury.<sup>2</sup>

## EXPERIMENTAL METHODS

In the femur of adult male Wistar rats a 5 mm defect was created and stabilized with an internal fixator. The microdialysis catheter was placed within the defect and the wound fluid was collected continuously under anaesthesia for 24 h. Samples were collected in 3 h intervals and used to quantify cytokines and growth factors by ELISA. Metabolites were analysed by mass spectrometry. At the end of experiment the microdialysis catheters were explanted, the proteins adsorbed to the membrane of the microdialysis catheter were extracted and were analysed after separation by 1D gel electrophoresis by nano-HPLC/nano-ESI-MS/MS. The functional annotation clustering was performed using the software packages PANTHER and DAVID.

## RESULTS AND DISCUSSION

Analysis of wound fluid by ELISA resulted in concentration profiles for 9 different cytokines and growth factors. For example, the detailed studies of potentially relevant chemokines like chemokine (C-X-C motif) ligand 4 (CXCL4) and CXCL7 showed a rapid decrease of the concentration of these proteins immediately after injury suggesting the release of these proteins by activated platelets (Figure 1A).

More than 600 proteins were detected at the membrane of the microdialysis catheter which were previously discussed as direct biomarker candidates such as matrix metalloproteases, oxidative stress markers, serin proteases, as well as complement factors. Cytokines or chemokines were not detected within the adsorbed proteins, but more than 50 proteins related to inflammation could be found.

In addition, we are also able to assign the identified proteins to more than 100 different pathways which

seem to be activated in the early stage of wound healing in bone defects. Major protein clusters were “response to wounding” (63 proteins), “homeostatic process” (58), “proteolysis” (57), “regulation of apoptosis” (57), “defense/ inflammatory response” (55), vesicle-mediated transport (40), “acute inflammatory response” (25), and “response to oxidative stress” (24).

Interestingly, 60 extracellular proteins could be allocated to at least one of the processes related to wound healing (Figure 1B).

Fig. 1: A) Protein concentration of CXCL4 (n=3) and CXCL7 (n=5) in the microdialysate. B) Functional clustering of the proteins related to wounding.

## CONCLUSION

Microdialysis and proteomics provide a promising approach for detailed and direct insight into the local extracellular microenvironment of a bone defect. It is possible to collect, enrich and purify proteins in a sufficient amount for a detailed analysis of selected cytokines and growth factors and a comprehensive proteome analysis of the wound fluid to gain complementary and time-resolved information of the same defect.

### INTRODUCTION

Collagen I is a key structural component of the extracellular matrix, providing resilience to tissues. As such it has been heavily utilized as a major structural component for a wide variety of biomaterial applications. In addition to its structural role collagen interacts with cell receptors such as the heterodimeric integrins  $\alpha_1\beta_1$  and  $\alpha_2\beta_1$ . This collagen-integrin interaction occurs through a major cell-binding motif (GFOGER) contained within the triple helical structure of collagens [1]. Through these interactions collagen influences many cellular functions such as attachment, spreading and proliferation.

Ice templating is well-established method for the fabrication of 3-dimensional (3D) porous collagen scaffolds. This involves the sublimation of an interpenetrating network of ice crystals from frozen collagen slurries. Stabilisation of these scaffolds often involves carbodiimide based chemical crosslinking strategies that bond carboxylic acid to amine containing amino acid side chains. As the interaction of integrins with collagen requires one such acidic side chain, the E of GFOGER, we have examined if carbodiimide crosslinking affects integrin-mediated cell interactions with collagen-based biomaterials.

### EXPERIMENTAL METHODS

**Collagen film preparation:** 0.5% w/v insoluble collagen was homogenised then dried onto plates. NHS/EDC crosslinking was performed as [2] (100% = 1.150g EDC:0.276g NHS:1g scaffold) then washed exhaustively in deionised H<sub>2</sub>O.

**Cell attachment;**  $5 \times 10^4$  of HT1080 cells were added to collagen films in 96 well plates for 45 min. Loosely bound cells were removed and bound cells were quantified using a phosphatase detection substrate.

**Cell spreading;**  $2.5 \times 10^4$  of HT1080 cells were added to collagen films for 60 min. After fixation cell spreading was quantified by phase contrast microscopy.

**Annexin V staining;**  $5 \times 10^4$  of HT1080 cells were added to collagen films for 60 min. These were stained using an Annexin V-FITC apoptosis detection kit (abcam) following the manufacturers protocol.

**Cell expansion;**  $1 \times 10^4$  of HT1080 cells were added to collagen films in 96 well plates. After 5 days in culture the number of cells per field of view was counted by phase contrast microscopy using a 20X objective lens.

**Purified integrin I domain binding;** 10 $\mu$ g/ml of GST tagged recombinant integrin I domain was added to collagen films for 60min. Bound I domain was detected using an anti-GST-HRP antibody.

### RESULTS AND DISCUSSION

Integrin  $\alpha_2\beta_1$  dependent HT1080 adhesion and spreading to collagen films was inhibited with increasing degrees of carbodiimide crosslinking (fig.

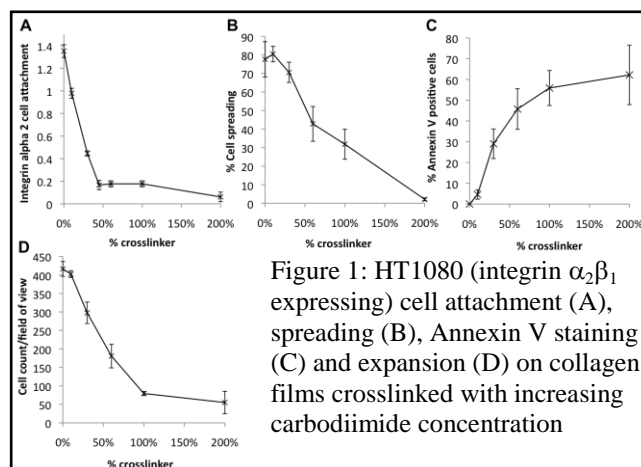

Figure 1: HT1080 (integrin  $\alpha_2\beta_1$  expressing) cell attachment (A), spreading (B), Annexin V staining (C) and expansion (D) on collagen films crosslinked with increasing carbodiimide concentration

1a,b). The number of apoptotic cells, as measured by Annexin V staining, increased dose dependently with increasing carbodiimide treatment of the collagen films (fig. 1c). Consistent with this increase in apoptosis, after 5 days in culture, the degree of cell expansion decreased with increasing carbodiimide crosslinking (fig. 1d). Together these data show that cellular engagement by collagen biomaterials is reduced with carbodiimide crosslinking. This results in decreased collagen dependent cell function.

Figure 2: Purified integrin binding to collagen films

Integrin  $\alpha_1\beta_1$  and  $\alpha_2\beta_1$  interact with collagen via an inserted A domain (I domain) contained within the  $\alpha$  subunit [1]. Purified integrin  $\alpha_1$  and  $\alpha_2$  I domain binding to collagen was found to be sensitive to the degree of carbodiimide crosslinking (fig.2).

### CONCLUSION

We propose that carbodiimide reaction with integrin binding motifs inhibit integrin-mediated biofunction on collagen-based biomaterials.

## Multicellular Spheroids and 3D Scaffold Cultures Up-Regulate Different Events in Osteogenic Differentiation of Adipose-Derived Mesenchymal Stem Cells

[slawomir.ruminski@wum.edu.pl](mailto:slawomir.ruminski@wum.edu.pl)

### INTRODUCTION

Adipose-derived mesenchymal stem cells are routinely cultured in standard polystyrene plates in a form of a monolayer. However, mesenchymal stem cells *in vivo* are embedded in a spatially arranged environment composed of extracellular matrix proteins and other cells. It was shown that ADSC cultured in a form of multicellular aggregates displayed up-regulation of “stemness” transcription factors and increased pro-angiogenic properties [1]. ADSC cultured in 3D spheroids produced a mineralized matrix containing extracellular matrix proteins- collagen type I and osteopontin [2]. In this study, we aimed to describe the differences in ADSC osteoblast differentiation process in standard monolayer cultures and two different 3D culture systems- multicellular spheroids and scaffolds. The study also addressed the role of exogenous attachment substrate in differentiation, which is provided in the 3D scaffolds but not in multicellular spheroids.

### EXPERIMENTAL METHOD

ADSC cells were detached from monolayer cultures with trypsin. Cellular spheroids were generated with the hanging drop method [3] with ADSC in osteogenic medium used for spheroid generation. ADSC were also seeded onto Alvetex® 3D polystyrene scaffolds and into standard polystyrene culture plates. Osteogenic medium was composed of DMEM with 10% FBS, 1% antibiotics, 50µg/ml ascorbic acid phosphate, 10nM dexamethasone and 3mM NaH<sub>2</sub>PO<sub>4</sub>. After 2 days, the formed spheroids were transferred to non-culture treated dishes and cultured in osteogenic medium for another 5 days on a rotary shaker. Live/Dead fluorescent staining was performed to qualitatively assess cell viability. The cultures were lysed with 0.1% triton buffer for DNA quantification with Picogreen assay and alkaline phosphatase (ALP) assay. The ALP activity was normalized to DNA quantity. Cells were also lysed in RLT buffer for RNA isolation and quantification of Runx2, Osterix and collagen type I α1 gene expression with Real-Time PCR.

### RESULTS AND DISCUSSION

ADSC cells maintained high viability in all three culture systems for 7 days as was judged from Live/Dead fluorescent staining. Cells cultured on standard polystyrene plates had higher proliferation rate than cells cultured in spheroids as could be seen by a much higher increase in DNA quantity between day 2 and day 7 of culture. ALP activity increased at 2 days in

all three osteogenic culture systems compared to undifferentiated cells but the activity was the highest in spheroids compared to both monolayer and scaffold cultures. Expression of collagen was up-regulated in monolayer and scaffold osteogenic cultures at 2 days but dropped below control in monolayer at 7 days. After 7 days of culture expression of collagen was 1.5-, 2.9- and 4.8-fold up-regulated in monolayer, spheroid and scaffold cultures respectively. The expression of Runx2 and Osterix genes was higher in spheroids compared to scaffolds (5.7 vs. 2.1 and 3.4 vs. 0.2, respectively). The expression level of those genes in monolayer culture did not increase over control (Fig. 1). These results suggest that the presence of exogenous attachment surface in Alvetex® scaffolds results in increased collagen I expression. On the other hand, enhanced cell-to-cell communication in spheroids is likely to potentiate differentiation signals resulting in elevated expression of osteogenic transcription factors.

### CONCLUSION

The results of this study confirmed that culture in 3D systems up-regulates osteogenic differentiation processes. However, the characteristics of different 3D systems may influence the differentiation events. Therefore biomaterials can be potentially used both to provide an increased cell attachment surface and enhanced cell-to-cell contacts in order to improve ADSC differentiation, which is an important factor to consider for successful bone regeneration with the use of mesenchymal stem cells isolated from adipose tissue.

### INTRODUCTION

Dermal wound healing requires the coordinated interaction of several cell types including fibroblasts and macrophages. Involved processes like migration, infiltration, proliferation and differentiation of these cells are regulated not only by soluble autocrine and paracrine signalling molecules (e.g. TGF- $\beta$ 1, IL-10), but furthermore, by the characteristics of the surrounding extracellular matrix (ECM). Especially, the 3D context and mechanical characteristics of the physiological situation has to be observed in relevant studies. In order to gain a better understanding of the regulation of scarless wound healing and dysregulation, like hypertrophy, 3D models are required for high-resolution *in vitro* studies.

Here, we set up a 3D ECM context of a wound healing model, based on fibrillar collagen, fibronectin und glycosaminoglycans at defined microstructure and composition. We asked on the subtle interplay of ECM parameters and temporal stimuli by the paracrine signals TGF- $\beta$ 1 and IL-10 on the differentiation of dermal fibroblasts (dFb) into myofibroblasts (MFb). The setup should simulate an intermediate stage of wound healing. By that we envision to reveal key factors in the homeostasis of fibroblast phenotypes under the control of IL-10 secreting regulatory macrophages.

### EXPERIMENTAL METHODS

Fibroblast from the human foreskin were cultured on collagen I matrices (2 mg/ml collagen concentration) of defined microstructure and mechanics<sup>1</sup>, optionally functionalized with fibronectin (FN) and sulfated or non-sulfated hyaluronic acid at different concentrations. The dFb were stimulated with TGF- $\beta$ 1 for 4 d at 5 ng/mL to induce MFb differentiation. To address the impact of paracrine IL-10 on dFb fate, cells were treated with IL-10 at different time points and doses (0...20 ng/mL). Wst-1 assay was performed to assess cell proliferation and viability. The MFb differentiation was analyzed by immunocytochemical staining of actin cytoskeleton and alpha-SMA, as well as gene expression using qPCR of  $\alpha$ -smooth muscle actin ( $\alpha$ SMA), collagen I ( $\alpha$ 1) (Coll I) and EDA variant of FN (EDA-FN). Additionally, cell invasion depth into the collagen matrices was quantified.

Besides global delivery of paracrine signals, a set of experiments used local secretion of TGF- $\beta$ 1 and IL-10 from protein-laden hydrogel microbeads, providing a short-range gradient over several days. Local changes in dFb phenotype were investigated by immunofluorescence inside the matrices and single cell tracking of cell migration and proliferation.

### RESULTS AND DISCUSSION

The dFb responded sensitively to FN functionalization in a dose-dependent manner. At increasing FN amount, an increase in cell invasion depth into collagen matrices could be observed. This behaviour was correlated with a reduced cell proliferation, while gene expression of  $\alpha$ SMA, EDA-FN and Coll I was unchanged. By inducing MFb phenotype using TGF- $\beta$ 1, characteristic genes ( $\alpha$ SMA, EDA-FN, Coll I) were expressed at higher levels and cell proliferation was increased compared to untreated cells. Cell invasion depth was found to be decreased. alpha-SMA staining confirmed the differentiation of dFb to MFb by TGF- $\beta$ 1. The results suggest that FN bound to the 3D collagen matrices regulates adhesion and migration and down-regulates proliferative capacity of dFb, but not MFb. Moreover, we found that MFb rearranged collagen fibrils in FN-functionalized matrices, which compares well to tissue contraction at early wound healing *in vivo*.

A subsequential stimulation by IL-10 did not influence proliferation and invasion of dFb and MFb. However, down-regulation of MFb genes was found. Furthermore, IL-10 treated MFb showed similar morphology to dFb and a reduction in actin stress fibres and  $\alpha$ SMA could be observed pointing to a de-differentiation of MFb into dFb triggered by IL-10.

Single cell tracking and immunofluorescence analysis inside matrices with local, cell-sized delivery of IL-10 could directly visualize the local, paracrine effect of MFb de-differentiation.

### CONCLUSION

We found that matrix-bound FN plays an important role in wound healing, by regulating migratory, proliferative and differentiation capacity of dFb. The results demonstrate that IL-10 is a cytokine to terminate new tissue formation by de-differentiation of MFb controlling scar formation at later stages of wound healing. Current studies in our lab ask on ECM stimuli to control macrophage function in the regulation of local and temporal IL-10 levels.

### INTRODUCTION

A variety of wound dressings and devices are currently used to treat different dermal lesions such as burns, chronic ulcers, etc.<sup>1</sup> Among them, biologic-synthetic dressings are bilayered systems formed by a synthetic polymer as the top layer and a bioactive and biologically derived material as the bottom layer.

This work reports the preparation and characterization of a bi-layered system with potential application as a wound dressing. A series of poly( $\epsilon$ -caprolactone) (PCL) based polyesterurethanes (PEUR) containing polyethyleneglycol (PEG) or Pluronic F127 were synthesized for the external layer and a gelatin (G) hydrogel was prepared for the internal bioactive layer.

### EXPERIMENTAL METHODS

Three types of PEURs were obtained containing PEG of  $M_n$  1000 or 10000, or Pluronic F127, which were labelled PEUR-1, PEUR-10 and PEUR-F127 respectively. The PEURs were synthesized in solution following a two-step approach according to Scheme 1.

PEUR membranes were obtained by the solvent casting method. G hydrogels were prepared from G aqueous solutions (3 wt-%) in the presence of genipin (GP) (5 wt-%) at room temperature for 48 h. The system was characterized by <sup>1</sup>H-NMR, ATR-FTIR, SEC, SEM, DSC, TGA, DMTA and microindentation assays. Swelling and stability behaviour was studied *in vitro*. Cellular behaviour was evaluated with human fibroblasts and HUVEC through MTT and Alamar Blue assays. Finally *in vivo* experiments were performed on wounds experimentally created on the back of Wistar rats.

### RESULTS AND DISCUSSION

<sup>1</sup>H-NMR and ATR-FTIR spectroscopy analysis of PEUR samples confirmed the expected chemical structure shown in Scheme 1. Chemical composition was determined from <sup>1</sup>H-NMR spectra from the intensities of the signal at 3.6 ppm due to oxyethylene protons ( $H_e$ ) and the signal at 4.1 ppm pertaining to PCL ( $H_d$ ) (see assignment in Scheme 1 and results in Table 1).

The ATR-FTIR spectrum of G xerogel showed changes in the bands of amide I and amide II, compared to that of native G, attributed to the formation of new covalent amide bonds between the  $-NH_2$  groups of G and the carboxylic groups of GP during the crosslinking reaction. From DSC studies values of melting temperature ( $T_m$ ) of PEURs were around 57 °C, attributed to melting of PCL which is the predominant component. Thermal stability of PEURs was lower than that of PCL mainly at the initial stages with lower  $T_{5\%}$  and  $T_{50\%}$  values. Storage moduli of PEURs obtained by DMTA were between 320 and 420 MPa, and

microhardness ( $H_v$ ) between 33 and 67 MPa, whereas  $H_v$  of G xerogel was 206 MPa.

Scheme 1. Synthesis of PEURs.

Table 1. Molar fraction ( $f_m$ ) of PCL, PEG and Pluronic F127, number average molecular weight ( $M_n$ ) and polydispersity index (P. I.) of the PEURs.

Sample	$f_m(\text{PCL})$	$f_m(\text{PEG/F127})$	$M_n$ (kDa)	P. I.
PEUR-1	0.990	0.010	118	1.36
PEUR-10	0.873	0.127	125	1.32
PEUR-F127	0.858	0.142	125	1.31

Swelling of PEURs was between 6 and 10% whereas that of G hydrogel was 274%. All samples were not cytotoxic in a standard MTT test. *In vivo* results after 4 weeks of implantation showed that the PEUR-10/G hydrogel system promotes wound healing (see Figure 1).

Fig.1. a) and b): Implantation of PEUR-10/G hydrogel. c) After 30 days.

### CONCLUSION

The bilayered PEUR-10/G system proved to be an effective tissue-engineered construct that can promote the healing of full-thickness skin lesions. With the support of further clinical trials, this procedure could be an alternative to wound healing for patients with partial- and full-thickness burns.

### INTRODUCTION

Biodegradable implants based on magnesium offer several advantages mainly the lack of the need for a second surgery for implant retrieval. However, negative effects of the degradation products can reduce the biocompatibility of those materials. Currently, the inflammatory reaction to implants mainly is analysed by histology which does not allow for quantification of the different cells involved in the foreign body reaction. Therefore, our group established a FACS immune cell panel for rat species as a standard animal model to characterize and compare the inflammatory reaction of degradable versus non degradable implants and to compare between the local response formed in the capsule and the systemic response in the blood by single cell analysis on a quantitative level.

### EXPERIMENTAL METHODS

One implant (round shape, 0.8cm) made from PEEK (negative control) or polystyrene (PS, positive control) or pure magnesium (MG) was implanted intramuscular (i.m.; M. gluteus) in 60 female 12 weeks old Lewis rats. After 1, 3, 7 and 14 days (21 days in case of magnesium; n=4) animals were sacrificed and the capsules around the implants were harvested. Blood samples were taken at the day of surgery and sacrificing. Tissue was digested with collagenase buffer. Blood was prepared with RBC lysis buffer (eBioscience) to remove red blood cells. Samples were stained for CD45, CD3, CD4, CD8 and granulocytes (HIS48) as well as a marker for ED2 tissue macrophages (HIS 36; only capsule samples) following the instructions of the manufacturer (eBioscience). FACS analysis was performed on MACSQuant. Cell counting results are presented in % of all cells (CD45+) resp. in % on CD45+ cells. Blood cell counts were normalized to the values of the day of surgery. Statistics: Kruskal Wallis Test, Man Whitney U Test, p0.05.

### RESULTS AND DISCUSSION

From day one to day 14 CD45+ immune cells (Fig A) significantly increased ( $p \leq 0.05$ ) in all groups. Granulocytes significantly decreased (Fig. B,  $p \leq 0.05$ ) in

all groups from day one to day 14. In Magnesium group also CD4 helper-cells significantly increased from day 1 to day 14 ( $p=0.029$ ). In PS also T-helper and T-killer-cells significantly increased from day 1 to 14 ( $p \leq 0.05$ ) Macrophages increased from day one to day 7 and decreased from day 7 to day 14 in all groups.

Fig A: Shows the results from CD45+ cell analysis

Fig B: Shows the results from granulocyte cell analysis.

MG implants showed signs of corrosion from day one. In one animal gas bubbles were found around the implant after 21 days (Fig C). Blood cell analysis showed no statistic differences.

Fig C: Shows PS (1,2) and MG implants (3,4) at day 14 resp 21

### CONCLUSION

The established FACS panel is a good tool to quantify the inflammatory response to implants in rats. The results show a moderate, local foreign body response to the implants. In the blood, no signs for systemic reactions were found. The degradation of pure magnesium did not increase the number of inflammatory cells indicating a good biocompatibility.

### INTRODUCTION

Wounds represent a significant and increasing burden on healthcare systems globally and new therapies and wound management approaches are urgently required. Numerous difficulties are associated to use of small animal models, for this reason *in vitro* wound models using human cells in two- and three-dimensional (2D and 3D) environments have been developed to delineate the molecular mechanisms of cellular repair [1].

Skin equivalents have already been developed to investigate *in vitro* wound healing. Although these studies extensively described the reepithelialization process, and the state of keratinocyte's differentiation during healing [2], to the best of our knowledge a few of information on dermal healing are reported in literature. In order to provide a model more closely resembles the *in vivo* system, the present study was carried out to describe the dermal wound healing process and the related ECM response. In this perspective, a new 3D human dermal equivalent (3D-HDE) [3], based on endogenous ECM, was used as model.

### EXPERIMENTAL METHODS

The 3D-HDE was prepared as reported by Palmiero C. *et al.* (2010) [3]. Sterile scalpel was used to create full thickness wounds. During 18 days of standard culture condition wound was monitored by using time-lapse microscopy. Morphological analysis was performed on histological section at 10, 16 and 20 days. Nucleus detections was assessed by using Sytox Green staining and alfa smooth muscle actin ( $\alpha$ SMA) was detected by using anti- $\alpha$ SM actin antibody. HA was detected by using an Alcian blue-P.A.S kit.

Figure 1. cut evolution in human dermis model.

### RESULTS AND DISCUSSION

The figure 1 showed the evolution of the wound during 20 days. It is evident a significant changing in geometry of the edge of the wound and an activation state and migratory abilities of the fibroblast. Thus, the results displayed a complete healing of the dermal wound in 18 days with a mean closure velocity of  $0.053 \text{ h}^{-1}$ .

In figure 2  $\alpha$ SMA (stained in red) and HA production during dermal healing are reported in the left and right column, respectively. We found that both  $\alpha$ SMA and HA signals presented the strongest signal at 16 days (fig. 2b). According to the literature,  $\alpha$ SMA expression was transient and it was not detectable at 20 days (fig. 2c). At this time HA levels was present (fig. 2f) but decreased compared to 16 days (fig. 2e). Taken together these results demonstrate that some of typical proteins involved in the wound healing process *in vivo*, are induced in our model following the same timing existing *in vivo*.

### CONCLUSION

In conclusion with our 3D-HDE *in vitro* model we can demonstrate the relationship between cell migration, differentiation marker and ECM production during the wound healing process (fig. 2).

We believe that our 3D-HDE wound model could be a starting point for a novel platform to test dermal wound therapies. As a fact, future developments could provide a complete model that will put the healthcare research into a better defined frame and more closely resembles the *in vivo* system.

### INTRODUCTION

Various studies have demonstrated that metal ions are capable to affect different cell types and biological processes essential for bone regeneration<sup>1-4</sup>. Therefore, a promising strategy to stimulate remodeling and new bone formation is the incorporation of such ions into the implant material. In this study, we have modified a brushite-forming calcium phosphate cement with various metal ions ( $\text{Cu}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{Cr}^{3+}$ ) and investigated the impact of these modifications on biocompatibility, resorption and new bone formation.

### EXPERIMENTAL METHODS

Brushite cements were produced by mixing  $\beta$ -TCP powder, which was sintered with the according amount of metal nitrates, in a molar ratio of 0.8 with dicalcium phosphate anhydrous ( $\text{Ca}(\text{H}_2\text{PO}_4)_2$ ). Afterwards, the powder was mixed with 0.1 M phytic acid in a powder to liquid ratio of 2 g/ml. Ion release from the cements was investigated during immersion in cell culture medium which was collected at different time points and analyzed by inductively coupled plasma mass spectrometry (ICP-MS).

Cytocompatibility was studied with human mesenchymal stem cells (hMSC) in indirect culture as well as in direct contact over 21 days. Osteogenic differentiation of hMSC was induced by addition of dexamethasone,  $\beta$ -glycerophosphate and ascorbic acid-2-phosphate to the cell culture medium. Osteoclast formation and activity was investigated in direct contact to the cement surface. Human monocytes were seeded onto the samples and cultivated in the presence of RANKL and M-CSF over 16 days. Resorption of the cements as well as new bone formation was studied in unloaded cylindrical defects in the tibia head of rats 3 and 6 months after implantation.

### RESULTS AND DISCUSSION

The phase composition of the set cements was not influenced by the different metal ions. Every cement formulation has formed brushite with a certain amount of unreacted  $\beta$ -TCP. During immersion in cell culture medium,  $\text{Cu}^{2+}$  and  $\text{Co}^{2+}$  were released with an initial burst followed by a sustained release, however, the concentrations in the release solution was always far below the cytotoxic threshold. In contrast, nearly no  $\text{Cr}^{3+}$  was released from the cements.

Indirect culture of hMSC revealed a higher cell proliferation and viability in the presence of extracts obtained from  $\text{Cu}^{2+}$  and  $\text{Cr}^{3+}$  modified cement samples compared to the reference cement. In addition, slightly higher values of alkaline phosphatase (ALP) activity indicated a positive effect of these modifications on osteogenic

differentiation. Cultivation of hMSC directly on the cement samples demonstrated a clear improvement of the cytocompatibility of brushite by incorporation of  $\text{Cr}^{3+}$ , but not of  $\text{Cu}^{2+}$  and  $\text{Co}^{2+}$ .

Multinuclear osteoclasts were formed from monocytes on reference cements as well as on  $\text{Co}^{2+}$  and  $\text{Cr}^{3+}$  modified cements. In contrast, monocytes did barely survive on the surface of  $\text{Cu}^{2+}$  modified cements. Highest osteoclast number as well as highest activity of the osteoclast-specific enzymes tartrate-resistant acid phosphatase (TRAP) and carbonic anhydrase II (CAII) were found on  $\text{Cr}^{3+}$  cements.

Figure 1: hMSC (day 14) on unmodified (A) and on  $\text{Cr}^{3+}$  modified brushite cements (B); osteoclasts (day 16) on  $\text{Cr}^{3+}$  modified brushite cements (C)

Compared to unmodified brushite cements, the addition of  $\text{Cr}^{3+}$  stimulated bone remodeling *in vivo* as indicated by an increased cellular activity and a significantly enhanced bone resorption after 3 and 6 month of implantation. The addition of  $\text{Cu}^{2+}$  and  $\text{Co}^{2+}$  showed no stimulating effect. Both, the *in vitro* and *in vivo* experiments indicate a positive effect of the  $\text{Cr}^{3+}$ -modification.

### CONCLUSION

The incorporation of metal ions into implant materials can influence their biocompatibility and resorption as well as the bone remodeling process. Data of our study demonstrated that the modification of a brushite cement with  $\text{Cr}^{3+}$ -ions could improve its performance.

### INTRODUCTION

Metallic implants are used throughout the body, particularly for the repair of orthopaedic and craniofacial defects. Irrespective of surgical domain, there are three inherent problems associated with such implants that are yet to be addressed: (1) relatively high rates of infection (5% in US<sup>1</sup>), (2) lack of customisation of fit to the tissue defect, and (3) a mismatch of mechanical properties between the implant and patient's bone. These issues compromise implant functionality. For example, the high stiffness of metals, such as Ti-6Al-4V, compared with bone may lead to localised resorption of native tissue and ultimately loosening of the implant.

This project aims to address the deficiencies associated with current metallic implants by using an additive layer manufacturing (ALM) method, to create customised implants with a defined internal porosity that may be infiltrated with a second phase that: (1) is of lower stiffness than the metal, and (2) may carry a biologically active molecule that may modify the tissue healing response or prevent infection altogether.

This study describes how cold-setting brushite cements have been modified for injection into a demonstration metal part (*Fig 1*), manufactured using selective laser melting (SLM). The physiochemical properties of the materials were evaluated using scanning electron microscopy, X-Ray diffraction, compression testing, and pycnometry. Furthermore, the efficacy of the cement as a release reservoir infiltrated into the

minutes. Selected samples were analysed via XRD ( $2\theta=5-60^\circ$ ) to determine the conversion rate to brushite and cylinders ( $h = 12 \text{ mm}$ ,  $d = 6 \text{ mm}$ ) were manufactured to assess microstructural development via SEM, compressive strength ( $n=10$ ; 1 mm/min), and porosity. Test SLM parts were designed using *Solidworks* (*Fig 1*), converted to STL format, and manufactured using a *Concept M2 Cusing System*.

### RESULTS AND DISCUSSION

SEM micrographs demonstrated significant morphological and average particle size variation (MCPM: 8.3 – 192  $\mu\text{m}$ ;  $\beta$ -TCP: 27.4 – 67.5  $\mu\text{m}$ ) between different reagent suppliers. Brushite cements produced at the same PLR and using the same liquid phase but using reagents from different suppliers exhibited significant differences in setting time and injectability. For example, at a PLR 3.0 using 1000 mM citric acid the setting time varied 62-223 minutes and injectability through a 15G needle was between 0 and 94%. Eight formulations were determined to exhibit an injectability >80% and setting time 10-30 minutes. Interestingly, no samples formed using orthophosphoric acid met this criteria, which was due to setting times either being too fast or samples with appropriate setting times having a high PLR and therefore poor injectability. The conversion rate to brushite for these 8 formulations varied between 77 and 92%. A positive correlation between conversion rate and injectability was observed ( $R^2=0.6$ ), suggesting that minimising the amount of unreacted  $\beta$ -tricalcium phosphate may facilitate minimally invasive delivery of the cement paste. The maximum compressive strength of uncompacted cements was <20 MPa and samples exhibited porosities from 49 to 64%. Surprisingly, no obvious correlation was observed between maximum compressive strength and porosity. Although this may be explained by other factors, such as the maximum pore diameter, which are known to influence strength.

*Fig 1*: CAD of part manufactured by SLM (dimensions in mm)

structure was evaluated by determining antibacterial potency and endothelial cell tubule formation.

### EXPERIMENTAL METHODS

Cement reagents were purchased from various suppliers and manufactured at powder to liquid ratios 2.0, 3.0, and 4.0 using water, 500 mM/1000mM citric acid or 500/1000 mM trisodium citrate as the liquid phase. Cement pastes were prepared by hand mixing the relevant powder and liquid phases for 30 s. The ease of injecting the cements pastes through a 5 mL syringe and a 15G hypodermic needle as well as setting time were determined. Formulations to inject into metal parts were then selected according to a criteria of >80% injectability and a setting time between 10 and 30

### CONCLUSIONS

This study demonstrates the ability to infiltrate brushite cements loaded with a therapeutic agent into customised metal parts; highlighting the potential of this strategy to impact on current orthopaedic and craniofacial implant design.

## The Influence of Phase Change Materials Based on Poly(Ethylene Glycol) on the Properties of Acrylic Bone Cements

Kinga Pielichowska, Katarzyna Filipek

Faculty of Materials Science and Ceramics, Department of Biomaterials,  
AGH University of Science and Technology, Poland

[kingapie@agh.edu.pl](mailto:kingapie@agh.edu.pl)

### INTRODUCTION

Commercial acrylic bone cements (mainly based on poly(methyl methacrylate) (PMMA)) have been used in total joint arthroplasty since late 1950s [1]. Acrylic bone cements are composed of solid and liquid phase. The solid phase consists of PMMA or its copolymers, initiator and radiological contrast ( $\text{ZrO}_2$  or  $\text{BaSO}_4$ ), while the liquid component is methyl methacrylate monomer, an activator and an inhibitor to avoid premature polymerization [2]. Now, PMMA-based bone cements are widely used in orthopaedic surgery, mainly for fixation of prostheses, but also for stabilizing compressive vertebral fractures or filling bone defects [3]. The major problem with the use of acrylic cement is thermal necrosis of surrounding bone tissue due to the high heat generation during curing process. Polymerization of the acrylic bone cement is an exothermal process, which can give a local temperature peak ranging from 50 to 120°C [4]. In this work we propose modification of acrylic bone cement with poly(ethylene glycol) as phase change materials (PCM) able to store thermal energy in the form of latent heat to decrease the maximum curing temperature.

### EXPERIMENTAL METHODS

Acrylic bone cement was modified by PEG with molecular weight of 1450 in amounts of 2.5, 5, 10, 15, 20%. The setting time was measured using the Gillmore needle method while maximum curing temperature  $T_{\text{max}}$  and setting time  $t_{\text{set}}$  were measured in accordance with ISO 5833 standard. Thermal properties were investigated using DSC and TG methods; mechanical properties were tested using compression tests and ultrasonic non-destructive method. Microstructure was observed using SEM. Moreover, samples were incubated at 37 °C according to EN ISO 10993-13 for 14 weeks in Ringer solution and in PBS. The pH, conductivity, and mass change were measured during incubation.

### RESULTS AND DISCUSSION

Results of setting time and temperature measurements during curing of acrylic bone cement with different PEG content are presented in Fig. 1. As it can be observed, the setting time of modified acrylic bone cements slightly increase with increasing PEG content. However, for all samples it does not increase above 15 min and is still consistent with ISO 5833:2002.

It can be also seen a significant decrease in maximum temperature in curing process – maximum temperature decreased from 71°C for unmodified cement to 60°C for cement with 15% of PEG that undergo melting during curing of acrylic bone cement due to large exothermal effect, and it stores thermal energy in form of latent heat of phase transition [5, 6].

Fig. 1. Setting time (left) and temperature (right) as a function of time for different PEG contents

Major changes in microstructure have been observed by SEM analysis – Fig. 2.

Fig. 2. SEM microphotographs of unmodified acrylic bone cement (left) and modified with 20% of PEG

### CONCLUSIONS

Modification of acrylic bone cement using PCM strongly influences the maximum setting of acrylic cement and can significantly reduce the temperature. The maximum temperature of curing process gets lower with an increase of the amount of PCM in cement. With an increase of PCM content, cement setting time is longer, but it is still below 15 min. As modification with PCMs influences cement's microstructure, some changes in the mechanical properties and in vitro stability have been observed.

### INTRODUCTION

Induction of *in vivo* responses by implanted biomaterials is of great interest in the medical device field. Calcium phosphate bone cements (CPCs) can potentially promote natural bone remodelling and ingrowth *in vivo* and, as such are becoming more common place in a range of orthopaedic procedures. However, concerns remain regarding their mechanical and handling properties. Compressive modulus and fracture toughness of CPCs can be improved, without compromising injectability and setting time, through the incorporation of bovine collagen fibres<sup>1</sup>. Incorporation of marine derived collagen fibres has also yielded similar improvements<sup>2</sup>. It is hypothesised that, due to its role in bone formation and function, that incorporation of collagen in CPCs will also result in biological benefits.

### EXPERIMENTAL METHODS

$\alpha$ -tricalcium phosphate and 5 wt%  $\text{Na}_2\text{HPO}_4$  in  $\text{dH}_2\text{O}$  were mixed at a liquid/powder ratio of 0.35 mL/g to produce a CPC ( $\alpha$ -TCP-CPC). Bovine (BC-CPC) and Marine (MC-CPC) collagen-CPC composites were produced by adding 1 wt% collagen into the powder and liquid phases respectively. A CPC based on a commercial formulation<sup>3</sup> (Merck-CPC) and a clinically used injectable poly(methyl methacrylate) bone cement (VP-PMMA - Vertebroplastic® Radiopaque Resinous Material, DePuy) were used as controls.

Human bone marrow stromal cell cytotoxicity, proliferation and differentiation were assessed *in vitro* using lactate dehydrogenase (LDH), PicoGreen and alkaline phosphatase (ALP) activity assays respectively.

New Zealand white rabbits were used as an *in vivo* model. Conical cement samples (8 mm long and 4 mm base diameter) were press fit into defects created in the distal femoral condyles; retrieval for analysis took place at 5 and 10 weeks. Bone apposition (BA) onto the implants and mineral apposition rate (MAR) were evaluated and tartrate resistant acid phosphatase (TRAP) staining was used to assess osteoclast activity in the implanted region.

### RESULTS AND DISCUSSION

Relatively low (< 15 %) levels of cytotoxicity were associated with each of the cements. Increased cell death was associated with collagen incorporation, but only to the extent observed for hydroxyapatite<sup>4</sup>, another common orthopaedic biomaterial. Cellular proliferation occurred on all cements, but the most notable variation between formulations was in induction of osteoblastic differentiation (Figure 1). ALP activity was significantly higher on each of the CPCs than on

VP-PMMA. Activity was similar on the collagen-CPCs at each time point; however, by Day 21 ALP activity was significantly higher on both unaugmented CPCs when compared to BC-CPC. This is likely to be due to the increased surface roughness of BC-CPC, which has been associated with delayed differentiation<sup>5</sup>.

Figure 1: ALP activity per  $\mu\text{g}$  dsDNA associated with each cement formulation.

All formulations were well tolerated *in vivo*. CPCs induced higher BA than VP-PMMA, though BA was unaffected by collagen incorporation. MAR was unchanged, suggesting little influence on bone growth rate at the times considered. Osteoclastic activity within CPC cracks was indicated by TRAP staining and bone growth within cracks also suggests that small scale cement remodelling occurred.

### CONCLUSION

The biological properties of  $\alpha$ -TCP-CPC were largely unchanged by the incorporation of marine derived collagen. However, as a result of significant improvements to the mechanical properties, its incorporation may still result in a suitable alternative to some commercially available bone cements.

## Cellular Uptake and Degradation of Poly(Lactide-co-Glycolide) Nanoparticles and its Influences on Cell Functions

Dahai Yu, Pengfei Jiang, Zhengwei Mao, Changyou Gao\*

MOE Key Laboratory of Macromolecular Synthesis and Functionalization, Department of Polymer Science and Engineering, Zhejiang University, Hangzhou 310027, China  
[cygao@zju.edu.cn](mailto:cygao@zju.edu.cn)

### INTRODUCTION

The polymeric nanoparticles (NPs) have been widely used in biological and biomedical fields such as drug/gene carriers, contrast agents, photo-thermal therapeutic materials, etc. However, the interaction between these NPs and cells, such as internalization process, intracellular fate and influence on cell functions, is still not fully addressed. This study is focused on the internalization processes and intracellular fate of functional polymeric NPs, especially poly(lactide-co-glycolide) (PLGA) NPs, and their influences on cells.

### EXPERIMENTAL METHODS

The polymeric NPs with different physiochemical properties such as charge, ligands, and stiffness were prepared. Their cellular uptake kinetics and pathways as well as intracellular transportation were studied by in vitro cell culture. The alternation of particle structures and functions inside cells was investigated via fluorescence resonance energy transfer (FRET) technique. The influences of particles on cell functions and phenotypes were also determined.

### RESULTS AND DISCUSSION

The physiochemical properties of particles significantly influenced particle-cell interactions. For example, endothelial cells preferred to ingest positively charged PLGA-PEI particles than negatively charged PLGA-BSA particles. Both types of particles were internalized into the cells via macropinocytosis and clathrin-mediated endocytosis pathways. Ingestion of the positively charged particles caused apparently a decrease in cell viability, proliferation, cell adhesion and migration, as well as wound healing ability. By contrast, uptake of negatively charged particles caused much less influence on cell functions. Uptake of the stiffer PLGA NPs enhanced the osteogenic differentiation of mesenchymal stem cells as evidenced by the higher expression of ALP activity and collagen type I and osteocalcin.

The PLGA-PEI particles were further covalently modified via grafting of fluorescein isothiocyanate (FITC), dimethyl 3,3'-dithiobispropionimidate (DTBP), amino-ended polyethyleneglycol (PEG), and tetramethylrhodamineisothiocyanate (TRITC), as shown in Figure 1. The Fluorescence resonance energy transfer (FRET) could be observed and the intensity ratio between 520 nm and 570 nm was used to evaluate the dissociation of disulfide bonds on the surface of PLGA particles. The dissociation of fluorescent dyes in the cells was significantly slower than that in simulated phosphate buffered saline (PBS) containing the same

concentration of reduction agent glutathione, revealing the difference of particle dissociation behaviors.

**Figure 1** Preparation of PPFDP particles and their FRET change caused by GSH reduction.

### CONCLUSION

The particle physiochemical properties can modulate cell uptake and cell functions such as viability, adhesion, migration and differentiation. The alternation of particle structures and functions in cells can be significantly different than that in simulated buffer, which should be taken into consideration for design of those intracellular delivery vehicles.

### INTRODUCTION

In the last decades the field of nanotechnology becomes the main focus of numerous research centers over the world. Nanomaterials are being used in rapidly increasing applications and many products in nano-scale have already been launched on the market. However, despite of new, unique and alternative properties of nanomaterials comparing to their bulk counterparts, the level of risk towards human health is still unclear and not fully examined<sup>1</sup>. In the view of above, the use of commercial products in biomedical applications raises big concerns – due to the investigated short- or long-term toxicity of nanoparticles and potential hazardous influence on human body<sup>2,3</sup>. In the present study, we investigated the biological effects of three commercially available nanoproducts: polyamidoamine dendrimers (PAMAMs) of 4.0 generation, silver nanopowders (SNPs) and multi-walled carbon nanotubes (MWCNTs) on EA.hy926 endothelial cell line. Owing to the extensive scope of this work it was possible to assess changes in endothelial cells on the structural as well as the molecular level.

### EXPERIMENTAL METHODS

After seeding on culture plates, endothelial cells were cultured in DMEM medium at 37°C for 24h in a fully humidified atmosphere of 5% CO<sub>2</sub>. Cells were then stimulated with examined nanoparticles for 24h. For assessment of morphological changes scanning electron microscope (Quanta FEG 250 FEI) working in high vacuum at accelerating voltage of 10 kV, 15 kV or 20 kV was used. To evaluate the cytotoxic potential of nanoparticles, LIVE/DEAD test was performed using Accuri C6 Flow Cytometer (Becton-Dickinson). For transcriptomic analysis, Agilent SuperPrint G3 Human GE 8×60K V2 oligonucleotide microarrays were used. Total RNA from EA.hy926 cell was isolated using TRI Reagent (Molecular Research), purified, labelled and hybridized for 17h at 65°C with a rotation speed 10 rpm. Gene Spring GX 12.6.1 (Agilent) Software was used to analyze gene expression data. For assessment of the whole proteome of endothelial cells, differential in-gel electrophoresis DIGE was used. Samples were labeled with Cy3, Cy5, isofocused on 18cm long DryStrip gels, pH 4-7 using IPGphor III (GE Healthcare) and separated in second dimension in Ettan DALTsix system (GE Healthcare). Obtained data were analyzed with ImageMaster 2D Platinum 7.0 DIGE (GE

Healthcare). Proteins under changed expression were identified with MALDI-TOF/TOF spectrometer (UltrafleXtreme Smartbeam II, Bruker Daltonics) and identification was performed via MASCOT search engine against Swiss Prot database.

### RESULTS AND DISCUSSION

Using scanning electron microscopy, we reported the differences in cell morphology under experimental conditions comparing to control, particularly apparent for SNP. It was observed that cells internalized SNP after 24h of incubation period what consequently might affect cell morphology and proliferation. These findings are correlated with flow cytometry analysis – we demonstrated increased value of SSC parameter for SNP and altered viability of cells for all nanomaterials compared to control. What is more, cytotoxic effect manifested by increased population of dead cells, is dose-dependent for SNP, while for PAMAM dendrimers and MWCNT the tendency was not clear and not statistically significant.

DIGE analysis revealed changes in the expression of a number of distinct proteins. In response to nanoparticle incubation, among almost 900 proteins expressed in cells at average for each nanomaterial and control, statistically significant changes were addressed to SNP for 100 proteins (including 74 down-regulation, 26 up-regulation), to MWCNT – 41 proteins (31 down-regulation, 10 up-regulation) and to PAMAM dendrimers – 50 proteins (29 down-regulation, 21 up-regulation). Transcriptomic analysis showed that more than 400 genes were in changed expression. We also observed that only several proteins identified by mass spectrometry corresponded to changes in genes' expression.

### CONCLUSION

Our findings highlight changes on both – structural and molecular level - in EA.hy26 cells due to exposure to nanoparticles at various concentrations. As these issues are crucial for commercial use of nanoproducts, it should be regarded with more attention and further studies must be carried out to achieve better knowledge in this field.

### INTRODUCTION

Recently, gold nanoparticles have shown to have interesting features to stimulate the osteogenic differentiation of mesenchymal stem cells as well as osteoblast-like cell toward osteoblast formation.<sup>1,2</sup> Due to their remarkable physicochemical properties, gold nanorods (AuNR) gain a lot of interest to be used for diagnosis, cell tracking, thermal therapy and drug delivery system (DDS) for regenerative medicine.<sup>3</sup> However, their surface modification is primordial in order to improve their biocompatibility and stability under biological conditions, while enable the controlled release of drugs/bioactive agents. In this purpose, the coating of gold nanorods within hydrogel as Gellan Gum (GG), a biodegradable and biocompatible natural-based polymers<sup>4</sup>, was performed and allowed to greatly fulfill the requirement needed to develop an efficient DDS for osteogenic differentiation.

### EXPERIMENTAL METHODS

Gold nanorods were prepared following the seed-mediated growth method and then, were pre-coated with a bilayer of polyelectrolytes. Subsequently, a solution of “Gelzan” Gellan Gum was previously heated at 90°C to allow dissolution. The nanorods were added to the GG solution and the mixture was stirred overnight at room temperature. The GG-coated nanorods (AuNR@GG) have been characterized by UV-visible spectrometry, zeta potential measurements and Transmission electron microscopy (TEM). The cell viability has been performed in normal and osteogenic media after 1, 3, 7 and 14 days of culture using MTS assay in SAOs-2 and rabbit adipose stem cell, and human adipose-derived stem cell. The internalization was characterized by TEM. The dexamethasone, osteogenic precursor, have therefore been adsorbed into gold nanorods suspension and then the mixture was added the GG solution for one night.

### RESULTS AND DISCUSSION

Gold nanorods were successfully coated with ~10 nm layer of gellan gum, as shown in figure 1. The AuNR@GG exhibited better stability than crude AuNRs and polyelectrolyte-modified AuNRs (data not shown) in different concentrations of salt and pH. The cell viability assays have shown that AuNR@GG are no cytotoxic after 14 days of culture in normal and osteogenic media in three different cell lines. Moreover, the particles have been uptaken inside cells, aggregated in vesicles (Figure 2). The incorporation of dexamethasone, and the stability of the drug-functionalized nanoparticles are significantly improved

in presence of the gellan gum (data not shown).

Figure 1. TEM images of A) pre-coated AuNR and B) AuNR@GG

Figure 2. TEM image of internalized AuNR@GG inside adipose stem cell

### CONCLUSION

In this study, we report the successful coating of individual gold nanorods within gellan gum and the ability to improve the drug loading yield. The proposed system has shown interesting features for osteogenesis, and further will be extended for cancer therapy and tissue engineering studies.

### INTRODUCTION

Extremely high mechanical properties, good thermal and electrical conductivity, combined with reported potential to stimulate cell's growth, differentiation and proliferation are major factors of an increased scientific interest in applying carbon nanotubes (CNTs) to various biomedical systems [1, 2]. However, within the literature, large discrepancies, concerning CNTs biocompatibility, can be found. In some studies, a cytotoxic reaction is reported [3], whereas in others, a successful application with no adverse effects can be found [4].

Most of the biocompatibility studies are focused on the impact of the various physiochemical properties of the CNTs dilutions on their outcome toxicity and are aimed to answer the question whether the CNTs are good candidates for targeted therapies [5]. However, different type of cellular reaction is expected when the cells are contacted with the CNTs surfaces.

The aim of the presented study is to reveal the correlation between the physiochemical properties of the CNTs layers and their outcome biocompatibility.

### EXPERIMENTAL METHODS

Functionalized multiwalled carbon nanotubes were either obtained from the producer (CNT\_OH) or fabricated from the pure CNTs via chemical reflux (CNT\_ox). The materials were supplied by NanoAmor, Inc. (stock # 1249YJF and 1213NMGS, respectively). Thin layers of CNTs were deposited through the EPD process. Physiochemical evaluation included wettability measurement, SEM observation, and the XPS study. Influence on cells was studied on the L929 cell line (mouse fibroblasts). In long-term *in vitro* experiments, cell apoptosis, lysis and viability was evaluated after being grown on materials. Simultaneously, cell adhesion was evaluated and spreading was observed under a fluorescence microscope.

### RESULTS AND DISCUSSION

CNT\_OH and CNT\_ox were found to differ majorly in terms of type and amount of functional groups. Consequently, these were found to affect the morphology and wettability of the obtained layers.

Finally, the study revealed that all of the presented factors have major influence on the outcome cell's reaction towards the materials.

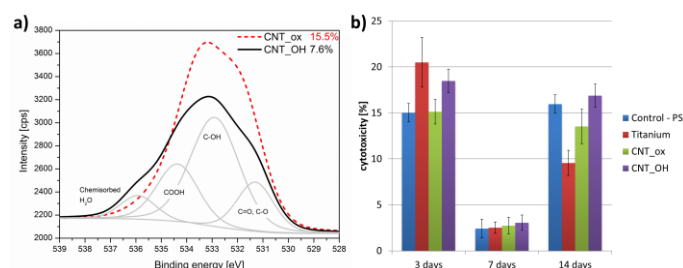

Fig. 1 reveals correlation between a) chemical composition revealed during an XPS study and c) cell's reaction towards the material

### CONCLUSION

Within the presented study, numerous analytical techniques were applied in order to evaluate influence of various physiochemical properties of the CNTs layers on the outcome cells' response. Presented results imply that outcome biocompatibility of the CNTs depends not only on their size and shape, but also – on the type and amount of different functional groups present on their outer sidewalls.

# Novel Collagen Type I-Hyaluronic Acid Bi-Phasic Conduit for Peripheral Nerve Repair: An *In Vivo* Study

Tijna Alekseeva, Phoebe E. Roche<sup>1</sup>, Amos Matsiko, Amro Widaa, William A. Lackington, Alan Ryan, Alan J. Hibbitts, Garry Duffy, Fergal J. O'Brien

Tissue Engineering Research Group, Department of Anatomy and

<sup>1</sup>Department of Otolaryngology, Royal College of Surgeons in Ireland, Ireland

[tijnaalekseeva@rcsi.ie](mailto:tijnaalekseeva@rcsi.ie)

## INTRODUCTION

Peripheral nerve (PN) injuries usually require surgical intervention associated with multiple risks and inferior functional outcomes<sup>1</sup>. Coupled with the diminishing capacity for regeneration associated with age<sup>2</sup> and underlying conditions such as diabetes<sup>3</sup>, there is a considerable demand for alternative treatments. A novel bi-phasic conduit for PN repair was developed in the Tissue Engineering Research Group at RCSI, Ireland, consisting of the outer collagen type I based conduit and inner hyaluronic based luminal filler (Fig.1A). This conduit is bio-compatible and bio-degradable, has an aligned porous microstructure and supports neuro- and gliogenesis *in vitro*. It was hypothesised that nerve conduit will support nerve regeneration across critical size defect *in vivo* (Fig.1B).

Fig.1: (A) Gross morphology of the novel nerve conduit. Colour is used to highlight bi-phasic composition. (B) Cellular response to the novel nerve conduit following PN injury

Here we present the encouraging results of a pilot *in vivo* study investigating the pro-regenerative capacity of the novel conduit in the critical size PN defect rat model.

The overall aim of this study was to assess the pro-regenerative performance of the nerve conduit *in vivo* in a critical length peripheral nerve injury model.

## EXPERIMENTAL METHODS

The conduits were implanted into a 10 mm sciatic nerve gap within Sprague Dawley rats (n=9) following approval from the RCSI Ethics Committee. At 8 weeks post-implantation, functional assessment of regeneration through the conduit was performed by measuring nerve conductivity across the regeneration site and the force of the motor response to the nerve stimulation. These data were compared to the contralateral uninjured control or negative control (10 mm injury, no treatment, n=9). Nerve regeneration was assessed morphologically by histomorphological analysis of the excised tissue using immunostaining.

## RESULTS AND DISCUSSION

Significant recovery of nerve functionality was achieved 8 weeks after implantation of the novel conduit. No functional recovery was detected in the negative control group confirming absence of

spontaneous regeneration and highlighting the role of the nerve conduit in recovery of the nerve function after injury. Functional recovery data were supported by the histomorphological analysis of the excised tissue showing aligned ingrowth of axons across the conduit (Fig.2 A, B) and into the distal nerve (Fig. 2C), using axonal marker neurofilament (shown in red)

Fig.2 Immunofluorescent images of the transverse (A) and longitudinal (B) sections of the nerve conduit after 8 weeks *in vivo*. Longitudinal section of the nerve distal to the site of implantation is shown in (C). Inserts show scanning electron microscopy images of the conduit prior to implantation. Demarcation between the outer conduit and luminal filler is indicated by dashed line. Arrows indicate the direction of axonal alignment.

Further histomorphological analysis demonstrated that explanted conduits were repopulated by the host SCs expressing SC-specific marker, S100 $\beta$  and myelin marker, Myelin Basic Protein, indicating regeneration of the normal PN morphology. Moreover, infiltrating SCs were able to lay down basal lamina proteins fibronectin and laminin, further highlighting pro-regenerative role of the nerve conduit.

## CONCLUSIONS

- Implantation of the novel bi-phasic conduit restored nerve functionality after 8 weeks.
- The conduit was capable of guiding axons across the injury site with a high degree of alignment.
- Furthermore, the conduit supported migration and pro-regenerative functional behaviour of Schwann cells.
- Future work involves further enhancement of the regenerative capacity of the conduit by incorporation of neuro-inductive growth factors and progenitor cells.

## Sustained Biochemical Signalling and Contact Guidance Provided by Electrospun Bicomponent Scaffolds for Enhancing Nerve Regeneration

Chaoyu Liu, Min Wang

Department of Mechanical Engineering, The University of Hong Kong, Pokfulam Road, Hong Kong  
[jamesliu@hku.hk](mailto:jamesliu@hku.hk)

### INTRODUCTION

Repairing severely injured peripheral nerves requires suitable devices for bridging the nerve and guiding axon growth. Electrospun fibrous scaffolds offer distinctive advantages and have gained popularity in nerve tissue repair. Nanofibrous scaffolds provide favourable conditions including high surface-area-to-volume ratio and structural similarity with extracellular matrix for Schwann cell migration and neurite outgrowth<sup>1</sup>. On the other hand, controlled local delivery of nerve growth factor (NGF) and/or glial cell line-derived growth factor (GDNF) promotes peripheral nerve regeneration. It was also shown that electrospun aligned fibres provided contact guidance, leading to elongation and alignment of cultured cells<sup>2</sup>. In this investigation, bicomponent scaffolds composed of random or aligned nanofibers which were incorporated with NGF and GDNF were fabricated for providing sustained biochemical signal and contact guidance for peripheral nerve regeneration.

### EXPERIMENTAL METHODS

Using dual-source dual-powder electrospinning (DSDP-ES)<sup>3</sup>, emulsion electrospinning (E-ES) and a drum collector rotating at different speeds, new bicomponent scaffolds composed of random or aligned fibers were made, incorporating NGF in poly(D,L-lactic acid) (PDLLA) fibers and GDNF in poly(lactic-co-glycolic acid) (PLGA) fibers. PDLLA emulsions (15 or 20% w/v) and PLGA emulsions (12 or 15% w/v) were used in electrospinning. The ratio of NGF/PDLLA fibers to GDNF/PLGA fibers in scaffolds was varied. The morphological and structural properties of scaffolds were assessed using SEM and TEM. *In vitro* release profiles of NGF and GDNF were studied using ELISA kit assay. For biological investigations, PC12 cells were seeded on scaffolds and cultured for up to 7 days. MTT assay was used for cell proliferation study. F-actin and neurofilament were stained at day 4 and day 7 for investigating cell differentiation using laser scanning confocal microscopy (LSCM). Neurite length and alignment were measured using an image analysis tool.

### RESULTS AND DISCUSSION

Robust GDNF/PLGA and NGF/PDLLA fibers with core-shell structures (Fig.1) were produced via E-ES. Through DSDP-ES, both types of nanofibers were evenly distributed in bicomponent scaffolds and desirable fiber ratios (and hence GF ratios) could be achieved (Fig.2). Within a 42-day release test period, GFs from bicomponent scaffolds showed an initial burst release within 24 h, followed by a sustained release. Both NGF and GDNF from scaffolds with various fiber ratios exhibited similar release profiles but different release amounts (Fig.3). The bioactivity of released NGF and GDNF was preserved at maximum. MTT

results showed that novel scaffolds had significant enhancement in PC12 cell proliferation as compared with the control group. It was shown that GF-containing scaffolds significantly enhanced cell differentiation in terms of neurite outgrowth and branching of PC12 cells (Fig.4). Larger GF release amounts led to higher differentiation levels. The synergetic effect of dual delivery of NGF and GDNF on cell differentiation occurred at the 2:1 ratio of NGF/PDLLA to GDNF/PLGA fibres for bicomponent scaffolds. Longer neurite outgrowth and alignment of PC12 cells were observed on scaffolds with aligned fibres.

Fig.1 TEM image

Fig.2 Confocal Image

Fig. 3 Release profile

Fig. 4 Cell Morphology

### CONCLUSION

Novel bicomponent scaffolds composed of aligned fibers containing designed amounts of NGF and GDNF could be made via DSDP-ES with E-ES. Good post-release bioactivity and sustained release of both GFs were achieved. Compared with the control group, bicomponent scaffolds containing GFs induced much enhanced PC12 cell differentiation. Furthermore, growth factors released from bicomponent scaffolds at a certain fiber ratio promoted cell differentiation in a synergetic manner and aligned fibers predominantly provided contact guidance, resulting in the elongation and alignment of cells. These scaffolds are promising for peripheral nerve regeneration.

## The “Micro” and “Macro”- Scale Approach in Building up Neural Stem Cell Microenvironments for Developmental and Toxicity Studies

Leonora Buzanska<sup>1,2</sup>, Marzena Zychowicz<sup>1,2</sup>, Krystyna Pietrucha<sup>3</sup>, Martyna Podobinska<sup>1,2</sup>, Jose Luis Gerardo-Nava<sup>4</sup>, Gary Brook<sup>4</sup>

[buzanska@imdik.pan.pl](mailto:buzanska@imdik.pan.pl)

### INTRODUCTION

Combining advances in stem cell research with emerging technologies of the stem cell niche bioengineering, allows the creation of paradigms that mimic *in vivo*-microenvironments. There are two different strategies to create such advanced “biomimetic” research systems *in vitro*. The first is to establish “microscale” environments to test cell behaviour, even at the single cell resolution<sup>1</sup>. The second approach is to provide a “macroscale” structural 3D template<sup>2</sup> for cell differentiation and function that allows the growth of complicated human tissues and organoids.

In this report we are presenting both, “micro” and “macro”- scale culture systems used by our group for developmental and toxicity studies of human neural stem cells derived from cord blood and neurally committed induced pluripotent stem cells (iPSC).

### EXPERIMENTAL METHODS

Human umbilical cord blood-derived neural stem cells (HUCB-NSC)<sup>3</sup> and virus-free, feeder-free human umbilical cord blood-derived iPSC (hiPSC, Life Technologies) were cultured and harvested at different stages of neuronal development. The cells were seeded on: 1) matrigel-coated plates, 2) different microprinted or microspotted patterns of extracellular matrix domains functionalized with signalling proteins (Shh, Wnt3a, Dkk1, Jagged1, CNTF)<sup>4</sup> and 3) chemically modified collagen scaffolds<sup>2</sup>. The last approach was to co-culture collagen scaffold/hiPSC hybrids with rat dissociated dorsal root ganglia neurons and organotypic spinal cord slices<sup>5</sup>, testing for cell migration and axonal growth between dissociated cells/slices and the seeded and non-seeded scaffold.

The “micro-scale” culture systems were obtained by soft lithography, microcontact printing of different biomolecules, mainly ECM proteins and by piezoelectric microspotting of ECM alone or combined with signalling proteins<sup>4</sup>. Collagen scaffolds were prepared from porcine collagen dispersion using a lyophilization technique to obtain 3D, porous scaffolds. Scaffolds cross-linking with carbodiimide ensured mechanical and thermal properties. Differentiation potential of neural stem cells was tested by immunocytochemical staining and real time PCR of developmental stage dependent markers. Microscopy was performed using an AxioScope with associated AxioCamMRC5 camera as well as a confocal LSM 510 system (Carl Zeiss, Germany).

### RESULTS AND DISCUSSION

Microcontact printing allows easy fabrication of complex patterns with one type of biomaterial for studying stem cell migration and differentiation on

different geometries. Micro-spotting is a versatile tool for depositing different biomolecules on the same chip, allowing rapid screening of the effects of multiple biomolecules at different concentrations on stem cell fate. We have shown that the potential to differentiate of HUCB-NSC and hiPSC depends on the type of functional domain and its geometry and that “smart” biodomains with signalling molecules can direct stem cell fate into neuronal or glial lineage. In macro-scale conditions, cells were seeded onto collagen scaffolds or forced for the self assembly into embryoid bodies in matrigel. The control cultures of hiPSC under neural-differentiating protocol revealed all typical changes from pluripotent to neuronal and glial phenotypes. RT-PCR and immunocytochemical analyses revealed that pluripotent markers (e.g. Oct4, Sox2 and Nanog) are gradually lost while neural markers (e.g. nestin, MAP-2,  $\beta$ -tubulin, GFAP) are acquired. The iPSC cells seeded on matrigel can form 3D aggregates/organoid spheres with cells representing three germ layers, which in proper differentiating conditions can obtain advanced neuronal markers MAP-2, Dbc, Synapsin, TH as well as glial markers: PDGFR $\alpha$ , GFAP and GalC.

Co-culture of iPSC-seeded collagen scaffolds with organotypic slices revealed only uni-directional migration/extension of cells and neural processes from the slice into the cell seeded scaffold.

### CONCLUSION

The micro-scale experimental approach such as cell culture platforms with microprinted and microspotted biofunctional domains can be used to test molecular mechanisms of neuronal differentiation while macro-scale systems, such as scaffolds colonized by stem cells and self-assembled tissue structures are more suitable for tracing of neuro-developmental processes and toxicological studies. The macro-scale approach allows us to build up a hybrid testing platform for medium/long term cultures of neural stem cells with a range of host tissues.

### INTRODUCTION

Damage to the peripheral nerve is a global clinical problem and can result in loss of function and considerable morbidity and affect patient's quality of life. Nerve guide conduits have emerged as a promising approach for the management of peripheral nerve injuries and a potential alternative to the autografts. We have developed the biodegradable-based nerve guide conduits made of poly caprolactone/ poly lactic acid with a micro-structured intraluminal surface (1). The grooved PCL/PLA conduits outperformed non-grooved conduits and showed comparable experimental outcomes to autografts during short and long term *in vivo* experiments (2).

To translate the developed medical device to the clinic and human applications several requirements should be fulfilled. The medical grade sterilisation method and its effect and limitation are one of the important factors that need to be assessed. The present study evaluated the outcome of two sterilisation methods including gamma radiation and E-beam on the PCL/PLA conduits. Several different radiation doses (15-45KGy) were used to identify the suitable dose for sterilisation of PCL/PLA conduits.

### EXPERIMENTAL METHODS

PCL/PLA conduits were sterilised with gamma and E-beam with 15, 20, 25, 30, 35, 40, 45 KGy (Synergy, UK). To analyse the mechanical properties, instron1122 was used to measure maximum stress, strain and Young Modulus. Differential scanning calorimetry (DSC) were used to assess the melting point temperature and crystallinity. Molecular weight of the samples was measured by gel permeable chromatography (GPC). Surface structure and grooves morphology were imaged and assessed by Scanning electron microscopy (SEM). One-way ANOVA was used to analyse the differences between groups of samples (Prism 6, GraphPad).  $P < 0.05$  was set as a threshold for significant difference.

### RESULTS AND DISCUSSION

Following sterilisation, surface structure and specifically grooved structure remained unaffected. The mechanical properties analysis showed no significant difference in the maximum stress of non-irradiated films, gamma and E-beam irradiated films with the highest dose (45KGy). However E-Beam radiation with the higher doses (40 and 45 KGy) decreased the maximum strain significantly ( $88.80 \pm 15.01\%$  and  $54.60 \pm 5.55\%$  for non-irradiated and 45KGy-irradiated films, respectively) ( $p < 0.05$ ). Furthermore, DSC analysis showed no significant differences in melting temperature ( $T_m$ ) and Glass transition temperature ( $T_g$ ), however the radiation with high dose (40 and 45KGy) increased the crystallinity of PCL/PLA samples.

### CONCLUSION

Choosing the suitable sterilisation method is essential for the development of medical device and specifically polymer-based biomaterial. The sterilisation process should be optimised to reduce its drawback on the material properties. In the present study we showed that gamma radiation and E-beam could be used as the potential sterilisation process for PCL/PLA conduits. However it is necessary to optimise the relevant radiation dose to minimise molecular scission and linkage and hence mechanical and chemical properties.

## INTRODUCTION

Magnetic resonance imaging (MRI) is used as an important diagnostic tool for whole-body. However, images of organs and tissue are disturbed around metallic implants and artifacts occur in intense magnetic field of MRI instruments. On the other hand, over 70% of implant devices consist of metals because of their high strength, high toughness and good durability, while magnetic susceptibility of metals is still relatively large. Therefore, metals show a low magnetic susceptibility or antimagnetic materials are required for medical devices. Among various pure metals, Zr possesses low magnetic susceptibility compared to Ti, Co and Fe alloys. We have developed Zr-based alloys, showing low magnetic susceptibility, high strength and corrosion resistance<sup>1-5</sup>. The magnetic susceptibilities of Zr alloys are almost one-third that of Ti-6Al-4V and one-seventh of Co-Cr alloy. In this study, we have attempted large-amount melting of Zr-1mass%Mo alloy and investigated mechanical properties, crystal phase, and magnetic susceptibility, for the commercialization of the alloy. Finally, MRI artifact of spinal instruments consisting of the alloy and implanted in sheep spine was observed.

## EXPERIMENTAL METHODS

Zr-1mass%Mo alloy was employed in this study because tensile strength was the largest among Zr-Mo alloys<sup>3</sup>. Cold crucible induction melting of Zr-1Mo alloy was attempted. Zr rods were sandwiched between Mo flakes lapped by Zr foil, layer by layer, and 5-kg ingot was obtained. The ingot was cast to rods with 30 mm in diameter. Test specimens were produced from the rod. Composition analysis, tensile test, X-ray diffraction, SEM-EBSD, TEM observation, and measurement of magnetic susceptibility were performed. Finally, pedicle screws, spinal cage, and rod were implanted in spine of sheep and observed with 3T MRI.

## RESULTS AND DISCUSSION

The large amount melting was succeeded because molybdenum in the alloy existed in a range of 1.06-1.14mass% in all region of the rod. XRD revealed that the phase was almost  $\alpha$ . Mass magnetic susceptibility was  $0.98 \times 10^{-6} \text{ cm}^3 \text{ g}^{-1}$  as low as the previous study<sup>3</sup>. Results of the tensile test were summarized in Table 1. Elongation to fracture of the alloy was 23% and much larger than that of Ti-6Al-4V. Crystal structure of the alloy was identified as follows. Regions with a width of 3  $\mu\text{m}$  where dislocation density was low were surrounded by a network (Fig. 1). The former consisted of  $\alpha$  phase contributing to plasticity and the latter consisted of  $\beta$  and  $\omega$  phases contributing to strength.

Artifact less than 2 mm was observed on 3T MRI image of the spinal instruments and the vertebral canal appeared (Fig.2).

Table 1 0.2% yield strength (YS), tensile strength (TS) and Elongation to fracture (EL) of Zr-1Mo and Ti-6Al-4V alloys.

	YS(MPa)	TS (MPa)	EL(%)
Zr-1Mo (top)	612	676	23
Zr-1Mo (bottom)	602	672	23
Ti-6Al-4V (cast)	791	845	11
Ti-6Al-4V (rough)	863	963	18

Fig. 1 TEM image and electron diffraction pattern.

Fig.2 MRI images of the screw and cage.

## CONCLUSION

Zr-1Mo alloy after large-amount melting showed large strength and elongation and low magnetic susceptibility. 3T MRI artifact of spinal instruments consisting of the alloy and implanted into sheep spine occupied in 2 mm and the vertebral canal appeared. Therefore, this alloy is a candidate of MRI compatible alloy.

## INTRODUCTION

Studies regarding biodegradable materials have shown that magnesium is a potential biomaterial for orthopedic application due to its major advantage to biodegrade in biological medium<sup>1</sup>. Different alloying element play an important role for experimental biodegradable magnesium alloys not just in term of properties but also considering that the degradation products are expected to be non-toxic<sup>2</sup>. Because the hydrogen release is a crucial fact in potentially using of these alloys as orthopedic biomaterials, we evaluate the hydrogen release in different testing media for all experimental magnesium alloys. Also, this work evaluates the degradation behavior and corrosion of different magnesium alloys (from the systems Mg-Zn-Zr or Mg-Ca) in different simulated biological medium through the evaluation of biodegradability and corrosion products. We take in consideration the application of these alloys as orthopedic biomaterials.

## EXPERIMENTAL METHODS

Different magnesium alloys from the systems Mg-Zn-Zr and Mg-Ca systems was used as experimental material. Experimental samples of circular shape and 2mm x10mm size were polished on metallographic papers and washed with ethanol. For immersion and corrosion tests were used three different mediums: Phosphate buffer solution (PBS), Hanks' Balanced Salt Solution (HBSS) and Dulbecco Modified Eagle Medium supplemented with fetal bovine serum (DMEM + 10% FBS). During immersion tests, the experimental samples were immersed in 50 ml solution each (total surface area to volume of solution = 314mm<sup>2</sup>:50mL) at 37 °C for 3, 7, and 21 days. The samples were weighted before and after the immersion and the hydrogen evolution was monitored. For microstructural characterization of experimental samples was used an Olympus BX51 optical microscope and a Philips XL30-ESEM scanning electron microscope. Also, scanning electron microscopy was used for surface analysis of the samples after immersion and corrosion tests. The surface of all experimental samples was analyzed in the terms of chemical composition using an energy dispersive X-ray (EDX) spectrometer. The experimental values were analyzed using the Student's t-test and expressed by the mean values  $\pm$  standard deviation (SD). A P-value(0.05) was considered statistically significant.

## RESULTS AND DISCUSSION

Immersed samples show different patterns of degradation depending on the magnesium alloy composition and type of medium, showing an accelerated degradation process with increasing immersion time. In the case of phosphate buffered solution (PBS) it can be noticed a fine crystals deposit

on the surface. For the samples tested in Hanks' Balanced Salt Solution (HBSS) we observed a different pattern of degradation with rapid accumulation of corrosion products and loss of integrity up to the end of the test. When we used Dulbecco Modified Eagle Medium supplemented with fetal bovine serum (DMEM + 10% FBS) we observed that the proteins seems to form a passivation layer on top.

In figure 1 we present an example of experimental results obtained using SEM coupled with EDS for an Mg-0,8Ca alloy samples after immersion in different testing medium (PBS, HBSS, DMEM) for 21 days.

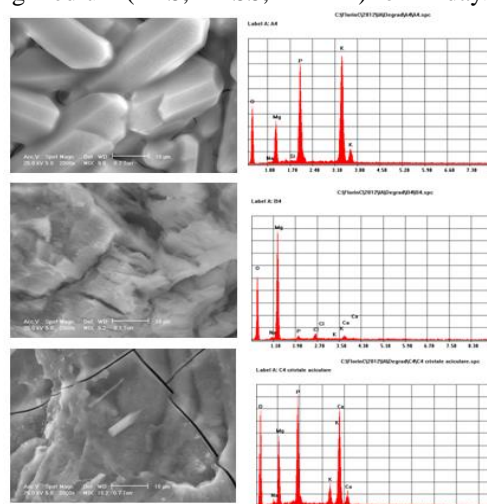

Fig. 1. SEM micrographs and EDS result of Mg-0,8Ca alloy samples after immersion in PBS, HBSS and DMEM after 21 days.

## CONCLUSION

The aim of this study was to evaluate the effects of different mediums on magnesium alloys and to determine the optimal degradation medium. Regarding this issue it have been used both phosphate-based and cell culture medium to observe the influence of amino acids and vitamins and also proteins present in the added amount of fetal bovine serum. This cell culture condition was introduced for simulate a more physiological corrosion environment. We demonstrate that the alloying elements from magnesium alloys influence the surface morphology, degradation and corrosion pattern.

### INTRODUCTION

The loss of an eye is found to be a significant issue for an individual from both an aesthetic and psychological point of view. Medically, the off-the-shelf orbital implants currently used unfortunately do not have a holistic regenerative approach. With current implants, those materials used which are commonly reported and currently on the market, are hydroxyapatite, porous polyethylene and silicone. During implantation extraocular muscles directly attach to either the implant or the ring and with this the implant attempts to simultaneously mimic the natural movement of the other eye<sup>1,2</sup>. In this study, the application of a porous polyurethane<sup>3</sup>/beta-tricalcium phosphate composite as an implant different to those in the literature has been investigated.

### EXPERIMENTAL METHODS

The orbital implant presented in this study is composed of polyurethane and ceramic components. As the degradable component, commercially available beta-tricalcium phosphate particles (1-2 mm, BMT Calsis Co., Turkey) were used. The polyurethane was synthesised with a prepolymer and polyol reaction. Methylene diisocyanate, caprolactone monomer, catalyst (3,6,9-triazaundecamethylenediamine) (all Sigma, Germany) and d.i.-water was used in the preparation of the polyurethane. The molar ratio of the reactants was calculated to give a product in which all NCO groups are reacted. The ceramic particles were introduced in to the mixture obtained before it set, and the whole mixture was then allowed to set over 24 hours in an orbital implant-shaped mould. The resulting structure was then analysed using differential scanning calorimetry (DSC), scanning electron microscopy (SEM) and micro-computerized tomography ( $\mu$ -CT). Cytotoxicity tests were performed to reveal biocompatibility.

### RESULTS AND DISCUSSION

The analyses revealed 96.93 % porosity within the composites. Mechanical compression testing found the Young's Modulus of the material to be 43.2 MPa. DSC and FTIR analyses confirmed the chemical structure and that all the NCO groups were consumed. Figure 1 displays the SEM image of the samples prepared.

Figure 1. A representative SEM micrograph of PU/TCP composites.

The WST-1 test used to determine the cytotoxicity have shown that the samples were highly biocompatible. Apoptosis and necrosis phenomena were investigated. The material was found to pose no negative effects on the cells.

### CONCLUSION

In this study, a new composite material that has the potential for used as an orbital implant has been proposed. This matrix, with a biocompatible, porous and lightweight structure, and with both suitability for tissue infiltration and incorporation potential, holds great promise. A material with enhanced integration through the fully biodegradable ceramic particles that remain within its structure post-implantation has been prepared.

## INTRODUCTION

The use of bioresorbable miniplates could offer many benefits as compared with commonly used metallic devices for osteotomies. Among them there are: no risk of corrosion, no need for reoperation, translucency for radiological diagnostics. The main advantage of the proposed composite is its multifunction - it means that the implant not only stabilizes fragments of the bone in the position but also resorbs and loses the strength during the polymer matrix degradation. The load is transferred to the healed bone, thus the bone tissue receives signals to remodel the structure according to the Wolff's law [1,2]. Additionally, nanoadditives realised from the polymer matrix have contact with the growing tissue, activating cells and enhancing osteointegration [3]. Regrettably, resorbable polymers such PLA, PGLA, PLLA, PLDL are rather weak and brittle, hence their clinical application is limited to the areas of moderate loads. Furthermore, it is crucial to establish their mechanical limits, especially the factors that may cause the damage of the plate during the implantation surgery.

This report summarizes the research on the development, mechanical and structural description and FEM simulations of the multifunctional miniplates made of PLLA- and PLLA-based composite with bioactive ceramic nanoadditives.

## EXPERIMENTAL METHODS

Three types of materials were prepared. Polymer poly(L-lactide) PLLA (Purasorb PL38, Purac) and two composites consisting of PLLA matrix and the following additives: nanosized TCP (Chema-Elektromed, Lublin, Poland) and both TCP and HAP (Chema-Elektromed, Lublin, Poland) in adequate volumes. Injection molding machine ( $T=200^{\circ}\text{C}$ ) was used to fabricate miniplates. Different shapes of implants were obtained (Fig.1).

Fig. 1 Miniplates - variability of types and shapes

Mechanical properties were examined on the universal testing machine Zwick 1435 in various tests: uniaxial tension (2 mm/min), 3pts (2 mm/min,  $d = 50\text{mm}$ ), 4pts bending (2 mm/min,  $d = 60\text{ mm}$ ,  $b = 22\text{ mm}$ ). During the fixation procedure two important

factors needed to be taken under consideration: the maximum tightening torque, which can be applied to the miniplate and the permissible deformation without damage. Tightening torque was determined with digital dynamometric screwdriver (Poltorque PRO, Poland). Deformation was measured in "single-side" bending test.

Number of stress cycles that a specimen sustains before failure was verified in fatigue tests, including cyclic dynamic uniaxial stretching (100.000 cycles, 30% of  $\epsilon_{\text{max}}$ ; both in normal and in simulated body fluids conditions (Ringer solution,  $37^{\circ}\text{C}$ ) and creeping tests (80-20%  $R_m$ ).

The material's microstructure was observed using optical and SEM microscope

Additionally, FEM analysis and simulations were performed (ABAQUS CEA).

## DISCUSSION

It is vital to investigating the mechanical aspects of resorbable miniplates used for bone fixation – the particular shapes not only normative samples. Such miniplates are more brittle than metallic ones, thus more prone to destruct during or shortly after implantation. It is very important to describe a variety of factors influencing implantation process and causing potential danger. The conducted research also verified mechanical stability of osteosynthesis. Both FEM simulation and the actual tensile and bending tests were analyzed. Maps of stresses and deformations gave information and helped to understand the mechanisms and the nature of the internal deformation of analyzed shapes and geometries of miniplates.

This data made it possible to determine safe values of tightening torque and the range deformation while fitting the composite miniplates to the bone so as to assure the stable and properly functioning osteosynthesis.

## INTRODUCTION

Superparamagnetic iron oxide nanoparticles (SPION) are excellent MR contrast agents, which are widely used in disease diagnosis and therapy<sup>1</sup>. However, side effects have been reported<sup>2</sup>. Recently, nanoparticles are considered as a new class of autophagy activator (Fig. 1)<sup>3</sup>. And it has been found that SPION are mainly recognized and eliminated by macrophages in RES (reticuloendothelial system) organs such as liver, lymph node, spleen, etc. In this study, we used clinically approved SPION to explore the relationship between their potential safety risks and autophagy effects in macrophage cells.

Fig. 1 Possible mechanisms of SPION induced autophagy.<sup>3</sup>

## EXPERIMENTAL METHODS

1. Western blot of nanoparticle induced autophagy was detected with transformation of LC3 I to LC3 II and up-regulation of P62. RIPA lysis of cells were loaded into 13.2 % SDS-PAGE for immune blot assay;
2. Cytokine secretion in cell culture supernatants was measured by ELISA, according to the manufacturer's standard protocol (DAKEW systems). Absorbance was measured at 450 nm on a microplate reader;
3. Data was analysed using Student's paired t-test and  $p < 0.05$  was considered statistically significant;

## RESULTS AND DISCUSSION

As shown in Fig. 2, clinically used MRI contrast agent Resovist and Feraheme can induce obvious variations of autophagy flux (LC3 transformation and p62 up-regulation) in macrophage cells including BMDM (bone marrow derived macrophage) (Fig. 2a), mouse macrophage cell lines Raw264.7 (Fig. 2b) and Ana-1 (data not shown). However, they could not induce autophagy in other cell lines such as Hela (Fig. 2c) and 293T cells (data not shown). The autophagy were mainly caused by iron oxide cores of nanoparticles other than its surface coating of dextran or excipient mannitol (Fig. 2d). At the same time, we found that macrophages treated with SPIONs secreted more inflammatory cytokines (IL-6, IL-1 $\beta$ , TNF- $\alpha$ ) than macrophages alone (Fig. 3).

Fig. 2 Iron oxide cores of SPION could induce macrophage autophagy. Cultured cells were treated with nanoparticles at indicated time points and concentrations. Cell lysis were collected for immune blot assay of LC3 transformation and p62 up-regulation.  $\beta$ -actin were detected as loading control. (abbreviation in Fig. 2d: Re: Resovist, Fe: Feraheme)

Fig. 3 SPION could induce inflammatory responses of macrophage. Macrophages were treated with 100  $\mu$ g/ml nanoparticles for 24 h. The production of cytokine was analysed by ELISA (IL-6, TNF- $\alpha$ ) or western blot (IL-1 $\beta$ ). (\*\*,  $P < 0.01$ , \*,  $P < 0.05$ ) (control: cells w/o Resovist or Feraheme treatment.)

These results demonstrated that iron oxide cores of SPION could induce autophagy and minimal inflammation in macrophages. And our data showed that macrophages treated with nanoparticles didn't exhibit proliferation inhibition and apoptosis. Most likely, the inflammatory response was regulated by autophagy and will be investigated in our future work.

## CONCLUSIONS

Iron oxide cores of clinically used SPION can induce autophagy of macrophages but not in unphagocytosed cells. The nanoparticles could induce macrophage activation and cytokine release; i.e. inflammatory responses.

<sup>3</sup>Rudolph Cimdins Biomaterials Innovation and Development Center, Riga Technical University, Latvia  
[vadims.klimecs@gmail.com](mailto:vadims.klimecs@gmail.com)

### INTRODUCTION

Periimplantitis is a loss of bone tissue correctly joined to dental implants after period of normal osseointegration in cases of 1 – 45 % going to implant loss in many cases<sup>1</sup>. In surgical periimplant treatment materials efficient is xenogenic Bio-Oss with manual debridement and resorbable barriers<sup>2</sup>.

### EXPERIMENTAL METHODS

From 2009 to 2015 years 0,5 1,0 mm of granules HAp produced in Riga Technical University, Rudolph Cimdins Biomaterials Innovation and Development Center as biphasic calcium phosphate bioceramic materials "pure" form was used in periimplantitis treatment on 29 patients. At least after 5 years clinical examination and 3D CT (iCAT) radiodensitometry was carried out in the same program in 9 points - 1 point crystal implantation center, 2 points with 2mm step in meiodistal direction, 2 points with 2mm step on the periapical and crone from the center, as well as 2 points with 2mm step in buccally-lingual direction Housfield (HU) units<sup>3</sup>.

### RESULTS AND DISCUSSION

The measurements in HU were as follows: in the central point - 734.0/514.6. meiodistal direction - from 648.6/422.6 to 632.3/388.0; periapical – crone - from 673.6/487 to 580.3/341; and buccal-lingual from - 665,6/422 to 666.0/520.3.

### CONCLUSION

Indicators of radiodensitometry after 5 years in the place after periimplantite treatment by HAp was minimally different from the patient's bone measurements; the difference of less than 10%, it could indicate a high degree of mineralization after HAp crystals implantation.

## Debris of a Carbon-Fibre-Reinforced Polymers (CFRP) Wrist Plate Led to a Destructive Synovitis in Human

Antonio Merolli, Lorenzo Rocchi, Alessandro Morini, Luigi Mingarelli, Paolo Scialabba, Francesco Fanfani

Gemelli Medical School, The Catholic University in Rome, Italy

[antonio.merolli@gmail.com](mailto:antonio.merolli@gmail.com)

### INTRODUCTION

Composite materials are largely applied in aerospace and car industry, where an accurate modelling of the possible strains and stresses endured by the artefact is possible. The more complex is the geometry and load-cycle of an artefact, the more difficult (and expensive) will be the design and production by composites. Application of CFRP artefacts in humans has been promoted in Orthopaedic and Trauma Surgery. A prominent advantage is their X-ray transparency. Literature documents the biocompatibility of materials used, namely carbon fibres and poly-ether thermoplastics, like poly-ether-ether-ketone (PEEK) and poly-ether-imide (PEI). Actually, the interface with living tissues is the matrix polymer alone, since the carbon fibres should remain deeply embedded.

In the past, literature showed that, sometimes, carbon fibres can be exposed to a direct contact with soft or hard tissues. In this case an inflammatory reaction may ensue because of the fibre geometry, regardless of the biologically inert character of the material [1-3]. A properly designed and accurately implanted composite artefact should not expose its fibres during or after surgery: however this may happen. We had the chance to document a case of severe destructive synovitis in a distal radius fracture treated by a CFRP wrist plate.

### EXPERIMENTAL METHODS

A white Caucasian woman of 64 years of age came to our attention 11 months after surgery for a right distal radial fracture. She had a CFRP plate in place (CarboFix™ Orthopaedics Ltd., Israel). A painful swelling was evident on the volar wrist 3 months after surgery, and it kept worsening. After 4 months she was unable to flex the thumb and soon afterwards she experienced inability in flexing the index finger and DIP joint of the third finger. She had normal active MCP flexion (thanks to intrinsic muscles); no instrumental evidence of neurological disorders; no laboratory evidence of Rheumatoid Disease. An ultrasound examination showed a massive synovitis.

### RESULTS AND DISCUSSION

We surgically explored the site. An aggressive erosive flexor tendons synovitis was present and there were eroded stumps of flexor tendons with loss of substance: we judged the damage beyond repair. We retrieved the CFRP plate which appeared positioned correctly and secured with screws in proper way. Histopathology showed granulomatous fibrogenic process with many black carbon fibres engulfed inside multinucleated giant cells. After surgical debridement we planned a second surgery

and performed a tendon transfer to the recover thumb-to-digits pinch.

We would like to discuss the point that biocompatibility of phase materials alone cannot suffice for the application of CFRP artefacts in humans. Complex geometries, like a wrist plate, may result in overwhelming difficulties in designing and producing an artefact which do not expose fibres, at a reasonable developing cost. Another occurrence may be that a CFRP implant may require an out-of-ordinary care in surgical technique to avoid the exposure of fibres. In any case, all of these seem major disadvantages.

### CONCLUSIONS

Our discussion is not focused on clinical reports, past and present. We advocate that if there is a key theoretical limit in a technology, this should be a permanent warning, regardless any initial report of short fail-safe clinical series. We should not wait a massive number of failures to uncover a problem which is supposed to be known “from the drawing-board”. We are aware that it is not easy to publish on sporadic adverse reactions. We ourselves underestimated the danger of carbon fibres as we reported on an adverse reaction in animals but we embedded this finding in an otherwise positive paper on the good biocompatibility of PEI [1]. We have no evidence that the retrieved plate was badly implanted. However, even if this would have been the case (despite provision from the firm of a leaflet of good surgical practice) this will not reduce our reluctance about implanting CFRP artefacts. It is our opinion that no demanding technique will ever bring a real progress in surgery, as it will always be a relative risk for the patient. It is likely that it will be abandoned as soon as a simpler technique will appear [4].

### INTRODUCTION

The development of implantology, required bone augmentation, bone reconstruction. To overcome autograft limits, several bone substitutes are proven the efficacy, however it remains numerous difficulties in the handling, and resorption capacity. Bioactive injectable bioceramics, are particularly devoted to these applications. In this clinical study we used a combination of CaP microporous granules and hydrogel for maxillofacial bone regeneration [1]. The non-interventional study) was to assess the safety and performance of the In'Oss<sup>TM</sup> bioceramic/hydrogel bone substitute in maxillofacial surgery. Specifically, the biomaterial was evaluated clinically and radiographically in healed extraction sockets filled with putty (In'Oss<sup>TM</sup>) in combination with a resorbable porcine collagen membrane ((EZ Cure) to protect the implantation site after the implantation.

### EXPERIMENTAL METHODS

In'Oss<sup>TM</sup> putty (Biomatlante SA) was constituted of MBCP<sup>TM</sup> granules with hydrosoluble hydrogel. Suspension was contained in syringe, ready to use, the putty is a non-hardening injectable biomaterial. The putty ensures bonding of the mineral phase with high permeability and suitable rheological property. In'Oss<sup>TM</sup> putty was CE mark and FDA approval. EZ Cure collagen membrane is crosslink porcine high purified collagen matrix. EZ Cure was used to protect the site of implantation,

The clinical study was classified "Case Analysis". Six international clinical centers were involved (USA, Korea, Europe) with 37 surgeons. The study comply with Institutional Review Board and Ethics committee requirements.

The 78 patients needed a single tooth extraction and would benefit from prosthetic reconstruction with a dental implant. Tooth sockets were filled with In'Oss<sup>TM</sup> putty and closed using the resorbable collagen membrane EZ<sup>TM</sup> for preservation of the alveolar ridge following tooth extraction. Five to 6 months post filling, a dental implant will be placed. The subjects were followed about 6 additional weeks. The followed up was performed at 1 and 3 months, recording clinical and radiological features. The efficacy for mucosa healing using EZ Cure resorbable collagen membrane for closing the site of implantation was assessed at 1 months and 3 months by clinical aspect taking in account the mucosa aspect with or without inflammation

In 11 patients, we have performed analysis of biopsies taken during the dental implantation sequence, (between 5 to 10 months). Micro CT, Scanning electron

microscopy, light microscopy and image analysis were performed. Resorption and bone ingrowth at the expense of the composite were analyzed by micro CT, Scanning electron microscopy, light microscopy and image analysis.

All data were expressed as averages and standard error. Differences were evaluated by analysis of variance (ANOVA) with Fisher's probability least significant difference (PLSD) post-hoc test. Differences were considered significant for  $p < 0.05$ .

### RESULTS AND DISCUSSION

The safety of the procedure using bioceramic putty and collagen membrane for implantation site closure was evidenced in more of 93% of the cases. 78 patients showed no major complications in 93%. One failure was listed, which was due to gingivitis and required reopening of the site. The post-filling follow-up of patients at 1 and 3 months indicated no inflammation/infection in more than 89% and 98% of the patients, respectively. The EZ Cure membrane was efficient in combination with the putty, preventing exposure and expulsion of the granules.

The post-filling follow-up of patients at 1 and 3 months indicated a completely radio-dense area at the bone-biomaterial interface in 61% and 77% of the cases respectively.

Classical follow-up and radiographical examinations revealed resorption and absorption of the composite after only 4 months. Also, interconnected bone trabeculae were progressively found to replace the biomaterials. During drilling for dental implantation, the density was similar to natural bone trabecula, and implant stability was perfect in more than 90% of the cases.

Bone histomorphometry revealed the resorption and absorption of the putty and bioceramic granules. In fact, at 6 months, 95% of the putty was resorbed and replaced by physiological bone.

### CONCLUSION

Taken together, the clinical, radiological, and histological data from this non-interventional clinical study have demonstrated the safety and efficacy of the In'Oss<sup>TM</sup> (bioceramic/hydrogel) bone substitute in bone regeneration during maxillofacial surgery.

### INTRODUCTION

Bacterial infections are a significant issue on post-transplant and surgery since bacteria can readily colonize the surface of implants<sup>1</sup>. The antibacterial potential of silicon-based biomaterials as well as their application in bone regeneration has been studied, suggesting that the presence of silicon (Si) can decrease bacterial activity<sup>2</sup>. Also, in a previous study it was demonstrated that starch-based scaffolds functionalized with silanol (Si-OH) groups sustain human adipose stem cells (hASC) osteogenic features in vitro<sup>3</sup>. However the antibacterial properties of these scaffolds are still unknown. Thus, this study aims to investigate the potential application of these scaffolds as antibacterial surfaces for biomedical implants by studying their effects against *Escherichia coli* (Gram negative) and *Staphylococcus aureus* (Gram positive).

### EXPERIMENTAL METHODS

Scaffolds were produced by wet-spinning using a blend of corn-starch with polycaprolactone (30/70 wt.%, SPCL) dissolved in chloroform. Two coagulation baths were used: methanol for SPCL scaffolds (control) and a calcium silicate solution for SPCL-CaSi scaffolds. The surface composition of the scaffolds was characterized by X-ray photoelectron spectroscopy (XPS). Scaffolds potential to sustain and improve hASC proliferation and osteogenic differentiation was evaluated by DNA and ALP quantification, respectively. The antibacterial properties of the scaffolds were evaluated against *E. coli* DH5 $\alpha$  and *Staphyl. aureus* ATCC 29213 through radial diffusion assay. Also, bacterial growth and viable bacteria counts (CFU mL<sup>-1</sup>) were evaluated. Biofilm formation and distribution were analysed by scanning electron microscopy (SEM). Each experiment was performed in triplicate. Statistical analysis was performed using a one-way ANOVA test, differences were considered statistically significant if  $p < 0.05$ .

### RESULTS AND DISCUSSION

XPS results demonstrate the effective incorporation of the ions on the surface of the produced scaffolds. Results showed that hASC readily proliferated on both scaffolds and expressed higher ALP activity when cultured on SPCL-CaSi scaffolds. The radial diffusion assay showed the formation of an inhibition zone on the

SPCL-CaSi scaffolds for *E. coli*. The number of viable bacteria counts of *E. coli* and *Staphyl. aureus* significantly decreased in the SPCL-CaSi scaffolds after 4h and 6h of incubation when

compared to both controls (bacteria alone and SPCL scaffolds) (Figure 1A). Bacteria adhesion and biofilm formation significantly decreased after 4h of incubation on SPCL-CaSi scaffolds, when compared to the control (Figure 1B). No biofilm formation was observed after 24h incubation. Results suggest that SPCL-CaSi scaffolds have an antibacterial effect, i.e. the capacity to prevent the bacteria adhesion.

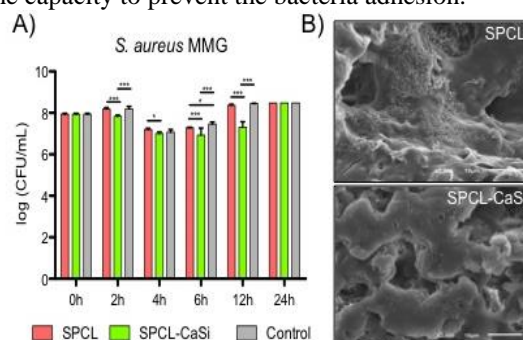

Figure 1-Number of viable *S. aureus* in Minimal medium with 0.4% glucose (MMG) (A) and SEM images of *S. aureus* cultured on SPCL and SPCL-CaSi scaffolds for 6h in MMG (B).

### CONCLUSION

The outcomes of this study suggest that SPCL scaffolds functionalized with Si-OH groups inhibited the formation of bacterial biofilm and adhesion to the scaffold surface. Moreover, it also demonstrates the positive effect of the presence of Ca and Si ions in preventing biofilm formation. The functionalized scaffolds could pose as a new strategy to device biomaterials capable of preventing bacterial proliferation associated to infections problems on prosthetic joints as well as a supporting matrix for hASC osteogenic differentiation.

## INTRODUCTION

Bacterial infections are the most current complication which could occur during the fitting of prosthesis in orthopaedic surgery. They can be the cause of morbidity and mortality and take place in 0.7 to 2.2% of the cases despite antibioprophyllaxis. Bacteria responsible for this kind of infections are *Staphylococcus epidermidis* or *Staphylococcus aureus* and mostly, it happens in per-operative conditions. Even if antibioprophyllaxis considerably decreases the rate of per-operative infections, it presents risks of allergy, side effects or bacteria resistance. Moreover, standard antibiotic protocols present little efficiency because of immunocompetent zone around implant, reduced sensitivities of bacteria growing in a biofilm and difficulties of achievement of the drug at the site of infection.

In a recent contribution to this field, we have presented a new biomaterial having applications as implant in orthopaedic surgery and allowing the release of an antibiotic (Gentamicin Sulphate, GS) only in case of infection [1, 2]. In order to optimise our material, we decided to investigate two strategies. In our first strategy, we increased the gentamicin density using a polymer capable of higher functionalization. In our second strategy, we explored a new route using another antibiotic grafted onto titanium (without possible release): Vancomycin (VAN).

Fig. 1. Representation of the bioactive biomaterial

## EXPERIMENTAL METHODS

$\alpha$ -norbornenyl poly(ethylene oxide) and  $\alpha$ -norbornenyl poly(ethylene oxide)-*block*-polyglycidol macromonomers were synthesized by anionic ring-opening polymerization of ethylene oxide or copolymerization of ethylene oxide and glycidol successively. Those macromonomers were  $\omega$ -functionalized with a carboxylic acid, with GS linked by an imine bond<sup>1</sup> or with VAN linked by an amide bond.

Characterisations were done by <sup>1</sup>H NMR, Size Exclusion Chromatography (SEC) and MALDI TOF. Nanoparticles were obtained by Ring-Opening Metathesis coPolymerization (ROMP) of norbornene with functionalized macromonomers in dispersed medium. Their colloidal stabilities were shown by Dynamic Light Scattering measurements. Nanoparticles

were grafted onto titanium discs ( $\varnothing = 5$  mm ;  $h = 3$  mm) functionalized with amine groups using aminosilane molecules (APTES). The grafting was characterized by Scanning Electron Microscopy (SEM) and fluorescence microscopy. The *in vitro* evaluations were carried out by Minimum Inhibitory Concentration (MIC), Minimum Bacterial Concentration (MBC) and bacterial survival measurements.

## RESULTS AND DISCUSSION

Well defined  $\alpha$ -norbornenyl macromonomers were obtained with a size of about 5000 g.mol<sup>-1</sup> for VAN-functionalized macromonomer and about 8000 g.mol<sup>-1</sup> for GS  $\omega$ -functionalized macromonomer and a narrow distribution (PDI < 1.1).

Nanoparticles were synthesized with total monomer and macromonomers conversions and diameters were about 350 nm for VAN-functionalized particles and 550 nm for GS-functionalized particles.

Controlled densities of NPs were anchored on biomaterial surfaces and those densities were measured by scanning electron microscopy observations.

Fig. 2. SEM observation of VAN-functionalized biomaterial (A). TEM observation of GS-functionalized particles (B).

The efficiency of vancomycin and gentamicin functionalized biomaterials was proved by *in vitro* bacterial inhibition tests using *Staphylococcus aureus* as bacterial strain.

## CONCLUSION

In this work was presented the synthesis of different types of bioactive biomaterials and their characterization. We equally demonstrated the *in vitro* activity of such materials. *In vivo* experiments on rabbits are now in progress.

## Anti-Bacterial Borosilicate Glass Formulations for Bone Tissue Engineering Applications

João S. Fernandes<sup>1,2</sup>, Margarida Martins<sup>1,2</sup>, Nuno N. Neves<sup>2</sup>, Ricardo A. Pires<sup>1,2</sup>, Rui L. Reis<sup>1,2</sup>

[joao.fernandes@dep.uminho.pt](mailto:joao.fernandes@dep.uminho.pt)

Bioactive glasses (BGs), including 45S5 glass, have been widely investigated in Bone Tissue Engineering (BTE) for more than three decades. They have been regarded as relevant materials for the repair and replacement of bone defects. However, the majority of BG particles show slow degradation rates and present no effect against bacterial infections<sup>1, 3</sup>. The Borosilicate matrix is known to possess a faster degradation rate, increases the formation of hydroxyapatite (HA) and presents an enhanced release of specific cations (e.g.: Ca, Sr and Mg)<sup>2</sup>. Such of those cations are known for their influence in the cell proliferation and differentiation, as well as, for their antimicrobial character. The aim of this study was to assess if borosilicate BGs are able to present antimicrobial properties for BTE applications.

### EXPERIMENTAL METHODS

Borosilicate glass compositions of general formula  $0.20\text{B}_2\text{O}_3 : 0.40\text{SiO}_2 : x\text{MgO} : y\text{CaO} : (0.35-x-y)\text{SrO} : 0.05\text{Na}_2\text{O}$  (molar ratio, where  $x, y = 0.35$  or  $0.00$ , and  $x \neq y$ ) were synthesized by melt quenching ( $T \approx 1450^\circ\text{C}$ ) and ground to obtain particles with a size  $< 63 \mu\text{m}$ .

The capacity to form calcium phosphate layer was tested after immersion of the BG samples into simulated body fluid (SBF) for 7 days.

Microbial susceptibility was measured using standardized inocula of *Pseudomonas aeruginosa*, *Escherichia coli*, *Staphylococcus aureus* and *Staphylococcus epidermidis* in contact with the BG samples. Disk diffusion (DD) and broth dilution (BD) methods were adapted to BG samples, testing known amounts of glass particles.

The cytotoxicity of the glass particles was assessed by direct contact with human osteosarcoma cell line during 7 days of incubation ( $37^\circ\text{C}$  and  $5\% \text{CO}_2$ ). Cell proliferation (DNA) and metabolic activity (MTS) profiles were followed along the culture time.

### RESULTS AND DISCUSSION

The BG samples were successfully obtained by melt quenching, ground and presented non-toxic effects up to 3 days.

Figure 1 - SEM images of BG samples after 1, 3 and 7 days of immersion in SBF solution. The Ca/P ratio on the glass surface, obtained by EDS, is presented on the top right corner.

After the immersion of BG samples into SBF, Ca- (BSCaO) and Sr-containing glasses (BSSrO) revealed the presence of bone-like apatite structures at their

surface, although at different stages of crystallization. However, after 7 days of immersion, the BSCaO glass displayed an increase in apatite-like deposition with a Ca/P ratio of  $\approx 1.67$ , similar to HA (Figure 1).

Figure 2 - Example of disc diffusion assay of the samples BSCaO, BSSrO, BSMgO (at different concentrations: 9, 18, 36, 72 mg/mL) in contact with *S. aureus*, *P. aeruginosa*, *E. coli* and *S. epidermidis* respectively.

The DD data demonstrate that the Mg-containing (BSMgO) and the BSSrO glasses inhibited the growth of bacteria *S. epidermidis* and *P. aeruginosa* respectively. Clear halos appeared around the glass-loaded agar discs. The inhibition zone for each bacterial strain is shown in Figure 2.

Figure 3 - Broth dilution assay of the BSSrO sample in Mueller Hinton culture medium (+Ctr.) in contact with *P. aeruginosa* (-Ctr. is Bioglass 45S5).

Moreover, BD data (Figure 3) showed a concentration dependent effect of BSSrO glasses against *P. aeruginosa* (e.g.: BSSrO\_18mg exhibiting a reduction of  $\approx 4 \log_{10}\text{CFU/ml}$ ).

### CONCLUSION

We were able to synthesise borosilicate-based glasses by melt quenching, and we observed no cytotoxic effects up to 3 days culture. Chemical characterization supported the high reactivity and their bioactivity (BSCaO sample with a Ca/P  $\approx 1.67$ ).

Bacterial tests with different concentrations (9, 18, 36 and 72 mg/ml of BG) indicate that BSMgO and BSSrO glasses have antibacterial activity against *S. epidermidis* and *P. aeruginosa* respectively. Moreover BSSrO glasses have specific bactericidal activity against *P. aeruginosa* for quantities equal or higher than 18 mg/ml. Results also revealed a concentration dependence on the anti-bacterial properties.

## INTRODUCTION

The bacteria, when present in the wound, begin to produce biofilm in response to reduction of nutrients, increased levels of reactive oxygen species, change in pH, and under influence of immune cells or antibiotics. Biofilm is a community of either single or multiple bacterial species enclosed in a self-produced extracellular polymeric substance (EPS), consisting of polysaccharide, protein and DNA<sup>1</sup>. Bacterial biofilms are adherent to an inert or living surfaces and in the latter case cause serious and persistent infections.

Treatment of chronic wounds is a major problem, not only in medical but also economic terms. Lack of an effective method of the bacterial biofilm destruction leads to a significant prolongation and complication of the medical treatment. Literature data show that the killing dose for any given antibiotic is more than 1000 times higher for biofilm forming bacteria than for planktonic bacteria of the same strain<sup>2</sup>. The poor efficacy of antibiotics against bacteria embedded in the biofilm is mainly associated with inefficient penetration of the antibiotic through the biofilm matrix either due to specific adsorption by polymeric matrix of biofilm or to physical barriers.

## EXPERIMENTAL METHODS

### Materials preparation

Alginate/chitosan (AL/ChS) beads were prepared using the emulsification/ionic gelation modified method described by Silva *et al.*<sup>3</sup>. Electrospun AL fibers with ChS sheath were prepared using procedure described by Bonino *et al.*<sup>4</sup> with some modifications. AL cores were loaded with a model drug *i.e.* ciprofloxacin or ibuprofen, while on ChS shells an appropriate lytic enzyme was immobilized.

### Materials characterization

Size and zeta potential were studied by nanoparticle tracking analysis (NTA) and dynamic light scattering technique (DLS), respectively. The presence of ChS layer on AL core was confirmed by FTIR analysis. Morphology of the resulting materials was investigated with SEM and TEM. Drug loading efficiency and cumulative drug release profiles were evaluated by UV-Vis analysis. Enzymatic activity of free and immobilized enzymes was measured by hydrolysis of a relevant substrate according to the supplied protocols. Cytotoxic activity *in vitro* on human lung adenocarcinoma epithelial cell line (A549) and mouse fibroblast cell line (NIT3T3) was determined by MTT assay. Antibacterial activity was evaluated against two

biofilm forming bacterial strains: Gram-negative *Pseudomonas aeruginosa* and Gram-positive *Staphylococcus aureus*.

## RESULTS AND DISCUSSION

Spherical in shape AL/ChS beads loaded with ciprofloxacin were successfully synthesized. Cumulative drug release studies revealed the extended over time antibiotic release profiles. The maximum of enzymatic activity of the immobilized lysozyme was observed after *ca.* 40 min. of beads incubation with enzyme.

AL fibers were electrospun and coagulated with ChS with co-axial technique application. The resulting fibers exhibited a core-sheath structure that was revealed by TEM analysis. The average diameter of the AL/ChS fibers ranged from 140 to 180 nm depending on the composition and electrospinning parameters.

The cytotoxic and antibacterial activity of obtained materials were studied *in vitro*. No significant cytotoxic effect on A549 and NIT3T3 cell lines was observed. Antibacterial experiments are in progress.

## CONCLUSION

The presented research was focused on preparation and characterization of AL/ChS materials, constructed of polymeric core loaded with antibiotic and polymeric shell with immobilized lytic enzyme. Proposed materials were designed for the biofilm structure degradation in order to facilitate a biocidal agent penetration and enable its antimicrobial activity.

# First Principles Modelling to Establish the Thermodynamically Most Favourable Form and Position of Silicon in Bone Mineral

Helen Chappell<sup>1</sup>, Ravin Jugdaohsingh<sup>1</sup>, Jonathan J Powell<sup>1</sup>

<sup>1</sup>MRC Human Nutrition Research Unit, University of Cambridge, UK

[Helen.chappell@mrc-hnr.cam.ac.uk](mailto:Helen.chappell@mrc-hnr.cam.ac.uk)

## INTRODUCTION

An important role for silicon in connective tissues has long been proposed<sup>1</sup>, although its biochemical function remains a matter of investigation. Recent work has shown that silicon is present in both the collagenous and mineral phase of bone<sup>2</sup> and indeed silicon is used in a number of commercial bone graft materials, which have enhanced biocompatibility compared to Si-free biomaterials. However, the form and position of silicon within the bone structure at the atomic level remains unclear. Previous simulations by one of the authors (HC) have shown that Si can substitute for phosphorus in a thermodynamically favourable way<sup>3</sup> but simulations looking at different positions and charge states have not before been carried out. In this work we simulated the substitution of silicon for phosphorus and compared it to the inclusion of ortho-silicic acid ( $H_4SiO_4$ ) as both a substitution for a phosphate ion and as a neutral interstitial molecule. The objective was to assess the thermodynamic stability of the various silicon substitutions and to predict, therefore, the most feasible interaction of silicon within the mineral phase of bone.

## EXPERIMENTAL METHODS

Bone mineral was approximated using a phase-pure hydroxyapatite (HA) unit cell. Substitutions were made in this unit cell and optimization was carried out using the Density Functional Theory, plane-wave code CASTEP<sup>4</sup>. Convergence testing determined a cut-off energy of 430 eV and a 3x3x3 Monkhorst Pack k-point grid. Formation energies were calculated upon optimization via Equation 1,

$$E_f = E_{HA\_Sub} - (E_{HA} - \mu_{PO4} + \mu_{H_4SiO_4}) \quad (1)$$

where  $E_{HA\_Sub}$  is the energy of the substituted HA unit cell,  $E_{HA}$  the energy of a phase-pure HA unit cell,  $\mu_{PO4}$  the chemical potential of a phosphate ion and  $\mu_{H_4SiO_4}$  the chemical potential of a single molecule of ortho-silicic acid. This equation was varied depending on the substitution being made. The test substitutions were:

1. Si for P
2.  $H_4SiO_4$  as an interstitial molecule
3.  $H_4SiO_4$  for  $PO_4$

The final substitution of  $H_4SiO_4$  for  $PO_4$  required charge compensation and 4 different compensation mechanisms were tried, which gave very similar results.

## RESULTS AND DISCUSSION

Figure 1 shows the disrupted structure predicted with interstitial  $H_4SiO_4$  and Table 1 provides the formation energies and lattice parameters of all the unit cells.

**Figure 1.** Phase-pure (a) and optimised  $H_4SiO_4$  substituted (b) HA unit cells. Oxygen shown in red, hydrogen pink, calcium green, phosphorus purple and silicon yellow.

Substitution	$x / \text{\AA}$	$y / \text{\AA}$	$z / \text{\AA}$	$E_f / \text{eV}$
HA	9.477	9.477	6.851	-
Si for P	9.410	9.497	6.900	-2.05
$H_4SiO_4$	9.365	9.378	9.192	2.86
$H_4SiO_4$ for $PO_4$	9.685	9.595	6.861	17.70

**Table 1.** Lattice data and formation energies for the different substitutions in comparison with phase-pure HA. The favourable  $E_f$  is shown in green and the unfavourable values in red.

The results show that silicon substitution for phosphorus (i.e. silicate for phosphate) is the only thermodynamically favourable way to include silicon in the unit cell. The other substitutions are energetically unfavourable and cause a large degree of physical distortion to the unit cell. Although silicon is likely to exist as ortho-silicic acid during and following absorption, it seems that the inclusion of silicon in bone mineral may occur only after chemical changes to the  $H_4SiO_4$  molecule.

## CONCLUSION

Inclusion of silicon as neutral ortho-silicic acid is unlikely from a thermodynamic perspective. This raises questions about the mechanism by which silicon enters bone mineral and its chemical speciation therein.

### INTRODUCTION

Diatoms, have the potential to be novel bio-functional materials as they display a diversity of patterns, and a unique micro- and nanostructure. Diatoms consist largely of amorphous silica<sup>1</sup>, a structure that is versatile and flexible for surface modification and has many functions that can be utilised for biomaterial platforms. Existing devices directly use the original structure of the bio-silica frustules, which limits the potential of the diatoms. Therefore, to fully utilize their application, alteration of the chemical composition of this intricate structure is essential<sup>2,3</sup>. The hypothesis of the study is that calcium can be up taken by the living diatom using the same mechanism as silica without altering the topography of its unique three-dimensional structure. The specific objective of this study is to optimize the incorporation of calcium hydroxide into the diatom during the frustule synthesis and monitor the effects toward the architectural parameter with surface analysis. Additionally, the amount of calcium incorporated will be investigated using bulk analysis.

### EXPERIMENTAL METHODS

Axenic *Thalassiosira weissflogii* cultures were grown in artificial seawater. Cultures were silica depleted for a minimum of 48 hours before inoculation with the calcium precursor and were inoculated at  $1 \times 10^4$  cells/mL in a final volume of 200 mL in a polystyrene tissue culture flask. Sodium metasilicate ( $\text{Na}_2\text{SiO}_3$ ) or calcium hydroxide (CaOH) was added to cultures and grown at a 14 hour:10 hour light:dark cycle at a light intensity of 3000 lux and temperature range of 16–22°C. Multiple additional cultures received further additions of  $\text{Na}_2\text{SiO}_3$  or CaOH at 48, 96, and 144 hours. Cultures were collected at 192 hours post-inoculation and cleaned of organic matter. Cell density was monitored during growth using a haemocytometer. The silica and calcium formation was studied using PDMPO-Rhodamine 123 and Calcium Green staining. The morphology of the frustule walls was investigated by SEM, TEM, AFM and the amounts of calcium were quantitatively determined by ICP-MS. To obtain further structural information, FTIR and XPS were used.

### RESULTS AND DISCUSSION

Fluorescence microscopy and XPS analysis confirmed that Ca was incorporated into the frustule of CaOH-modified *T. weissflogii* (Figure 1,2). This amount was dependent on the dosing regimen of Ca that the culture received. No adverse effect was observed on the topography of the modified diatom.

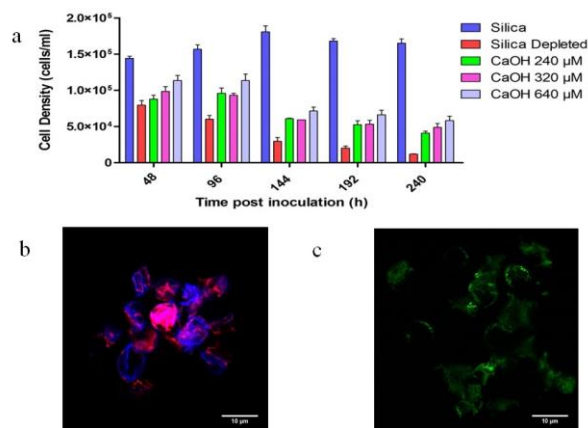

Figure 1. a) Growth profile of *T. weissflogii* for unmodified and CaOH-modified diatom. Two way ANOVA revealed an effect of time and treatment, statistical significant with  $** p < 0.01 (n = 3)$ . b) Staining of the silica valve using dual marker PDMPO-Rhodamine c) Staining of Ca from diatom valve using Calcium Green

Figure 2. Quantitative analysis of diatom using XPS. a) Spectra of unmodified *T. weissflogii*, b) Spectra of CaOH-modified *T. weissflogii*. Result show that an increase ratio of ca peak has been observed in the CaOH-modified diatom compare to unmodified diatom.

### CONCLUSION

The modification of the diatom frustule with calcium has been achieved and the characteristic architectural features were unaltered.

## Fabrication and Histological Evaluation of Carbonate Apatite Coated Calcite

Kunio Ishikawa<sup>1</sup>, Kanji Tsuru<sup>1</sup>, Masako Kobayashi<sup>2</sup>, Youji Miyamoto<sup>2</sup>

<sup>1</sup>Department of Biomaterials/Faculty of Dental Science, Kyushu University, Japan

<sup>2</sup>Department of Oral Surgery/Institutes of Health Bioscience, The University of Tokushima, Japan  
[ishikawa@dent.kyushu-u.ac.jp](mailto:ishikawa@dent.kyushu-u.ac.jp)

### INTRODUCTION

Although bone apatite is known as carbonate apatite (CO<sub>3</sub>Ap), it decomposes to other calcium phosphates at high temperature required for sintering process. Therefore, sintered hydroxyapatite (HAp) has been used as artificial bone substitute since 1970's. We have proposed fabrication method of CO<sub>3</sub>Ap by compositional transformation reaction based on dissolution-precipitation reaction using a precursor such as calcite<sup>1</sup>. CO<sub>3</sub>Ap thus fabricated was found to up-regulate differentiation of osteoblastic cells when compared to sintered HAp. Histological studies also revealed that CO<sub>3</sub>Ap shows higher osteoconductivity than sintered HAp. In the present study, CO<sub>3</sub>Ap coated calcite (CO<sub>3</sub>Ap/CaCO<sub>3</sub>) was fabricated and its tissue response was evaluated by implanting CO<sub>3</sub>Ap/CaCO<sub>3</sub> granular in the bone defect of rabbit femur.

### EXPERIMENTAL METHODS

CO<sub>3</sub>Ap/CaCO<sub>3</sub> granular was fabricated by immersing 300-600 µm CaCO<sub>3</sub> granular, which was made by exposing Ca(OH)<sub>2</sub> compact to CO<sub>2</sub>, into 1 mol/L Na<sub>2</sub>HPO<sub>4</sub> solution at 40°C, 60°C and 80°C up to 20 hours. Compositional analysis was made by powder x-ray diffraction and EDAX. Morphology of the granular was observed by SEM. Bone defects made at the femur of rabbits were reconstructed with CO<sub>3</sub>Ap, 10% CO<sub>3</sub>Ap/CaCO<sub>3</sub>, 30% CO<sub>3</sub>Ap/CaCO<sub>3</sub> and CaCO<sub>3</sub>. The µ-CT images and histological analysis were made 4 and 8 weeks after implantation.

### RESULTS AND DISCUSSION

Calcite transformed to CO<sub>3</sub>Ap with time when immersed in Na<sub>2</sub>HPO<sub>4</sub> solution. Transformation was faster in the Na<sub>2</sub>HPO<sub>4</sub> solution with higher temperature as shown in Fig. 1. EDAX analysis of the cross section granular revealed that surface of the granular was CO<sub>3</sub>Ap and inside was CaCO<sub>3</sub> indicating that dissolution-precipitation reaction occurred from surface to inside. Immersion of CO<sub>3</sub>Ap/CaCO<sub>3</sub> in the Na<sub>2</sub>HPO<sub>4</sub> solution at 60°C for 4 hours and 16 hours result in the fabrication of 10% CO<sub>3</sub>Ap/CaCO<sub>3</sub> and 30% CO<sub>3</sub>Ap/CaCO<sub>3</sub>, respectively.

The µ-CT images and histological analysis made 4 weeks after implantation of rabbit femur defect revealed largest amount of bone formation in the case of 10% CO<sub>3</sub>Ap/CaCO<sub>3</sub> granular followed by 30% CO<sub>3</sub>Ap/CaCO<sub>3</sub>, CO<sub>3</sub>Ap and CaCO<sub>3</sub> (Fig. 2). After 8 weeks, amount of the new formed bone around the granular increased to reach the same level in the case of CO<sub>3</sub>Ap, 10%CO<sub>3</sub>Ap/CaCO<sub>3</sub>, and 30%CO<sub>3</sub>Ap/CaCO<sub>3</sub>. In contrast, new bone formed around the granular decreased when compared to 4 weeks in the case of CaCO<sub>3</sub>. This decrease is thought to be caused by the dissolution of CaCO<sub>3</sub>.

Fig. 1 Conversion of calcite to CO<sub>3</sub>Ap as a function of time when immersed in 1 mol/L Na<sub>2</sub>HPO<sub>4</sub> solution at 40, 60 and 80°C.

Fig. 2 Four weeks histological pictures of specimens when used to reconstruct bone defect made at the femur of rabbits.

### CONCLUSION

CO<sub>3</sub>Ap/CaCO<sub>3</sub> was found to be fabricated by regulating the reaction temperature and duration of immersion time of CaCO<sub>3</sub> in Na<sub>2</sub>HPO<sub>4</sub> aqueous solution. 10% CO<sub>3</sub>Ap/CaCO<sub>3</sub> demonstrated higher osteoconductivity than CO<sub>3</sub>Ap.

## INTRODUCTION

Biomaterials based on hydroxyapatite  $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$ , HA, tricalcium phosphate  $\text{Ca}_3(\text{PO}_4)_2$ , TCP (in  $\alpha$ - and  $\beta$ -forms), and octacalcium phosphate  $\text{Ca}_8(\text{HPO}_4)_2(\text{PO}_4)_4 \cdot 5\text{H}_2\text{O}$ , OCP, can be prepared from amorphous calcium phosphate, ACP [1].

Calcium pyrophosphate  $\text{Ca}_2\text{P}_2\text{O}_7$ , CPP, known in  $\alpha$ -,  $\beta$ -,  $\gamma$ -forms [2], has not yet been widely considered as a biomaterial. Nevertheless, it was recently found that porous  $\beta$ -CPP has the potential to be used as a prospective biomaterial because it was more incorporated into newly formed bone and more rapidly resorbed than porous HA in vivo [3].

CPP is normally prepared by calcination of crystalline dicalcium phosphate dihydrate, brushite,  $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$  (DCPD), or dicalcium phosphate anhydrous, monetite,  $\text{CaHPO}_4$  (DCPA).  $\gamma$ -CPP is formed at relatively low temperatures,  $\beta$ -CPP – at intermediate temperature, and  $\alpha$ -CPP is the high-temperature phase. Here we aim to reveal the crystallization peculiarities and thermal evolution of the CPP polymorphs and the formation conditions of a metastable calcium pyrophosphate,  $\alpha^1$ -CPP, depending on the structural state (amorphous and /nanocrystalline) of DCPA prepared from ACP with an initial Ca/P ratio of 1.

## EXPERIMENTAL METHODS

The preparation of the initial ACP powder was based on the fast precipitation variety of the nitrous synthesis. The solutions of stock salts ( $\text{Ca}(\text{NO}_3)_2$  and  $(\text{NH}_4)_2\text{HPO}_4$ ) were rapidly mixed at a molar Ca/P ratio of 1, pH 10-11 and 5°C. The vessel with the mixture was shaken (1 min) and put into a freezer (-25°C, 24 h). The obtained friable powders were used unwashed or after 3- or 6- times washing with aqueous ammonia (pH 10-11, 5°C) and repeated lyophilization. The powders are designated as UW, 3W- and 6W in the following, respectively. Powder samples were examined as-prepared and upon heating in air in the range of 25 to 980°C by XRD, TG-DTA, IR and mass spectrometric thermal analysis, MSTA.

## RESULTS AND DISCUSSION

All initial powder samples were X-ray amorphous. The UW samples were converted at 600-640°C into a metastable pyrophosphate,  $\alpha^1$ -CPP, which by composition and structure was similar to the high-temperature polymorph  $\alpha$ -CPP (normally occurring above 1200°C).  $\alpha^1$ -CPP was stable to about 780°C (a small amount of the medium-temperature polymorph  $\beta$ -

CPP was also present). Above 800°C,  $\alpha^1$ -CPP gradually transformed to  $\beta$ -CPP, and only  $\beta$ -CPP was detected at 980°C. The temperature phase evolution in the 3W and 6W samples was qualitatively similar. The washed samples crystallized in a somewhat higher temperature range of 680-730°C into a four-phase mixture:  $\alpha^1$ -TCP,  $\beta$ -TCP,  $\beta$ -CPP and  $\alpha^1$ -CPP;  $\alpha^1$ -TCP is a metastable analogue of the high-temperature polymorph  $\alpha$ -TCP (normally occurring above 1150°C); the relative amount of the phases decreased in this order. The phase composition was preserved until 800°C. Above this temperature,  $\alpha^1$ -TCP and  $\alpha^1$ -CPP gradually transformed into  $\beta$ -TCP and  $\beta$ -CPP, respectively, and a biphasic mixture of  $\beta$ -TCP and  $\beta$ -CPP was detected in the samples upon heating to 980°C.

The occurrence of the two metastable phases,  $\alpha^1$ -CPP and  $\alpha^1$ -TCP is associated with the Ostwald effect. The increase of the Ca/P ratio to a value that ensured the crystallization of the TCP phases with a notably higher Ca/P ratio (1.5:1), than that in the mother liquor (1:1), is mainly attributed to the hydrolyses of initially present amorphous monetite and partly to the carbonate substituting for hydrogen phosphate ( $\text{CO}_3^{2-}$  ions were detected in the washed samples) during the washing process.

## CONCLUSION

1. Novel calcium phosphate biomaterials, including a low-temperature metastable pyrophosphate, can be prepared using the results of this study by simple, fast and inexpensive processing routes.
2. The observed increase of the Ca/P ratio in an ACP precipitate during washing (ageing) implies that a precursor for bioapatite formation may have a small Ca/P ratio as 1:1. Therefore, the suggested ACP precursor with Ca/P = 1.5:1 (Posner's version) might be formed on a later stage of the biomineralization process.

### INTRODUCTION

Articular cartilage defects are a major clinical problem for orthopedic surgeons. Among them, osteo-chondral lesions affect active young and over sixty years old patients as well, and lead to a progressive but relentless joint mechanical instability<sup>1,2</sup>.

Scaffolds for osteo-chondral regenerative medicine should have both load-bearing properties, able to mimic the bone structure, and more flexible ones, mimicking the physiology of cartilage ECM<sup>3</sup>.

Our research activity is aimed at designing and developing a novel functionally-graded hybrid (FGHY) scaffold where the load-bearing structure is a PU foam, CaPs with a graded composition represent the biomimetic component, and pectin gel is used as cell carrier (Fig. 1). This FGHY scaffold should be able to support MSCs proliferation and promote their differentiation for osteo-chondral defect repair.

The present work was aimed at designing the FGHY scaffold and at optimizing the materials processing techniques.

Fig. 1: an open-pore PU foam is the matrix graded-coated and/or loaded with CaPs, perfused with pectin gel as cell carrier

### EXPERIMENTAL METHODS

A PU foam (PU) was synthesized by one-step process, using MDI prepolymer (Bayer), an ad hoc polyether-polyol mixture, FeAA as catalyst and water (2% w/w<sub>polyol</sub>) as expanding agent<sup>4</sup>. Different coating approaches were performed to obtain through the foam the presence of Ca ions necessary to induce pectin gelification<sup>6</sup>. The foam was interpenetrated with  $\beta$ -TCP using a novel vacuum-assisted procedure (VAC, [approach 1](#)). Two strategies (NUCL-SBF and NUCL) were investigated to obtain the precipitation and nucleation of CaPs. In particular, a uniform HA layer on the surface of PU pores was obtained both in NUCL-SBF by using different salt solutions and 1.5 SBF ([approach 2](#)), and in NUCL due to a chemical reaction between Ca and P ions ([approach 3](#)).

Low methoxyl citrus pectin (PECT) was used to obtain the gel coating onto the PU foam previously treated with CaPs.

SEM, FTIR, and XRD analysis were performed on the CaP-based coatings. FGHY scaffolds were characterized by SEM, water uptake (37°C, PBS),

compression mechanical properties, and *in vitro* tests with human placenta-derived stem cells (hPDCs)<sup>7</sup>.

### RESULTS AND DISCUSSION

After characterization, VAC approach was selected due to the presence of a CaP gradient (Fig. 1) and a higher quantity of CaPs available for pectin gelification, compared to NUCL-SBF and NUCL. SEM images of PU/VAC/PECT showed a thin continuous layer of pectin gel, homogeneously distributed on all the surfaces (Fig.2a). Compression mechanical tests showed a  $\sigma_{max}$  higher for PU/VAC/PECT than PU matrix ( $p < 0.05$ ), indicating that the mechanical strength resistance increased for interpenetrated samples (Fig.2b). Compared to PU matrix, PU/VAC/PECT showed a significantly different creep/recovery behaviour in terms of residual strain, indicating that the pectin gel influenced the viscoelastic behavior of the PU matrix.

Fig. 2: a) SEM image of PU/VAC/PECT (scale bar 200  $\mu$ m); b)  $\sigma_{max}$  in compression mechanical test

### CONCLUSION

These novel FGHY scaffold displayed morphology and mechanical properties suitable for osteo-chondral defect repair and resulted adequate for hPDCs adhesion, and differentiation<sup>7</sup>. *In vivo* experimentation of FGHY scaffolds on the rabbit model will be the focus of future work.

### INTRODUCTION

Due to their breathability, specific mechanical properties, i.e. high flexural and fatigue strength relative to their weight ratio and biocompatibility, activated carbon clothes (ACC) have previously been considered for hard and soft tissue implanting. However, their poor biological activity restricts their extensive use in medical applications and therefore needs to be enhanced<sup>1,2,3</sup>. Thanks to their excellent biocompatibility, osteoconductivity and bioactivity, calcium phosphate (CaP) ceramics, especially hydroxyapatites (HA), have received much attention in the biomedical materials field and have been clinically applied in orthopaedics<sup>3</sup>. So, carbon fiber-reinforced HA composites, combining the highly biocompatible CaP matrix with the properties of carbon fibers, are promising bioceramic materials, which could be particularly useful in the reconstruction of bone defects<sup>3</sup>.

### EXPERIMENTAL METHODS

To get bioactive hybrid materials to be further used as scaffolds, CaP coatings are deposited on activated carbon substrates by a sono-electrodeposition process. A mixture of  $\text{Ca}(\text{NO}_3)_2$ ,  $4\text{H}_2\text{O}$  and  $\text{NH}_4\text{H}_2\text{PO}_4$  is used as electrolyte. A three electrode system connected with a potentiostat-galvanostat is used to apply a cathodic polarization at the carbon electrode. The influence of electrochemical parameters is connected to the quantity, microtexture, structure and chemical composition of CaP phases.

The biocompatible properties of materials were determined by culturing human osteoblast-cells (HOST) in contact with CaP/ACC hybrid materials.

### RESULTS AND DISCUSSION

Data show that polarization duration influences the deposit thickness: from 500 nm to 5  $\mu\text{m}$ . The mass uptake tends to a limit corresponding to the decrease of nucleation sites. The current density influences the CaP deposit quantity, morphology and chemical composition. Indeed, at low regime, the quantity of deposit is proportional to the applied current density. During CaP deposition, two phenomena occur due to water electrolysis:  $\text{H}_2$  release at working electrode surface leads to a more or less homogeneous coating and the electrolyte pH decrease along polarization leads to CaP re-dissolution. The carbonate amount in CaP ceramics is controlled by addition of carbonate salt in the electrolyte. SEM, TEM and FTIR characterizations show that the coating consists in a mixture of plate-like

octocalcium phosphate and carbonated calcium phosphate phases for low current densities and needle-like carbonated calcium deficient HA (cdHA) together with calcium carbonates allotropic forms for high current densities.  $^1\text{H}$  and  $^{31}\text{P}$  NMR MAS performed on deposits confirm the presence of carbonated cdHA and underline the presence of minority disordered CaP phases.

Concerning biological experiments, first results have shown evidence of biocompatibility of hybrid materials (Fig. 1). Osteoblasts culture is employed in order to assess the *in vitro* viability and bioactivity of our hybrids biomaterials.

Mechanical tests are in progress to assess the adhesion properties between cloth and deposit.

Figure 1: SEM images of human osteoblasts cultured for 7 days in the presence of CaP/ACC hybrid material obtained at low current density.

### CONCLUSION

The sono-electrodeposition process consists in a co-precipitation of calcium and phosphate ions with hydroxides ions provided by water electrolysis. It is an efficient method to obtain a controlled thickness, morphology (platelets or needles) and chemical composition of CaP deposits. Preliminary *in vitro* studies of HOST interaction with CaP/ACC material show a good biocompatibility whatever CaP morphologies.

## Emulsion Templating: A Versatile Route to the Preparation of Biodegradable and Biocompatible Scaffolds for Tissue Engineering

Caitlin R Langford<sup>1</sup>, David W. Johnson<sup>2</sup>, Neil R Cameron<sup>1</sup>

<sup>1</sup>Department of Materials Engineering, Monash University, Clayton 3800, Victoria, Australia

<sup>2</sup>Department of Chemistry, Durham University, Durham, DH1 3LE, UK

[Caitlin.langford@monash.edu](mailto:Caitlin.langford@monash.edu)

### INTRODUCTION

The emulsion templating process, offers a route to highly porous polymers with well-defined morphologies<sup>1</sup>. The process, whereby the continuous phase of a high internal phase emulsion (HIPE) is polymerized, results in materials referred to as polyHIPEs. Recent developments in the photo-initiated polymerization of HIPEs have allowed for the preparation of polyHIPE polymers from monomers which form highly unstable emulsions, such as multifunctional thiol and alkene (typically acrylate) monomers<sup>2</sup>. The resulting polymers are biodegradable and have been found to be biocompatible in initial cell culture studies<sup>3</sup>. The surface chemistry of these materials can be altered by a variety of post-polymerization functionalization techniques<sup>4,5</sup>.

### EXPERIMENTAL METHODS

Biodegradable polyHIPEs were prepared by radically initiated network formation between combinations of thiols and acrylates where the combined functionality of the monomers is at least 5. Example procedure: The HIPE oil phase, consisting of a trithiol (10.0 mmol), triacrylate (10.0 mmol), solvent (7 ml), surfactant (3 wt% of organic phase), and photoinitiator (7 wt% of monomer content) were combined in a 2-neck round bottom flask with continuous stirring at 350 rpm from an overhead stirrer fitted with a D shaped PTFE paddle. Water (80 wt% of total emulsion) was added dropwise to form the HIPE. The HIPE was then poured into a mould and cured by passing under a UV lamp. The resulting polyHIPE is then washed by immersion in acetone and dried under reduced pressure.

### RESULTS AND DISCUSSION

A range of biodegradable polyHIPE polymers can be prepared by the described method. Typical monomers used are shown in Figure 1.

Figure 1. Acrylate and thiol monomers used in thiol-acrylate polyHIPE synthesis.

The above monomers are sufficiently hydrophobic to produce an emulsion kinetically stable enough for photopolymerization to occur without significant emulsion collapse (Figure 2.)

Figure 2. Synthesis of thiol-acrylate polyHIPE. Scale bar = 50  $\mu$ m.

The resulting polyHIPE materials have well-defined and interconnected porosities, allowing for cell penetration into the polymer. A variety of cell lines have been successfully cultured on such thiol-acrylate polyHIPEs for periods of up to 7 days (Figure 3), indicating they are biocompatible.

Figure 3. a) MTT assay of cultured cell line on thiol-acrylate polyHIPE vs control. b, c) Micrographs of H&E stained sections of thiol-acrylate polyHIPE after 3 (b) and 7 (c) days of culture. Scale bar = 100  $\mu$ m.

### CONCLUSION

PolyHIPEs have been prepared from multifunctional thiol and acrylate monomers by emulsion templating. These polymers have been shown to be biodegradable and biocompatible in initial cell culture studies.

### INTRODUCTION

Regeneration of bone defects with the aid of artificial macroporous implants is a complex task, because the implants have to withstand mechanical stress on the one hand and, on the other hand, provide high macroporosity to allow for tissue ingrowth, remodelling and vascularisation. Moreover, materials need to be biocompatible and bioactive with regards to the formation of a mechanically stable bone-implant interface. Last but not least the production costs of these implants should be reasonable and the technology should allow for easy up-scaling at reproducible product quality.<sup>1</sup>

We developed an organic-inorganic hybrid material based on a silicate glass produced via the sol-gel route, reinforced with organic cross-linkers. Furthermore, we present a templating technique for scaffold generation based on a mold produced by rapid prototyping that allows for the generation of macroporous scaffolds with defect-specific architecture.

### EXPERIMENTAL METHODS

We produced macroporous hybrid-glass scaffolds by cross-linking a silica sol, derived from tetraethoxysilane (TEOS), with silane functionalized trimethylolpropane-ethoxylate (TMPEO) of different molecular weights. This hybrid sol was cast into molds printed from polycaprolactone, (PCL) using a melt extrusion print head (Bioscaffolder<sup>®</sup>, Syseng). The molds had a closed outer structure and stacked grids of 200 µm wide PCL strands forming double layers alternating in orientation by 90°. We systematically modified the silica sol with TMPEO of molecular weights of 170 (T170), 450, 730 and 1014 g/mol and crosslinker contents from 1 to 40% and evaluated the mechanical strength of the scaffolds. To this end, 6 scaffolds of each composition were compressed between two parallel plates until failure (crosshead speed 1 mm/min, 50 kN load cell). Scaffold morphology was examined by scanning electron microscopy (SEM). To determine the biological activity of the hybrid scaffolds, we seeded Saos-2 cells on 4 scaffolds each and determined the proliferation, mineralisation and the cells' distribution throughout the scaffold over 14 days of dynamic culture with osteogenic medium.

### RESULTS AND DISCUSSION

SEM imaging revealed a uniform pore structure with tubular pores and interconnect sizes of at least 120 to 140 µm. Compression testing showed good mechanical compatibility of the implants to cancellous bone. We

observed compressive strengths up to 32 MPa for the T170 hybrid and could cover a wide range of compressive moduli from 24 MPa to 568 MPa, while maintaining good mechanical strength. These values fall within the range of the values for cancellous bone which are 2-12 MPa for the compressive strength and 50-500 MPa for compressive modulus<sup>2</sup>. Systematic variation of the cross-linker content revealed a maximum strength for 20-30% of TMPEO in the silica sol whereas at higher organic contents the organic cross-linker dominated over the influence of the silica phase, leading to softer materials with higher elasticity. Concerning the influence of cross-linker molecular weight, we found decreasing mechanical strength with increasing Mr likely due to a lower crosslinking degree at constant cross-linker mass content in the hybrid.

Cell culture tests showed a good attachment of Saos-2 cells on the scaffolds. We observed proliferation in the first seven days and mineralization of the cells as well as the scaffolds until day 14. Microscopic analysis of cryosections revealed that the cells spread homogeneously through the pores and also mineralized throughout the scaffold. They formed a tight cell layer on the material surface, which indicates effective nutrient and oxygen supply, even in the inner pores of the scaffolds.

### CONCLUSION

We fabricated macroporous hybrid glass scaffolds using rapid prototype templates. By using this templating technique, we were able to produce hybrids of a wide variety of compositions. In addition, the templating technique allows for modification of the scaffolds' pore size and geometry as well as for an individualization of size and shape of the implant, while a high reproducibility is guaranteed.

## INTRODUCTION

Recently, a new generation of self-setting inks were developed, which avoid the high temperature treatments commonly needed to consolidate robocasted ceramic scaffolds<sup>1</sup>. These inks are based on the hydrolysis of alpha tricalcium phosphate ( $\alpha$ -TCP) into calcium deficient hydroxyapatite (CDHA) and incorporate a hydrogel as printing additive. Nonetheless, until now the influence of the hydrolysis process on the properties of such scaffolds has not been studied. This work explores the influence of several hydrolysis conditions on the nano/microstructure, composition and mechanical strength of robocasted scaffolds. Furthermore, different hydrolysis conditions were combined with different printed patterns to tailor in an independent manner the macro and nano/micro structure of the scaffolds.

## EXPERIMENTAL METHODS

$\alpha$ -TCP powder was obtained as described elsewhere<sup>1</sup>. This powder was mixed with poloxamer F127 solution (20 wt%) at liquid to powder ratio of 0.5 mL/g. Cylindrical scaffolds (6 mm  $\varnothing$  x 12 mm height) were fabricated using a customized robocasting device (Fundacio CIM). The paste was dispensed with 250  $\mu$ m tapered tips following three different patterns: honey comb (HC), orthogonal (O) and orthogonal rotated at 45 degrees (OR). In all cases the material infill was set up at 45 %. Printed scaffolds were then consolidated either by autoclaving (hydrothermal condition at 121 °C for 30 min) or by immersion in deionized water at 37 °C for 7 days (biomimetic condition). For hydrothermal consolidation two alternatives were studied i) samples immersed in deionized water and ii) samples exposed to a moisture atmosphere (MA). X-ray powder diffraction (XRD) was performed to quantify the crystalline phases present; scanning electron microscopy (SEM) was used to observe sample microstructure; uniaxial compressive strength (CS) was determined in the parallel direction of the axes of the cylindrical sample, at a rate of 1 mm.s<sup>-1</sup>; mercury intrusion porosimetry (MIP) was employed to quantify the entrance pore size distribution; and X-ray computed microtomography ( $\mu$ CT; GE v|tome|x L 240) scans of voxel size 25  $\mu$ m were acquired to assess the architecture of the macroporosity.

## RESULTS AND DISCUSSION

Fig. 1 shows  $\mu$ CT reconstructions of the printed scaffolds together with their CS and macroporosity (mP: free spaces between scaffold strands) when consolidated at 37 °C. In congruence with its lowest mP, HC structure was the most resistant. In contrast, OR structure, with similar mP than HC, presented the lowest CS. O structure, with the highest mP, presented an intermediate CS, which evidenced a higher load bearing efficiency in comparison with OR. Since all

samples were consolidated in the same condition, the nano/microporosity ( $\mu$ P: spaces within the scaffold strands) can be considered to be the same (~30 % in all cases). Fig. 1 also shows the pore entrance size distribution and the microstructure of the strands for three consolidation conditions. Clear differences were observed, not only in terms of microstructure but also in the amount of  $\mu$ P and pore size distribution. Hydrothermal-MA led to the lowest  $\mu$ P, and XRD showed only a partial conversion of  $\alpha$ -TCP to CDHA together with a partial allotropic transformation to  $\beta$ -TCP. SEM images revealed low crystal entanglement, which can be the cause of a low mechanical strength for these type of materials. In contrast, the conversion to CDHA was complete in the other two methods. However, whereas the transformation took only 30 min in the autoclave with the samples immersed in water, in the biomimetic condition it took 7 days. The microstructure was very different, with needle-like crystals in the autoclaved samples and plate-like crystals in the biomimetic method, which resulted in scaffolds 1.3 times stronger than the former.

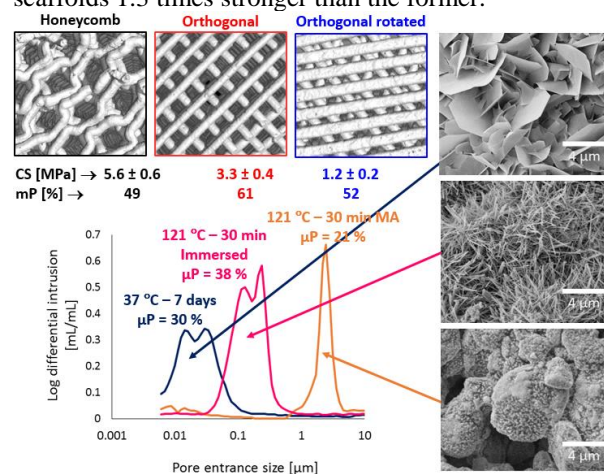

Fig. 1:  $\mu$ CT reconstructions, CS, mP, pore entrance size distribution and microstructure of studied scaffolds.

## CONCLUSION

Varying consolidation conditions allows tailoring  $\mu$ P and microstructure, while varying the printed pattern allows tailoring the mP content and architecture, all essential parameters to induce specific cell responses in future applications of these scaffolds in bone tissue engineering.

## Development of Bioactive and Antimicrobial 3D Plotted PCL Scaffolds for Bone Tissue Engineering

Giuseppe Cama, Myriam Gomez Tardajos, Peter Dubruel

Polymer Chemistry and Biomaterials Research Group,  
Ghent University, Krijgslaan 281, 9000 Ghent, Belgium  
[giuseppe.cama@ugent.be](mailto:giuseppe.cama@ugent.be)

**INTRODUCTION** The treatment of “critical” bone defects (i.e. bone deficiency that precludes the spontaneous healing of the natural tissue leading to severe functional impairments) represents a challenge for orthopaedic and oral-maxillofacial surgeons due to the lack of therapeutic approaches that are able to fully restore the lost bone<sup>1</sup>.

A way of reducing the drawbacks of the conventional treatments is to use bone graft substitutes with a tailored porosity, suitable to ensure nutrient and metabolic waste transport to and from the core of the scaffold, a critical issue for proper vascularization and new bone tissue formation. To this purpose rapid prototyping techniques have been developed in order to fabricate 3D polymeric layered grids with the desired thread size and thread spacing as well as with different orientations of the grids between one layer and the other. Poly-ε-caprolactone (PCL) is a biocompatible polymer extensively employed to fabricate 3D plotted structures due to its easy processability. However, it is not properly a bioactive material (i.e. able to bond to the living bone tissue) and it does not show antimicrobial activity. This latter property is highly required for a material to be used for the treatment of bone defect considering that infections associated with implantation of bone graft substitutes represent a challenging problem for surgeons and patients alike<sup>2</sup>. The aim of this work is to overcome the PCL limitations by coating 3D plotted PCL structures with bioactive calcium phosphate (CaP) crystals and chitosan (CH) functioning as antimicrobial agent.

**EXPERIMENTAL METHODS** 3D plotted PCL (Sigma-Aldrich, Mw 70.000–90.000 g/mol) scaffolds with a cubic shape (l=10mm) and square shaped pores (l= 300 μm) were fabricated using a Bioscaffolder® (Sys-Eng, Germany) device. Briefly, PCL in form of granules (d~3mm) was melted at a temperature of about 120 °C and extruded through a 27-gauge needle. The pressure during extrusion was maintained at 5 bar. The plotted structures were subjected to 30 seconds of Argon plasma treatment and then functionalised by grafting Methacrylic acid N-hydroxysuccinimide ester (NHSMA) by immersion in a solution with a molar concentration equal to 0.5M. The polymerization was carried out for 30 minutes under UV-C. Subsequently, the samples were chitosan coated by placing them overnight in a 2% wt of chitosan solution at pH 5. Then, the scaffolds were CaP coated by immersion in Milli-Q water where CaCl<sub>2</sub> and disodium hydrogen phosphate (Na<sub>2</sub>HPO<sub>4</sub>) (molar ratio of Ca/P equal to 1.67) powders were let to dissolve and precipitate onto the PCL struts.

**RESULTS AND DISCUSSION** A qualitative preliminary investigation showed the precipitation of a

CaP phase onto the PCL struts (Figure 1). FTIR analysis reported brushite (DCPD: CaHPO<sub>4</sub>·2H<sub>2</sub>O) as the precipitated phase (Figure 2). The acid pH value (pH=4.5±0.1) measured immediately after the immersion of the reactants powders could be the main cause that drove the precipitation process towards the formation of brushite, which is the CaP phase generally found in acid aqueous solution<sup>3</sup>.

Figure 1 A: Optical image (200x) of a 3D plotted PCL coated with brushite. B: SEM analysis of the precipitated brushite crystals.

PCL was functionalized by grafting a methacrylate containing succinimide functionality (NHSMA) after plasma activation. Subsequently, the NHS groups of the grafting were used to coat native chitosan as shown in Figure 2.

Figure 2: scheme of functionalization method of PCL using NHSMA for the subsequent immobilization of native chitosan.

Preliminary XPS analysis showed the presence of the peak of nitrogen on the grafted surface and an increase of the %N after the chitosan coating. Qualitative changes of the contact angle were also observed in the different steps of the process.

**CONCLUSION** Coating 3D plotted PCL scaffolds with chitosan and calcium phosphate crystals could be considered as a potential strategy to produce biologically improved materials for bone tissue engineering applications. Antimicrobial tests will be performed and reported on during the meeting.

### INTRODUCTION

Two photon polymerization (2pp) is a high-resolution photolithographic technique which allows the prototyping of 3D nanostructures suitable for cell-surface interaction investigations, tissue engineering, and regenerative medicine.<sup>1</sup>

The possibility to combine different nanoparticles with traditional photoresists opens new perspectives for the photofabrication of 3D structures characterized by several tunable properties.<sup>2</sup> As an example, piezoelectric materials can be exploited for sensing/actuating purposes, both at cellular and tissue level. In this context, piezoelectric barium titanate nanoparticles (BTNPs) were already successfully exploited for stem cell stimulation.<sup>3</sup>

In this work, we propose for the first time the 2pp of 3D nanocomposite structures prepared with the commercially available Ormocomp® photoresist doped with a high concentration (1:10 mass ratio) of BTNPs.

### EXPERIMENTAL METHODS

#### *Fabrication of nanocomposite 3D structures*

BTNPs were obtained from Nanostructured and Amorphous Materials (Houston, TX, USA) and were homogeneously mixed with the Ormocomp® photopolymer by applying ultrasounds (8 W, 2 min, with a Ultrasonic Homogenizer 7 mini 20, Bandelin). Subsequently, 2pp of the BTNPs dispersion in Ormocomp® was achieved by using a Direct Laser Writing system (Photonic Professional, Nanoscribe GmbH) and a Zeiss microscope equipped with an oil-immersion objective (100x, numerical aperture = 1.4). The photon wavelength was 790 nm and the pulse duration was 120 fs. The 3D structures were fabricated thanks to a layer-by-layer writing approach. At the end of the procedure, the unexposed resist was removed with Ormodev® developer.

#### *Characterization of the polymerized structures*

The nanoparticles were detected on the surface and inside of the polymerized 3D structures thanks to atomic force microscopy (AFM, MultiMode Veeco) and confocal microscopy (C2s, Nikon), respectively. For the confocal scans we exploited the excitation at 642 nm, at which BTNPs resulted detectable without any further labeling.

Furthermore, we combined focused ion beam and scanning electron microscopy (dual beam system, FEI Helios 600) with energy dispersive X-ray spectroscopy (EDX, Bruker) for a deeper characterization of the fabricated structures.

### RESULTS AND DISCUSSION

The successful 2pp of the Ormocomp® photopolymer doped with BTNPs (1:10 mass ratio) into a desired structure (in this case, as an example, the 3D logo of our

institution, IIT) was analyzed (Fig. 1). Fig. 1a is an AFM scan showing the presence of BTNPs on the surface, while Fig. 1b is a confocal z-stack of the whole structure (BTNPs in green) and Fig. 1c the 3D reconstruction of the signal collected by all the z-stacks (pseudo-colors indicate depth).

Fig. 1. AFM surface scan (a), single confocal z-stack (b) and 3D reconstruction (c) of the IIT logo obtained by the two-photon polymerization of Ormocomp® doped with barium titanate nanoparticles (BTNPs).

Thanks to the AFM and to the confocal imaging, it is possible to appreciate the high concentration of nanoparticles, which are uniformly dispersed into the 3D structure.

This observation is confirmed by SEM analysis. In particular, after milling the first layers of the structure by using a focused ion beam, a SEM scan (Fig. 2a) revealed the presence of BTNPs in the whole depth of the structure, and the elemental microanalysis (Fig. 2b) demonstrated the presence of barium titanate.

Fig. 2. SEM scan after milling the first layers of the logo by using a focused ion beam (a). Elemental microanalysis of the same area reveals the presence of barium titanate (b).

Collectively, all the analyses not only demonstrated the presence of BTNPs inside the polymerized structure, but also highlighted as the polymerization process was not affected by the presence of the nanoparticles in the photoresist.

### CONCLUSION

Concluding, we obtained for the first time a two-photon polymerized 3D nanocomposite structure based on Ormocomp® doped with piezoelectric nanoparticles.

The exploitation of these structures for the piezoelectric stimulation of cells and tissues could represent an interesting approach in tissue engineering and regenerative medicine, which deserves future deeper investigations.

### INTRODUCTION

An interesting self-assembly route for production of highly porous polymeric materials is emulsion templating via high internal phase emulsions (HIPEs). To form porous polymers from HIPEs typically a dispersed aqueous droplet phase is used with a curable pre-polymer continuous phase. During the curing process a foam is produced in which the pores are interconnected (a polyHIPE).<sup>1</sup> In this paper we report the use of polyHIPEs as a material for additive manufacturing, in particular microstereolithography ( $\mu$ SL). In  $\mu$ SL a laser is scanned through a photocurable resin to build up a 3D objects with micrometre length scale resolution. This enables the production of hierarchical structures based on polyHIPEs where the internal porosity is governed by the emulsion templating process and macroscopic structuring is governed by the  $\mu$ SL process.<sup>2</sup> This study assesses the ability of acrylate based PolyHIPE scaffolds to support bone cells *in vitro* by seeding with immortalised human embryonic stem cells. Scaffolds with different stiffness and surface chemistries are used to evaluate their effects on differentiation.

### EXPERIMENTAL METHODS

3D structured scaffolds with varying mechanical properties have been produced via combining the water-immiscible monomers 2-Ethylhexy acrylate (EHA) and Isobornyl acrylate (IBOA) with a triacrylate crosslinking agent, photoinitiator and a surfactant (see Fig. 1). The HIPE is cured into woodpile structures by scanning the UV light (355 nm) generated by a Nd:YAG microchip laser (0.5 ns pulse duration, 16.6 kHz, 10 mW) over the photocurable resin. The scanning patterns were generated via a computer controlled xyz-stage (Aerotech). 3D structures were produced from polyHIPE with internal porosity ranging from 75 to 90%.

SEM analysis of 4-layer 3D grid arrays produced via  $\mu$ SL were used to assess the porosity and surface features. The tunability of the mechanical properties of PolyHIPE monomer blends was studied via nanoindentation and tensile testing. The surfaces of the scaffolds were rendered hydrophilic via both oxygen plasma treatment and plasma polymerisation of acrylic acid and the scaffolds were tested *in vitro* for cell ingrowth with human embryonic stem cell-derived mesenchymal progenitors (hES-MPs). Resazurin reduction assays were used to assess viability and Alkaline Phosphatase (ALP) and DNA assays for osteogenic differentiation.

### RESULTS AND DISCUSSION

3D structures built from polyHIPEs with a range of mechanical properties and porosities. Young's Moduli of PolyHIPEs ranged from  $0.36 \pm 0.04$  to  $63.01 \pm 9.13$  MPa and Ultimate Tensile Strength ranged from  $0.11 \pm 0.01$  to  $2.03 \pm 0.33$  MPa. 13 mm diameter woodpile scaffolds were made from 0%, 50% and 100% EHA compositions at 80% porosity with a fibre diameter of 350  $\mu$ m and a spacing of 650  $\mu$ m (Fig. 1). All scaffolds supported cells, with an increase in viability over time and no significant differences between compositions. Composition also had no significant effect on differentiation, with the exception of the stiffest scaffold in combination with an acrylic acid plasma treatment which exhibited a significant higher ALP activity.

**Figure 1:** PolyHIPE woodpile scaffold showing micro- and macro-porosity

### CONCLUSION

PolyHIPEs can be used to create regular porous structures by microstereolithography with micropores. This hybrid technique addresses the resolution trade-off between macro structuring with micro resolution, while maintaining user control over structural parameters throughout the process. Mechanical properties of these scaffolds can be varied by changing the monomer concentration to provide a range of application specific stiffnesses relevant for bone tissue engineering.

### INTRODUCTION

A major challenge in the repair of joint injuries lies in the reattachment of the soft tissue to the bone<sup>1</sup>. Failure to regenerate these interfaces results in compromised graft stability and poor long-term clinical outcomes<sup>2</sup>. Fabrication of scaffold constructs that promote the formation of bone-to-ligament interfaces is limited<sup>3</sup>. Therefore development of a construct with the ability to promote bone and soft tissue regeneration is a priority.

In this study we propose that the sustained, localized delivery of osteogenic nanoparticles (NPs) from a biomaterial scaffold will promote osteogenesis, enhancing formation of interfacial tissue. A series of *in vitro* tests were performed to determine whether NPs comprised of an amphipathic peptide (RALA) incorporating  $\alpha$ -tri-calcium phosphate ( $\alpha$ -TCP) and the RUNX2 gene, released via thermo-responsive hydrogels, elicited an osteogenic response in human osteoblast cells.

### EXPERIMENTAL METHODS

**Formulation of RALA/ $\alpha$ -TCP NPs:** Particle size and zeta potential (ZP) were measured using a Malvern Zetasizer to determine the optimal formulation. NP stability was tested over time and temp range.

**Cell viability:** The effects of RALA/ $\alpha$ -TCP, RALA/RUNX2 NPs and NP-loaded hydrogel on human osteosarcoma cells MG63 and normal human osteoblasts was assessed every 7 d using MTS, LDH and live/dead cell assays up to 28 d

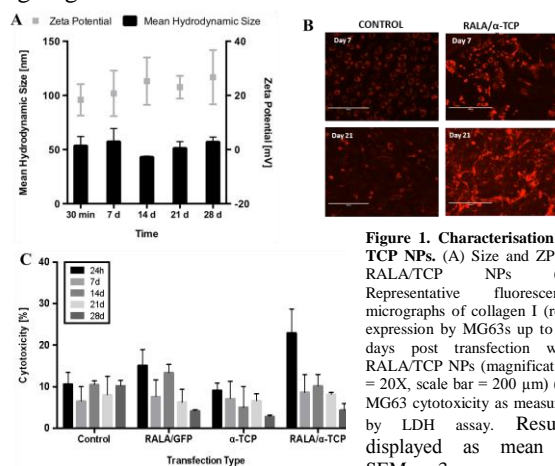

**RT-PCR analysis:** Cells were cultured with RALA/ $\alpha$ -TCP, RALA/RUNX2 NPs and NP-loaded hydrogels. RNA was extracted up to 28 d post transfection and complementary DNA (cDNA) synthesised. RT-PCR was performed and relative gene expression of osteoblastic markers determined using REST software.

**Immunocytochemistry (ICC) & quantification of osteogenic proteins:** Cells were fixed, permeabilised and blocked prior to incubation with col-I, RUNX2 and osteocalcin (OC) primary antibodies. Following incubation secondary antibodies samples were visualized by fluorescence microscopy. Quantification of col-I, OC and ALP was determined using quantitative colorimetric assays

**Mineralisation Assay:** Mineralisation activity was evaluated using Alizarin red (AR) staining. Cells were fixed and stained with AR at room temperature for 45 min. CPC extraction was performed to quantify staining.

### RESULTS AND DISCUSSION

NPs prepared with a mass ratio of 5:1 were observed to have a size of  $43 \pm 4.5$  nm and a zeta potential of  $26 \pm 4.3$  mV. The NP size and ZP remained consistent for up to 28 d at room temperature and across a broad range of temperatures (4–40°C) (Figure 1.A). Cell viability was seen to decrease 24 h post-transfection with the RALA/ $\alpha$ -TCP NP treatment. However cytotoxicity decreased to a level similar to that observed untreated control group 7 d after transfection (Figure 1.B). ICC staining for collagen I (red) up to 21d post-transfection with RALA/ $\alpha$ -TCP NPs indicated MG63 cells treated with NPs exhibit enhanced col-I expression compared to an untreated control (Figure 1.C). Taken together these data demonstrate that RALA/ $\alpha$ -TCP form stable NPs that elicit an osteogenic response in MG63 cells. ICC and quantification of osteogenic proteins is ongoing.

**Figure 1. Characterisation of TCP NPs.** (A) Size and ZP of RALA/TCP NPs (B) Representative fluorescence micrographs of collagen I (red) expression by MG63s up to 21 days post transfection with RALA/TCP NPs (magnification = 20X, scale bar = 200  $\mu$ m) (C) MG63 cytotoxicity as measured by LDH assay. Results displayed as mean  $\pm$  SEM, n=3

### CONCLUSION

We have successfully demonstrated that the RALA peptide was capable of forming NPs with  $\alpha$ -TCP, which were stable across a range of temperatures and over an extended duration. Furthermore these NPs were shown to induce osteogenesis in osteosarcoma cells and osteoblasts, and when loaded into a hydrogel form a potential biomimetic interface between bone and ligament.

### INTRODUCTION

The current worldwide accepted standard fixation for modern metal-on-metal hip RA (resurfacing arthroplasty) is a hybrid technique using a cemented short-stem femoral component in combination with an uncemented acetabular component (e.g., Birmingham Hip Implant, Cormet 2000 Implant, DePuy ASR Implant, etc.). With our elaborated prototype of the multispiked connecting scaffold (MSC-Scaffold), invented by Rogala<sup>1</sup> and designed, manufactured<sup>2</sup> and tested by our research team<sup>3</sup>, we propose completely non-cemented biofixation of RA endoprostheses. The aim of this contribution is to present the main results of pilot experimental studies in 10 animals on the prototype of the MSC-Scaffold with Ca-P (or HA) modified surface, performed to establish the suitable constructional directives for manufacturing in SLM technology the subsequent prototype of such scaffold for RA endoprostheses. The possibilities of affecting the pro-osteoconduction functionality of the MSC-Scaffold, which is essential for its proper successive osteointegration with the periarticular trabecular bone tissue, has been evaluated in the associated ESB2015 contribution (Uklejewski, Winiecki *et al.*)<sup>4</sup>.

### EXPERIMENTAL METHODS

The prototype of the MSC-Scaffold for non-cemented RA endoprostheses was investigated on its constructional prototype variants (Fig. 1a) with thermo-electrochemically Ca-P (or HA) modified bone contacting surfaces, which were implanted (Fig. 1a,b) in hip and knee joints of 10 animals (swine; breed: Polish Large White) in a veterinary clinic operating room with permission of the Local Ethic Commission. After 6-7 weeks the animals were scarified and the bone-prototypes preparations were made (Fig. 2a) and the bone tissue contacting and surrounding the prototypes was microscopically evaluated in the Pathomorphology Unit of the J. Strus Clinical Hospital of Poznan Medical University.

Fig. 1. a) MSC-Scaffold prototype variant, b) partial knee resurfacing endoprosthesis prototype with the MSC-Scaffold implanted into swine knee joint, c) assisted laboratory biomechanical test on the MSC-Scaffold prototypes (push-in test in periarticular cancellous bone of swine femoral head).

### RESULTS AND DISCUSSION

The exemplary pathomorphological microscopic slides of bone tissue contacting and surrounding the implanted prototypes are presented in Fig. 2a,b. It was found, that the Ca-P (or HA) modification of the MSC-Scaffold significantly improves its osteointegration with the surrounding periarticular bone. Due to the technical difficulties in the bone-prototype microscopic slides preparation, the special 2D X-ray analysis (Fig. 2c) and micro-tomography analysis have been undertaken in cooperation with the COMEF Scientific and Research Equipment Company.

Fig. 2.: a,b) exemplary pathomorphological microscopic slides of bone tissue surrounding the implanted MSC-Scaffold prototypes, c) 2D X-ray radiogram (XPRT 40, Kubtec, USA) of swine knee joint with implanted partial knee resurfacing endoprosthesis prototype with the MSC-Scaffold.

### CONCLUSIONS

On the base of the performed pilot experimental studies in animal models (assisted by the biomechanical push-in test) on the constructional prototype variants of the MSC-Scaffold for RA endoprostheses, and the obtained results, it was possible to establish the suitable constructional directives for the engineering design and manufacturing the prototypes of partial and total RA endoprostheses for knee and hip joints, which – according to the ISO 10993 recommendations – should be verified in the full standard experimental study on animal models (in the planned next research project).

## INTRODUCTION

Induced membrane technique has been first proposed by Masquelet and his collaborators for wide segmental diaphysal bone reconstruction with autologous cancellous bone graft [1]. Historically, a PMMA spacer is placed in a bone defect to prevent fibrous ingrowth into the site and to induce the formation of a cavity surrounded by the induced membrane that can be filled with a graft in a second surgical intervention. Induced membrane technique can be applied for two-staged bone reconstruction in carcinologic context with irradiation. To reduce donor site morbidity following bone harvest, synthetic bone substitutes in combination or not with bone morphogenetic protein 2 (BMP-2) to the graft were proposed. Statins were investigated in numerous studies showing an enhanced expression of BMP-2 mRNA and osteoblastic differentiation *in vitro* and *in vivo*. The aim of this study was to evaluate the osteogenic properties of several combinations of grafts and the osteoinductive capacity of simvastatin in comparison to BMP-2 in an induced membrane filled with a HA/  $\beta$ -TCP bone substitute (MBCP+™) in association with bone marrow allografts in a segmental, critical size femoral rat defect. Furthermore, the stability of a semi-flexible silicone spacer for membrane induction was tested in this model.

## EXPERIMENTAL METHODS

36 Wistar RjHan rats received an osteosynthesis plate that was fixed on the anterior surface of the femur with two cortical screws (all SYNTHES, Solothurn, Switzerland). The osteosynthesis plate was removed, a segmental defect of 6 mm length was created and the silicone spacer (A-H, see table below) was placed in the defect site and stabilized with stiches against the metal plate. Rats of two conditions (E, F) received radiotherapy (50 Gy over 5 weeks). Bone marrow and spongy bone allografts were harvested from long bones and condyles of same strain rats.

Condition	MBCP+™	Total bone marrow	BMP-2 (InductOs®)	Simvastatin	radiotherapy (50Gy)	spongy bone	cavity not filled	no spacer implantation after defect
A	x							
B	x	x						
C	x	x	x					
D	x	x		x				
E	x	x	x		x			
F	x	x		x	x			
G						x		
H							x	
I								x

Bone mineral densities (BMD), as well as the overall stability of the model, were investigated by  $\mu$ CT scanning and X-ray acquisition. The percentages of collagenous and osteoid tissue within the induced membrane were measured with adapted software from histological sections.

## RESULTS AND DISCUSSION

Overall, conditions that received the silicone spacer in the first surgical and MBCP+™ in the second intervention showed the highest stability. Osteosynthesis plates stayed straight and the distance between the screws stayed stable within the group. Only in conditions that were left empty after membrane induction and after defect creation (H and I), osteosynthesis plates bended, so that the distance between the screws was significantly reduced in comparison to the other seven conditions. There was no significant difference in BMD within the six conditions with MBCP+™. Only the non-irradiated condition with BMP-2 (C) showed a significant increase in BMD in comparison to the control conditions (G-I). Measurements of collagenous content within MBCP+™ filled induced membrane indicated a significantly lower percentage for the non-irradiated condition with BMP-2 (C) in comparison to 3 other conditions. When investigating the osteoid percentage, the two conditions with BMP-2 (C, E) showed significantly increases in comparison to the material by itself (A), or associated with total bone marrow (B). In comparison, conditions with simvastatin (D, F) showed more fibrosis and less osteoid tissue, BMD and stability were comparable with BMP-2 containing conditions. Irradiation did not influence the evaluated factors.

## CONCLUSION

Conditions with BMP-2 showed a high stability, the highest mineral content, the lowest fibrosis and a high present of osteoid tissue. In comparison with simvastatin, BMP-2 seems to favour bone regeneration in our segmental femoral model in rats.

### INTRODUCTION

Next generation biomaterials supporting bone regeneration are expected to mimic callus properties and guide cell behavior towards functional tissue formation rather than providing properties of intact bone tissue [1]. This study aims at combining A), a previously developed macroporous biomaterial scaffold with a highly orientated pore architecture for guided tissue growth, and B), calcium phosphate (CaP) microparticles for improved bioactivity. The influence of the mechanical and geometrical properties of this biomaterial scaffold as well as the biological response to CaP incorporation were investigated under *in vitro* and *in vivo* conditions.

### EXPERIMENTAL METHODS

Fine  $\alpha$ - and  $\beta$ -tricalcium phosphate (TCP) particles were prepared by solid state synthesis and subsequent milling. Hydroxyapatite (HAp) powder was synthesized via a wet-chemical process. All three calcium phosphates had comparable particle size distributions and mean particle sizes smaller 10 $\mu$ m. Powder X-ray diffraction (XRD) confirmed high phase purity and crystallinity of both  $\alpha$ - and  $\beta$ -TCP, whereas the HAp powder was mainly amorphous. Highly orientated collagen scaffolds were produced by directional solidification, freeze-drying and chemical crosslinking. CaP microparticles were incorporated avoiding any impairment of pore geometry and CaP properties. Structural characteristics of the scaffolds were analyzed via scanning electron microscopy. Using human primary fibroblasts, *in vitro* cell organization and ECM formation inside collagen/CaP hybrid scaffolds were studied longitudinally via (immune)histology and confocal/multiphoton microscopy up to 14 days. Gene expression patterns related to osteogenic differentiation of human mesenchymal stromal cells (hMSCs) were analyzed after 7 days of culture in the scaffold prototypes via real time quantitative PCR. Finally, *in vivo* bone formation in a 5mm critical sized defect in rats was quantified via  $\mu$ -CT analysis (newly formed bone) and histomorphometry (callus composition).

### RESULTS AND DISCUSSION

Mineral particles were uniformly distributed after incorporation in the highly orientated collagen-I scaffolds. No pronounced alteration of scaffold inner architecture (pore size, pore orientation and geometry) was observed while maintaining the high porosity (>98%). Fibroblasts showed an increasing degree of alignment over time resulting in a highly anisotropic

network of newly formed fibronectin at day 14 in the hybrid scaffolds comparable to CaP free collagen scaffolds. However, formation of fibrillar collagen was delayed in hybrid scaffolds as a consequence of the changed microenvironment. Strongest upregulation of osteogenic genes like alkaline phosphatase (ALP), osteocalcin (OC), and osteopontin (OP) was induced by HAp particles compared to  $\alpha$ - and  $\beta$ -TCP and osteogenic medium. This may be attributed to the very high specific surface of HAp (>80m<sup>2</sup>/g) compared to the TCP's (approx. 1m<sup>2</sup>/g), which seemed to outbalance its lower solubility ( $\alpha$ -TCP >  $\beta$ -TCP > HAp). Even though HAp microparticles showed to be effective in enhancing MSC differentiation towards the osteoblast lineage under *in vitro* conditions, no increase in volume of newly formed bone was observed in the bone defect model. At the same time cartilage was completely absent at 6weeks in any of the three hybrid scaffold types in contrast to the pure collagen scaffolds. It was concluded that the bioactivity of CaP particles in the highly orientated collagen scaffold structure favors osteogenic processes but suppresses cartilage formation *in vivo*. Thus the particles seemed to induce a switch in the mechanism of bone tissue formation from endochondral to intramembranous ossification. While the mineralized callus was observed to infiltrate the scaffold material for the pure collagen scaffold, the incorporation of CaP particles leads to a more periosteal bone formation.

### CONCLUSION

The induced alterations in bone formation highlight the role of the concerted interactions between structural, mechanical and chemical signals for healing of large bone defects. The gained knowledge will help to develop biomaterial approaches that mimic the early phases of endogenous callus formation for efficient bone formation. This seems to be a promising alternative to common approaches mimicking the mechanical and chemical properties of intact bone tissue.

### INTRODUCTION

Cardiovascular diseases (CVDs) are accounting for nearly one-third of deaths worldwide. For CVDs treatment, it is expected to develop small diameter blood vessels. Previously, the artificial small diameter blood vessels have been developing [1, 2]. Recently, novel small diameter blood vessels were investigated by using tissue-engineering technologies, such as cell sheet engineering, 3D bio-printer and decellularized tissue. Our group also have developing decellularized blood vessel using high hydrostatic pressure (HHP) technology. The in vivo good performance of the HHP-decellularized aorta and carotid artery was demonstrated due to the good preservation of the basement membrane of the HHP decellularized arteries [3,4]. While the HHP decellularized carotid artery is a candidate of small diameter blood vessels, it is short length for clinical usage. In this study, the HHP decellularized aorta was fabricated to make a small diameter blood vessel having long length. The electrospinning technology was used to control the strength of small diameter blood vessels for various applications.

### EXPERIMENTAL METHODS

Fresh porcine aorta was purchased from a local slaughterhouse (Tokyo Shibaura Zouki, Japan). The intima-media (300-500  $\mu$ m) of aorta was peeled and treated with HHP at 10,000 atm for 15 min and washed with saline containing DNase. The decellularization of aortic intima-media was evaluated by hematoxylin and eosin (H & E) staining and residual DNA quantification.

Segmented polyurethane (SPU, Pellethane® 2363-80AE) was used. SPU solution in THF/dioxane of 100/1 was prepared at various concentrations. The decellularized intima-media was rolled onto a mandrel (4 mm diameter, 150 mm length). The mandrel was set on our original rotating collector (Fig. 1). Nanofibers were electrospun to the outside surface of decellularized intima-media. The obtained small diameter decellularized blood vessel covered with electrospun nanofibers was investigated by SEM observation, mechanical strength test.

### RESULTS AND DISCUSSION

The optimal electrospinning condition of SPU was decided and the diameter of SPU fibers with 0.3-1.5  $\mu$ m was obtained. The decellularization of the intima-media of aorta by HHP method was confirmed using H & E stain and DNA quantification. Using our original electrospinning apparatus, the small diameter blood vessel covered with SPU fibers was obtained. Figure 2 shows macro and micro graphs of the small diameter

Figure 1. The schematic diagram of electrospinning apparatus for preparation of a small diameter decellularized blood vessel.

Figure 2 The obtained small diameter decellularized blood vessel. (A) Macro-image and (B) SEM image.

decellularized blood vessel with SPU fibers. The outer and inner layers were SPU fibers and decellularized intima-media, respectively. The SPU fibers were covered on the tissue surface with the homogenous thickness and a porous 3-dimension structure. The physical properties of small diameter decellularized blood vessel were similar to that of native carotid artery when the SPU fibers layer was adjusted (data not shown).

### CONCLUSION

In this study, the small diameter blood vessels composed of decellularized intima-media of aorta and electrospun SPU fibers was obtained.

### INTRODUCTION

Cardiovascular diseases are the main cause of death worldwide with the cost of treatment for the patients expected to surpass 1.5 trillion dollars only in the USA by 2030 according to the American Heart Association <sup>1</sup>. Besides heart transplantation, there have been developed several therapeutic strategies including the design of biological, polymeric and hybrid bio-artificial scaffolds. These scaffolds can mimic the extra-cellular matrix (ECM) enabling cells to repopulate a site in the heart that has been damaged and new tissue to grow. Electrospinning is a facile and cost-effective technique that can produce 3D biocompatible structures to serve as extracellular matrix (ECM)-like scaffolds where cells can be seeded and proliferate eventually forming a hybrid bio-artificial tissue <sup>2</sup>. Fibrous mats, tubes and more complex 3D shapes can be successfully engineered not only to induce cell proliferation but also to release in a controllable manner biomolecules (e.g. proteins, growth factors) that can further support tissue formation <sup>3</sup>.

### EXPERIMENTAL METHODS

Polycaprolactone (PCL) and chitosan (CS) were dissolved as a blend in 99.8% acetic acid (AAC) at concentrations of 190 mg/ml and 12.5 mg/ml respectively. Electrospinning was performed at a custom made apparatus, at temperature and relative humidity of  $23 \pm 1$  °C and  $35 \pm 5\%$ , respectively. Structural and morphological analysis of the collected fiber mats was performed by scanning electron microscopy (SEM) while the samples were previously sputter-coated with gold for better quality imaging. Cyclic sinusoidal uniaxial mechanical tests were performed with an electroforce dynamic tensile testing system by BOSE®, equipped with a 200 N load cell. Rectangular, 15x10 mm strips were cut and tested at 0-30% strain, 1 cycle/sec, RT, dry conditions. The applied force and the local principal strain were monitored and stress/strain data was computed. Mechanical properties like Young's modulus (the elastic modulus at high slope - post transition phase - linear portion of stress/strain curve) were evaluated<sup>4</sup>. A nano-indentation system based on an atomic force microscope (AFM) apparatus with a special tip was used to examine the hardness of the samples and the Young's modulus. Each sample was tested in 15 different sites using 100 & 500 µN force. Static water contact angle experiments were performed to study the nature of the fibers' surface and its hydrophilicity. Chemical characterization including Fourier-Transformed Infrared Spectroscopy (FTIR) and X-rays diffraction (XRD) was carried out in order to

determine the physicochemical state of the polymeric compounds in the fibers. Statistical analysis was performed using Origin Pro 8.5 and IBM SPSS Statistics v.21 (One-way ANOVA with post-hoc Tukey/Bonferroni) and statistical differences were considered significant if  $p < 0.05$ .

### RESULTS AND DISCUSSION

Structural and morphological analysis indicated that the created fibers have a smooth, "spaghetti-like" shape with an average diameter of  $2.42 \pm 0.38$  µm and an average pore size of  $8.27 \pm 0.83$  µm<sup>2</sup> with random orientation. The average values of Young's modulus and stiffness calculated from the nano-indentation studies were  $31.55 \pm 1.52$  MPa and  $3.76 \pm 0.11$  MPa when the applied force was 500µN and  $61.29 \pm 4.25$  MPa and  $6.28 \pm 0.63$  MPa for the 100µN applied force. The hysteresis ratio  $h$  was  $0.46 \pm 0.10$  revealing the viscoelastic nature of the fibers. The surface of the fiber-mats can be considered relatively hydrophilic as the static water contact angle was  $74.5 \pm 2.5$  °. FTIR and XRD data lead to the conclusion that PCL and CS interact in the blend, possibly forming non-covalent bonds with PCL being in a semi-crystalline state and CS in an amorphous form in the fibers.

### CONCLUSION

The experimental results showed that the polymeric fiber mats can be considered as suitable candidates for bio-artificial scaffolds in order to enable cell seeding, proliferation and repopulation of a damaged tissue after a cardiovascular incident.

## INTRODUCTION

The formation of aneurysms is an extremely dangerous degenerative pathology of arterial tissues, especially common in adult and elderly populations, whereby the wall of the artery weakens locally and largely expands. Aortic Abdominal Aneurysms (AAA), are the most common and fatal type of aneurysms.

Until 1991, the only treatment available entailed an open surgical procedure, whereby the dilated segment of the artery was replaced by an artificial vascular graft. In the early nineties, endografts consisting of a modified vascular prosthesis mounted on a stent and deployed intra-luminally at the aneurysmal site using a balloon, were introduced. Unfortunately, several factors restrict significantly the use of these devices. Most importantly, anatomical constraints that largely limit the access to the aneurismal site often prevent the use of the endograft.

This lecture introduces a polymeric device for AAA treatment that is deployed intra-luminally at the aneurismal site and then expanded so it tightly attaches to the aorta, proximally and distally to the aneurysm.

The implantation of these devices is divided into two parts: {a} the insertion through the iliac artery, the navigation to the site and the expansion stages, during which flexibility is critical, and {b} its performance at the aneurismal site, where the device is required to display appropriate mechanical properties.

Two strategies were pursued: (1) The device is thermally softened using a balloon filled with warm saline, so it can be easily expanded, followed by its firm and conformable attachment to the arterial wall, proximally and distally to the aneurysm. While in its expanded configuration, the endograft is then cooled down to 37°C and attains the mechanical properties required. (2) The endograft consists of an Expandable Component (EC) and a “Smart” Component (SC), with the latter being present within the former. The SC is a low molecular weight, polymerizable or crosslinkable precursor that fulfills two different roles: {a} It acts as a plasticizer of the EC during the early stages of the procedure (navigation and expansion), rendering it with the required flexibility, and, {b} It stiffens the device after its expansion and attachment to the vessel wall, once it polymerizes or crosslinks, imparting to the endograft the necessary mechanical properties.

## EXPERIMENTAL METHODS

PEU thermoplastic elastomers softening between 50 and 60 degrees were used when following the first strategy, while poly(meth)acrylates and PEsUs performed as the EC, and methacrylates such as hydroxyethyl methacrylate

(HEMA) were used as the SC. The various polymers were characterized by NMR, DSC, GPC and their mechanical properties were determined using an Instron Universal Testing Machine. Their ex-vivo performance was assessed in a cadaveric pig aorta segments and the acute *in vivo* feasibility of the device was evaluated by implanting it in a pig for eight hours.

## RESULTS AND DISCUSSION

Following the basic working concept of this study, various expandable conduits were generated, differing in their composition, their mechanical properties, their expandability ratio, and the technique used to produce them. As an example, an elastomeric PEsU was blended with hydroxyethyl methacrylate (HEMA) at different concentrations. HEMA molecules soften the PEsU EC during the early stages of the procedure, and remarkably stiffen it when polymerization takes place (Fig. 1), after the device is expanded and tightly attached to the aortic wall, proximally and distally to the aneurismal sac.

Figure 1. Mechanical behavior of a PEsU/HEMA device.

The expandability of the devices created was demonstrated in both cadaveric pig aorta sections and in an acute *in vivo* experiment in a pig. This was also demonstrated by measuring the displacement force required to pull out our device (~45N), well above devices presently in clinical use (4.5-25 N)<sup>1</sup>.

## CONCLUSION

The *in vivo* Proof of Principle of these devices, namely their ability to be deployed and inflated at the aneurismal site, following minimally invasive procedures that are routinely used in the clinic, and generate a stable and safe conduit, was demonstrated *in vitro* and acutely (eight hours) in the abdominal aorta of pigs

### INTRODUCTION

Cardiovascular related diseases such as coronary artery disease, cardiomyopathy, valvular disease, etc. are currently the main cause of death worldwide. However, nowadays there is no effective biomaterial to treat these diseases, especially as small-diameter (<6 mm) bypass grafts<sup>1</sup>. Among the synthetic polymers used in the cardiovascular area, segmented polyurethanes (SPUs) have played a significant role due to their excellent mechanical properties as well as relatively good biocompatibility<sup>2</sup>. However, when used as small diameter vascular graft one of the key factors that need to be considered is the matching of their mechanical properties with the host artery/vein in order to avoid hyperplasia in the anastomoses. In turn, thrombosis of vascular grafts results in a change of mechanical properties promoting early graft failure<sup>3</sup>. Therefore, an artificial vascular graft device has to comply with either ISO 7198 or ANSI/AAMI VP20-1994 standards for vascular graft prosthesis<sup>4</sup>. Recently, our group reported that the use of segmented polyurethanes based on amino acids promotes the growth of endothelial cells<sup>5</sup>. In order to fully assess their performance, in this study we present the mechanical characterization of small diameter vascular grafts made of SPUs based on alkaline amino acids.

### EXPERIMENTAL METHODS

SPUR and SPUK were synthesized by the reaction of poly ( $\epsilon$ -caprolactone) diol (PCL) with an excess of 4,4'-methylene-bis-cyclohexyl diisocyanate (HDMI) in the first step and then extended with L-Arginine (R) or L-Lysine (K) respectively<sup>5</sup>. Small diameter vascular grafts were obtained after wrapping an SPU film around 5.5 mm diameter mandrel. Films and small caliber vascular grafts were characterized by FTIR, DSC, TGA and AFM while their mechanical properties were assessed following ISO 7198 in terms of longitudinal and circumferential tensile strength, probe burst strength and suture retention strength. Tecoflex™ (LifeSciences) was used for comparison purposes.

### RESULTS AND DISCUSSION

FTIR showed urethane group absorptions at 3300 cm<sup>-1</sup> (NH) and at 1525 cm<sup>-1</sup> (-NHCOO-) <sup>1</sup> and C=O from the PCL at 1730 cm<sup>-1</sup>. Through DSC these polymers exhibited Tm=49.6°C and 47.8°C for SPUR and SPUK respectively. TGA thermograms indicate that the first mass loss occurs at 348°C and 426°C for SPUK and SPUR whereas a second decomposition occurred at 455°C and 520°C, respectively. AFM showed that the internal surfaces of SPUK and Tecoflex have a higher roughness than the outer surface of the vascular grafts. In general, films' elastic moduli were similar (6.4, 6.3

and 6.2 MPa for SPUR, SPUK and Tecoflex) but a difference was observed in their longitudinal (Table 1) and circumferential (Table 2) modulus (E) and strength ( $\sigma_{break}$ ). These values are higher than the iliac artery (0.4-0.77 MPa) and iliac vein (1.8-5.3 MPa) for longitudinal tension but similar to iliac vein (1.3-4.8 MPa) and iliac artery (4.8-6.3 MPa) for circumferential tension. In addition, probe burst strength was higher in Tecoflex (25.5±5.60 N) than SPUR (9.9±4.95 N) but similar to SPUK (24.4±4.45). Finally, SPUK exhibited lower suture retention strength than SPUR (18 N vs 14 N) but this was higher compared to the resistance to suture in native arteries 2.7 N<sup>6</sup>. These values also depended on the type of suture material. In general it was lower when 3-0 silk was used instead of 2-0 nylon.

**Table 1 Longitudinal tensile properties of SPUR and SPUK**

Sample	E (MPa)	$\sigma_{break}$ (MPa)	$\epsilon_{max}$ (%)
PUUR	5.53 ± 0.99	7.90 ± 1.97	564 ± 60
PUUK	4.34 ± 0.55	1.70 ± 0.19	339 ± 82
Tecoflex	6.65 ± 1.25	11.1 ± 1.95	563.7 ± 39

**Table 2 Circumferential tensile properties of SPUR and SPUK**

Sample	E (MPa)	$\sigma_{break}$ (MPa)	$\epsilon_{max}$ (%)
PUUR	3.76 ± 0.77	985 ± 352	679 ± 43
PUUK	4.44 ± 1	673 ± 245	396 ± 142
Tecoflex	4.22 ± 1.34	1730 ± 380	862 ± 130

### CONCLUSION

Small diameter vascular grafts were made from PUs based on amino acids of L-Arginine and L-Lysine. The mechanical properties of the synthetic grafts showed differences between the longitudinal and transverse directions, suggesting anisotropy. These findings in addition to good endothelial cell biocompatibility suggest them as good candidates for use as vascular grafts.

## INTRODUCTION

The development of electrodes for direct interface with the brain has the potential to greatly improve prostheses to aid victims of spinal injury or similar disablement. However, the development of such electrodes relies on careful engineering of the biological-electronic interface with control of scarring, cell phenotype and tissue organisation. Diamond-like-carbon (DLC) may be an ideal material for coating electrodes as it has flexible electrical properties, it is extremely stable *in vivo* and is already used as a coating for orthopaedic implants<sup>1</sup>. Chemical modification is essential, however, to control and promote adhesion, differentiation and organisation of neurons and glia. A combination of atom transfer radical polymerisation (ATRP) and pulsed laser ablation was used to modify the surface properties of DLC with a high degree of spatial control.

## EXPERIMENTAL METHODS

DLC was coated on silicon by chemical vapour deposition. The surface chemistry of the DLC was modified by atom transfer radical polymerization (ATRP) in order to produce PEG-coated non-cell-adhesive surfaces. Patterns were generated by pulsed laser ablation using a sub-nanosecond pulsed Nd YAG DPSS laser focused onto the sample surface which was translated using a programmable three-axis translation stage. The functionalised and ablated DLC surfaces were characterised by contact angle measurement, XPS and Raman spectroscopy.

NG108 neuron-like cells were seeded to the DLC samples and allowed to differentiate for 7 days. Rat neural stem cells (NSCs) were isolated from E18 embryos and cultured in the presence of bFGF and EGF before being seeded to the DLC samples. Growth factors were withdrawn and spontaneous differentiation was allowed for 25 days in Neurobasal/B27 medium. Morphology, phenotype and neuritogenesis were investigated using immunocytochemistry.

## RESULTS AND DISCUSSION

Upon functionalisation with PEG brushes the DLC became more hydrophilic. The modified surfaces were non-fouling and resisted the adsorption of laminin from solution. Pulsed laser ablation removed the top layer of material from the region directly irradiated by the laser. In addition, a region surrounding the ablated region (the heat affected zone) was also modified and ceased to be non-fouling. Polyornithine and laminin were then adsorbed onto the ablated regions, allowing subsequent cell adhesion.

Fig.1 – (a) XPS C 1s spectrum of DLC functionalised with PEG brushes by ATRP. (b) Fluorescence micrograph of FITC-labelled laminin adsorbed on ablated track. Scale = 25  $\mu\text{m}$  (c) Differentiating NG108 cells stained for  $\beta 3$ -tubulin (green) and TOPRO3 (red). Scale = 200  $\mu\text{m}$  (d) Differentiating rat NSCs stained for  $\beta 3$ -tubulin (green) and DAPI (blue). Scale = 100  $\mu\text{m}$ .

NG108 cells and NSCs adhered onto ablated tracks and adopted oriented morphologies. Upon differentiation the NG108s expressed  $\beta 3$ -tubulin and remained confined to the ablated tracks. In contrast, over time the NSCs differentiated but broke free of the ablated tracks and populated the entire ablated region. However, extremely long neurites were observed to follow the topographical cues from the ablated tracks over several hundred micrometres.

## CONCLUSION

Spatial control over neuron cell adhesion and differentiation was achieved on DLC using a combination of ATRP and pulsed laser ablation. Both NG108s and NSCs were constrained within ablated tracks and adopted elongated morphologies. Over 25 days the NSCs differentiated and spread over the DLC surface, although long neurites tracked along the ablated features over long distances demonstrating the potential for preparing *in vitro* neural networks on DLC with a great degree of control.

[claus.moseke@fmz.uni-wuerzburg.de](mailto:claus.moseke@fmz.uni-wuerzburg.de)

Electrochemically assisted deposition (ECAD) (see Figure 1) was utilized to produce dense struvite coatings on titanium. The coatings were modified by incorporation of strontium ions and characterized regarding their physicochemical properties, ion release kinetics, and biocompatibility.

## INTRODUCTION

Despite the generally good success rates of enossal implants concerning healing and retention time there is still a need for further improvements, particularly for use in more challenging situations, e.g. in the case of a weakened osseous bed, caused by systemic diseases like osteoporosis. The aim of this study was the functional modification of biocompatible struvite coatings on titanium discs with strontium ions, in order to reduce osteoclast activity in affected bone regions.

## EXPERIMENTAL METHODS

The aqueous coating electrolytes for struvite deposition were composed of 1.9167 g ammonium dihydrogen phosphate, 1.0075 g magnesium oxide, and 3.3 g nitric acid, dissolved in a total volume of 500 ml. Doping with Sr ions was achieved by addition of various amounts of strontium nitrate (0.0135-2.706 g) to the electrolyte. In addition, the total amount of deposited struvite was adjusted by variation of the coating parameters current density and deposition time.

Figure 1: Principle of ECAD in aqueous electrolyte.

The resulting coatings were characterized by scanning electron microscopy (SEM) with a Zeiss DSM 940 regarding their surface morphology. Phase analysis was performed by X-ray diffraction (XRD) with a Siemens D5005 powder diffractometer in Bragg-Brentano geometry using  $\text{CuK}_\alpha$  radiation with a voltage of 40 kV and a current of 40 mA. The Sr content of the deposited struvite was determined by dissolving the coatings in nitric acid and elemental analysis by inductively coupled plasma mass spectrometry (ICP-MS). ICP-MS was also used to examine the release kinetics of Mg, Sr,

and phosphate ions as well as the chemical behaviour in synthetic body fluid (SBF).

## RESULTS AND DISCUSSION

A total coating mass of  $1.3 \text{ mg/cm}^2$  was achieved with a current density of  $-3.8 \text{ mA/cm}^2$  being applied for 25 min. Sr contents up to 14.4 wt.% could be reached. Sr ions were released from the doped coatings over 14 days of immersion in SBF with a total released amount of about  $25 \mu\text{g}$  (about 55 % of the absolute strontium content in the coating). XRD and SEM analysis before and after immersion revealed the transformation of the struvite to dense coatings with hydroxyapatite-like morphology (Figure 2).

Figure 2: SEM image of Sr-doped struvite coating after 10 days immersion in SBF.

## CONCLUSION

Strontium ions were successfully co-deposited with struvite on titanium substrates. Content as well as the release kinetics of Sr ions could be varied in a wide range, which makes this method a most promising technique for the fabrication of biocompatible implant coatings with tailored and beneficial properties regarding the regulation of osteoclasts in bone tissue adjacent to the functionalized orthopaedic implant.

### INTRODUCTION

Immediately after surgery, a “race for the surface”<sup>1</sup> between cells and bacteria occurs on the exterior of body implants. Since the outcome depends on the physico-chemical properties of the inserted material, in the last few decades a lot of research has been addressed on surface modifications of Ti-based body implants. The aim is to improve the quality of the natural passivation layer, made of amorphous titanium dioxide (TiO<sub>2</sub>), by creating a higher protective interlayer at the implant-tissue interface.

### EXPERIMENTAL METHODS

The synthesis of fully-dense and stable nanocrystalline TiO<sub>2</sub>-anatase coatings can be achieved by hydrothermal treatment (HT) of different Ti-based bone implants. Such coatings showed superior topographical, mechanical and electrochemical surface properties than the bare Ti-substrates<sup>2</sup>, as well as higher hydrophilicity, especially after photo-activation by UV irradiation<sup>3</sup>.

In the present work, coatings with different crystals morphology, wettability and surface charge were used both in non-irradiated and UV pre-irradiated state, in comparison with the non-treated titanium (Ti NT).

The HT TiO<sub>2</sub>-coatings were analysed in terms of biological interactions at the biointerface.

Firstly, primary human mesenchymal stem cells (hMSCs) were cultured on the HT TiO<sub>2</sub>-coatings up to 28 days (study approved by the Local Ethics Commission, Ref. no: 245/13). The alkaline phosphatase (ALP) production and Ca<sup>2+</sup> uptake from the culture medium were probed to evaluate the cell activity and the osteogenesis process. Fluorescence and scanning electron (SEM) microscopy were also applied to observe the cell morphology and spreading.

Next, the estimation of adhesion of a green fluorescent protein-expressing *Escherichia coli* strain on the TiO<sub>2</sub>-coatings was performed after 1h of incubation in contact with the surfaces. The fraction of alive and dead bacteria adhered to the surface was estimated.

### RESULTS AND DISCUSSION

An extensive physico-chemical characterization of the HT TiO<sub>2</sub>-coating properties was performed prior any *in vitro* assessment, in order to correlate the surface properties to the biological response.

The hMSCs studies revealed the cell ability to proliferate and differentiate into osteoblasts, once

seeded upon the HT-coatings. Also, the UV pre-irradiated samples showed a significant increase in the amount and rate of osteogenesis, as demonstrated by the higher cell activity, enhanced uptake of calcium ions and formation of a well-developed mineral phase and bone-like nodules. More extended actin filament network and cell spreading were also observed. Therefore, the UV photo-induced wettability proved to be the key factor which positively influenced the cell development<sup>4</sup>.

On the other hand, the adhesion of *E. coli* in contact with the HT-substrates was largely affected by surface micro-topography, surface charges, and, least, wettability. In particular, the presence of anatase nanocrystals resulted in micro-asperities with specific width, which prevented the adhesion of *E. coli* by allowing only “contact-point” interactions with the TiO<sub>2</sub> coating. Oppositely, machined non-treated titanium surfaces provided a high surface contact area, which increased bacterial adhesion by “interlocking” effect<sup>5</sup>.

### CONCLUSION

The results suggested that the hydrothermally synthesized TiO<sub>2</sub>-anatase coatings, with adequate morphology and surface properties, stimulate the osseointegration, especially after photo-activation, and significantly reduce the bacterial adhesion on the implant surface. Therefore, hydrothermally grown TiO<sub>2</sub>-coatings have a large potential to be applied on medical devices to positively boost the bio-events at the implant interface.

## INTRODUCTION

Titanium (Ti) is the most widely used material for bone substitution due to its biomechanical properties. However, in some cases the osseointegration is not achieved due to Ti poor biological activity, ending with implant failure. Hence, several surface modifications have been proposed to improve the cellular interactions. These interactions rely on fundamental processes such as protein adsorption and ligand-receptor interactions which determine the subsequent cellular response. In order to mimic the natural interaction of cells with the extracellular matrix (ECM), several strategies are being developed. In this respect, the covering with micro- and nanofibers (NFs) produced by electrospinning are gaining interest because they mimic the spatial distribution of ECM providing ECM-like stimuli<sup>1</sup>. Polylactic acid (PLA) and their derivatives are of special interest because they are biocompatible, biodegradable and also easy to prepare. However, the cellular interaction with these materials is low and their biological improvement is required.

The aim of this study was to modify the Ti surface by generating an ECM-like structure composed of PLA derivative NFs with ECM-derived protein incorporated in order to improve the bone cell response.

## EXPERIMENTAL METHODS

Titanium discs (10 mm diameter) were polished using Al<sub>2</sub>O<sub>3</sub> suspension (0.05 µm). Then, surfaces were activated by plasma treatment and silanized using APTES aminosilane. Fibronectin Cell Attachment Site (CAS) fragment containing the type III<sub>8-10</sub> domains (which contains RGD and PHSRN cell adhesive motifs) was synthesized using recombinant protein methods. Poly(L-lactide-co-D,L-lactide) (PLDLLA) was dissolved in hexafluoroisopropanol at 20 mg/mL at room temperature and was mixed with CAS fragment obtaining a final concentration of 4% PLDLLA and 100 µg/mL of CAS. NFs of PLDLLA or PLDLLA/CAS were randomly deposited onto silanized titanium discs for covalently attachment by electrospinning the polymer solution for 2 min. The applied voltage was 20–25 kV, the distance between the needle tip and the collector was 125 mm, and the pump flow rate was 0.3 mL/h. Non silanized titanium samples were used as control. Distribution of NFs was observed by SEM. NFs chemical stability was evaluated fluorometrically after depositing FITC-labelled CAS containing NFs and incubating for 5, 24 and 72h. In addition, stability of covalent attached NFs was also evaluated after 5 min sonication. Osteoblastic cells (SaOS-2) were seeded in

serum-free conditions on the different samples and cell adhesion (LDH and immunofluorescence evaluation), proliferation (LDH) and differentiation (ALP) were quantified after 4h and 7, 14 and 21 days.

## RESULTS AND DISCUSSION

Random and aligned NFs were obtained with similar diameters ( $331 \pm 77$  nm). The silanization process increased the stability of CAS-PLDLLA NFs compared to the PLDLLA NFs due to the covalently interaction between silane and CAS, even after sonication process. Although there were no statistically significant differences in the number of cells adhered, cells were well spread when the CAS recombinant fragment was present in PLDLLA NFs compared to plain PLDLLA NFs, where cells were rounded and no actin filaments were developed (Figure 1). In addition, proliferation and also differentiation was improved when cells were cultured on CAS-PLDLLA NFs.

**Figure 1.** Immunofluorescence images showing cell spreading on PLDLLA NFs (A) and CAS-PLDLLA NFs (B).

## CONCLUSION

The development of a NF network for improving the biocompatibility of Ti implants is a novel and interesting approach. Herein, we seek to further improve the biological activity of PLDLLA NFs by incorporating a fibronectin recombinant fragment before the fabrication of NFs, which allows the presence of the protein fragment at the NFs surface. Being relatively stable for several days under physiological conditions, CAS-PLDLLA NFs were well recognized by osteoblastic cells, presumably generating ECM-like stimuli that triggered osteoblasts proliferation and also differentiation.

### INTRODUCTION

Titanium (Ti) is widely used in orthopaedic surgery for permanent bone replacement implants and for temporary stabilization devices like screws or external fixators in osteosynthesis. For the latter application, the device has to be removed after successful fracture healing. While sufficient cell colonization is needed for long-term anchorage of permanent implants, the cell-material interface firmness for temporary devices should remain limited to facilitate uncomplicated removal.

therefore, anti-adhesive coatings could inhibit cell attachment onto the Ti surface. This can be achieved with plasma-fluorocarbon-polymer (PFP) films created by low-temperature plasma processes<sup>1</sup>. This study aimed at examining the influence of PFP films on the time course of local tissue response after intramuscular implantation in rats.

### EXPERIMENTAL METHODS

**Implants and PFP film preparation.** PFP films were created on Ti6Al4V plates (5×5×1mm) by (1) microwave discharge plasma (MW; 2.45 GHz, 500-1200W, 10-50Pa, 300-1000s; C<sub>3</sub>F<sub>8</sub>/ H<sub>2</sub> or C<sub>6</sub>F<sub>6</sub>/ H<sub>2</sub> mix) or (2) capacitively coupled radiofrequency discharge plasma (RF; 13.56 MHz, 20-150W, 20-60Pa, 20-1000s; C<sub>3</sub>F<sub>8</sub>/ H<sub>2</sub> mix)<sup>1</sup>. The three PFP sample series were designated as MW-C3F8, MW-C6F6 and RF-C3F8, respectively. Plates without PFP film served as controls.

**In vivo study.** One sample from each series was simultaneously implanted i.m. into the neck of male Lewis rats (n=24). Tissue containing the implants was retrieved from each 8 animals after 7, 14 and 56 days.

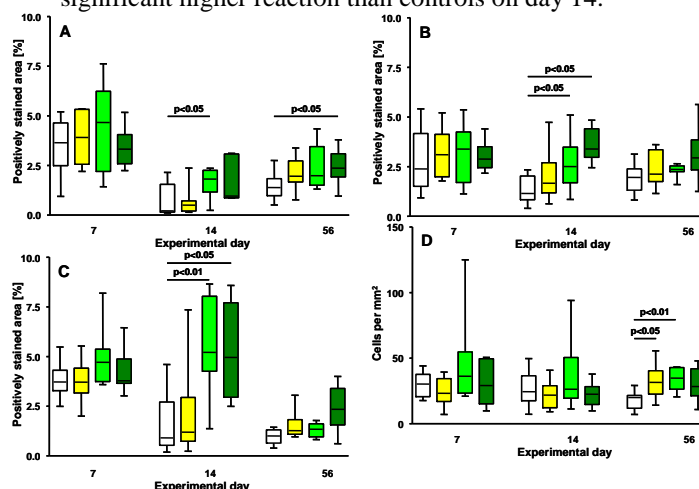

**Histological examination.** Following careful removal of Ti plates from the shock-frozen tissue and filling of the pockets with Cryomatrix™, cryosections were stained for CD68<sup>+</sup> macrophages/ monocytes (ED1), CD163<sup>+</sup> macrophages (ED2), T lymphocytes (R73), IL-2R<sup>+</sup> cells (OX39), antigen-presenting cells (OX6) and activated NK cells (ANK61) with the APAAP system. Mast cells were detected by toluidine blue staining. Morphometric results (ImageJ) were expressed as percentage of stained area or cells per mm<sup>2</sup> for low cell numbers (R73, OX39, ANK61, toluidine blue).

**Statistics.** The non-parametric Mann-Whitney test was used for data analysis.

### RESULTS AND DISCUSSION

The tissue reactions were influenced by either the PFP films itself (PFP vs. controls), by precursor chemistry (C<sub>3</sub>F<sub>8</sub> vs. C<sub>6</sub>F<sub>6</sub>) or by the process technology (MW vs.

RF). For CD68<sup>+</sup> macrophages/ monocytes (Fig. 1A), MW-C3F8 had a significantly stronger reaction than controls on day 14, while MW-C6F6 demonstrated a similar trend on day 14 and a significantly stronger reaction on day 56. In contrast, RF-C3F8 did not differ from controls on any day. For CD163<sup>+</sup> macrophages (Fig. 1B) and antigen-presenting cells (Fig. 1C), MW-C3F8 and MW-C6F6 had a significant higher response than controls on day 14 while no difference was observed on day 56. However, the antigen-presenting cells on day 56 were increased for MW-C6F6 compared to controls, MW-C3F8 and RF-C3F8. T lymphocytes (Fig. 1D) were increased for all three PFP series on day 56 compared to controls, significantly for RF-C3F8 and MW-C3F8. A similar outcome was observed for the IL-2R<sup>+</sup> cells, indicating T lymphocyte activation. For activated NK cells and mast cells, MW-C6F6 had a significant higher reaction than controls on day 14.

**Figure 1:** Response of CD68<sup>+</sup> macrophages/ monocytes (A), CD163<sup>+</sup> macrophages (B), antigen-presenting cells (C) and T lymphocytes (D) for Ti6Al4V controls (□) or Ti6Al4V plates with RF-C3F8 (■), MW-C3F8 (■) and MW-C6F6 (■) films

### CONCLUSION

The results demonstrate that PFP films, particularly RF-C3F8, have no negative effects on local inflammatory reactions. However, further studies regarding choice of plasma technology, precursor chemistry and process parameters are needed to optimize the in vivo response.

### INTRODUCTION

Among numerous different approaches, diamond-like carbon (DLC) layers are the most frequently applied solution due to the combination of highly desirable properties in the context of biomedical applications<sup>1-2</sup>. DLC coatings exhibit high biocompatibility confirmed in both *in vitro* and *in vivo* studies<sup>3-4</sup>. However, the usability of DLC coatings is limited by certain disadvantages, such as low thermal stability<sup>5</sup> and high internal stress leading to insufficient adhesion<sup>5-6</sup>.

Various studies have shown that those issues may be solved by the incorporation of particular elements into the DLC matrix, such as Si, which improves the thermal stability<sup>7</sup> of DLC layers and increases the adhesion strength<sup>8</sup>. Furthermore, also other useful parameters of carbon coatings, including cell behaviour and body reaction towards the DLC surface, can be tailored through the addition of different elements<sup>9</sup>. For instance, the introduction of Ti and Si results in better mechanical and tribological characteristics<sup>10-11</sup>. As far as biological properties are concerned, for elements such as Ti or Si the enhanced osseointegration was observed with the simultaneous reduction in the bone resorption<sup>10,12</sup>.

### EXPERIMENTAL METHODS

Round samples, commercial screws and regular implants made of AISI316L stainless steel and Ti6Al4V alloy were modified by Si-DLC coatings and used for all conducted tests. In order to evaluate the physicochemical and mechanical properties the fabricated coatings were tested using AFM, Raman, XPS, nanoindentation technique. The *in vitro* evaluation was conducted on the osteoblast Saos-2 cells and endothelial cells line EA.hy 926. The proliferation and cytotoxicity were checked using "live/dead" test. For *in vivo* model the rabbits and guinea pigs were used to obtain results with reference to irritation, intradermal reactivity, sensitization, local effects after implantation with the histopathological examination after 1, 3, 6, 9, 12-months of observation. The clinical trials were conducted on two kinds of bone implants modified by carbon coating with Si: proximal femoral intramedullary nail (GAMMA type) and volar plate for distal radius fixation.

### RESULTS AND DISCUSSION

XPS results have shown that the silicon content for each group of samples, both steel and titanium alloy, was about 3, 4 and 5%. Tests revealed that addition of silicon in the range of 3-5% does not negatively affect

the mechanical and structural properties of the modified surface and from this point of view, all the criterion of strength. Performed studies confirmed good mechanical properties of Si-DLC coatings too. *In vitro* studies indicated the optimal concentration of silicon in the coating, where the material is biocompatible. Biocompatibility was also confirmed by irritation and sensitization testing in the *in vivo* model. Bone screws coated by Si-DLC had no negative impact on the morphological and biochemical indices of blood and the surrounding tissues. The results of clinical trials indicate a high medicinal values and biocompatibility of coated implants. Radiological monitoring of fractures suggests a slightly earlier (a few days) adhesion fractures treated using coated plates.

Obtained results indicated the positive influence of Si-DLC coating for biological response, improve mechanical properties and can enhance the fractures healing processes.

### CONCLUSION

The Si-DLC coatings can be apply for medical devices in order to improve their biocompatibility and mechanical properties ensuring a proper work in living organism as a commercial product.

## INTRODUCTION

Copper sulphide nanoparticles (CuSNPs) provide an alternative to gold nanoparticles (AuNPs) in converting optical energy into thermal energy. As semiconductor, CuSNPs exhibit strong optical absorption at near infrared (NIR) wavelengths (650-1100 nm) originated from the d-d transitions of copper (Cu) ions and hence are not sensitive to size, shape or solvents. CuSNPs are not dependent on the dielectric constant of the surrounding matrix to absorb NIR light and can be metabolized, thus overcoming the major drawbacks of AuNPs in photothermal therapy protocols. CuSNPs biodegradation, which involves a slow release of Cu ions, can account for attractive bioeffects in regenerative medicine. For example, Cu ions are involved in the activity of transcription factors and enzymes required for cell proliferation and matrix remodeling; and can bind to cell membrane complexes to facilitate growth factor release from producing cells. In this work, CuSNPs were added as fillers within *in situ* polymerized fibrin hydrogels (CuSNPs-hydrogels). These matrices were used to encapsulate cells, derived from a mesenchymal multipotent C3H/10T/1/2 cell line, which harbors a transgene controlled by a heat-activated and rapamycin-dependent gene switch. We tested the extent to which optical properties of CuSNPs-hydrogels can be used to control transgene expression and growth factor delivery after NIR-irradiation in the presence of rapamycin. Furthermore, we investigated the bioactive effect of CuSNPs biodegradation on the cellular component included in NIR-responsive cell-constructs.

## EXPERIMENTAL METHODS

CuSNPs were synthesized according to a previously reported method<sup>1</sup> with the slight modification of adding 400  $\mu\text{L}$  of the  $\text{Na}_2\text{S}$  (320  $\text{mg mL}^{-1}$ ) solution to increase the stability of the resulting nanoparticles. C3H/10T/1/2-fLuc and C3H/10T/1/2-BMP2 clonal cell lines were obtained after stable transfection of C3H/10T/1/2 cells with a heat-activable, rapamycin-dependent gene switch for the control of firefly Luciferase (fLuc) or Bone Morphogenetic Protein 2 (BMP2), respectively. Fibrin-based hydrogels filled with CuSNPs were prepared after mixing 10  $\text{mg mL}^{-1}$  bovine fibrinogen (fbg), 0.03-0.25  $\text{mg mL}^{-1}$  CuSNPs and 2 NIH units  $\text{mL}^{-1}$  thrombin in a final volume of 250  $\mu\text{L}$  of Dulbecco's Modified Eagle's Medium. Cells were added to the mixture at a final concentration of  $1 \times 10^6$  cells  $\text{mL}^{-1}$ . For fibrinolysis assays, the polymerization mixture was supplemented with 30  $\mu\text{g mL}^{-1}$  of fbg-Alexa Fluor 546. Scaffolds polymerized at 37°C in a  $\text{CO}_2$  incubator for 1 h. Concentration of  $\text{Cu}^{2+}$  in culture media was determined by inductively coupled plasma mass spectrometry. Hydrogels were irradiated with an 808 nm laser diode at 37-44  $\text{mW mm}^{-2}$  for 5-15

min. Cell viability was evaluated after NIR-irradiation, using the alamarBlue assay. Induced target gene activity was evaluated by bioluminescence imaging assay and ELISA using a specific immunoassay for BMP2. For confocal laser scanning microscopy examination, cell constructs were fixed and stained with Phalloidin-TRITC and Hoechst. Gene expression profiling of cells encapsulated in CuSNPs-hydrogels was analyzed by real-time quantitative RT-PCR assays.

## RESULTS AND DISCUSSION

IR-thermal imaging of NIR-irradiated fibrin hydrogels showed a rapid temperature increase in matrices containing CuSNPs. Temperature in the hydrogels increased as a function of the amount of CuSNPs embedded in the fibrin network. Entrapment of CuSNPs in the fibrin matrix did not negatively affect the viability of cells encapsulated within the hydrogel, demonstrating the good biocompatibility of the system. NIR-irradiation in the presence of rapamycin triggered 3-dimensional patterns of transgene expression that matched the illuminated areas of CuSNPs-hydrogels loaded with C3H/10T/1/2-fLuc cells. In the presence of rapamycin, laser treatment of CuSNPs-hydrogels encapsulating C3H/10T/1/2-BMP2 cells led to robust secretion of BMP2 into the culture medium. Compared to hydrogels lacking CuSNPs, we observed a sustained release of  $\text{Cu}^{2+}$  ions into the culture media as well as an increase of cell-mediated fibrinolysis in CuSNPs-hydrogels, regardless of NIR irradiation and drug treatment. These effects were accompanied with changes in the shape of cells that arranged in cord-like structures within the scaffold. Finally, we observed that expression profile of genes related to vasculogenesis and extracellular matrix remodeling changed significantly in C3H10T-1/2 cells that populate CuSNPs-hydrogels.

## CONCLUSION

Optical properties of CuSNPs-hydrogels efficiently enabled photothermal regulation of transgene expression to control growth factor bioavailability. Biodegradation of CuSNPs embedded in fibrin matrices resulted in a sustained release of  $\text{Cu}^{2+}$  ions which promoted phenotypic changes in multipotent cells that dramatically affected the dynamics of scaffold remodeling.

### INTRODUCTION

Phenolic resin derived activated carbon adsorbent biomaterials with advanced nanoporous domains have a range of biomedical applications related to adsorption of protein bound and high molecular weight biotoxins which are difficult to remove by other methods. For example, haemodialysis and peritoneal dialysis are life-saving treatments for patients with kidney failure but fail to remove high molecular weight and protein bound toxins which drive pathophysiology. The removal of such molecules is only possible by adsorption and remains a major issue in the optimisation of these systems [1, 2]. Our group has developed bead and monolith adsorbents with nanoporosity optimised for broad spectrum biotoxin removal [3-5]. The haemocompatibility and adsorptive properties of blood contacting synthetic, nanoporous activated carbon was investigated comparing bead and monolith forms to overcome issues created by packed bed columns such as undesirable high column back pressure and cross-column pressure drop during haemoperfusion [6]. The potential use of this ACM as an adjunct to improve the current HD treatment regime was explored.

### EXPERIMENTAL METHODS

#### 1. Material physical characterisations

Mercury porosimetry and scanning electron microscopy (SEM) imaging were used to study the material porosity and internal structure.

#### 2. *in vitro* adsorption of biotoxins

The efficacy of the nanoporous activated carbon beads (ACB) and monoliths (ACM) were determined by their capability in adsorbing selected protein bound and high molecular weight toxin markers p-cresyl sulphate (PCS), indoxyl sulphate (IS) and interleukin (IL6). Small scale batch adsorption study were

#### *ex vivo* haemocompatibility assessment

ACB and ACM were pre-conditioned by circulating 20 ml of NaCl (0.9%) solution at a flow rate of 5 ml/min for 30 min. Then freshly drawn healthy donor blood (20 ml) was perfused through the monolith at a rate of 1 ml/min. A tubing only control was also included. Blood samples were collected before perfusion, after first pass, 30 and 60 min of perfusion.

**Complement activation** was evaluated by ELISA measurement of C3a concentration in plasma using lithium heparin anticoagulant and a Zymosan A complement activation positive control.

**Platelet activation** was assessed by flow cytometry using citrated blood samples stained with fluorophore conjugated antibodies PE/CD61, APC /D62P, and FITC/PAC-1. Adenosine 5'-diphosphate sodium salt

(ADP) was used as positive control.

**T cell activation** was analysed by flow cytometry using EDTA anticoagulated donor blood and measurement of phosphorylated cell-signalling protein Stat3 and STAT signalling pathway activation following T-cell activation (BD Phosflow T cell Activation Kit). Cytokine IL6 was used as a positive controls for Stat3 phosphorylated protein expression

### RESULTS AND DISCUSSION

Within 60 minutes of *in vitro* plasma direct contact, both ACB and ACM showed efficient removal of the spiked toxin markers from the plasma indicating adsorptive capacity for these toxins and the potential application of these nanoporous carbon materials. The *ex vivo* haemocompatibility studies indicated no additional stimulation of complement, platelet and T-cell activation compared to tubing only controls and a marked increase in the positive activation controls compared to the monolith filtration samples

### CONCLUSION

It is shown the first time *in vitro* study that both ACB and ACM were capable of removing marker key uraemic target toxins from a circulating spiked plasma pool. In addition, the *ex vivo* perfusion of healthy donor whole blood through the ACM did not trigger excessive complement activation, platelet activation or T cell activation, confirming haemocompatibility of the adsorbent and potential use as an adjunct to improve current HD therapy. This makes them very useful for treatment of range of conditions where biotoxins cause problems - sepsis, liver and kidney failure.

## INTRODUCTION

Biodegradable polymers exhibiting temperature-responsive sol-gel transition between room temperature and body temperature are expected to be applied as injectable polymer (IP) systems in biomedical applications. IP solution containing drugs or living cells can be injected by simple syringe injection at the target site in the body to form a hydrogel acting as sustained drug releasing depot or scaffold for tissue regeneration. For example, Lee and coworkers reported ABA-type triblock copolymer of poly(lactide-co-glycolide) and poly(ethylene glycol), PLGA-*b*-PEG-*b*-PLGA, as biodegradable injectable polymer exhibiting temperature-responsive sol-gel transition between room temperature and body temperature<sup>1</sup>. We also reported several biodegradable IP systems exhibiting temperature-responsive sol-gel transition and relatively high mechanical strength in gel state using block copolymers of polylactide and branched PEG<sup>2,3</sup>. However, these copolymers are usually sticky paste in dry state at room temperature, and inconvenient for storage and weighing. Moreover, it takes a long time (usually more than 5 hours) to be dissolved in aqueous solution. On these issues, Jeong *et al.* reported solidification of the triblock copolymers containing poly( $\epsilon$ -caprolactone), PCL-*b*-PEG-*b*-PCL, exhibiting temperature-responsive sol-gel transition<sup>4</sup>. However, the copolymers must be heated above melting temperature upon dissolution. In this study, in order to provide convenient IP system for instant use at clinical scene, which is solid state in dry condition and can be dissolved in short time, we synthesized a triblock copolymer of poly( $\epsilon$ -caprolactone-co-glycolide) and PEG, PCGA-*b*-PEG-*b*-PCGA, and investigated the effect of some additives on dissolution time of IP formulation. Then, we succeeded to develop an IP formulation quickly preparative at room temperature<sup>5</sup>.

## EXPERIMENTAL METHODS

A series of triblock copolymer of poly( $\epsilon$ -caprolactone-co-glycolide) and PEG, PCGA-*b*-PEG-*b*-PCGA, was synthesized by ring-opening polymerization of  $\epsilon$ -caprolactone and glycolide using PEG and Sn(Oct)<sub>2</sub> as an initiator and a catalyst, respectively. Temperature-responsive sol-gel transition behavior of PCGA-*b*-PEG-*b*-PCGA solution was investigated by a test tube inverting method and by a dynamic rheometer (HAAKE, Thermo HAAKE RS600). Then, we investigated the effect of additives (hydrophilic polymers or saccharides) on the dissolution time and sol-gel transition for the mixture of PCGA-*b*-PEG-*b*-PCGA and these additives in aqueous solution.

Figure 1. Preparation of PCGA-*b*-PEG-*b*-PCGA + additive (PEG) formulation: from powder form in dry state, to PBS solution (suspension) at 25°C, and then to the hydrogel form at 37°C.

Figure 2. The phase diagrams of PCGA-*b*-PEG-*b*-PCGA solution at various temperature and concentrations.

## RESULTS AND DISCUSSION

The obtained PCGA-*b*-PEG-*b*-PCGA could be freeze-dried to show powder form morphology in dry state at room temperature (Fig. 1). Its aqueous solution exhibited temperature-responsive sol-gel transition between room temperature and body temperature (Fig. 2). We found that formulations composed of PCGA-*b*-PEG-*b*-PCGA and PEG as additives could be distributed in PBS to give suspension within 1 min at room temperature (Fig. 1). The obtained suspension was opaque, but could be sucked by syringe, and exhibited temperature-responsive sol-gel transition between room temperature and body temperature.

## CONCLUSION

We found instantly preparative IP/additive system, which can be distributed in PBS within 1 min. This system should be convenient for instant preparation of IP formulation at clinical scene.

## INTRODUCTION

The development of localised drug delivery systems (DDSs) represents a valuable option to overcome the typical drawbacks associated with conventional systemic administration, which is not directed to the target organ or tissue<sup>1</sup>. In this context, injectable polymer dispersions have emerged as a superior, non-surgical alternative for tissue regeneration<sup>2</sup>. For example Tan *et al* (2012) developed alginate based injectable hydrogel for tissue engineering<sup>3</sup>. However these studies have limited success due to lack of high mechanical strength and tedious synthetic procedures.

In this study, we propose the use of novel thermo-responsive poly(Alginate-g-N-isopropylacrylamide) (P(Alg-g-NIPAAm)) hydrogel with the aim of identifying a system that meets all necessary requirements for soft tissue repair, i.e. biocompatibility, biodegradability and adequate mechanical strength. In addition, this study assessed the effect of the lower critical solution temperature (LCST) and cytotoxicity of the hydrogel with and without drug loading.

## EXPERIMENTAL METHODS

**Preparation of hydrogel:** Sodium alginate (Alg) and poly (N-Isopropylacrylamide) (PNIPAAm) were coupled via free radical polymerisation to form P(Alg-g-NIPAAm) hydrogel of various ratios. All copolymers were characterised by <sup>1</sup>H NMR and FTIR. Rheological measurements were performed during the process of sol-gel transformation with a constant shear rate (6.283 rad/s). Temperature sweep experiments from 20 to 50°C were conducted at a heating rate of 3°C/min.

**Formulation of RALA/GFP plasmid NPs:** The RALA/GFP plasmid nanoparticles (NPs) were formed by self-assembly via electrostatic interactions. Particle size and zeta potential (ZP) was measured using a Malvern Zeta sizer Nano ZS.

**Drug Delivery:** Fluorescein sodium salt was loaded in a 5% hydrogel solution and the release profile was assessed at 37°C in PBS at pH. 7.4. The samples were collected at regular intervals and measured the fluorescence (Ex at 480nm and Em at 520 nm).

**DNA Delivery:** 5% P(Alg-g-NIPAAm) was loaded with RALA/GFP plasmid. Hydrogel-NP constructs were placed in trans-wells adapted for 24-well plate and immersed in water at 37°C. The release profile was assessed by sampling the supernatant at different time points and measuring nucleic acid content using Picogreen<sup>®</sup> assay.

**Cell viability:** MG63 cells were co-cultured with the hydrogel for up to 28 d. The biocompatibility of the

P(NIPAAm-co-Alg) hydrogel was assessed every 7 d using MTS assay.

## RESULTS AND DISCUSSION

The P(Alg-g-NIPAAm) hydrogels exhibited a drastic increase in the viscosity of the gels around 32-34°C, which is the low critical solution temperature of P(Alg-g-NIPAAm) polymer. At LCST the free flowing aqueous solutions were transformed to gel like material. Consequently, the storage modulus ( $G'$ ) and loss modulus ( $G''$ ) of a 5% w/w P(Alg-g-NIPAAm) hydrogel increased from 32-34°C onwards. This change in the storage modulus is also reflected on the mechanical strength of the P(Alg-g-NIPAAm), which was approx. 800 Pa at 37°C.

**Figure 1.** a) Storage modulus ( $G'$ ) and loss modulus ( $G''$ ) of 5% P(NIPAAm-co-Alg) solution in PBS. pH:7.4 (insert: the LCST behaviour of polymer solution).

## CONCLUSION

We have successfully produced a thermo-responsive polymer with the potential to behave as both a scaffold and delivery vehicle. Furthermore, we have demonstrated delivery of small molecules and NPs via thermo-responsive hydrogel.

## INTRODUCTION

In regenerative medicine, an effective cell separation method that can provide adequate purity, yield, and function have been needed for fabricating transplantable tissues.<sup>1</sup> In the present study, poly(*N*-isopropyl acrylamide (IPAAm)-*co-N,N*-dimethylaminopropyl acrylamide(DMAPAAm)-*co-N-tert*-butylacrylamide (tBAAm)) brush grafted surfaces were prepared through surface-initiated atom transfer radical polymerization (ATRP). Temperature-dependent adhesion and detachment behaviour of human bone marrow mesenchymal stem cell (hbmMSC) was observed for investigating the possibility of the copolymer brush surface as a cell separating materials.

## EXPERIMENTAL METHODS

An ATRP initiator, 2-(*m/p*-chloromethylphenyl) ethyltrimethoxysilane, was modified on glass coverslips (Fig. 1). Copolymerization of IPAAm (75mol%), DMAPAAm(5mol%), and tBAAm(20mol%) was performed through surface-initiated ATRP for 16 h at 25 °C using CuCl/Me<sub>6</sub>TREN as a catalyst and 2-propanol as reaction solvent.<sup>2</sup> In the polymerization,  $\alpha$ -chloro-*p*-xylene was added as free initiator and brush length was estimated using the prepared copolymer in the reaction solution. Cell adhesion and detachment behaviour of hbmMSC and other human bone marrow derived cells were observed at 37 and 20 °C.

## RESULTS AND DISCUSSION

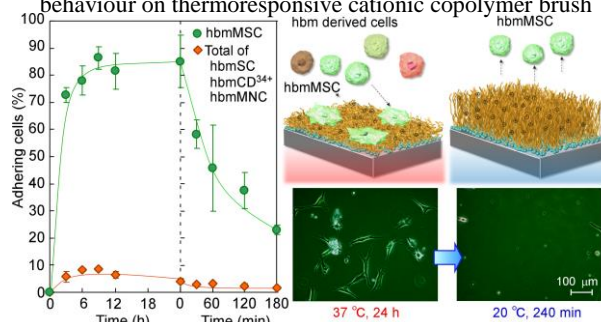

Prepared cationic copolymer brush was characterized by ATR/FT-IR, GPC measurement and zeta potential measurement. As result, amount of grafted copolymer and graft density were 1.51  $\mu\text{g}/\text{cm}^2$  and 1.04 chains/nm<sup>2</sup>, respectively. Zeta potential of copolymer brush was 19.8 mV. These result indicated that densely packed cationic copolymer brush was formed on glass substrate. Cells adhesion and detachment properties on copolymer brush were observed using hbmMSC and other bone marrow derived cells. hbmMSC adhered on the cationic copolymer brush at 37 °C, while other bone marrow cells did not adhered (Fig.2). With reducing temperature to 20 °C, adhered hbmMSC detached from cationic copolymer brush. Using this properties, purification of hbmMSC was performed simply by changing temperature. Mixture of hbm derived cells were seeded on cationic copolymer brush and hbmMSC adhered on cationic copolymer brush (Fig.3). Subsequently, temperature reduced to 20 °C, and purified hbmMSC was successfully recovered from the copolymer brush. The result indicated that thermoresponsive cationic copolymer brush would be useful tool for purification of hbmMSC from other

cells.

**Fig.2** hbm derived cells adhesion and detachment behaviour on thermoresponsive cationic copolymer brush

**Fig.3** Purification of hbmMSC from human bone marrow derived cells using thermoresponsive copolymer brush

## CONCLUSION

Thermoresponsive cationic copolymer brush can selectively adhered and detach hbmMSC. Thus, the thermoresponsive cationic copolymer brush would be useful for purification of hbmMSC simply by changing temperature.

### INTRODUCTION

Successful preservation of mammalian cells builds the foundation for cell therapy that relies on delivery of new live cells into a tissue of a patient, such as blood transfusion, stem cell transplantation, and fertility preservation<sup>1,2</sup>. Currently cryopreservation is the only technology that allows for reliable long-term storage of most cells. Cryopreservation is usually accomplished utilising high concentrations of toxic cryoprotectants, such as DMSO. Therefore, significant interest exists in development of alternative protectants, such as sugars, most notably trehalose that is a hydrophilic disaccharide accumulated in a variety of freezing- and desiccation-tolerant organisms<sup>3,4</sup>.

As sugar molecules are normally impermeable to the cell membrane, the primary obstacle to the realisation of viable mammalian cell preservation using sugars is the requirement of the high concentrations not only around but also within cells for optimum bioprotection<sup>3,5</sup>. A few techniques have been investigated for delivering trehalose into cells for biopreservation. However, the methods yielding sufficient intracellular trehalose for cell preservation have utilised hazardous materials, such as mutant bacterial toxins<sup>3</sup>, or have lacked scalability, such as the use of microinjection<sup>5</sup>. Low concentrations of trehalose (15 mM) have been introduced into human red blood cells using a safer liposomal delivery system<sup>6</sup>, below a threshold intracellular trehalose concentration range of 100 – 200 mM for bioprotection development in mammalian cells<sup>3,5,7</sup>.

This presentation will cover our recent efforts in the precise control of cell membrane permeabilisation using non-toxic, biocompatible and cell-permeating synthetic biopolymers to improve the loading of sugars into cells. These amphipathic polymers, which incorporate weakly ionisable carboxyl groups and hydrophobic side chains, were designed to mimic viral peptide structure and membrane permeabilising activity<sup>8</sup>. They can undergo a conformational change from extended charged chains to aggregated hydrophobic structures as pH drops below their pKa, facilitating interaction with the hydrophobic interiors of lipid bilayers and subsequent cell membrane permeabilisation<sup>8-11</sup>.

### EXPERIMENTAL METHODS

The linear poly(L-lysine *iso*-phthalamide) backbone-derived biopolymers were synthesised according to the procedure which we have published previously<sup>8,9</sup>. Cells such as erythrocytes were incubated with trehalose and polymer of selected concentrations in PBS buffer. The

intracellular trehalose concentrations were tested based on the anthrone method. The cells with loaded trehalose were preserved using two methods: cryopreservation (in a –80 °C freezer or in liquid nitrogen) and desiccation (vacuum drying) respectively. Percent cell survival after freeze/thaw or desiccation/rehydration was measured based on the haemolysis assay. Cells were imaged by confocal microscopy and atomic force microscopy<sup>12,13</sup>.

### RESULTS AND DISCUSSION

These biomimetic biopolymers reversibly increased the cell membrane permeability, yielding trehalose loading dependent on polymer structure, polymer concentration, pH, external trehalose concentration, incubation time and temperature (intracellular trehalose concentration up to  $251 \pm 6$  mM). The trehalose loading resulted in  $83 \pm 3\%$  erythrocyte survival after freeze-thaw processes, an improvement of  $20.4 \pm 5.6\%$  in cryosurvival over the unloaded erythrocytes. This improvement indicates that extracellular trehalose alone is insufficient for optimum cryoprotection. Trehalose uptake in cells also facilitated an increase in the membrane integrity of vacuum dried cells by a factor of  $9 \pm 1$  and reduced the extent of haemoglobin oxidation in dried cells from  $66 \pm 1\%$  to  $23 \pm 3\%$ . Herein, the intracellular loading of other sugar molecules and the resulting effects on mammalian cell preservation were compared against trehalose. The mechanism of the biopolymer-mediated delivery of sugar molecules was also elucidated.

### CONCLUSION

The non-toxic biopolymers can deliver sugar molecules into cells efficiently without causing cell damage. The results provide a foundation for the cryopreservation and desiccation of a wide variety of mammalian cells and stem cells using non-toxic sugars and an important step towards viable cell lyophilisation and cell therapy.

## INTRODUCTION

Biopolymer-based hydrogels find widespread applications in the field of regenerative medicine and drug delivery<sup>1</sup>. Hydrogels are able to provide local delivery of hydrophilic therapeutic agents, but the diffusion of agents from the hydrogels can be rapid and not easily time-controllable. On the other hand, nano-sized objects are being increasingly investigated for *in vivo* drug delivery<sup>2</sup>. In this regard, we have developed lipid nanoparticles (LNPs) as promising carriers for lipophilic drugs and therapeutic biomolecules<sup>3</sup>. This work deals with designing original hybrid biomaterials composed of LNPs entrapped within hydrogels in view of their application for drug sustained release. In particular, we selected two biocompatible polysaccharides which are currently used in pharmaceutical and biomedical applications: carboxymethylcellulose (CMC) and chitosan, which are negatively and positively-charged respectively.

## EXPERIMENTAL METHODS

CMC-PEG and chitosan-PEG hydrogels were chemically cross-linked using photo-induced thiol-ene chemistry<sup>4</sup>. Fluorescently labelled LNPs (50 nm diameter) with different surface charge were prepared using a previously described sonication process<sup>3</sup>, characterized by Dynamic Light Scattering (NanoSizer ZS, Malvern), and suspended into the polysaccharide solution before cross-linking to achieve the particle-loaded biomaterials. The physico-chemical properties (swelling ratio, rheological properties (AR2000 rheometer, TA Instruments)) of the obtained hydrogels and the release kinetics of the LNPs (fluorescence titration (LS50B fluorimeter, Perkin Elmer) were evaluated according to the surface charge and the concentration of LNPs entrapped into the hydrogels.

## RESULTS AND DISCUSSION

The presence and the homogeneous distribution of the labelled LNPs within the hydrogels were confirmed by confocal laser scanning microscopy observations. The LNP loading, up to a concentration of 50% (w/w<sub>polymer</sub>), did not prevent the gel formation, nor significantly modify the rheological and swelling properties of the obtained materials (Figure 1). Similarly, particle hydrodynamic diameter and polydispersity index after their recovery from the digested material were not affected for a few weeks after material loading. LNPs were slowly released from the hydrogels immersed in NaCl 154 mM (Figure 2). Interestingly, significant differences in the release kinetics were observed depending on the surface charge properties of the LNPs.

Figure 1. Elastic moduli ( $G'$ ) of the CMC-PEG materials obtained after loading of negative (-), neutral (N), or positive (+) LNPs with different payloads.

Figure 2. Kinetics of release of negative (-) and neutral (N) LNPs loaded at 50% (w/w<sub>polymer</sub>) in CMC-PEG hydrogels.

## CONCLUSION

LNPs were included in CMC-PEG and chitosan-PEG matrices with high payloads while not affecting material properties. Release of the particles and their lipophilic drug content is sustained in time and easily tuneable with particle design.

### INTRODUCTION

Superparamagnetic Iron Oxide Nanoparticles (SPIONs) are of great interest in biomedical applications because of their characteristic magnetic properties exhibited only in the magnetic field. SPIONs are hydrophobic nanoparticles and for this reason they tend to aggregate in bloodstream through van der Waals interactions and are more likely to be removed by the RES. To prevent this, SPIONs usually undergo surface modification. One way of elegant SPION modification can be represented by SPION loading in drug delivery vehicle. SPIONs are usually considered to be inert imaging agents without intended pharmacological functions. However, we have noticed that SPIONs may be selectively cytotoxic when they are encapsulated in polymeric micelle made from hydrophobized hyaluronic acid<sup>1</sup>.

### EXPERIMENTAL METHODS

SPIONs (5-20 nm) were incorporated in acylated hyaluronan (HAC6, HAC8, HAC10, HAC18, HAC18:0-HAC18:3) by sonication. The obtained polymeric micelles loaded with SPIONs were characterized by DLS, TEM, ICP-OES and NMR relaxometer. MTT assay and flow cytometry were performed for *in vitro* cell cytotoxicity evaluation.

### RESULTS AND DISCUSSION

All of the tested hydrophobized (acylated) hyaluronic acid samples (HAC6-HAC18:3) were able to form self-assembled particles while loading SPIONs. As observed by TEM, multiple SPIONs were clustered in the micelle cores and the mean diameter of SPION loaded HA particles was about 100 nm. The loading capacity was 1-2 %wt. and the encapsulation efficiency was about 30-40%. A good stability of loaded micelles was indicated by high absolute value of zeta potential (around -40 mV). There was no detected aggregation of loaded micelles within 5 days after their dispersion in aqueous medium. The estimated relaxivity around 200 mM<sup>-1</sup>S<sup>-1</sup> at 1 T was comparable to some of the commercial SPION compositions and indicates good potential to serve as contrast agent for *in vivo* applications.

The cytotoxicity of SPION loaded HA polymeric micelles was tested using control (normal human dermal fibroblasts (NHDF), murine 3T3 Swiss fibroblasts) and cancer cell lines (human cancer cell lines: A2058, A549, C3A, Caco-2, HCT-116, HT-29, MDA-MB231 and MCF-7). Except for A2058, there

was a significant inhibition of cancer cell line viability, while the growth of control cells was positively affected. Comparing the tested samples, the most prominent difference in viabilities between control and cancer cells was observed for HAC18:1-SPION (Figure 1). This sample even showed selective inhibition of cell growth when it was incubated with a mixture of NHDF and HT-29 cells. According to our data, the selective cytotoxicity cannot be connected with an enhanced CD44 uptake or ROS formation, but rather with a different way of SPION intracellular release from the HA micelle.

Figure 1. Cell growth inhibition of HAC18:1-SPIONs on NHDF and 3T3 Swiss and HT-29 cell lines.

### CONCLUSION

HA-SPION polymeric micelles are highly cytotoxic towards some cancer cell lines, while at the same time they are harmless towards healthy cell lines and primary cells. The selective *in vitro* behaviour was observed even when HA-SPION was incubated with a mixture of healthy and cancerous cell line. The current explanation of such behaviour failed to be connected with an enhanced CD44 uptake or ROS formation. It is rather connected with different release mechanism of SPIONs from HA micelles in the cells.

### INTRODUCTION

In the treatment of arthritis, drug delivery systems are of mayor interest since they ensure a controlled release of the active substance in the region of interest. Moreover one possible and often used treatment of osteoarthritis is by intra-articular injection of hyaluronic acid (HA) in order to restore the elastic and viscous properties of the synovial fluid<sup>1</sup>. A significant research effort has been devoted to alter the HA physic-chemical and viscoelastic properties by chemical modification. The idea of this study was to combine viscosupplementation approach with the controlled delivery of an anti-inflammatory drug *in situ*. In this work we tested the potential use of chemically modified HA as viscosupplementation agent and at the same time able to control the release of a hydrophobic drug. To this aim, modified HA samples were characterized from a rheological point of view. The solubility of a hydrophobic drug was studied and its *in vitro* drug release kinetics was evaluated.

### EXPERIMENTAL METHODS

A HA derivative bearing respectively ethylenediamino (EDA) and octadecyl pendant groups (HA-EDA-C<sub>18</sub>) was obtained as elsewhere reported<sup>2</sup>. As anti-inflammatory drug dexamethasone (DM) (Sigma-Aldrich), was chosen. HA-EDA-C<sub>18</sub> based samples were prepared at different polymer concentrations (1%, 3% and 5% w/v) in bidistilled water (DDW) and Dulbecco's Phosphate-Buffered Saline (DPBS). To improve the solubility of both HA-EDA-C<sub>18</sub> and DM, also  $\beta$ -CD (Sigma-Aldrich), at different concentrations (1%, 2% w/v) were used. The viscoelastic properties of the samples were evaluated on a rotational rheometer (Mars HAAKE III, Thermoscientific, Germany) at 25°C.

HA-EDA-C<sub>18</sub> samples were subjected to small amplitude frequency sweep tests to evaluate the dependence of the elastic and viscous moduli,  $G'$  and  $G''$  upon frequency. Solubility tests were carried out by dissolving DM (0.05%), HA-EDA-C<sub>18</sub> and  $\beta$ -CD in DDW and DPBS.

DM release from HA-EDA-C<sub>18</sub> samples was studied by loading the gel in dialysis membranes (molecular cut off: 25 kDa), which were immersed in DPBS at 37 °C. At different time points, the release medium was withdrawn and analyzed by UV.

### RESULTS AND DISCUSSION

HA-EDA-C<sub>18</sub> samples showed a rheological behavior typical of a weak gel. The mechanical spectra was characterized by a elastic modulus  $G'$  greater than loss modulus  $G''$  in all frequency range. In particular for the sample characterized by HA-EDA-C<sub>18</sub> concentration of 3% w/v and  $\beta$ -CD of 1% w/v, at a frequency of 1 Hz,  $G'$  was about 185 Pa and  $G''$  about 50 Pa. Furthermore the viscoelastic properties of HA-EDA-C<sub>18</sub> samples were dependent upon polymer concentration. The increase in HA-EDA-C<sub>18</sub> concentration lead to an increase of both  $G'$  and  $G''$ . They have behaved as weak gel.

The drug solubility tests showed that the presence of hydrophobic groups on HA influenced the drug solubilization positively.

The release tests have shown that the presence of HA-EDA-C<sub>18</sub> leads to an increase of the percentage of drug released until reaching a plateau after one week.

### CONCLUSION

Amphiphilic HA derivative was able to solubilize hydrophobic drug and showed rheological properties of weak gel suitable for viscosupplementation applications. Moreover it was able to sustain the release of an anti-inflammatory drug for at least one week.

## INTRODUCTION

Chronic inflammation may lead to a number of serious illnesses such as e.g. atherosclerosis, rheumatoid arthritis, cancer. It is also believed to be active in many other diseases such as asthma, chronic peptic ulcer, tuberculosis, or chronic active hepatitis. Therefore the effective treatment of inflammation is a subject of intense studies. One of the vital problems is the limited solubility of the most effective anti-inflammatory drugs, such as corticosteroids. Some of the promising candidates for anti-inflammatory drugs (e.g. curcumin) are also highly hydrophobic. This leads to their low bioavailability which either totally prevents the effective application or implies the use of high doses, resulting in serious side-effects<sup>1</sup>. One of possible solutions is to design a biocompatible, polymeric delivery system which allows for controlled, sustained delivery of the anti-inflammatory agent in its place of action<sup>3</sup>. Here we propose and compare two different approaches, both based on natural polysaccharides: microspheres encapsulating active agent and drug-releasing conjugate. Two model compounds were tested: dexamethasone<sup>2</sup> (DEX, potent corticosteroid) and curcumin<sup>3</sup> (CUR, highly promising natural agent). The release profiles in physiological conditions were measured and optimized. The influence of the microsphere's size, preparation methodology, pH and additional coating was also studied.

## EXPERIMENTAL METHODS

Sodium alginate/hydroxypropyl cellulose (ALG/HPC) microspheres were obtained either by cross-linking in microemulsion or by injecting of the polymer solution into the cross-linker (calcium chloride) solution under the stream of inert gas. The chitosan-DEX conjugate was synthesized in the three-step process, including ionic modification of the polymer followed by introduction of the spacer and binding of the drug to the polymeric chain. The products were characterized using FTIR, <sup>1</sup>H NMR, mass spectrometry and elemental analysis. Release profiles were obtained in physiological conditions (buffered aqueous media, 37°C), all measurements were done at least in triplicate. The release of CUR was followed by UV-Vis spectrophotometry, while DEX was assessed using HPLC with DAD detection using Waters C<sub>18</sub> column and acetonitrile/acetic buffer (65:35) mixture as eluent.

## RESULTS AND DISCUSSION

Both active compounds, CUR and DEX, were successfully encapsulated in polysaccharide-based microspheres. In order to increase the encapsulation

efficiency, prior to introduction into the polymeric matrix, curcumin was solubilized into micelles formed by Pluronic P-123<sup>®</sup>. This synthetic, biocompatible copolymer forms micelles at relatively low concentrations facilitating incorporation of the hydrophobic compound into the hydrophilic microspheres. Through injection into calcium chloride solution the particles of significantly larger sizes, in the range of hundreds of micrometers, were obtained. Cross-linking performed in water/cyclohexane emulsion, on the other hand, gave microspheres in the range of tens of micrometers.

DEX was modified using succinic anhydride to obtain water soluble product DEX-SA. Product identity was confirmed using mass spectrometry and FTIR spectroscopy. SA additionally functioned as a linker in the conjugate. Chitosan was first modified using glycidyltrimethylammonium chloride in order to increase its solubility in aqueous media. Finally DEX-SA was conjugated with cationic chitosan and the final product was characterised using NMR and FTIR spectroscopies and elemental analysis. Release studies for conjugate were performed after it was cross-linked with genipin forming gel. The influence of pH on the release profiles for both: microspheres and conjugate was studied.

## CONCLUSION

Two different polymeric systems were developed and studied as a possible solution for the optimized delivery of highly hydrophobic anti-inflammatory agents: CUR and DEX. Both compounds were successfully incorporated into ALG/HPC microparticles. The preparation procedure was optimized by using small amounts of Pluronic P-123, adjusting size of the particles and improving control of the release process. The influence of pH on the release profiles for both types of systems was studied. Both systems proved to be promising for defined areas of applications.

## INTRODUCTION

Recent advances in biotechnology to the production of various clinically useful peptides and proteins. Sustained peptide delivery can be established through different non-covalent retention mechanisms including physical entrapment, absorption and complexation, or in a covalent manner, using coupling agents. Current work employs a porous gelatin scaffold for the sustained delivery of an human BMP-2 derived-peptide, already applied clinically in bone regeneration for its high osteoinduction activity [1]. One strategy which has been used to produce a quite stable interactions is polyion complexation, in which release from a biodegradable and charged polymeric carrier may occur by electrostatic interactions. The consecutive treatment to guarantee a release in a long time, is the chemical immobilization of peptide into the scaffold [2]. However, because biodegradation of the carrier matrix would be the more likely mechanism of release, it is possible to control drug release kinetics by adjusting the rate of polymeric carrier degradation. In this work, we consider a gelatin (IEP of 5 or IEP of 9) as a polymeric matrix in order to realize a new gelatin crosslinked scaffold used as a vehicle for BMP2 release. Moreover, the combination of chemical immobilization and polyion complexation of peptide with matrix were done to obtain a release able to guarantee an appropriate biological response from human mesenchymal stem cells for bone tissue regeneration.

## EXPERIMENTAL METHODS

BMP-2 modified peptide (IEP of 8.59) (PM=2041.3Da H-NSVNSKIPKASSVPTLSAI-amide), was synthesized by Fmoc chemistry solid phase synthesis, using a microwave synthesizer (Initiator, Biotage). For the synthesis, Tentagel-S NH<sub>2</sub> resin functionalized by Rink Amyde Linker was used to obtain an amide peptide, with only C-terminal extremity with a carboxyl group. In our system, peptide immobilization occurs between COOH<sub>gelatin</sub> and NH<sub>2BMP2-mod</sub>; to induce this reaction, carboxylic acid groups of gelatin (Gel-COOH) were activated by adding EDC [EDC:Gel-COOH of 1.0:1.0] and amino groups of peptide by NHS [NHS:BMP2-mod-NH<sub>2</sub> of 0.2:1.0], both in 0.05M MES-buffer (pH 5.60) 2%w/v. The peptide amount is related to the free carboxyl acid groups in the gelatin crosslinked scaffold tested by titration analysis. Meanwhile, the polyion complexation was obtained by rehydrating crosslinked gelatin (IEP = 5) scaffold with BMP2 solution (50-200µM), and treated in incubator at 37°C for 2hrs.

## RESULTS AND DISCUSSION

Herein, the strategy was based on the design of a

crosslinked gelatin scaffold as controlled delivery vehicle for BMP-2 peptide. The high purity and molecular weight of BMP-2 (>95%) was verified by reverse phase HPLC chromatogram and mass spectrometry analysis.

Crosslinked gelatin scaffolds were prepared starting to a gelatin solution; freeze-drying technology produce a three-dimensional structure with interconnected pores. Titration and FTIR tests were used to analyze the crosslinking degree and peptide immobilization. In particular FTIR analysis, spotting the presence of amide band, confirms the occurred bond. For these systems, there seemed to be a rapid initial release of peptide (burst effect caused by peptide residues not linked at scaffold), followed by modulate release induced by electrostatic and chemical interaction between matrix and peptide.

Figure 1: SEM analysis of gelatin scaffold after 28 days of hMSC cell culture in basal medium.

Already after 3 days, the burst effect induces an higher alkaline phosphatase (ALP) activity in basal medium than the plate control ones in the first days of incubation. The trend of biological response remains optimal due to the subsequent modulate release in time, as shown in figure 1.

## CONCLUSION

This work demonstrated that by two different release mechanisms, polyion complexation and peptide immobilization, is possible to obtain a controlled release system. The optimized crosslinked gelatin structure and BMP-2 peptide concentration, induce an early osteogenic differentiation in basal medium.

## INTRODUCTION

The loading of growth factors (GF) into biomaterials and tissue engineering scaffolds has become focus of research in the last years since the local delivery of GF into a specific bone defect could help to increase defect healing via recruitment of bone-specific precursor cells as well as stimulation of their differentiation and activity. Low targeting efficiency and general side effects could be overcome by avoiding the systemic administration. Hydroxyapatite-forming calcium phosphate (CaP) bone cements, in particular, could be ideal carriers for growth factor delivery since they are highly biocompatible and resorbable, possess mild setting conditions and can easily be modelled into any bone defect. Since the direct integration of a sensitive GF may still deteriorate the protein structure and unspecific protein binding to the CaP allows only very limited control of its release kinetics, a carrier system entrapping and gradually releasing the GF is of interest.

Therefore, we investigated the applicability of sol-gel derived mesoporous bioactive glass (MBG) particles and granules as GF-loaded component in CaP bone cements. Besides bovine serum albumin (BSA) and lysozyme (LYZ) as model substances we investigated the applicability of the CaP/MBG system to gradually release the *brain derived neurotrophic factor* (BDNF) that has recently been demonstrated to also stimulate bone cells and thus new bone formation [1] and therefore could be an interesting GF in bone regeneration applications.

## EXPERIMENTAL METHODS

A sol-gel approach based on tetraethyl-orthosilicate was used to obtain MBG with intrinsic pores of approx. 5 nm diameter as described by Zhu et al. [2]. The MBG was ground to obtain a 50-150 µm powder fraction. Furthermore, a three channel 3D plotting system, developed by the Fraunhofer IWS (Dresden, Germany) on the basis of the Nano-Plotter<sup>TM</sup> device from GeSiM (Großerkmannsdorf, Germany) was employed to obtain 100-200 µm MBG granules via single-drop deposition into an silicone oil bath (Wacker Chemie, Germany). MBG was characterised by SEM and TEM. 10 wt-% MBG and granules were intermixed with an  $\alpha$ -tricalcium phosphate-based CaP cement (InnoTERE, Germany). After setting in humid atmosphere [3] porosity (He-pycnometry) and compressive strength were evaluated. BSA, LYZ and BDNF loading of MBG was performed by co-immersion in PBS for 30 min, followed by freeze-drying. BSA, LYZ and BDNF release from MBG and CaP/MBG composites was quantified by Bradford, Lysozyme assay and ELISA, respectively. *In vitro* cytocompatibility of GF-free composites was

investigated using primary human mesenchymal stem cells. Furthermore, the biologic activity of BDNF released from MBG was tested using primary human osteoprogenitor cells.

## RESULTS AND DISCUSSION

Characterisation of MBG powders and granules revealed a high intrinsic porosity and meso-pores in the range of 5 nm diameter. Granules had a regular spherical morphology (Fig. 1A). Compressive strength of the composites did not differ significantly from the unmodified CaP cement. No cytotoxic effect of the MBG modification on hMSCs could be detected. BSA (Fig. 1B) and LYZ release from pure MBG powders was shown to depend on the total loading and was fast compared to BDNF, where only ~3% of the initially loaded GF (30 ng/sample) was released within 48 h. Still, *in vitro* tests revealed a positive influence of the BDNF-modification on the adherence of bone precursor cells and thus proof the release of biologically active protein from the composite.

Fig. 1: MBG spheres (A) and re-release of BSA from MBG powder (B).

## CONCLUSION

CaP/MBG composites offer the possibility to deliver controlled amounts of biologically active, sensitive GF molecules into a specific defect location and thus could help in the regeneration of bone defects.

## Development of Novel Bioresorbable Iron-Silver Materials and their *in Vitro* Degradation Behavior

Sanjaya K. Swain, David Starosvetsky, Irena Gotman, Elazar Y. Gutmanas

Department of Materials Science and Engineering, Technion, Haifa, 32000, Israel

[swains@technion.ac.il](mailto:swains@technion.ac.il)

### INTRODUCTION

Bioresorbable implants are increasingly considered for applications in orthopedic and cardiovascular surgery as an attractive alternative to permanent prosthetic devices. The limited load-bearing capacity of biodegradable polymers has led to strong interest in resorbable metals<sup>1</sup>. Iron-based alloys have high strength and can corrode in the body, albeit too slowly for most prospective applications. Thus, current research activities on bioresorbable Fe are focused on accelerating its degradation rate. One approach is to uniformly disperse nanoparticles that are cathodic towards Fe matrix to generate multiple galvanic nanocouples<sup>2</sup>. Silver (Ag) nanoparticles seem especially attractive, both due to their high electrode potential and recognized antimicrobial activity<sup>3</sup>. Here, we report the preparation of dense Fe-Ag specimens with different volume fractions of Ag by attrition milling and high pressure consolidation, their mechanical properties and corrosion behavior.

### MATERIALS AND METHODS

Fe powder ( $\sim 2 \mu\text{m}$ ) was mixed with 10, 20 and 30 vol.% silver oxide ( $\text{Ag}_2\text{O}$ ) powder ( $< 2 \mu\text{m}$ ) by attrition milling for 4 h in hexane under Ar, at 20:1 balls-to-powder ratio. The obtained powder blends were compacted at 400 MPa and annealed at  $450^\circ\text{C}$ , 1 h in  $\text{H}_2$ -flow to reduce  $\text{Ag}_2\text{O}$ . The compacts were then high pressure consolidated at 2.5 GPa, at  $T_{\text{room}}$  to the final dimensions of 10 mm diameter by  $\sim 1.2$  mm thickness. A part of specimens were annealed at  $600^\circ\text{C}$ , 2 h and repressed at 3 GPa. The density of the specimens was measured by the Archimedes method and their mechanical properties tested in an Instron machine. The microstructure and phase composition of the composites were characterized by x-ray diffraction (XRD) and scanning electron microscopy (SEM/EDS). The corrosion/degradation behavior was assessed in Ringer's solution by immersion and electrochemical tests.

### RESULTS AND DISCUSSION

According to XRD analysis, partial reduction of  $\text{Ag}_2\text{O}$  to metallic silver occurred already during attrition milling. Following  $\text{H}_2$ -treatment, the oxide was completely reduced to Ag as indicated by the disappearance of  $\text{Ag}_2\text{O}$  peaks from the XRD patterns. For all the compositions, SEM examination revealed a homogeneous distribution of submicron Ag in Fe matrix. High pressure consolidation resulted in  $\geq 95$  % density which was further increased 1-3 % after annealing and repressing. In Fig. 2, the 3-point bending strength of different Fe-Ag specimens is presented. The already high value of  $\sim 400$  MPa achieved by high pressure consolidation was increased 2.5-4 fold after annealing, with or without repressing. The behaviour of Fe-10Ag specimen after the  $600^\circ\text{C}$  anneal is especially

noteworthy: it exhibited a very high yield stress of 1450 MPa coupled with large ductility.

Fig. 1: Three-point bending strength of Fe-Ag (10, 20 and 30 %) after different processing steps, and after 7 days immersion in Ringer's solution (repressed specimens).

In corrosion experiments, Fe-30Ag behaved similarly to pure Fe, Fig. 2. In contrast, Fe-10Ag showed the highest corrosion current density indicating that the corrosion rate also increased. Following one week in Ringer's solution, Fe-10Ag specimens lost  $\sim 12\%$  of strength (less than the other compositions). Some acidification of immersion medium around Fe-10Ag (vs. pH increase for Fe-20/30Ag) is attributed to faster Fe dissolution.

Fig. 2: Corrosion current density of Fe-Ag (10, 20 and 30 %) and pure Fe as a function of time.

### CONCLUSION

Dense and strong Fe-Ag specimens were produced by attrition milling of powders followed by high pressure consolidation. Fe-10vol.% Ag composites exhibited high bending strength, large ductility and faster dissolution rate as compared to pure Fe, making them a promising biodegradable material for medical applications.

## INTRODUCTION

Calcium phosphate invert glasses (Ca-IGs), which consist of short phosphate chains such as ortho- and pyrophosphate, have been focused in our group<sup>1</sup>. Ca-IGs show *in vitro* and *in vivo* bioactivity<sup>2</sup>. Niobium-containing Ca-IGs showed a small amount of Nb<sup>5+</sup> ion, i.e., 0.04 ~ 0.06 mM, dissolved from the glasses enhanced ALP activity<sup>3</sup>. Magnesium-containing phosphate invert glasses showed excellent glassification in our previous work<sup>4</sup>. Mg<sup>2+</sup> ions accelerate osteoblasts' adhesion and enhance their cell proliferation and differentiation<sup>5,6</sup>. In this work, magnesium/titanium- or niobium-containing phosphate invert glasses with the compositions of MgO > 60 mol% were prepared and their dissolution behaviours and structures were characterized.

## EXPERIMENTAL METHODS

Magnesium/titanium- or niobium-containing glasses with the compositions of  $x\text{MgO} \cdot (90 - x)\text{P}_2\text{O}_5 \cdot 10\text{TiO}_2$  (mol%,  $x = 60$  to 66, nominal composition) and  $y\text{MgO} \cdot (94.5 - y)\text{P}_2\text{O}_5 \cdot 5.5\text{Nb}_2\text{O}_5$  (mol%,  $y = 66$  to 69, nominal composition) were prepared by a conventional melt-quenching method (1500°C). Glass transition temperature ( $T_g$ ) and crystallization temperature ( $T_c$ ) were estimated from differential thermal analysis (DTA; heating rate 5 K/min) and glassification degree<sup>7</sup> ( $(T_c - T_g)/T_g$ ; in K/K) was calculated. The glasses structure was examined by Raman spectra and <sup>31</sup>P magic angle spinning nuclear magnetic resonance (MAS-NMR). Their dissolution behaviours in Tris buffer solution (37 °C, 1 to 7 days) were evaluated by inductively coupled plasma atomic emission spectroscopy (ICP-AES).

## RESULTS AND DISCUSSION

Glassification degrees of the samples decreased with increasing Mg/P ratio in the glasses. Raman spectra showed the peak intensities corresponding to orthophosphate (980 cm<sup>-1</sup>), TiO<sub>4</sub> (830 cm<sup>-1</sup>) and NbO<sub>4</sub> (830 cm<sup>-1</sup>) increases, and TiO<sub>6</sub> (660 cm<sup>-1</sup>) and NbO<sub>6</sub> isolated (915 cm<sup>-1</sup>) decreased with increasing Mg/P ratio in the glasses. Fig.1 shows the peak area fractions of orthophosphate ( $Q^0$ ) and pyrophosphate ( $Q^1$ ) groups, estimated from <sup>31</sup>P MAS-NMR spectra.  $Q^0$  fraction increased with increasing Mg/P ratio in glasses, and the glasses of Mg/P > 1.25 indicated the  $Q^0$  fraction was larger than  $Q^1$  one. With the increase in the fraction of  $Q^0$  in the glasses, intermediate oxides such as TiO<sub>2</sub> and Nb<sub>2</sub>O<sub>5</sub> act as network formers, and they take the form of TiO<sub>4</sub> or NbO<sub>4</sub> tetrahedral in the glasses. Mg<sup>2+</sup> and P<sup>5+</sup> ions amounts dissolved from the glasses increased with increasing Mg/P ratio in glasses. Mg<sup>2+</sup> ion of 1 to 2 mM, which may enhance cell adhesion, dissolved from the glasses in day 3. 1.8 mM of Mg<sup>2+</sup> ion were reported to

promote cell adhesion<sup>5</sup>. In cases of titanium and niobium, no significant differences in ion dissolution amounts were observed between 1.00 and 1.24 of Mg/P ratios in the glasses. In the glasses of Mg/P = 1.36, the dissolution amount of Ti<sup>4+</sup> and Nb<sup>5+</sup> ions decreased, since gel layer may form on the glass surface. Magnesium/titanium- or niobium-containing glasses showed lower chemical durabilities compared with Ca-IGs, since Mg<sup>2+</sup> ion coordinates preferentially with phosphate groups and inhibits the formation of P-O-Ti/Nb bonds, which improve the chemical durability of phosphate glasses.

Fig. 1 Contents of  $Q^n$  groups in the glass.

## CONCLUSION

Calcium-free phosphate invert glasses were prepared. With increasing Mg/P ratio in the glasses, the chemical durability of the glasses decreased, since Mg<sup>2+</sup> ions predominantly bond with phosphate groups and inhibit to make bonds between intermediate oxides and phosphate groups. MgO-P<sub>2</sub>O<sub>5</sub>-TiO<sub>2</sub>/Nb<sub>2</sub>O<sub>5</sub> glasses may be used for coating layer on Ti or Ti-alloys for enhancing cell adhesion owing to Mg<sup>2+</sup> ions dissolved from the glasses.

## INTRODUCTION

Cryopreservation of cells refers to storing of cells under very low temperature for a long time. The conventional cryoprotectants (CPAs) like dimethyl sulfoxide (DMSO) and glycerol have many problems and need to be replaced with newer CPAs for various biomedical purposes.<sup>1</sup> In this research; structurally analogous novel synthetic polyampholytes were synthesized via living radical polymerization and examined for their propensity to cryopreserve cells. These Polyampholytes surprisingly exhibited disparate cryoprotective properties.<sup>2</sup> And we believe this structure activity relationship study of polyampholytes could lead us further towards elucidation of molecular mechanism which is crucial for its employment in regenerative medicines and more efficient design of CPAs in the future. The interaction of the different synthetic polymers with cell membrane and their mode of action during freezing, i.e., the mechanism of cryopreservation were evaluated for the first time ever and it revealed that cryoprotective polyampholytes inhibit the recrystallization of ice and forms an irreversible matrix which protects cells from freezing damage.

## EXPERIMENTAL METHODS

Various polymers were synthesized via reversible addition fragmentation chain transfer (RAFT) polymerization. Polymer kinetics and control of its living nature was studied by using  $^1\text{H}$ -NMR and gel permeation chromatography. Interaction of polyampholytes with cell membrane was analysed by using liposome as a cell membrane mimic and various physicochemical analysis like infrared spectroscopy, differential scanning calorimetry, leakage experiment, electron spin resonance (ESR), etc. were carried out. Behaviour of polymer solution during freezing was examined using cryomicroscopy and  $^1\text{H}$  and  $^{23}\text{Na}$  solid state NMR under magic angle spinning conditions.

## RESULTS AND DISCUSSION

Copolymer of methacrylic acid and 2-dimethylaminoethylmethacrylate, poly-(MAA-DMAEMA), showed excellent cryoprotective properties and incorporation of hydrophobicity enhanced cell viability significantly. On the other hand, poly-carboxymethylbetaine (poly-CMB) didn't show any such property, whereas poly-sulfobetaine (poly-SPB), showed intermediate cryoprotective properties. Cooling splat assay demonstrated that poly-(MAA-DMAEMA) inhibits the recrystallization of ice during freezing to the maximum extent as compared to other polymers and thus prevents cell death caused by growth of ice crystals and, introduction of hydrophobicity inhibited ice recrystallization almost completely (Fig. 1). ESR

studies revealed that the polyampholytes' penetration inside the cell membrane has a strong influence on its cryoprotective behaviour.

**Figure 1** Micrographs of poly-nucleated ice crystals after 30 minutes annealing at  $-6^\circ\text{C}$  (scale bars =  $100\mu\text{m}$ )

FTIR and DSC studies unveiled the chemical nature of interaction of the polyampholytes with the membrane and its effect on the phase transition temperature of the membrane after freezing. Solid state  $^1\text{H}$  NMR studies of the polyampholytes showed lower molecular motion in poly(MAA-DMAEMA) during freezing, which means that poly-(MAA-DMAEMA) forms a matrix around the membrane during freezing, thus preventing its damage from ice crystals (Fig. 2).  $^{23}\text{Na}$  NMR showed that polymers trap ions during freezing which protects it from osmotic stress.

**Figure 2** Solid state  $^1\text{H}$ -NMR spectra of polyampholytes in saline solutions at  $-20^\circ\text{C}$ .

## CONCLUSION

Synthetic polymers can efficiently cryopreserve various types of cells and addition of a small amount of hydrophobicity can significantly enhance its cryopreservation potential. Moreover, the polyampholyte structure is crucial for its cryoprotective property. Cryoprotective polyampholytes act by inhibiting the recrystallization of ice and they have more interaction with the cell membrane which is characterized by their membrane penetration. Also they protect cells from stresses such as drastic changes in soluble space size and osmotic pressure.

## INTRODUCTION

For ages the ideal component required to formulate the tissue engineering constructs includes cells, growth factors and scaffolds that results in regenerative response. In order to recapitulate the features pre-existing in nature, currently various nanoceramics such as synthetic silicates<sup>1</sup> and nano-hydroxyapatite are used. Injectable hydrogels that can be applied with minimally applied pressure that is with shear thinning<sup>2</sup> property has opened the new avenues in the field of tissue engineering. In this current study we have focused on the development of new polymer –nanocomposites with novel inorganic/ organic network structures based on laponite (XLG) and succinylated poly-L-lysine (PLL-SA). Previously, our group has reported that poly-L-lysine based polyampholytes are potent cryoprotectants<sup>3</sup> and it can be formulated into hydrogel with cryoprotective property<sup>4</sup>. Our main goal of this study is to develop such a system in which cells can be cryopreserved by the use of PLL-SA and then after thawing this can be converted to gel by physical crosslinking of the polymer and laponite. Here PLL-SA has been used to synthesise physically crosslinked polymer-laponite based hydrogel with tunable mechanical property.

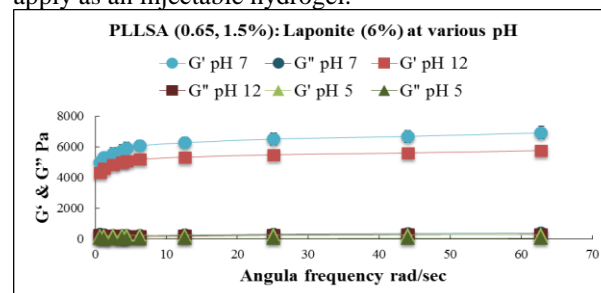

## EXPERIMENTAL METHODS

PLL-SA was synthesised by reacting PLL aqueous solution with succinic anhydride in different mole ratios from 0-80% against  $\text{NH}_2$  group. This differently succinylated PLL was then mixed with laponite in appropriate amounts to formulate the hydrogel. Various parameters were varied to tune the mechanical properties like polymer and laponite concentration, pH and succination ratio. These hydrogels were analysed by XRD and ATR-IR. Dynamic mechanical analysis (DMA) was also carried out.

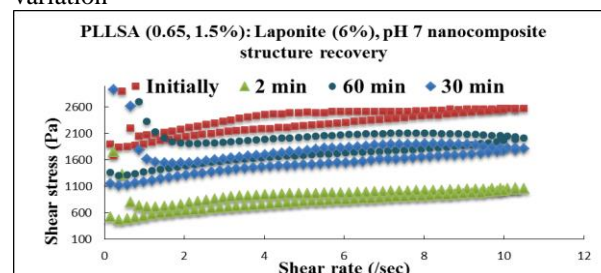

## RESULTS AND DISCUSSION

XRD data reveals that due to anisotropic distribution of charges in laponite and polyampholytes, intercalation of the polymer is taking place. It also demonstrates that intercalation of the polymer can be tailored by varying pH and degree of substitution of succination in PLL. This unique interaction of the polymer and the laponite leads to the development of smart hydrogels, which have different mechanical properties ranging from 500 Pa to 10 kPa (Figure 1). They exhibit thixotropic property through autonomic reconstruction of crosslinks across damaged interface (Figure 2). The biomedical relevance of this system can be seen through the cell adhesion and proliferation on their surface. Cryopreservation of mouse preosteoblasts cells MC3T3

was successfully carried out using 65% succinylated PLL (PLL-SA (0.65)). It shows excellent post thaw survival efficiency. These results indicate that cryopreserved cells with PLL-SA could directly form hydrogel by mixing with laponite just after thawing to apply as an injectable hydrogel.

**Figure 1** Tuning of mechanical strength of gel by pH variation

**Figure 2** Shear-thinning property of gel by DMA

## CONCLUSION

The current study clearly demonstrates that PLL-SA-laponite based system exhibit tunable mechanical property and they are suitable candidates for the smart hydrogels. This system can be used as injectable hydrogels that can be employed with minimally applied pressure due to shear thinning property. Thus, these hydrogels can serve as scaffolds with thixotropic and cryoprotective properties that also provide structural integrity to tissue constructs.

## INTRODUCTION

The rupture of the anterior cruciate ligament (ACL) is the most frequent injury of the knee joint with 47%. The reconstruction with autologous tissue from patellar or hamstring tendons has proven its worth despite various risks, such as differing biomechanics or donor site morbidity.

Tissue engineering represents a potential alternative. Biocompatible scaffolds with defined biomechanical properties are required. As one of the textile production processes, embroidery technology facilitates the variation and control of the mechanical characteristics.

## EXPERIMENTAL METHODS

Embroidery technology was used to fabricate three-dimensional (3D) scaffolds (Fig. 1A) from absorbable filaments of poly-L-lactic (PLA, multifilament, 155 dtex) and poly(lactic-co-ε-caprolactone) (PLA-CL, monofilament, 100 dtex).

Scaffolds consisted of 3 two-dimensional layers each with one upper and lower thread, which were stacked and locked to build up a 3D structure according to the dimensions of lapin ACL (10 mm×4 mm×2 mm). Scaffolds were manufactured on water soluble polyvinylalcohol nonwoven, which was washed out in water after the locking process. Scaffolds were rinsed with pure ethanol for 30 min in preparation for the degradation study. Two types of embroidered structures (n=5) were analysed, *MOCO* (mono-component) with PLA as upper and lower thread as well as *BICO* (bi-component) consisting of PLA-CL as upper and PLA as lower thread.

Hydrolytic degradation was performed under physiological conditions in culture medium. The mechanical properties (Fig. 1B) of three different test groups were evaluated at different degradation time points with a tensile testing machine. Results were represented as mean ± standard deviation.

## RESULTS AND DISCUSSION

The influence of hydrolytic degradation on viscoelastic behaviour of embroidered scaffolds was investigated

and compared to lapin ACL. Embroidered scaffolds demonstrated the ability to adapt the biomechanical properties by configuring the embroidery pattern and the material combination<sup>1</sup>.

The intensity of relaxation decreased with previous hysteresis loading for both scaffold types. The relaxation behaviour was more pronounced for *BICO* compared to *MOCO*. However the relaxation behaviour of *BICO* and *MOCO* was comparable to lapin ACL (Fig. 1C)<sup>2</sup>.

The ultimate tensile properties showed no significant differences for both scaffold types whether the scaffolds were unloaded or preloaded by relaxation and/or hysteresis. There were no measurable degradation effects on the mechanical properties after 28 days in culture medium.

In addition to the promising mechanical properties, Hoyer et al. investigated ACL cell adherence and activity on embroidered collagen hybrid scaffolds and demonstrated the potential of this reconstruction strategy<sup>3</sup>.

## CONCLUSION

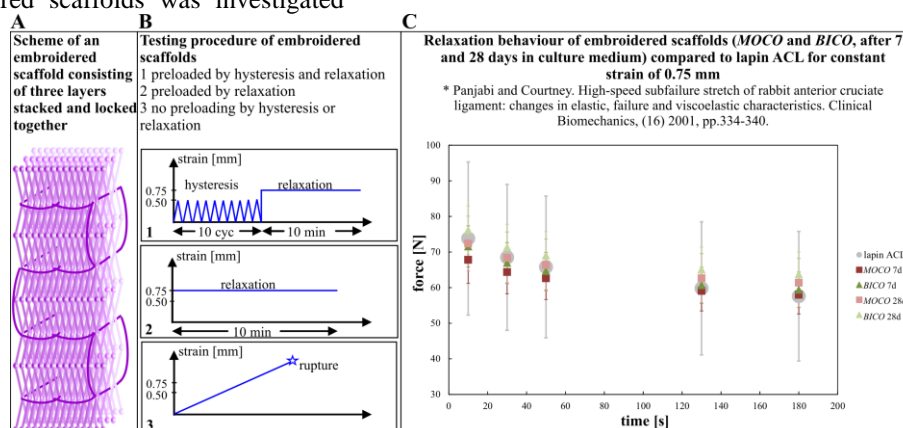

The qualitative and quantitative characterisation of the mechanical properties of embroidered scaffolds was investigated to find an optimal adjustment to native ligament tissue. The viscoelastic behaviour of embroidered scaffolds is comparable to lapin ACL either in dry state or under hydrolytic degradation.

## Exploring the Limits of Scaffold Interconnectivity for Cell Type Specific Invasion

Jennifer Ashworth<sup>1</sup>, Marco Mehr<sup>2</sup>, Paul Buxton<sup>2</sup>, Serena Best<sup>1</sup>, Ruth Cameron<sup>1</sup>

### INTRODUCTION

Structural cues in collagen scaffolds have great potential for influencing the characteristics of cell invasion.<sup>1</sup> Since accessibility to cells is a necessity for tissue engineering scaffolds, it is vital that the relationship between scaffold structure and cell invasion is well understood. However, there are still gaps in this understanding. In particular, the link between cell invasion and scaffold interconnectivity is obscured by the difficulties involved in interconnectivity characterisation.<sup>2</sup> In this study, we demonstrate how new Micro-CT analysis can allow interconnectivity parameterisation and correlation to the invasion behaviour of various cell types. This method has the potential to provide new criteria for scaffold design, allowing invasion control according to cell type.

### EXPERIMENTAL METHODS

Scaffolds were fabricated by freeze-drying a 1% w/v suspension of insoluble type I bovine collagen from Achilles tendon. Systematic control of scaffold interconnectivity at constant pore size was achieved by variation of fabrication parameters including suspension medium and freezing temperature. X-ray Micro-Computed Tomography (Micro-CT) analysis allowed assessment of pore structure. Scaffold interconnectivity was parameterised by measurement of percolation diameter,  $d_c$ : the largest spherical object able to travel through an infinitely large scaffold. For the cell invasion tests, periodontal ligament fibroblasts (PDLF), MC3T3 or HT1080 cells were seeded onto the scaffold surfaces at 64,000 cells per 1 cm<sup>2</sup>. After 3 days of culture, Phalloidin-staining, cross-sectioning and confocal microscopy allowed assessment of cell invasion. Median cell position was then measured to quantify invasion distance. Mean  $\pm$  standard error is displayed for both  $d_c$  (n=3) and invasion distance (n=6).

**Figure 1:** Representative Phalloidin-stained scaffold sections showing cell position at day 3. Scale bar 1 mm.

### RESULTS AND DISCUSSION

Representative cross-sections in figure 1 show that scaffold interconnectivity has a variable influence on invasion, according to cell type. At a constant pore size of 70  $\mu$ m, an increase in  $d_c$  from 47 to 77  $\mu$ m allowed both MC3T3 and PDLF cells to invade at visibly greater efficiency. Conversely, there was no clear correlation between scaffold structure and invasion of fibrosarcoma HT1080 cells, which instead showed erratic behaviour that may be explained by their origin. Extension of the range of scaffolds under investigation as in figure 2 revealed a sharp increase in PDLF invasion efficiency as interconnectivity exceeds  $d_c > 40$   $\mu$ m. Combined with the results from figure 1, this indicates the existence of a critical interconnectivity threshold between  $40 < d_c < 50$   $\mu$ m for PDLF invasion, with a similar threshold for MC3T3 cells. The comparatively enhanced HT1080 invasion at low  $d_c$ , however, suggests a lower critical interconnectivity threshold for these cells. Previous studies in microfluidic channels indicate that cells alter their migration behaviour in channels of widths close to that of a single cell.<sup>3</sup> Here we have demonstrated that by quantitative interconnectivity characterisation, similar structure-function correlations may be identified in natural polymer scaffolds.

**Figure 2:** Plot of median cell position against  $d_c$  for PDLF cells after three days culture.

### CONCLUSION

Parameterisation of scaffold interconnectivity has identified a critical interconnectivity threshold required for efficient cell invasion, which varies with cell type. This result indicates future potential for directing cell type specific invasion by control of scaffold design.

## The Impact of Thrombocytes on the Cell Proliferation within the 3D Scaffolds

Kateřina Pilařová<sup>1</sup>, Věra Jenčová<sup>1</sup>, Jana Horáková<sup>1</sup>, Jakub Erben<sup>1</sup>, Jiří Chvojka, David Lukáš<sup>1</sup>

Department of Nonwovens and Nanofibrous Materials, Technical University of Liberec, Czech Republic  
[katerina.pilarova1@tul.cz](mailto:katerina.pilarova1@tul.cz)

Thrombocytes are well known to be involved in blood coagulation and hemostasis. But they also play an important role in inflammatory and immune responses, cardiovascular diseases and wound healing and many others. They possess number of different granules with a large variety of molecules including chemokines, cytokines, adhesive molecules and immune receptors, which can be secreted when the platelets are activated. Due to all these factors, platelets could help cell proliferation and migration within different scaffolds.

### INTRODUCTION

The platelets possess many good features<sup>1</sup>, among others, they contain a number of active molecules as cytokines, chemokines, adhesive molecules and immune receptors<sup>2</sup>. They are able to attach other cells and stimulate their proliferation<sup>3</sup>. Thus, it would be advantageous to support the cell growth on the scaffolds naturally by these molecules produced by platelets. In our experiments, platelets were able to adhere to our scaffolds and even they supported the cell proliferation and migration into the inner structure of the material.

### EXPERIMENTAL METHODS

The 3D scaffolds made from PCL (Sigma) by combination of melt-blown and electrospinning method<sup>4</sup> were used for in vitro experiments. The samples were analysed by SEM, followed by image analysis.

The scaffolds were treated with platelets for 2 hours prior to cell seeding. Scaffolds were seeded by 3T3 mice fibroblasts ( $1 \times 10^4$  / well) for evaluation of the rate of cell adhesion and proliferation. Controls were taken as follows: scaffolds treated only by platelets, scaffolds seeded only with cells.

Scaffolds were tested for platelet adhesion and activation and cell adhesion and proliferation by fluorescent (anti-CD41-FITC and propidium iodide, respectively) and scanning electron microscopy and by MTT assay. Scaffold were tested 2 hours after platelets treatment and at day 1, 3, 7 and 14 after cell seeding.

### RESULTS AND DISCUSSION

The 3D scaffolds were made from PCL by melt-blown technology and electrospinning. The average electrospun fiber diameter was  $732 \pm 292$  nm, the average meltblown fiber diameter was  $6,5 \pm 4,4 \mu\text{m}$ . The porosity of scaffolds was 95%. Scaffolds were seeded with cells, thrombocytes and cells or thrombocytes only. Our results from fluorescent microscopy as well as from SEM show, that our scaffolds are capable of thrombocytes adhesion (Fig. 1).

**Fig. 1:** Fluorescent microscopy, magnification 400x (A) and SEM (B) of adhered thrombocytes after 2h of incubation. Scale bar: 10  $\mu\text{m}$ .

From the MTT assay results it is obvious that scaffolds treated with thrombocytes prior to cell seeding show higher proliferation rate than cells only (Fig. 2). Thus, thrombocytes' treated scaffolds support the growth of 3T3 mice fibroblast better than melt-blown scaffolds alone.

**Fig. 2:** MTT assay results after day 3, 7 and 14 after cell seeding.

### CONCLUSION

Our results show that the melt-blown scaffolds are capable for platelets' adhesion. According to the MTT assay the scaffolds treated with platelets show higher proliferation rate of 3T3 mice fibroblasts.

### INTRODUCTION

Chronic venous insufficiency has an incidence of 0.3-3% in Western Europe and North America<sup>1</sup>. Usually, dysfunctional veins are replaced by synthetic grafts that, however, lead to early infection, as well as to degeneration, dilation and calcification. Decellularised native valved venal grafts have the potential to offer a promising solution for venal reconstructions that can overcome the limitations of current alternatives<sup>1,2</sup>. The aim of this study was to develop a decellularised porcine saphenous vein scaffold suitable for venal reconstruction.

### EXPERIMENTAL METHODS

Saphenous veins were isolated from 6-9 months pigs and tested within 4 hours of animal slaughter. Valved venal samples were treated with a protocol incorporating sodium dodecyl sulphate (SDS) and Triton X-100. Treated samples, together with native veins were assessed histologically, biochemically and immunohistochemically. The cellular content and gross histoarchitecture of treated and untreated veins were determined by haematoxylin & eosin (H&E), DAPI and collagen IV staining, whereas collagen and elastin were visualised by Masson's trichrome and Van Gieson stain, respectively. Total collagen content was determined by hydroxyproline (HXP) quantification, and glycosaminoglycan (GAG) content by papain digestion. The cytotoxicity of the decellularised scaffolds was assessed by contact and extract cytotoxicity tests, according to ISO 10993-5. The results were analysed by Student's t-test for comparison of two group means and one-way ANOVA for more than two groups at the 95% confidence interval.

### RESULTS AND DISCUSSION

Histology and immunohistochemistry confirmed the complete removal of the cells and the preservation of extracellular matrix (ECM) in the decellularised scaffolds. Collagen IV was observed in the media and basement membrane of both the native and decellularised tissue with no apparent differences. As previously reported, an intact basement membrane is beneficial for the effective graft endothelialization<sup>3</sup>. Furthermore, no significant difference was found in the total collagen level between the native vein and decellularised scaffold. On the other hand, the GAG content was significantly reduced in the treated samples compared to the native tissue. The *in vitro*

biocompatibility assessment indicated that the treated tissue did not induce any cytotoxic effects to L929 murine fibroblasts.

Figure 1. (a) Fresh porcine saphenous vein stained with H&E. (b) Decellularised vein stained with H&E. (c) Fresh vein stained for collagen IV. (d) Decellularised vein stained for collagen IV.

### CONCLUSION

This work successfully developed a non-cytotoxic decellularised saphenous vein valved scaffold, which grossly maintained its natural histoarchitecture and biochemical composition. Future work will focus on the assessment of the  $\alpha$ -gal content of the decellularised scaffolds, as well as on the assessment of its biomechanical and haemodynamic performance.

## INTRODUCTION

Porous and biocompatible hydrogels able to deliver hydrosoluble drugs, cells or active compounds have been largely employed in biomedicine<sup>1</sup>. The major problems with the use of these biomaterials are related to a difficult control of the release kinetics of the loaded drugs. The mesh size of hydrogels, which depends on the crosslinking reaction, is a powerful means to tune the diffusion of molecules within the polymeric matrix<sup>2</sup>. Collagen is a natural polymer can be molded into various forms of scaffolds and/or drug delivery systems for a number of biomedical applications. One the most effective chemical crosslinker for collagen is the formaldehyde but is well known as being strongly toxic which limits its use for *in vivo* experiments and applications<sup>3</sup>. In this work, non-toxic magnetite nanoparticles (NPs) are proposed and used in a double role: NPs can work as effective crosslinkers for porous hydrogel matrices and can also provide the matrix with a sharp and accurate sensitivity to an external trigger. The paramagnetic behavior of NPs permits to use an external stimulus, i.e. the application of a magnetic field, to induce and control the release of any loaded substance from the gel matrix. It is worth noting that the interaction among nanoparticles and collagen fibers can also guarantee the magnetite NPs stabilization, preventing their aggregation and oxidation.

## EXPERIMENTAL METHODS

**Synthesis of porous collagen gel (CG).** An aqueous suspension of 0,5% w/v Type I collagen from bovine dermis was prepared by mixing for 5-6 hours at 10°C. Following casting, freeze-drying and dehydrothermal crosslinking treatment (DHT) porous collagen gel was obtained. **Crosslinking by Formaldehyde (CGFA).** Hydrated CG samples were immersed in a 0,4% (v/v) FA aqueous solution for 2h. **Fabrication of Porous Paramagnetic Collagen Gel (NPsCG).** The NPs aqueous solution was added to the collagen slurry while stirring. The suspension was then treated as for CG porous matrices.

**Characterization experiments.** FTIR Analysis, SEM, TG Analysis and Swelling studies were carried out. Release properties were studied by means of fluorescence spectroscopy. The cytotoxicity of all the samples was assessed *in vitro* using a 3T3 cell line, by means of MTT assay.

## RESULTS AND DISCUSSION

A biocompatible cross-linker represented by paramagnetic NPs was used to create a collagen-based gel able to retain water-soluble molecules and then activate their release in the presence of an external magnetic field. By means of infrared spectrometry, the interactions between collagen fibers and NPs were

studied. N-H group vibrations, both stretching and bending modes, and the absorption band of C=O and C-N groups of amide I and amide III drastically change in the presence of the paramagnetic nanoparticles, suggesting the formation of a network among the collagen fibers. The role of NPs was confirmed by scanning electron microscopy that showed a porous matrix with an average pore dimension of 50  $\mu$ m, comparable to that one observed when using formaldehyde as the crosslinker. In addition, to ensuring biocompatibility, paramagnetic nanoparticles allowed to use an external stimulus, the magnetic field, to induce the release of a substance loaded in the gel matrix. Fluorescein was used as the model compound. Release of fluorescein from the MNPs-collagen gel was clearly triggered and controlled by consecutive magnet applications, as demonstrated by means of fluorescence spectroscopy (Figure 1). The preliminary MTT assay seemed to suggest that, not only CG and NPsCG are not cytotoxic, but also the potential degradation products (mainly free NPs) do not affect cell viability.

Figure 1. Release of fluorescein from NPsCG

## CONCLUSION

The results obtained in this study suggest the possibility to use the paramagnetic iron oxide NPs-collagen hybrid matrix as a smart scaffold for the controlled release of drugs and other biologically active substances.

## INTRODUCTION

Polymer-based nanoparticles have been studied extensively for their use in tumour-targeted drug delivery. Leaky vasculature and damaged lymphatic drainage in solid tumours allow appropriately sized nanoparticles to selectively accumulate in the tumour.<sup>1</sup> The tumour-targeting ability of nanoparticles, however, is not only dependent on their sizes, but also on their biological behaviours. Some types of nanoparticles are more likely than others to be cleared by the reticuloendothelial system (RES) when entered the body, leaving low accumulation in the tumour and high accumulation in the RES organs, such as the liver.<sup>2</sup> The unintended RES accumulation of nanoparticles not only lowers the availability of nanoparticles to be accumulated in the tumour, but also increases toxicity. The chemical structure and other physicochemical properties of the base materials may provide reliable means to predict stability, solubility, drug loading efficacy, and cytotoxicity of nanoparticles. However, it has remained impractical to predict the relative level of RES clearance of nanoparticles *in vivo* without a direct testing on animals. Consequently, we have developed an *in vitro* system based on differential uptake of nanoparticles by macrophages that enables the prediction of RES accumulation of nanoparticles *in vivo*.

## EXPERIMENTAL METHODS

Five types of nanoparticles with different base materials (polystyrene, carboxymethyl dextran titanium dioxide, dextran sulphate, hyaluronic acid, and glycol chitosan) were prepared to have a mean diameter of approximately 250 nm.<sup>3,4</sup> The hydrodynamic sizes of the nanoparticles were measured by dynamic light scattering. The zeta potentials of the nanoparticles dispersed in distilled water were determined by electrophoretic light scattering. The morphologies of the nanoparticles were observed by using transmission electron microscopy. The structural rigidities were evaluated by conducting a filtration test.<sup>4</sup> Murine macrophage cell line (RAW 264.7) and squamous cell carcinoma cells (SCC7) were fed with NIRF dye-labelled nanoparticles for two hours to observe the uptake level. Confocal laser scanning microscopy was used to detect the fluorescence signals. SCC7 cells were subcutaneously injected to the left flank of inbred female C3H/HeJ mice to establish tumour xenografts (n=15). The nanoparticles were injected intravenously and their distributions *in vivo* were scanned by an optical imaging module. *Ex vivo* imaging and histological analyses were followed after 24 h of real-time *in vivo* imaging.

## RESULTS AND DISCUSSION

**Figure 1.** (a) Chemical structures and illustrations of the nanoparticles. (b) Cellular uptake of the nanoparticles by macrophage cell line and squamous carcinoma cell line. (c) Differences in the cellular uptake efficiencies in the two different cell lines. A higher value indicates a better uptake of the nanoparticles by SCC7 cells than by RAW 264.7 cells. (d) Fluorescence signals from the excised livers and the tumours at 24h post-injection. (e) Signal intensities from the tumour compared to those from the liver. A higher value indicates more accumulation in the tumour and less accumulation in the liver.

The nanoparticles that shared similar physicochemical properties showed different levels of cellular uptake by macrophages and by cancer cells. The affinities of the nanoparticles to cancer cells or to macrophages were closely related to their distribution *in vivo*. The nanoparticles with a high tumour cell affinity accumulated in the tumour, and those with a high macrophage affinity accumulated in the liver. Furthermore, these nanoparticles were observed co-localized with the resident macrophages in the liver.

## CONCLUSION

The strong correlation between the *in vitro* macrophage uptake and the *in vivo* distribution of the nanoparticles provides evidence to the viability of using this *in vitro* system to predict the *in vivo* fate of nanoparticles. The significance of this finding is that it may decrease the number of sacrificed animals during the development of a nanoparticle-based cancer drug delivery system.

## Development of Novel Biomaterials, Natural Polymers, Polyhydroxyalkanoates (PHAs), for Biomedical Applications

Barbara Lukasiewicz, Pooja Basnett, and Ipsita Roy

Department of Molecular and Applied Biosciences, University of Westminster, London, UK

[barbara.lukasiewicz@my.westminster.ac.uk](mailto:barbara.lukasiewicz@my.westminster.ac.uk)

### INTRODUCTION

Polyhydroxyalkanoates (PHAs) are natural biopolymers produced by various microorganisms as a reserve of carbon and energy under nutrient limiting condition with excess of carbon<sup>1</sup>.

PHAs are promising materials for biomedical applications because they are biodegradable, non-toxic and biocompatible. Homopolymers, random copolymers and block copolymers of PHAs can be produced depending on the bacterial species and growth conditions. Physical properties of PHAs are defined by the number of carbon atoms in a monomer unit<sup>2</sup>.

Due to their characteristics, biodegradable polymers can be used in a variety of applications including medicine, pharmacy, implants, packaging, chemical industry, food industry, cosmetology and photography<sup>3</sup>. However, one of the greatest potential applications of PHAs are in the area of medicine, which includes wound management, nerve regeneration, drug delivery systems, stents, repair of soft tissue and hard tissue and heart tissue engineering<sup>4</sup>.

In this study we have presented results obtained from screening experiments using several bacterial strains and various carbon sources for PHA production with special emphasis on *scl-mcl*-PHA copolymers.

### EXPERIMENTAL METHODS

PHAs were produced using *Pseudomonas* sp., *Cupriavidus* sp. and *Comamonas* sp. Various carbon sources were introduced, such as: fatty acids, oils, carbohydrates and waste materials. Bacterial cultures were grown on mineral salt media under nutrient limitation with excess of carbon source. Different fermentation strategies were used. After cultivation time, obtained biomass was freeze dried. Polymer was extracted by solvent dispersion method. Pure polymer were analysed by Fourier Transformed Infrared Spectroscopy (FTIR), Nuclear Magnetic Resonance (NMR) and Gas Chromatography – Mass Spectrometry (GC-MS).

### RESULTS AND DISCUSSION

The examples of obtained PHAs are presented in Table 1. All tested bacterial strains were able to produce PHAs. Preferences towards each group of PHAs (*mcl/scl*) depend on the carbon source and bacterial metabolic pathway.

Bacterial strain	Carbon source	Polymer yield (% dcw)	GC-MS results	PHA type
<i>Pseudomonas</i> sp.	Sodium octanoate	24.0	P(3HO-3HD)	<i>Mcl</i> -PHA
	Sucrose	4.0	P(3HB-3HV-3HD)	<i>Scl-mcl</i> PHA copolymer
	sucrose+valeric acid	15.4	P(3HB-3HV)	<i>Scl</i> -PHA copolymer
	glucose+butyric acid	25.6	P(3HO-3HD-3HDD)	<i>Mcl</i> -PHA copolymer
	hexanoic acid +glucose	4.8	P(3HB-3HO-3HD)	<i>Scl-mcl</i> -PHA copolymer
	sucrose+ sodium octanoate	4.5	P(3HO-3HD)	<i>Mcl</i> -PHA copolymer
	Butyric acid+sodium octanoate	5.5	P(3HO-3HD)	<i>Mcl</i> -PHA copolymer
	Waste frying oil	38.9	P(3HO-3HD-3HDD)	<i>Mcl</i> -PHA copolymer
<i>Comamonas</i> sp.	1,4-butandiol	6.0	P(3HB-3HO)	<i>Scl-mcl</i> -PHA
	$\gamma$ -butyrolactone + sodium propionate	2.98	P(3HB-3HV)	<i>Scl</i> -PHA copolymer
<i>Cupriavidus</i> sp.	$\gamma$ -butyrolactone + sodium propionate	3.8	P(3HB)	<i>Scl</i> -PHA
	$\gamma$ -butyrolactone	6.70	P(3HB)	<i>Scl</i> -PHA

Table 1: Chemical characterisation of PHAs obtained from various carbon sources.

*Pseudomonas* sp. mainly produced *mcl*-PHAs, whereas *Cupriavidus* sp. mainly produced only P(3HB) polymer. Exploratory work towards more novel copolymers is in progress.

### CONCLUSION

PHAs were successfully produced from various carbon sources. *Mcl*-PHAs, *scl*-PHAs, *mcl*-PHA copolymers, *scl*-PHA copolymers and *mcl-scl*-PHA copolymers were obtained. Copolymers are more attractive materials than homopolymers, because of their intermediate properties as well as better processability.

### INTRODUCTION

Polyurethanes (PU) are synthetic polymers, which properly designed may be biocompatible and biodegradable. Due to this characteristic, they have found wide spectrum of applications in biomedical field<sup>1</sup>. In this study, we tried to improve biological properties of obtained materials by ascorbic acid addition into PU matrix. Ascorbic acid was used due to its antioxidative property and large influence on tissue regeneration. To evaluate the results of this procedure we performed the indirect cytotoxicity test with the use of MTT [3-(4,5-dimethyl-2-thiazolyl)-2-5-diphenyl-tetrazolium bromide] assay according to ISO 10993-5 standard.

### EXPERIMENTAL METHODS

**Synthesis.** Unmodified polyurethanes were obtained with the use of oligomeric  $\alpha,\omega$ -dihydroxy(ethylene-butylene adipate)diol, 1,6-hexamethylene diisocyanate (HDI) or 4,4'-methylene (biscyclohexyl diisocyanate) (HMDI) and 1,4-butanediol chain extender. The standard PU synthesis was carried out at 80°C for 4h in the presence of dibutyltin dilaurate (DBTDL) catalyst. Modification was performed as follows: to the prepolymer 2 wt% of ascorbic acid (AA) was added. The mixture was intensively stirred for 1h. After that time PUs were cast into the mold and the synthesis was completed in the drier set at 80°C for 24h. **Cytotoxicity test:** In order to obtain extracts the sterile PU samples were incubated in cell culture medium (Dulbecco's Modified Eagle's Medium, DMEM supplemented with Fetal Bovine Serum, FBS and antibiotics) for 5 days at 37°C. The ratio of the total surface area of samples to the volume of extraction medium was 3 cm<sup>2</sup>/ml. 3T3 cells were incubated with extracts for 24, 48 and 72h. DMEM was used as a negative, non-toxic, control. To determine cell viability the colorimetric MTT metabolic activity assay was used. Each day of the test the MTT was added (0,5 ml) to the wells and incubated for 3h at 37°C. After that time formed insoluble formazan crystals were dissolved using 2 ml of dimethylsulfoxide (DMSO, Sigma D2650 tissue culture grade) and optical densities were measured at a test wavelength of 570 nm at Cecil CE 201 spectrometer. The results were presented as reduction of metabolic activity in percentage when compared to control cells cultured in medium only (100%). All assays were performed in triplicate. The statistical analysis was performed with the use of the Origin Pro 8.5. To evaluate statistical differences the two-way ANOVA ( $\alpha=0,05$ ) and post hoc Tukey test ( $\alpha=0,05$ ) were used.

### RESULTS AND DISCUSSION

Figure 1 presents 3T3 cells viability after incubation with extracts of unmodified (PU/HDI/AA0) and ascorbic acid modified (PU/HDI/AA2) PUs obtained with the use of HDI.

Fig. 1

Figure 2 presents 3T3 cells viability after incubation with extracts of unmodified (PU/HMDI/AA0) and ascorbic acid modified (PU/HMDI/AA2) PUs obtained with the use of HMDI.

Fig. 2

In case of unmodified and ascorbic acid modified PUs, obtained with the use of HDI, higher cells viability was observed in comparison to unmodified and ascorbic acid modified PUs, obtained with the use of HMDI. These differences were statistically significant ( $p<0.05$ ). In this case the presence of AA provided suitable environment for cells proliferation. In contrary, the application of HMDI diisocyanate and ascorbic acid modification caused severe cytotoxic effect on cells of such PU samples. It could be explained by lower reactivity of HMDI diisocyanate. In that case part of AA, which was not introduced to PU chain, was exposed to the oxygen and AA degradation products may be released and enclosed into PU matrix.

### CONCLUSION

In this study we applied ascorbic acid to improve PUs biocompatibility. In case of PUs, obtained with the use of HDI, this goal was achieved what is in contrary to PU obtained with the use of HMDI. PU obtained with the use of HDI and modified with AA can be suitable candidates for soft tissue engineering.

### INTRODUCTION

Calcium pyrophosphate,  $\text{Ca}_2\text{P}_2\text{O}_7$ , CPP, results from the thermal decomposition of dicalcium phosphate dihydrate,  $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$ , brushite, DCPD, or dicalcium phosphate anhydrous,  $\text{CaHPO}_4$ , monetite, DCPA. CPP normally exists in three polymorphs.  $\gamma$ -CPP is formed from CPDA at relatively low temperatures 300–500 °C,  $\beta$ -CPP– from  $\gamma$ -CPP in the range 600–800 °C, and  $\beta$ -CPP transforms into the high-temperature polymorph  $\alpha$ -CPP above 1200 °C<sup>1</sup>. However, the temperature ranges are not strongly defined. The kinetic parameters of the decomposition have been also actually not ascertained because few data have been obtained and they are contradictory.

It was recently found that ceramics of  $\beta$ -CPP were more bioactive in vivo than of HA<sup>2</sup>. It was also detected that calcination of ACP with an atomic Ca/P ratio of 1:1 prepared by the flame spray synthesis resulted in  $\alpha^1$ -CPP, a metastable medium-temperature polymorph of the high-temperature  $\alpha$ -CPP<sup>3</sup>. However, the synthesis is complex, expensive and has a low yield.

The work reports on the preparation of an ACP powder with Ca/P ratio 1:1 by the known simple, inexpensive and highly productive nitrous synthesis and the examination of crystallization and phase transitions in the ACP powder depending on its processing and heating conditions with the aim of subsequent fabrication of improved CPP ceramics.

### EXPERIMENTAL METHODS

The preparation of initial amorphous DCPA was based on a fast precipitation variety of the nitrous synthesis<sup>4</sup>. A 0.43 M solution of  $(\text{NH}_4)_2\text{HPO}_4$  was rapidly added into a vessel with a 0.43 M solution of  $\text{Ca}(\text{NO}_3)_2$ .

The two solutions before mixing were adjusted by ammonia to pH10–11 and cooled to 5 °C. The vessel with mixture was tightly closed, vigorously shaken and put into a freezer. The whole process from the outset of mixing took about 3 minutes. In another case, before freezing, the slurry in the vessel was six times washed with cold ammoniated water. The vessel was kept in the freezer at – 25 °C. The frozen mass was then taken from the freezer and slowly warmed up to 0 °C. The liquid occurred was removed by a blotting paper. The resultant moist slurry was put back into the freezer and kept there until its weight became stable. Friable products resulted that are hereafter designated as UW (unwashed) and 6W (six times washed) powders. Before examination, the powders were additionally dried in vacuo.

Powder samples were examined as prepared and upon heat treatments in air in the range 25–1000 °C in a

muffle furnace. They were studied by XRD, TG-DTA, and IR.

### RESULTS AND DISCUSSION

Thermal behavior of two kinds of XRD amorphous powders prepared from ACP precipitates with a given Ca/P ratio of 1:1 of the nitrous synthesis was studied.

An UW powder from unwashed precipitate crystallized at 530–640 °C mainly into  $\alpha^1$ -CPP, a metastable polymorph of the high-temperature polymorph  $\alpha$ -CPP, and some admixture of  $\beta$ -CPP. This phase composition slightly changed to 800 °C. Above 800 °C,  $\alpha^1$ -CPP gradually transformed into the stable  $\beta$ -CPP polymorph, so biphasic mixtures with increasing  $\beta$ -CPP/ $\alpha^1$ -CPP ratios were formed from 1:2 at 800 °C to 2:1 at 980 °C.

A 6W powder from six-time washed precipitate consisted of a major part unaffected by the washing procedure and a minor part hydrolyzed during washing to ACP with a Ca/P ratio about that of OCP (1.33). The major part crystallized in the range 620–720 °C mainly into  $\alpha^1$ -CPP with little admixture of  $\beta$ -CPP. Heating above this range exhibited the decomposition of OCP into  $\beta$ -CPP and  $\beta$ -TCP and gradual transformation of  $\alpha^1$ -CPP into  $\beta$ -CPP. As a result, powders upon heating were triphasic of  $\beta$ -CPP,  $\alpha^1$ -CPP and  $\beta$ -TCP with variable phase contents and with the relative amount 3:1:1 at 980 °C. The reason for appearance of TCP (Ca/P = 1.5) from ACP (Ca/P = 1) was discussed.

### CONCLUSION

The activation energy for crystallization of ACP into the metastable polymorph  $\alpha^1$ -CPP was first determined as 165 kJ/mol (39.5 kcal/mol).

The powders are presented as prospective superior biomaterials because they combine effective bioactive phases with a novel metastable  $\alpha^1$ -CPP polymorph. A peculiar feature of the fabricated powders is that they include a metastable  $\alpha^1$ -CPP additionally to the known effective bioactive CPP and CP phases. Biomaterials having such composition is expected to exhibit superior biological behavior compared to that of the HA family.

### INTRODUCTION

Hydrogels are often and widely used biomaterials in medical and research applications. Depending on the application there are different hydrogels for, e.g., soft tissue replacement, organ patches, or drug delivery systems. Hence, there is a great interest to investigate the degradation behavior of these materials non invasively *in vivo* in animal models. Because hydrogels mainly consist of water, proton MRI (magnetic resonance imaging), especially T2-weighted sequences, seems to be suitable for hydrogel visualization and quantification. But due to the high water content of the surrounding tissue, there is a need to investigate if the MRI signal correlates with the actual volume of the used hydrogel.

### EXPERIMENTAL METHODS

The hydrogels were synthesized by reacting a 10 wt.-% gelatin solution with 3-fold (G10\_LNCO3) or 8-fold (G10\_LNCO8) molar excess of isocyanate groups of ethyl lysine diisocyanate compared to amino groups of gelatin. Hydrogel samples were implanted subcutaneously in immunocompetent, hairless SKH-1 mice. The volume of implanted hydrogels was determined using dedicated 7 T small animal MRI with a T2-weighted measuring sequence at different time points after implantation *in vivo*. After the measurements the animals were euthanized and material containing tissues were explanted. The tissue samples were dehydrated by incubation in 30, 50 and 70 vol.-% ethanol solution for 1 day each. Afterwards, the samples were incubated for 49 days in 0.3 wt.-% phosphotungstic acid (PTA) in 70 vol.-% ethanol. PTA is a contrast agent for computed tomography (CT) which binds to fibrin and collagen. It is therefore used to visualize different soft tissues. For the *ex vivo* quantification the tissue samples were measured using CT at 55 keV voltage and 600 ms acquisition time. For quantification of both the MRI and CT measurements a voxel-based evaluation method was applied.

### RESULTS AND DISCUSSION

Both hydrogels could clearly be visualized by MRI. Quantification was realized by applying a threshold. Due to their higher amount of water compared to the surrounding tissue a stronger signal intensity of the hydrogels in the T2-weighted measurement could be observed. Interestingly the signal intensity was independent from the crosslinking level.

The PTA stained tissue samples could be visualized similarly. Binding of PTA in hydrogels was higher than in the surrounding tissue. Therefore, a higher X-ray absorption could be detected at the material site.

Figure 1: Correlation between MRI and CT measurement based volume quantification.

Both MRI and CT allowed for quantification of hydrogel degradation over the time. However, a much higher volume was observed in the *in vivo* MRI compared to *ex vivo* CT measurements. A strong correlation ( $r=0.9691$ , Pearson correlation coefficient) between both quantification methods could be calculated (Figure 1,  $R^2=0.9392$ ). The MRI quantified volume is higher by a factor of 10 compared to CT quantified volume independent of hydrogel degradation state. The reason for this difference between both volumes lies in the dehydration of the hydrogels for the PTA staining. Because of the high amount of water in the swollen hydrogel the dehydrated volume is much lower.

### CONCLUSION

The *in vivo* MRI volume measurement of hydrogels could be verified by CT contrast agent measurements *ex vivo*. Both methods reflect the hydrogel degradation state. Taken together this imaging study revealed MRI as suitable non invasive method to quantify the volume of gelatin based hydrogels *in vivo*.

## INTRODUCTION

Posterior capsular opacification (PCO) is the capsule fibrosis developed on implanted intraocular lens (IOL) by the de-differentiation of lens epithelial cells (LECs) undergoing epithelial-mesenchymal transition (EMT). It is generally accepted that the acrylic hydrophilic materials have higher PCO rate than acrylic hydrophobic ones<sup>1</sup>. We recently highlighted their particular properties in terms of adhesion forces, LECs adhesion, and tissue response as indicators of posterior capsular opacification development risk<sup>2</sup>. Our strategy in PCO control is to improve the hydrophilic IOL capsular biocompatibility by creating a higher LEC affinity surface via bioactive peptides (Fig. 1).

## EXPERIMENTAL METHODS

The surfaces of acrylic hydrophilic disks of 25% water content (HA25) were functionalized with cell-adhesion peptides (RGD peptides) and characterized by X-ray photoelectron spectroscopy as well as contact angle measurements. To evaluate the performance against PCO, the *in vitro* LEC culture was performed and compared to acrylic hydrophobic material named GF (glistening free) used as PCO-negative reference. Additionally, in order to ensure that the surface functionalization process does not compromise the material properties, optical and mechanical properties of functionalized polymers were conducted and compared with control materials.

## RESULTS AND DISCUSSION

The surface functionalization process was accomplished by oxygen plasma treatment followed by conjugation, and the washing procedure consisted of consecutive

water extraction in autoclave temperature. The results show the innovative biomaterial improves LEC adhesion, and also exhibits similar optical (light transmittance, contrast sensitivity, dioptre measurement) and mechanical (haptic compression force, IOL injection force) properties comparing to the starting material. In addition, comparing to the hydrophobic IOL material, this bioactive biomaterial exhibits similar abilities in LEC adhesion, morphology maintenance, and EMT biomarker expression. The *in vitro* assay results suggest this biomaterial has the potential to reduce some risk factors of PCO development<sup>3</sup>.

## CONCLUSION

Our pioneering *in vitro* study of the bio-mimicking strategy suggests that the LEC adhesion is promoted and this surface-functionalized IOL material exhibits no detectable effect toward EMT, which is the molecular cell biology mechanism of PCO. This hypothesis still needs to be examined by *in vivo* assays to validate the effectiveness of PCO prevention.

### INTRODUCTION

Submicrometric topography has been shown to influence lineage commitment of human mesenchymal stem cells cultured on flat substrates<sup>1</sup>. Elevated osteogenic gene expression and mineralization was observed in the absence of osteogenic media supplements on substrates with disordered but uniform topography features<sup>1</sup>. However, translating those findings to 3D has so far been difficult, because the nanoroughness created by the usual electrospinning<sup>2</sup> or etching<sup>3</sup> approaches is often heterogeneous. Here we use nanoparticle-decorated porogens as templates to produce silk fibroin scaffolds with nanotopography that can be tuned in size and shape through nanoparticle choice.

### EXPERIMENTAL METHODS

Polycaprolactone (PCL) microparticles with average size of 310  $\mu\text{m}$  were produced by microfluidics. Electrostatic adsorption was used to deposit latex nanoparticles onto those PCL particles using an intermediate positively charged polyelectrolyte layer (see Figure 1a). First, the PCL particles were treated with 1:1 methanol/2M NaOH for 15 minutes and rinsed with water. Then, they were immersed in a 1 % polyallylamine hydrochloride solution for 1 h followed by rinsing with water. Negatively charged polystyrene latex particles were then adsorbed from a 0.25 % suspension overnight and the PCL microparticles rinsed again with water. The decorated PCL particles were afterwards dried, assembled in a mold, subjected to a heat treatment at 57  $^{\circ}\text{C}$ /25 % relative humidity and infiltrated with a 12 % silk fibroin aqueous solution. After complete drying, the scaffolds were placed in methanol for 1 h. The particles were finally leached in dichloromethane for 8 h. Scaffolds were imaged using scanning electron microscopy.

### RESULTS AND DISCUSSION

Negatively charged latex particles of various sizes with both carboxy or sulfate functional groups could be adsorbed onto the polycaprolactone microparticles via a positively charged intermediate polyelectrolyte. Figure 1b shows 1  $\mu\text{m}$  sulfate-functionalized latex adsorbed onto a 310  $\mu\text{m}$  polycaprolactone particle. After infiltration and porogen leaching, imprints of the latex particles could be observed in the silk fibroin pore walls (Figure 1d). Those imprints had diameters of about 55 % of the original latex particle size.

Figure 1: a. Schematics showing the electrostatic adsorption process to create a nanoparticle-decorated porogen for templating. b. 1  $\mu\text{m}$  latex adsorbed onto PCL particles. c. Silk fibroin scaffold d. Imprints made by the latex on the dry silk fibroin scaffold pore wall after template removal.

The presented method offers a simple way of generating tunable random nanotopography in silk fibroin scaffolds. The use of core-shell and monodisperse nanoparticles might enable further control over feature spacing and arrangement.

### CONCLUSION

A simple and versatile route to decorate porogen microparticles with nanoparticles via electrostatic adsorption has been developed. Silk fibroin scaffolds with submicrometric and uniform roughness could be produced using the decorated microparticles as porogens. Future investigations will concentrate on evaluating the effect of such roughness on human mesenchymal stem cell response, both in presence and absence of osteogenic cues in the medium.

## INTRODUCTION

Calcium phosphate ceramics in combination with implant surface geometry have been shown to influence biological performance. Ripamonti et al. have extensively investigated the osteoinductive effect of repetitive surface concavities on bulk ceramics and calcium phosphate coated titanium implants<sup>1-3</sup>. These studies have shown that the presence of concavities allows for osteoinductive capacity without loading the ceramic scaffold with osteogenic soluble factors or osteogenic cells.

In our previous study, we tried to rationalize the mineralization process through an *in vitro* test in SBF<sup>4</sup>. Bianchi et al. showed that the mineralization process started preferentially within the concavities in hydroxyapatite (HA) disks sintered at 1200 °C and that concavity size controlled the extent of mineralization.

It is also known that micro- and nano-scale morphology of the calcium phosphate surface can strongly influence osteoblast and stem cell adhesion, proliferation, and differentiation<sup>5-7</sup>. In our current study, we aimed to investigate how cells populate concavities and to what extent concavity size influences cellular mineralization. We hypothesized that surface concavities facilitate cell proliferation and mineralization and that these effects are increased in the smaller concavity due to increased 3D cellular organization.

## EXPERIMENTAL METHODS

Cavity sizes of 440, 800 and 1800 µm were created on the surface of HA disks sintered at 1200°C and cultured with adipose tissue mesenchymal stem cells (AT-MSCs) in osteogenic medium for up to 28 days at 37°C. At selected time points (3, 7, 14, 21, and 28 days), samples were removed and after fixation, cells were fluorescently labeled with phalloidin-Alexa 568 (1:250; molecular probes) for filamentous (F-) actin and DAPI (1:2500) for nuclear staining. Cells were imaged and examined with a confocal laser scanning microscopy (CLSM) Olympus FV1000.

## RESULTS AND DISCUSSION

Immunofluorescence-based three-dimensional (3D) image analysis showed differences in cell number between concavities. The highest number of cell nuclei was found in the 440 µm cavity (Figure 1) and the lowest number in the 1800 µm. Additionally, cells were able to migrate toward the concavities and adhere to their edges and walls. Preferential mineralization was observed inside the concavities. Cells spread over and to the bottom of concavities covering all their volume and creating multilayers on their surfaces.

**Figure 1.** 3D reconstruction of confocal microscopy imaging of small, medium, and large concavities after 28 days of culture.

## CONCLUSION

High resolution 3D images gave qualitative and quantitative data on concavity volumes. CaP ceramics with surface concavities induced cell (AT-MSCs) organization within the concavities and were able to create cell multilayers. Results from this study suggest a correlation between concavity size, cellular organization, mineralization and concavity induced osteoinductive properties.

### INTRODUCTION

Bioinert ceramics for orthopaedic devices, such as Zirconia or Alumina, represent a growing market due to their superior performance in dental and joint substitutions. Attempts have been made in the past to improve their interactions with cells by means of roughness, yielding different results. Unfortunately modifying the roughness inevitably creates defects that affect the fracture resistance of ceramics due to their fragility. Another strategy is to modify the chemical composition of the surface without affecting the bulk properties. This would influence the way proteins and cells perceive the surface, without impacting the higher mechanical performance of ceramics. In this way, the development of Self-Assembled Monolayer (SAM) is proven to be an effective and versatile technique of modifying the cell/material interactions<sup>1</sup>. In the present work, we explored a new way of modifying the surface of Zirconia (3Y-TZP) by grafting a Self-Assembled Monolayer (SAM) of 3-aminopropyltrimethoxysilane (APDMES) directly on the surface.

### EXPERIMENTAL METHODS

The surfaces of polished zirconia discs were prepared by oxygen plasma and exposed to APDMES in pentane. The modified surfaces were studied by means of XPS, and a modified ADECA method<sup>2</sup> (a colorimetric method allowing the estimation of the density of amine groups on the surface). To study the effect of the treatment on the mechanical performance, 15 treated and 15 untreated discs were tested by 3-ball-on-3-ball biaxial bending in a universal testing machine, and later studied with Weibull probability. Cytotoxicity tests were performed by means of PrestoBlue® assay of MG-63 (osteoblast-like cells) on treated and non-treated surfaces, studying the cell proliferation after 3, 6 and 10 days, and using 5000 cells per well and three samples per condition and repetition.

### RESULTS AND DISCUSSION

Both ADECA and XPS analysis confirmed the presence of amino groups, proving the chemical procedure managed to introduce an APDMES SAM over Zirconia. The estimation of silane density in the surface was  $8.6 \cdot 10^{13}$  molecules per  $\text{cm}^2$ , which is very close to the silanol number ( $4.9 \cdot 10^{13}$  OH per  $\text{cm}^2$ ) given by Zhuravlev corresponding to a fully saturated silica surface<sup>3</sup>.

Mechanical results (figure 1) yielded no evidence of statistical difference between treated and untreated

samples (t-test,  $p \approx 0.5$ ). This proves that neither oxygen plasma nor the liquid-phase silanisation modifies the mechanical behaviour of the material. In regards of the cytotoxicity, results show no difference of cell proliferation between both types of surface, meaning that no traces of toxic solvents remained after the surface modification.

“Figure 1 shows no difference in mechanical behaviour between treated and non-treated samples.”

### CONCLUSION

In the past, researchers have evidenced the potential of SAMs in surface modification<sup>4</sup>. In this work, we demonstrate that a non-silica oxide surface can be directly silanized as well, without the necessity of a silica interlayer. In the future, APDMES could be easily swapped by any other silane with a more interesting functional group, tailoring the surface to specific needs.

We have shown as well that the treatment has no impact whatsoever on the mechanical integrity, making the procedure ideal for orthopaedic devices designed to withstand very high loads. No adverse effects were found on the proliferation of MG-63 cells, which will enable cell adhesion tests as the next step in this research.

### INTRODUCTION

Angiogenesis, the formation of new blood vessels from pre-existing vascular beds, is essential for tumor growth, invasion and metastasis formation. Thus, the therapeutic suppression of angiogenesis could be the key to prevent tumor progression<sup>1</sup>. We describe the use of injectable, *in situ* cross-linkable SF hydrogels to suppress angiogenic activity and tumor progression, using *in vitro* and *in vivo* models. Recently, it was found that proteins (e.g. silk fibroin) with tyrosine groups can be used to prepare hydrogels *in situ* via an enzyme-mediated cross-linking reaction, using horseradish peroxidase (HRP) and hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>)<sup>2</sup>. Silk fibroin (SF) contains 5 mol% tyrosine groups, which are easily chemically modified, demonstrating the promising application of this protein for the production of injectable systems and non-toxic hydrogels.

### EXPERIMENTAL METHODS

The present work provides a novel route for obtaining enzymatically cross-linked SF hydrogels within a few minutes in physiological conditions, using high concentrate aqueous SF solution (16 wt%), mediated by a HRP/H<sub>2</sub>O<sub>2</sub> complex<sup>3</sup>. The dominant conformation presented by the SF hydrogels was assessed over time, allied to its potential anti-tumoral applications. The  $\beta$ -sheet conformation transition was analyzed by means of Transmission Electron Microscopy (TEM), Thioflavin T and Congo red staining. Human neuronal glioblastoma (U251) and human cervical adenocarcinoma (HeLa) cell lines were encapsulated within the SF hydrogels and cultured for 14 days under standard culture conditions. Cell viability and proliferation were assessed through ATP and DNA quantification assays, respectively. In order to evaluate the *in vivo* biocompatibility of the SF hydrogels, a subcutaneous implantation was performed in mice model for a period of 2 weeks, followed by H&E staining.

### RESULTS AND DISCUSSION

The SF hydrogels presented ionic strength and pH stimuli responsiveness. The  $\beta$ -sheet conformation transition analysis revealed that the fast-formed hydrogels presented mainly an amorphous conformation and transparent appearance during the first week, but a conversion to a dominant  $\beta$ -sheet conformation and opaque appearance was verified from day 7.

Additionally, U251 and HeLa cells were successfully encapsulated within the hydrogels. ATP quantification showed a cell-dependent decrease of cell viability over culture period and from DNA quantification analysis it was possible to conclude a decrease of cell proliferation after 14 days of culture. The *in vivo* results showed that the SF hydrogels did not induce any acute inflammatory reaction after 2 weeks of subcutaneous implantation (Figure 1). The SF hydrogels underwent a  $\beta$ -sheet conformation transition after 7-10 days of *in vitro* cell encapsulation and 2 weeks of *in vivo* implantation, revealing that the observed conformation transition may be responsible for inhibiting cell viability and proliferation.

**Figure 1-** Subcutaneous implantation of the SF hydrogels in mice for 2 weeks. (a-b): Macroscopic images of the explants. (c): H&E staining of the explants (Scale bar: 100  $\mu$ m).

### CONCLUSION

This study provides a straightforward approach to produce injectable SF hydrogels with superior biocompatibility and fast-gelation property to be used as a whole or combined with bioactive agents. Thus, the enzymatically cross-linked SF hydrogels can be a very useful and tunable system for different biomedical applications, including suppressing angiogenesis and tumors progression *in vivo*.

[jkarbow@agh.edu.pl](mailto:jkarbow@agh.edu.pl)

### INTRODUCTION

Titanium alloys are an important group of materials for orthopedic applications due to their high strength, good corrosion resistance, low weight, low elastic modulus and biocompatibility. Regardless their distinctive properties some problems may occur that could lead to implant failure and revision surgery. One of the risks are surgery-related bacterial infections which prolongs post-implantation patients recovery and may even cause implant rejection. Possible solution to reduce the risk of the infection might be coatings with antibacterial activity<sup>1</sup>. Zinc oxide (ZnO) nanoparticles can release  $Zn^{2+}$  ions which inhibit biofilm formation by affecting bacterial active sugar transport and metabolism<sup>2</sup>. Thus ZnO nanoparticles could be applied as the antibacterial agent in coatings.

### EXPERIMENTAL METHODS

The investigation was performed on two phase ( $\alpha+\beta$ ) Ti6Al7Nb alloy. This alloy was surface treated by electrophoretic deposition (EPD) method, considering a multilayer approach. The first coating was composed of chitosan (Ch). For the second layer polyvinyl alcohol (PVA), alginate (Alg) zinc oxide nanoparticles (nZnO) and bioactive glass particles (45S5 Bioglass®, BG) were used. Two types of suspensions were prepared with composition: PVA-Alg/nZnO and PVA-Alg/nZnO-BG. The suspensions' stability was verified by zeta potential measurements.

Obtained coatings were investigated in terms of their microstructure, chemical composition and wettability by means of SEM, SEM-EDS and static water contact angle measurement. The deposition yield was calculated based on the change of the samples weight before and after deposition.

### RESULTS AND DISCUSSION

Zeta potential values of PVA-Alg/nZnO and PVA-Alg/nZnO-BG suspensions were found to be  $-32.6 \pm 0.4$  mV and  $-35 \pm 1$  mV, respectively. Both suspensions were stable and negatively charged, thus the deposition was anodic. The interlayer of chitosan was found to increase the deposition yield as well as the coatings homogeneity and attachment to the substrate.

Both coatings had hydrophilic surfaces, the wettability measured by contact angle was  $54 \pm 4^\circ$  for PVA-Alg/nZnO and  $61 \pm 4^\circ$  for PVA-Alg/nZnO-BG.

Coatings deposited from PVA-Alg/nZnO-BG suspension were rough with individual, micrometer sized, sharp-edged bioactive glass particles and homogeneously distributed nZnO. However some larger

clusters of zinc oxide particles, not separated during ultrasonication, were also observed in the polymer matrix (Fig. 1).

Coatings deposited from PVA-Alg/nZnO suspensions had similar microstructure as the previous one, with well distributed nanoparticles as well as larger clusters of ZnO in the polymer matrix.

Antibacterial tests against G+ and G- bacteria are in progress, results under evaluation.

Fig.1. Microstructure of the coating prepared from PVA-Alg/nZnO-BG suspension. Magnified details: a) BG particle, b) cluster of ZnO particles in polymer matrix; SEM-SE images.

### CONCLUSION

EPD is a simple and cost efficient method to modify the surface of different metals by depositing complex coatings. It allows the improvement of the properties of materials to be applied in the medical field. Coatings with antibacterial activity are a promising solution to prevent bacterial adhesion on the surface of the implant and biofilm formation, thus reducing the risk of infection during surgery.

## INTRODUCTION

Metallic materials have found wide application as orthopaedic implants. Nowadays, AISI 316L stainless steel is presumably the most widely used material to produce bone implants due to its high strength, toughness and much lower cost as compared to titanium alloys. However, there is always a concern about corrosion of stainless steel in body fluids and its surface activity which was found to affect cell functions<sup>1</sup>. One of the ways of minimizing corrosion and promoting cells adhesion and growth on metallic surface is applying protective and functional coatings<sup>1,2</sup>.

In this study, authors proposed bioactivation of SiO<sub>2</sub> sol-gel derived coatings on metallic implants by using: osteoinductive factor which plays a crucial role in regeneration process - L-ascorbic acid (LAA), anti-inflammatory drug - salicylic acid (SAL) and neurotransmitter taking part in regulation of bone metabolism - dopamine (DOPA).

## EXPERIMENTAL METHODS

Pure silica coatings (SiO<sub>2</sub>) and SiO<sub>2</sub> coatings doped with active molecules: LAA, SAL and DOPA in adjusted molar ratios: SiO<sub>2</sub>/0.4M LAA, SiO<sub>2</sub>/0.7M SAL, SiO<sub>2</sub>/3.5mM DOPA were prepared by the sol-gel method. Obtained sols were applied on the 316L AISI by dip-coating technique. For the sol-gel synthesis two silica precursors: tetraethoxysilane (TEOS) and n-propyltriethoxysilane (PtEOS) containing different substituents (-C<sub>2</sub>H<sub>5</sub>, -C<sub>2</sub>H<sub>5</sub> and C<sub>3</sub>H<sub>7</sub>, respectively) were used.

The surface morphology, elemental analysis and topography of the coatings were determined using a scanning electron microscope (SEM), EDX analysis and atomic force microscopy (AFM), respectively. Raman spectroscopy measurements were carried out to characterize the chemical structure of obtained materials. Hydrophilicity, water contact angle and surface free energy (SFE) were evaluated by using a drop shape analysis system. The corrosion resistance of coated metal samples was investigated in Ringer's solution. The corrosion characteristics included: corrosion potential ( $E_{CORR}$ ), polarization resistance ( $R_p$ ) and corrosion current density ( $i_{CORR}$ ) which were extracted from the curves, calculated via Stearn-Geary method. Moreover, cytocompatibility of investigated coatings was tested in vitro using osteoblast-like MG-63 cells. Cell adhesion, morphology and distribution were evaluated using fluorescence microscopy after live/dead (calcein AM/propidium iodide) and DAPI/eosin staining. Viability was studied by Alamar Blue test and proliferation factor (PF) was calculated.

## RESULTS AND DISCUSSION

SEM-EDX analysis indicated that all received silica coatings showed characteristic microstructure, without cracks and uniformly covered the metallic substrate (Figure 1); their thickness was about 240 nm.

Figure 1. SEM micrographs of functionalised sol-gel derived coatings: SiO<sub>2</sub>/0.4M LAA (A) SiO<sub>2</sub>/0.7M SAL (B) and SiO<sub>2</sub>/3.5mM DOPA (C) applied on AISI 316L stainless steel, at 500x magnification.

AFM measurements revealed differences in nanotopography of the coatings. Moreover significant decrease in roughness parameter ( $R_a$ ) in the case of SiO<sub>2</sub>/0.7M SAL compared to pure silica coatings SiO<sub>2</sub> (TEOS) was observed. Raman spectroscopy showed the characteristic bands for chemical structures forming the silica network. Additionally the spectra analysis confirmed presence of characteristic groups of active molecules in doped SiO<sub>2</sub> coatings. Water contact angle ( $\theta_w$ ) measurements showed that all coated surfaces were hydrophilic ( $\theta_w < 90^\circ$ ); LAA and SAL dopants resulted in significant decrease in  $\theta_w$ . The results of electrochemical analysis indicated that the surface modification by applying sol-gel coatings improved corrosion resistance of the tested biomaterials in Ringer's solution. Biological assays approved that all coatings were cytocompatible with osteoblast-like cells (MG-63) and supported cell adhesion.

## CONCLUSION

Obtained results showed that proposed functionalization procedure of SiO<sub>2</sub> sol-gel derived network with selected active molecules enabled synthesis of bioactive coating materials on metallic substrate, which were cytocompatible and promoted cell adhesion and proliferation. Moreover it can be concluded that immobilization of proper dopant within silica network, enables control of wettability and nano-topography of received coatings using sol-gel route.

## INTRODUCTION

Histomorphometric analysis is considered the gold standard for analysis of bone formation in tissue scaffolds; however, these 2D sections can bias 3D features. Additionally, the process of fixation, sectioning and polishing can introduce artefacts such as movement and shrinkage (dehydration) of tissue. Micro-computed tomography ( $\mu$ CT) can be readily applied to non-destructively image and quantify bone formation. Combining these techniques can provide multimodal imaging to gain further understanding of tissue growth. In this study,  $\mu$ CT was utilised to non-destructively image and evaluate bone formation in a porous titanium implant, followed by destructive histological sectioning and imaging. Digital registration of  $\mu$ CT and histological images was then performed to compare and contrast the benefits of each method.

## EXPERIMENTAL METHODS

Porous titanium scaffolds with an average porosity of 65 % (1) were fabricated from grade 1 commercially pure titanium using selective laser melting. The scaffolds were implanted in rats, using a 3 mm diameter medial aspect defect in the right tibia. Individual tibial samples were assessed for bone ingrowth at 2, 3, 4 and 6 weeks after implantation. The tibiae were scanned in a laboratory  $\mu$ CT with an isotropic voxel size of 9  $\mu$ m. The tibial specimens were fixed, embedded in resin, sectioned transversely, stained with haematoxylin and imaged optically. A methodology was then developed to register the histology images with the  $\mu$ CT data, with key steps consisting of data segmentation and iterative registration. A comparison study was then performed on the bone ingrowth measured from 3D  $\mu$ CT volume, histology and the corresponding 2D slice in the  $\mu$ CT data. In 3D, the bone ingrowth was further subdivided relative to the surface of the implant (edge, sub-surface and core), allowing quantification of the bone penetration.

## RESULTS AND DISCUSSION

Figure 1 shows new bone successfully formed in the porous scaffold. Good bone contact suggests that the porous implant promotes a stable fixation.

Figure 1.  $\mu$ CT image of implant in the rat tibia after (a) 2 weeks and (b) 6 weeks implantation

Histology provides insight into bone maturity and other cellular information of the bone and surrounding tissue; however, it can also introduce artefacts and is limited in that only a single slice is quantified. Figure 2a shows a 3D  $\mu$ CT volume and 2D histology image of a rat tibia 6 weeks after implanting a Ti scaffold. Due to the size of the Ti scaffold, the histological sections were often taken near the edge of the implant, which biased the results, as shown by comparison to 3D  $\mu$ CT results (Figure 3). Bone ingrowth is fastest near the edge, hence histology has a tendency to overestimate bone ingrowth. Additionally, shrinkage of the histology section during preparation can add errors (Figure 2b).

Figure 2. Correlation between 3D  $\mu$ CT and histology, the new bone (green) is observed in the porous titanium scaffold (grey) at 6 week, the old bone is visualised in brown (a), a good correlation was observed in histology and its corresponding 2D  $\mu$ CT slice (blue: bone, green: titanium) (b).

Figure 3. Percentage bone ingrowth from the edge to the core of the implant after 4 and 6 weeks.

## CONCLUSION

Multimodal imaging and registration is a promising hybrid approach to quantify bone formation in scaffolds.  $\mu$ CT removes potential biasing due to histological sectioning near to edge, rather than in the centre, of porous titanium implants.

## INTRODUCTION

Colloidal gels are a particularly attractive class of hydrogels for applications in regenerative medicine that allow for a “bottom-up” fabrication of multi-functional biomaterials. Hyaluronic acid (HA) is a biopolysaccharide that has excellent biocompatibility and biodegradability properties and it plays an essential role for bone remodeling. Nanocrystalline apatites exhibit a great ionic mobility, as well as ion exchange and adsorption capacities. They can be surface functionalized with organic molecules including polymers, peptides, proteins or nucleic acids. Hydroxyapatite reinforced hyaluronic acid composite gels may offer a strongly enhanced gel elasticity, shear-thinning and gel stability at high ionic strengths, while chemical, potentially cytotoxic, functionalization may be not necessary to introduce sufficiently strong cohesive interactions. Thus, hydroxyapatite-hyaluronate composites gels may provide with a better control over cell-biomaterials interaction. Bone defects filled with both HA and OHAp demonstrated superior healing compared to defects filled with OHAp alone<sup>1</sup>. Thus, the aim of this work is to establish an appropriate reaction to functionalize apatite with HA and the ability to produce injectable materials.

## EXPERIMENTAL METHODS

Hydroxyapatites have been synthesized through a wet chemistry process by mixing the appropriate proportions of CaCl<sub>2</sub>, H<sub>3</sub>PO<sub>4</sub> and KOH. Some of the batches incorporate also ZnCl<sub>2</sub> to improve the immunological response of the system towards the composite. Hydroxyapatites have been functionalized using three different approaches. For the first one, a hyaluronate solution is added during the synthesis reaction of the hydroxyapatite. For the second one, hyaluronate is added after the synthesis reaction is completed. For the third one, a preliminary step of hyaluronate oxidation is introduced. Hyaluronate-hydroxyapatite composites gels are characterized through FTIR, Raman Spectroscopy, DRX, CHN analysis, TGA, SEM, EDS, specific surface area, zeta potential analysis and rheology measurements.

## RESULTS AND DISCUSSION

Hydroxyapatite formation has been verified by FTIR and XRD. XRD patterns confirm the presence of a single apatitic crystalline phase also for the Zn ions containing samples. No secondary phases have been detected. A decrease on the *a* cell parameter from

9.449 to 9.439 Å, for calcium hydroxyapatite and Zn hydroxyapatite respectively confirms the incorporation of the Zn ion into the apatite structure. A carbon contents in the 1.4-1.6% range and the weight loss observed in the 200-450°C range in the TGA curve confirms the incorporation of 2,4-3,8% hyaluronate on the hydroxyapatite. The method that incorporates hyaluronate after the hydroxyapatite synthesis reaction is completed yields smaller particles that in the case of the incorporation of the apatite during the synthesis reaction. The isoelectrical point disappears for OH-Ap/HA and OH-Ap/oxi-HA and at pH 7 the Z potential decreases from -19 up to -22 and -23 for OHAp, OH-Ap/HA and OH-Ap/oxi-HA respectively. Oxidation of HA has been demonstrated by the appearance of bands at 1737, 2849 and 2918 cm<sup>-1</sup> due to the aldehyde groups in the spectra of oxidized samples that can be attributed to the formation of the aldehyde and it cannot be observed in the spectra of the as received HA. The presence of bands at 2897 and 2984 cm<sup>-1</sup>, attributed to the C-H groups from the HA component are significantly stronger in the spectra for oxidized hyaluronic acid functionalized hydroxyapatite (OH-Ap/oxi-HA), than for the functionalization with hyaluronic acid (OH-Ap/HA) suggesting that the interaction of the oxi-HA acid with the ions of the OHAp is stronger than the interaction of the HA with the OHAp. Suspensions with a 2,7·10<sup>-3</sup>-7,2·10<sup>-3</sup> Pa.s<sup>-1</sup> viscosity can be achieved for gels containing 3.1% and 7.5% hydroxyapatite. These systems can be fully injected with a 5mL syringe.

## CONCLUSION
